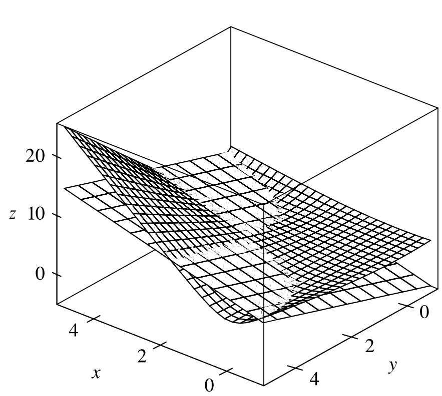
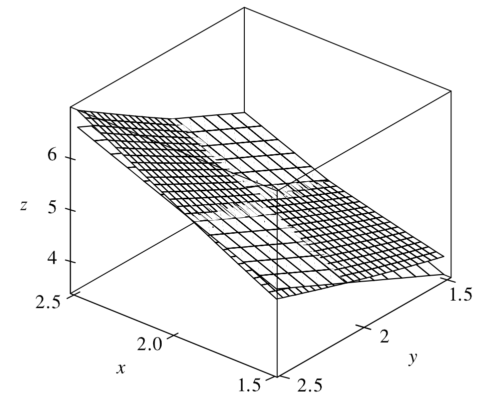
8. $z = f(x, y) = \sqrt{9 + x^2y^2} \quad \Rightarrow \quad f_x(x, y) = \frac{1}{2}\left(9 + x^2y^2\right)^{-1/2}(2xy^2) = xy^2/\sqrt{9 + x^2y^2}$, $f_y(x, y) = \frac{1}{2}\left(9 + x^2y^2\right)^{-1/2}(2x^2y) = x^2y/\sqrt{9 + x^2y^2}$, so $f_x(2, 2) = \frac{8}{5}$ and $f_y(2, 2) = \frac{8}{5}$. Thus an equation of the tangent plane is $z - 5 = f_x(2, 2)(x-2) + f_y(2, 2)(y-2) \quad \Rightarrow \quad z - 5 = \frac{8}{5}(x-2) + \frac{8}{5}(y-2)$ or $z = \frac{8}{5}x + \frac{8}{5}y - \frac{7}{5}$. After zooming in, the surface and the tangent plane become almost indistinguishable. (Here the tangent plane is shown with fewer traces than the surface.) If we zoom in farther, the surface and the tangent plane will appear to coincide.

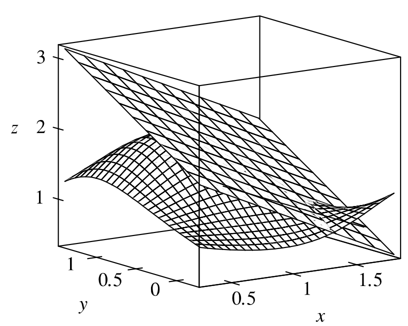


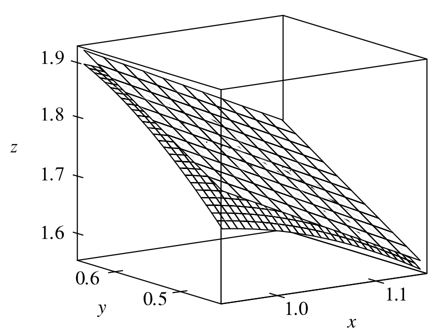


9. $f(x,y) = \dfrac{1+\cos^2(x-y)}{1+\cos^2(x+y)}$. A CAS gives

$$f_x(x,y) = -\frac{2\cos(x-y)\sin(x-y)}{1+\cos^2(x+y)} + \frac{2\left[1+\cos^2(x-y)\right]\cos(x+y)\sin(x+y)}{\left[1+\cos^2(x+y)\right]^2} \quad \text{and}$$

$$f_y(x,y) = \frac{2\cos(x-y)\sin(x-y)}{1+\cos^2(x+y)} + \frac{2\left[1+\cos^2(x-y)\right]\cos(x+y)\sin(x+y)}{\left[1+\cos^2(x+y)\right]^2}.$$ We use the CAS to evaluate these at $(\pi/3, \pi/6)$, giving $f_x(\pi/3,\pi/6) = -\sqrt{3}/2$ and $f_y(\pi/3,\pi/6) = \sqrt{3}/2$. Substituting into Equation 2, an equation of the tangent plane is $z = -\frac{\sqrt{3}}{2}\left(x - \frac{\pi}{3}\right) + \frac{\sqrt{3}}{2}\left(y - \frac{\pi}{6}\right) + \frac{7}{4}$. The surface and tangent plane are shown in the first graph below. After zooming in, the surface and the tangent plane become almost indistinguishable, as shown in the second graph. (Here, the tangent plane is above the surface.) If we zoom in farther, the surface and the tangent plane will appear to coincide.



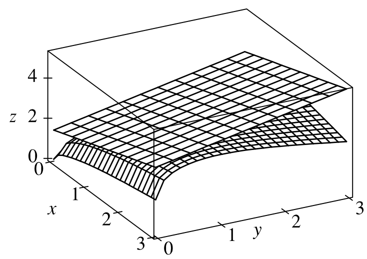


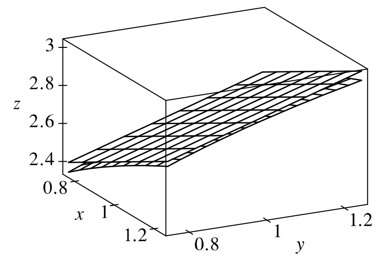
10. $f(x,y) = e^{-xy/10}\left(\sqrt{x} + \sqrt{y} + \sqrt{xy}\right)$. A CAS gives

$$f_x(x,y) = -\tfrac{1}{10}ye^{-xy/10}\left(\sqrt{x} + \sqrt{y} + \sqrt{xy}\right) + e^{-xy/10}\left(\frac{1}{2\sqrt{x}} + \frac{y}{2\sqrt{xy}}\right) \text{ and}$$

$$f_y(x,y) = -\tfrac{1}{10}xe^{-xy/10}\left(\sqrt{x} + \sqrt{y} + \sqrt{xy}\right) + e^{-xy/10}\left(\frac{1}{2\sqrt{y}} + \frac{x}{2\sqrt{xy}}\right).$$ We use the CAS to evaluate these at $(1,1)$, and then substitute the results into Equation 2 to get an equation of the tangent plane: $z = 0.7e^{-0.1}x + 0.7e^{-0.1}y + 1.6e^{-0.1}$.

The surface and tangent plane are shown in the first graph below. After zooming in, the surface and the tangent plane become almost indistinguishable, as shown in the second graph. (Here, the tangent plane is above the surface.) If we zoom in farther, the surface and the tangent plane will appear to coincide.





11. $f(x,y) = 1 + x\ln(xy-5)$. The partial derivatives are $f_x(x,y) = x \cdot \dfrac{1}{xy-5}\,(y) + \ln(xy-5)\cdot 1 = \dfrac{xy}{xy-5} + \ln(xy-5)$ and $f_y(x,y) = x \cdot \dfrac{1}{xy-5}\,(x) = \dfrac{x^2}{xy-5}$, so $f_x(2,3) = 6$ and $f_y(2,3) = 4$. Both f_x and f_y are continuous functions for $xy > 5$, so by Theorem 8, f is differentiable at $(2,3)$. By Equation 3, the linearization of f at $(2,3)$ is given by $L(x,y) = f(2,3) + f_x(2,3)(x-2) + f_y(2,3)(y-3) = 1 + 6(x-2) + 4(y-3) = 6x + 4y - 23$.

12. $f(x,y) = \sqrt{xy} = (xy)^{1/2}$. The partial derivatives are $f_x(x,y) = \frac{1}{2}(xy)^{-1/2}(y) = y/\left(2\sqrt{xy}\right)$ and $f_y(x,y) = \frac{1}{2}(xy)^{-1/2}(x) = x/\left(2\sqrt{xy}\right)$, so $f_x(1,4) = 4/\left(2\sqrt{4}\right) = 1$ and $f_y(1,4) = 1/\left(2\sqrt{4}\right) = \frac{1}{4}$. Both f_x and f_y are continuous functions for $xy > 0$, so f is differentiable at $(1,4)$ by Theorem 8. The linearization of f at $(1,4)$ is $L(x,y) = f(1,4) + f_x(1,4)(x-1) + f_y(1,4)(y-4) = 2 + 1(x-1) + \frac{1}{4}(y-4) = x + \frac{1}{4}y$.

13. $f(x,y) = x^2e^y$. The partial derivatives are $f_x(x,y) = 2xe^y$ and $f_y(x,y) = x^2e^y$, so $f_x(1,0) = 2$ and $f_y(1,0) = 1$. Both f_x and f_y are continuous functions, so by Theorem 8, f is differentiable at $(1,0)$. By Equation 3, the linearization of f at $(1,0)$ is given by $L(x,y) = f(1,0) + f_x(1,0)(x-1) + f_y(1,0)(y-0) = 1 + 2(x-1) + 1(y-0) = 2x + y - 1$.

14. $f(x,y) = \dfrac{1+y}{1+x} = (1+y)(1+x)^{-1}$. The partial derivatives are $f_x(x,y) = (1+y)(-1)(1+x)^{-2} = -\dfrac{1+y}{(1+x)^2}$ and $f_y(x,y) = (1)(1+x)^{-1} = \dfrac{1}{1+x}$, so $f_x(1,3) = -1$ and $f_y(1,3) = \frac{1}{2}$. Both f_x and f_y are continuous functions for $x \neq -1$, so f is differentiable at $(1,3)$ by Theorem 8. The linearization of f at $(1,3)$ is $L(x,y) = f(1,3) + f_x(1,3)(x-1) + f_y(1,3)(y-3) = 2 + (-1)(x-1) + \frac{1}{2}(y-3) = -x + \frac{1}{2}y + \frac{3}{2}$.

15. $f(x,y) = 4\arctan(xy)$. The partial derivatives are $f_x(x,y) = 4 \cdot \dfrac{1}{1+(xy)^2}(y) = \dfrac{4y}{1+x^2y^2}$, and $f_y(x,y) = \dfrac{4x}{1+x^2y^2}$, so $f_x(1,1) = 2$ and $f_y(1,1) = 2$. Both f_x and f_y are continuous functions, so f is differentiable at $(1,1)$ by Theorem 8. The linearization of f at $(1,1)$ is $L(x,y) = f(1,1) + f_x(1,1)(x-1) + f_y(1,1)(y-1) = 4(\pi/4) + 2(x-1) + 2(y-1) = 2x + 2y + \pi - 4$.

16. $f(x,y) = y + \sin(x/y)$. The partial derivatives are $f_x(x,y) = (1/y)\cos(x/y)$ and $f_y(x,y) = 1 + (-x/y^2)\cos(x/y)$, so $f_x(0,3) = \frac{1}{3}$ and $f_y(0,3) = 1$. Both f_x and f_y are continuous functions for $y \neq 0$, so f is differentiable at $(0,3)$, and the linearization of f at $(0,3)$ is

$L(x,y) = f(0,3) + f_x(0,3)(x-0) + f_y(0,3)(y-3) = 3 + \frac{1}{3}(x-0) + 1(y-3) = \frac{1}{3}x + y.$

17. Let $f(x,y) = e^x\cos(xy)$. Then $f_x(x,y) = e^x[-\sin(xy)](y) + e^x\cos(xy) = e^x[\cos(xy) - y\sin(xy)]$ and $f_y(x,y) = e^x[-\sin(xy)](x) = -xe^x\sin(xy)$. Both f_x and f_y are continuous functions, so by Theorem 8, f is differentiable at $(0,0)$. We have $f_x(0,0) = e^0(\cos 0 - 0) = 1$, $f_y(0,0) = 0$ and the linear approximation of f at $(0,0)$ is

$f(x,y) \approx f(0,0) + f_x(0,0)(x-0) + f_y(0,0)(y-0) = 1 + 1x + 0y = x + 1.$

18. Let $f(x,y) = \dfrac{y-1}{x+1}$. Then $f_x(x,y) = (y-1)(-1)(x+1)^{-2} = \dfrac{1-y}{(x+1)^2}$ and $f_y(x,y) = \dfrac{1}{x+1}$. Both f_x and f_y are continuous functions for $x \neq -1$, so by Theorem 8, f is differentiable at $(0,0)$. We have $f_x(0,0) = 1$, $f_y(0,0) = 1$ and the linear approximation of f at $(0,0)$ is $f(x,y) \approx f(0,0) + f_x(0,0)(x-0) + f_y(0,0)(y-0) = -1 + 1x + 1y = x + y - 1$.

19. We can estimate $f(2.2, 4.9)$ using a linear approximation of f at $(2,5)$, given by

$f(x,y) \approx f(2,5) + f_x(2,5)(x-2) + f_y(2,5)(y-5) = 6 + 1(x-2) + (-1)(y-5) = x - y + 9$. Thus

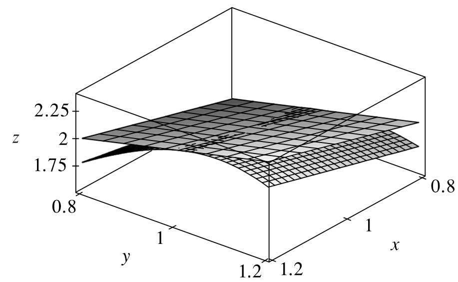
$f(2.2, 4.9) \approx 2.2 - 4.9 + 9 = 6.3$.

20. $f(x,y) = 1 - xy\cos\pi y \quad\Rightarrow\quad f_x(x,y) = -y\cos\pi y$ and

$f_y(x,y) = -x[y(-\pi\sin\pi y) + (\cos\pi y)(1)] = \pi xy\sin\pi y - x\cos\pi y$, so $f_x(1,1) = 1$, $f_y(1,1) = 1$. Then the linear approximation of f at $(1,1)$ is given by

$$\begin{aligned} f(x,y) &\approx f(1,1) + f_x(1,1)(x-1) + f_y(1,1)(y-1) \\ &= 2 + (1)(x-1) + (1)(y-1) = x + y \end{aligned}$$

Thus $f(1.02, 0.97) \approx 1.02 + 0.97 = 1.99$. We graph f and its tangent plane near the point $(1,1,2)$ below. Notice near $y = 1$ the surfaces are almost identical.



21. $f(x,y,z) = \sqrt{x^2+y^2+z^2} \quad\Rightarrow\quad f_x(x,y,z) = \dfrac{x}{\sqrt{x^2+y^2+z^2}}$, $f_y(x,y,z) = \dfrac{y}{\sqrt{x^2+y^2+z^2}}$, and

$f_z(x,y,z) = \dfrac{z}{\sqrt{x^2+y^2+z^2}}$, so $f_x(3,2,6) = \frac{3}{7}$, $f_y(3,2,6) = \frac{2}{7}$, $f_z(3,2,6) = \frac{6}{7}$. Then the linear approximation of f

at $(3, 2, 6)$ is given by

$$f(x, y, z) \approx f(3, 2, 6) + f_x(3, 2, 6)(x - 3) + f_y(3, 2, 6)(y - 2) + f_z(3, 2, 6)(z - 6)$$
$$= 7 + \tfrac{3}{7}(x - 3) + \tfrac{2}{7}(y - 2) + \tfrac{6}{7}(z - 6) = \tfrac{3}{7}x + \tfrac{2}{7}y + \tfrac{6}{7}z$$

Thus $\sqrt{(3.02)^2 + (1.97)^2 + (5.99)^2} = f(3.02, 1.97, 5.99) \approx \frac{3}{7}(3.02) + \frac{2}{7}(1.97) + \frac{6}{7}(5.99) \approx 6.9914$.

22. From the table, $f(40, 20) = 28$. To estimate $f_v(40, 20)$ and $f_t(40, 20)$ we follow the procedure used in Exercise 14.3.4. Since $f_v(40, 20) = \lim\limits_{h \to 0} \dfrac{f(40 + h, 20) - f(40, 20)}{h}$, we approximate this quantity with $h = \pm 10$ and use the values given in the table:

$$f_v(40, 20) \approx \frac{f(50, 20) - f(40, 20)}{10} = \frac{40 - 28}{10} = 1.2, \qquad f_v(40, 20) \approx \frac{f(30, 20) - f(40, 20)}{-10} = \frac{17 - 28}{-10} = 1.1$$

Averaging these values gives $f_v(40, 20) \approx 1.15$. Similarly, $f_t(40, 20) = \lim\limits_{h \to 0} \dfrac{f(40, 20 + h) - f(40, 20)}{h}$, so we use $h = 10$ and $h = -5$:

$$f_t(40, 20) \approx \frac{f(40, 30) - f(40, 20)}{10} = \frac{31 - 28}{10} = 0.3, \qquad f_t(40, 20) \approx \frac{f(40, 15) - f(40, 20)}{-5} = \frac{25 - 28}{-5} = 0.6$$

Averaging these values gives $f_t(40, 15) \approx 0.45$. The linear approximation, then, is

$$f(v, t) \approx f(40, 20) + f_v(40, 20)(v - 40) + f_t(40, 20)(t - 20) \approx 28 + 1.15(v - 40) + 0.45(t - 20)$$

When $v = 43$ and $t = 24$, we estimate $f(43, 24) \approx 28 + 1.15(43 - 40) + 0.45(24 - 20) = 33.25$, so we would expect the wave heights to be approximately 33.25 ft.

23. From the table, $f(94, 80) = 127$. To estimate $f_T(94, 80)$ and $f_H(94, 80)$ we follow the procedure used in Section 14.3. Since $f_T(94, 80) = \lim\limits_{h \to 0} \dfrac{f(94 + h, 80) - f(94, 80)}{h}$, we approximate this quantity with $h = \pm 2$ and use the values given in the table:

$$f_T(94, 80) \approx \frac{f(96, 80) - f(94, 80)}{2} = \frac{135 - 127}{2} = 4, \qquad f_T(94, 80) \approx \frac{f(92, 80) - f(94, 80)}{-2} = \frac{119 - 127}{-2} = 4$$

Averaging these values gives $f_T(94, 80) \approx 4$. Similarly, $f_H(94, 80) = \lim\limits_{h \to 0} \dfrac{f(94, 80 + h) - f(94, 80)}{h}$, so we use $h = \pm 5$:

$$f_H(94, 80) \approx \frac{f(94, 85) - f(94, 80)}{5} = \frac{132 - 127}{5} = 1, \qquad f_H(94, 80) \approx \frac{f(94, 75) - f(94, 80)}{-5} = \frac{122 - 127}{-5} = 1$$

Averaging these values gives $f_H(94, 80) \approx 1$. The linear approximation, then, is

$$f(T, H) \approx f(94, 80) + f_T(94, 80)(T - 94) + f_H(94, 80)(H - 80)$$
$$\approx 127 + 4(T - 94) + 1(H - 80) \qquad [\text{or } 4T + H - 329]$$

Thus when $T = 95$ and $H = 78$, $f(95, 78) \approx 127 + 4(95 - 94) + 1(78 - 80) = 129$, so we estimate the heat index to be approximately 129°F.

24. From the table, $f(-15,50)=-29$. To estimate $f_T(-15,50)$ and $f_v(-15,50)$ we follow the procedure used in Section 14.3. Since $f_T(-15,50)=\lim\limits_{h\to 0}\dfrac{f(-15+h,50)-f(-15,50)}{h}$, we approximate this quantity with $h=\pm 5$ and use the values given in the table:

$$f_T(-15,50)\approx\frac{f(-10,50)-f(-15,50)}{5}=\frac{-22-(-29)}{5}=1.4$$

$$f_T(-15,50)\approx\frac{f(-20,50)-f(-15,50)}{-5}=\frac{-35-(-29)}{-5}=1.2$$

Averaging these values gives $f_T(-15,50)\approx 1.3$. Similarly $f_v(-15,50)=\lim\limits_{h\to 0}\dfrac{f(-15,50+h)-f(-15,50)}{h}$, so we use $h=\pm 10$:

$$f_v(-15,50)\approx\frac{f(-15,60)-f(-15,50)}{10}=\frac{-30-(-29)}{10}=-0.1$$

$$f_v(-15,50)\approx\frac{f(-15,40)-f(-15,50)}{-10}=\frac{-27-(-29)}{-10}=-0.2$$

Averaging these values gives $f_v(-15,50)\approx -0.15$. The linear approximation to the wind-chill index function, then, is $f(T,v)\approx f(-15,50)+f_T(-15,50)(T-(-15))+f_v(-15,50)(v-50)\approx -29+(1.3)(T+15)-(0.15)(v-50)$. Thus when $T=-17^\circ\text{C}$ and $v=55$ km/h, $f(-17,55)\approx -29+(1.3)(-17+15)-(0.15)(55-50)=-32.35$, so we estimate the wind-chill index to be approximately -32.35°C.

25. $z=e^{-2x}\cos 2\pi t \quad\Rightarrow$

$$dz=\frac{\partial z}{\partial x}dx+\frac{\partial z}{\partial t}dt=e^{-2x}(-2)\cos 2\pi t\,dx+e^{-2x}(-\sin 2\pi t)(2\pi)\,dt=-2e^{-2x}\cos 2\pi t\,dx-2\pi e^{-2x}\sin 2\pi t\,dt$$

26. $u=\sqrt{x^2+3y^2}=(x^2+3y^2)^{1/2}\quad\Rightarrow$

$$du=\frac{\partial u}{\partial x}dx+\frac{\partial u}{\partial y}dy=\tfrac{1}{2}(x^2+3y^2)^{-1/2}(2x)\,dx+\tfrac{1}{2}(x^2+3y^2)^{-1/2}(6y)\,dy=\frac{x}{\sqrt{x^2+3y^2}}\,dx+\frac{3y}{\sqrt{x^2+3y^2}}\,dy$$

27. $m=p^5q^3\quad\Rightarrow\quad dm=\dfrac{\partial m}{\partial p}\,dp+\dfrac{\partial m}{\partial q}\,dq=5p^4q^3\,dp+3p^5q^2\,dq$

28. $T=\dfrac{v}{1+uvw}\quad\Rightarrow$

$$\begin{aligned}dT&=\frac{\partial T}{\partial u}\,du+\frac{\partial T}{\partial v}\,dv+\frac{\partial T}{\partial w}\,dw\\&=v(-1)(1+uvw)^{-2}(vw)\,du+\frac{1(1+uvw)-v(uw)}{(1+uvw)^2}\,dv+v(-1)(1+uvw)^{-2}(uv)\,dw\\&=-\frac{v^2w}{(1+uvw)^2}\,du+\frac{1}{(1+uvw)^2}\,dv-\frac{uv^2}{(1+uvw)^2}\,dw\end{aligned}$$

29. $R=\alpha\beta^2\cos\gamma\quad\Rightarrow\quad dR=\dfrac{\partial R}{\partial\alpha}\,d\alpha+\dfrac{\partial R}{\partial\beta}\,d\beta+\dfrac{\partial R}{\partial\gamma}\,d\gamma=\beta^2\cos\gamma\,d\alpha+2\alpha\beta\,\cos\gamma\,d\beta-\alpha\beta^2\sin\gamma\,d\gamma$

30. $L = xze^{-y^2-z^2} \quad \Rightarrow$

$$dL = \frac{\partial L}{\partial x}\,dx + \frac{\partial L}{\partial y}\,dy + \frac{\partial L}{\partial z}\,dz = ze^{-y^2-z^2}\,dx + xze^{-y^2-z^2}(-2y)\,dy + x[z \cdot e^{-y^2-z^2}(-2z) + e^{-y^2-z^2} \cdot 1]\,dz$$
$$= ze^{-y^2-z^2}\,dx - 2xyze^{-y^2-z^2}\,dy + x(1-2z^2)e^{-y^2-z^2}\,dz$$

31. $dx = \Delta x = 0.05$, $dy = \Delta y = 0.1$, $z = 5x^2 + y^2$, $z_x = 10x$, $z_y = 2y$. Thus when $x = 1$ and $y = 2$,
$dz = z_x(1,2)\,dx + z_y(1,2)\,dy = (10)(0.05) + (4)(0.1) = 0.9$ while
$\Delta z = f(1.05, 2.1) - f(1,2) = 5(1.05)^2 + (2.1)^2 - 5 - 4 = 0.9225.$

32. $dx = \Delta x = -0.04$, $dy = \Delta y = 0.05$, $z = x^2 - xy + 3y^2$, $z_x = 2x - y$, $z_y = 6y - x$. Thus when $x = 3$ and $y = -1$,
$dz = (7)(-0.04) + (-9)(0.05) = -0.73$ while $\Delta z = (2.96)^2 - (2.96)(-0.95) + 3(-0.95)^2 - (9 + 3 + 3) = -0.7189.$

33. $dA = \dfrac{\partial A}{\partial x}\,dx + \dfrac{\partial A}{\partial y}\,dy = y\,dx + x\,dy$ and $|\Delta x| \leq 0.1$, $|\Delta y| \leq 0.1$. We use $dx = 0.1$, $dy = 0.1$ with $x = 30$, $y = 24$; then the maximum error in the area is about $dA = 24(0.1) + 30(0.1) = 5.4\text{ cm}^2$.

34. Let V be the volume. Then $V = \pi r^2 h$ and $\Delta V \approx dV = 2\pi rh\,dr + \pi r^2\,dh$ is an estimate of the amount of metal. With $dr = 0.05$ and $dh = 0.2$ we get $dV = 2\pi(2)(10)(0.05) + \pi(2)^2(0.2) = 2.80\pi \approx 8.8\text{ cm}^3$.

35. The volume of a can is $V = \pi r^2 h$ and $\Delta V \approx dV$ is an estimate of the amount of tin. Here $dV = 2\pi rh\,dr + \pi r^2\,dh$, so put $dr = 0.04$, $dh = 0.08$ (0.04 on top, 0.04 on bottom) and then $\Delta V \approx dV = 2\pi(48)(0.04) + \pi(16)(0.08) \approx 16.08\text{ cm}^3$. Thus the amount of tin is about 16 cm^3.

36. $W = 13.12 + 0.6215T - 11.37v^{0.16} + 0.3965Tv^{0.16}$, so the differential of W is

$$dW = \frac{\partial W}{\partial T}\,dT + \frac{\partial W}{\partial v}\,dv = (0.6215 + 0.3965v^{0.16})\,dT + \left[-11.37(0.16)v^{-0.84} + 0.3965T(0.16)v^{-0.84}\right]dv$$
$$= (0.6215 + 0.3965v^{0.16})\,dT + (-1.8192 + 0.06344T)v^{-0.84}\,dv$$

Here we have $|\Delta T| \leq 1$, $|\Delta v| \leq 2$, so we take $dT = 1$, $dv = 2$ with $T = -11$, $v = 26$. The maximum error in the calculated value of W is about $dW = (0.6215 + 0.3965(26)^{0.16})(1) + (-1.8192 + 0.06344(-11))(26)^{-0.84}(2) \approx 0.96$.

37. $T = \dfrac{mgR}{2r^2 + R^2}$, so the differential of T is

$$dT = \frac{\partial T}{\partial R}\,dR + \frac{\partial T}{\partial r}\,dr = \frac{(2r^2 + R^2)(mg) - mgR(2R)}{(2r^2 + R^2)^2}\,dR + \frac{(2r^2 + R^2)(0) - mgR(4r)}{(2r^2 + R^2)^2}\,dr$$
$$= \frac{mg(2r^2 - R^2)}{(2r^2 + R^2)^2}\,dR - \frac{4mgRr}{(2r^2 + R^2)^2}\,dr$$

Here we have $\Delta R = 0.1$ and $\Delta r = 0.1$, so we take $dR = 0.1$, $dr = 0.1$ with $R = 3$, $r = 0.7$. Then the change in the tension T is approximately

$$dT = \frac{mg[2(0.7)^2 - (3)^2]}{[2(0.7)^2 + (3)^2]^2}\,(0.1) - \frac{4mg(3)(0.7)}{[2(0.7)^2 + (3)^2]^2}\,(0.1)$$
$$= -\frac{0.802mg}{(9.98)^2} - \frac{0.84mg}{(9.98)^2} = -\frac{1.642}{99.6004}mg \approx -0.0165mg$$

Because the change is negative, tension decreases.

38. Here $dV = \Delta V = 0.3$, $dT = \Delta T = -5$, $P = 8.31\,\dfrac{T}{V}$, so

$dP = \left(\dfrac{8.31}{V}\right) dT - \dfrac{8.31 \cdot T}{V^2}\, dV = 8.31\left[-\dfrac{5}{12} - \dfrac{310}{144} \cdot \dfrac{3}{10}\right] \approx -8.83$. Thus the pressure will drop by about 8.83 kPa.

39. First we find $\dfrac{\partial R}{\partial R_1}$ implicitly by taking partial derivatives of both sides with respect to R_1:

$\dfrac{\partial}{\partial R_1}\left(\dfrac{1}{R}\right) = \dfrac{\partial\left[(1/R_1) + (1/R_2) + (1/R_3)\right]}{\partial R_1} \quad\Rightarrow\quad -R^{-2}\dfrac{\partial R}{\partial R_1} = -R_1^{-2} \quad\Rightarrow\quad \dfrac{\partial R}{\partial R_1} = \dfrac{R^2}{R_1^2}$. Then by symmetry,

$\dfrac{\partial R}{\partial R_2} = \dfrac{R^2}{R_2^2}$, $\dfrac{\partial R}{\partial R_3} = \dfrac{R^2}{R_3^2}$. When $R_1 = 25$, $R_2 = 40$ and $R_3 = 50$, $\dfrac{1}{R} = \dfrac{17}{200} \quad\Leftrightarrow\quad R = \frac{200}{17}\ \Omega$. Since the possible error for each R_i is 0.5%, the maximum error of R is attained by setting $\Delta R_i = 0.005 R_i$. So

$$\Delta R \approx dR = \frac{\partial R}{\partial R_1}\,\Delta R_1 + \frac{\partial R}{\partial R_2}\,\Delta R_2 + \frac{\partial R}{\partial R_3}\,\Delta R_3 = (0.005)R^2\left(\frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3}\right) = (0.005)R = \tfrac{1}{17} \approx 0.059\ \Omega.$$

40. The errors in measurement are at most 2%, so $\left|\dfrac{\Delta w}{w}\right| \le 0.02$ and $\left|\dfrac{\Delta h}{h}\right| \le 0.02$. The relative error in the calculated surface area is

$$\frac{\Delta S}{S} \approx \frac{dS}{S} = \frac{0.1091(0.425w^{0.425-1})h^{0.725}\,dw + 0.1091w^{0.425}(0.725h^{0.725-1})\,dh}{0.1091w^{0.425}h^{0.725}} = 0.425\frac{dw}{w} + 0.725\frac{dh}{h}$$

To estimate the maximum relative error, we use $\dfrac{dw}{w} = \left|\dfrac{\Delta w}{w}\right| = 0.02$ and $\dfrac{dh}{h} = \left|\dfrac{\Delta h}{h}\right| = 0.02 \quad\Rightarrow$

$\dfrac{dS}{S} = 0.425\,(0.02) + 0.725\,(0.02) = 0.023$. Thus the maximum percentage error is approximately 2.3%.

41. (a) $B(m,h) = m/h^2 \quad\Rightarrow\quad B_m(m,h) = 1/h^2$ and $B_h(m,h) = -2m/h^3$. Since $h > 0$, both B_m and B_h are continuous functions, so B is differentiable at $(23, 1.10)$. We have $B(23, 1.10) = 23/(1.10)^2 \approx 19.01$, $B_m(23, 1.10) = 1/(1.10)^2 \approx 0.8264$, and $B_h(23, 1.10) = -2(23)/(1.10)^3 \approx -34.56$, so the linear approximation of B at $(23, 1.10)$ is

$B\,(m,h) \approx B(23, 1.10) + B_m(23, 1.10)(m-23) + B_h(23, 1.10)(h-1.10) \approx 19.01 + 0.8264(m-23) - 34.56(h-1.10)$

or $\ B(m,h) \approx 0.8264m - 34.56h + 38.02$.

(b) From part (a), for values near $m = 23$ and $h = 1.10$, $B(m,h) \approx 0.8264m - 34.56h + 38.02$. If m increases by 1 kg to 24 kg and h increases by 0.03 m to 1.13 m, we estimate the BMI to be $B(24, 1.13) \approx 0.8264(24) - 34.56(1.13) + 38.02 \approx 18.801$. This is very close to the actual computed BMI: $B(24, 1.13) = 24/(1.13)^2 \approx 18.796$.

42. $\mathbf{r}_1(t) = \left\langle 2 + 3t, 1 - t^2, 3 - 4t + t^2\right\rangle \quad\Rightarrow\quad \mathbf{r}_1'(t) = \langle 3, -2t, -4 + 2t\rangle$, $\quad \mathbf{r}_2(u) = \left\langle 1 + u^2, 2u^3 - 1, 2u + 1\right\rangle \quad\Rightarrow$

$\mathbf{r}_2'(u) = \left\langle 2u, 6u^2, 2\right\rangle$. Both curves pass through P since $\mathbf{r}_1(0) = \mathbf{r}_2(1) = \langle 2, 1, 3\rangle$, so the tangent vectors $\mathbf{r}_1'(0) = \langle 3, 0, -4\rangle$ and $\mathbf{r}_2'(1) = \langle 2, 6, 2\rangle$ are both parallel to the tangent plane to S at P. A normal vector for the tangent plane is

$\mathbf{r}_1'(0) \times \mathbf{r}_2'(1) = \langle 3, 0, -4 \rangle \times \langle 2, 6, 2 \rangle = \langle 24, -14, 18 \rangle$, so an equation of the tangent plane is $24(x-2) - 14(y-1) + 18(z-3) = 0$ or $12x - 7y + 9z = 44$.

43. $\Delta z = f(a + \Delta x, b + \Delta y) - f(a, b) = (a + \Delta x)^2 + (b + \Delta y)^2 - (a^2 + b^2)$

$= a^2 + 2a\,\Delta x + (\Delta x)^2 + b^2 + 2b\,\Delta y + (\Delta y)^2 - a^2 - b^2 = 2a\,\Delta x + (\Delta x)^2 + 2b\,\Delta y + (\Delta y)^2$

But $f_x(a, b) = 2a$ and $f_y(a, b) = 2b$ and so $\Delta z = f_x(a, b)\,\Delta x + f_y(a, b)\,\Delta y + \Delta x\,\Delta x + \Delta y\,\Delta y$, which is Definition 7 with $\varepsilon_1 = \Delta x$ and $\varepsilon_2 = \Delta y$. Hence f is differentiable.

44. $\Delta z = f(a + \Delta x, b + \Delta y) - f(a, b) = (a + \Delta x)(b + \Delta y) - 5(b + \Delta y)^2 - (ab - 5b^2)$

$= ab + a\,\Delta y + b\,\Delta x + \Delta x\,\Delta y - 5b^2 - 10b\,\Delta y - 5(\Delta y)^2 - ab + 5b^2$

$= (a - 10b)\,\Delta y + b\,\Delta x + \Delta x\,\Delta y - 5\,\Delta y\,\Delta y,$

but $f_x(a, b) = b$ and $f_y(a, b) = a - 10b$ and so $\Delta z = f_x(a, b)\,\Delta x + f_y(a, b)\,\Delta y + \Delta x\,\Delta y - 5\Delta y\,\Delta y$, which is Definition 7 with $\varepsilon_1 = \Delta y$ and $\varepsilon_2 = -5\,\Delta y$. Hence f is differentiable.

45. To show that f is continuous at (a, b) we need to show that $\lim\limits_{(x,y)\to(a,b)} f(x, y) = f(a, b)$ or equivalently $\lim\limits_{(\Delta x,\Delta y)\to(0,0)} f(a + \Delta x, b + \Delta y) = f(a, b)$. Since f is differentiable at (a, b), $f(a + \Delta x, b + \Delta y) - f(a, b) = \Delta z = f_x(a, b)\,\Delta x + f_y(a, b)\,\Delta y + \varepsilon_1\,\Delta x + \varepsilon_2\,\Delta y$, where ϵ_1 and $\epsilon_2 \to 0$ as $(\Delta x, \Delta y) \to (0, 0)$. Thus $f(a + \Delta x, b + \Delta y) = f(a, b) + f_x(a, b)\,\Delta x + f_y(a, b)\,\Delta y + \varepsilon_1\,\Delta x + \varepsilon_2\,\Delta y$. Taking the limit of both sides as $(\Delta x, \Delta y) \to (0, 0)$ gives $\lim\limits_{(\Delta x,\Delta y)\to(0,0)} f(a + \Delta x, b + \Delta y) = f(a, b)$. Thus f is continuous at (a, b).

46. (a) $\lim\limits_{h\to 0} \dfrac{f(h, 0) - f(0, 0)}{h} = \lim\limits_{h\to 0} \dfrac{0 - 0}{h} = 0$ and $\lim\limits_{h\to 0} \dfrac{f(0, h) - f(0, 0)}{h} = \lim\limits_{h\to 0} \dfrac{0 - 0}{h} = 0$. Thus $f_x(0, 0) = f_y(0, 0) = 0$.

To show that f isn't differentiable at $(0, 0)$ we need only show that f is not continuous at $(0, 0)$ and apply Exercise 45. As $(x, y) \to (0, 0)$ along the x-axis $f(x, y) = 0/x^2 = 0$ for $x \neq 0$ so $f(x, y) \to 0$ as $(x, y) \to (0, 0)$ along the x-axis. But as $(x, y) \to (0, 0)$ along the line $y = x$, $f(x, x) = x^2/(2x^2) = \frac{1}{2}$ for $x \neq 0$ so $f(x, y) \to \frac{1}{2}$ as $(x, y) \to (0, 0)$ along this line. Thus $\lim\limits_{(x,y)\to(0,0)} f(x, y)$ doesn't exist, so f is discontinuous at $(0, 0)$ and thus not differentiable there.

(b) For $(x, y) \neq (0, 0)$, $f_x(x, y) = \dfrac{(x^2 + y^2)y - xy(2x)}{(x^2 + y^2)^2} = \dfrac{y(y^2 - x^2)}{(x^2 + y^2)^2}$. If we approach $(0, 0)$ along the y-axis, then $f_x(x, y) = f_x(0, y) = \dfrac{y^3}{y^4} = \dfrac{1}{y}$, so $f_x(x, y) \to \pm\infty$ as $(x, y) \to (0, 0)$. Thus $\lim\limits_{(x,y)\to(0,0)} f_x(x, y)$ does not exist and $f_x(x, y)$ is not continuous at $(0, 0)$. Similarly, $f_y(x, y) = \dfrac{(x^2 + y^2)x - xy(2y)}{(x^2 + y^2)^2} = \dfrac{x(x^2 - y^2)}{(x^2 + y^2)^2}$ for $(x, y) \neq (0, 0)$, and if we approach $(0, 0)$ along the x-axis, then $f_y(x, y) = f_x(x, 0) = \dfrac{x^3}{x^4} = \dfrac{1}{x}$. Thus $\lim\limits_{(x,y)\to(0,0)} f_y(x, y)$ does not exist and $f_y(x, y)$ is not continuous at $(0, 0)$.

APPLIED PROJECT The Speedo LZR Racer

1. $v(P,C) = \left(\dfrac{2P}{kC}\right)^{1/3} \quad \Rightarrow$

$$f(x,y) = \frac{v(P+xP,C+yC)-v(P,C)}{v(P,C)} = \frac{v(P+xP,C+yC)}{v(P,C)} - \frac{v(P,C)}{v(P,C)} = \frac{\left(\dfrac{2(P+xP)}{k(C+yC)}\right)^{1/3}}{\left(\dfrac{2P}{kC}\right)^{1/3}} - 1$$

$$= \left(\frac{2P(1+x)}{kC(1+y)} \cdot \frac{kC}{2P}\right)^{1/3} - 1 = \left(\frac{1+x}{1+y}\right)^{1/3} - 1$$

Both power and drag cannot be reduced by more than 100%, but both could be increased by any percentage, so $x \geq -1$ and $y \geq -1$. But f is undefined when $y = -1$, so the domain is $\{(x,y) \mid x \geq -1,\ y > -1\}$.

2. If x and y are small, then we can say they are near zero and we can use a linear approximation to f at $(0,0)$.

We have $f(x,y) = (1+x)^{1/3}(1+y)^{-1/3} - 1$ so the partial derivatives are

$f_x(x,y) = \frac{1}{3}(1+x)^{-2/3}(1+y)^{-1/3} = \dfrac{1}{3(1+x)^{2/3}(1+y)^{1/3}}$ and

$f_y(x,y) = -\frac{1}{3}(1+x)^{1/3}(1+y)^{-4/3} = -\dfrac{(1+x)^{1/3}}{3(1+y)^{4/3}}$. Note that f_x and f_y are continuous functions for $x > -1, y > -1$ so f is differentiable at $(0,0)$. Then $f_x(0,0) = \frac{1}{3}$ and $f_y(0,0) = -\frac{1}{3}$, and the linear approximation is

$f(x,y) \approx f(0,0) + f_x(0,0)(x-0) + f_y(0,0)(y-0) = 0 + \frac{1}{3}(x-0) - \frac{1}{3}(y-0) = \frac{1}{3}x - \frac{1}{3}y$. According to the linear approximation, a small fractional increase in power results in 1/3 that fractional increase in speed, and a small decrease in drag has the same effect.

3. $f_{xx}(x,y) = \dfrac{1}{3(1+y)^{1/3}} \cdot \left(-\frac{2}{3}\right)(1+x)^{-5/3} = -\dfrac{2}{9(1+x)^{5/3}(1+y)^{1/3}}$,

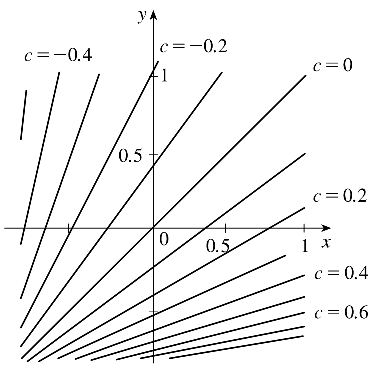
$f_{yy}(x,y) = -\frac{1}{3}(1+x)^{1/3} \cdot \left(-\frac{4}{3}\right)(1+y)^{-7/3} = \dfrac{4(1+x)^{1/3}}{9(1+y)^{7/3}}$. Because $f_x(x,y)$ is positive in the domain of f, an increase in power results in an increase in speed, but $f_{xx}(x,y)$ is negative, so as the fractional power increases, the fractional speed increases at a declining rate. (We can say that in the positive x-direction, f is increasing and concave downward.) Thus the linear approximation gives an overestimate for an increase in power. Since $f_y(x,y)$ is negative, a *decrease* in drag *increases* speed. But $f_{yy}(x,y)$ is positive, so f_y increases as y increases and f_y decreases (f_y becomes larger and larger negative) as y decreases. (In the positive y-direction, f is decreasing and concave upward.) Thus as the fractional drag decreases, the fractional speed increases at an accelerating pace and the linear approximation gives an underestimate of the increase in power. This explains why a decrease in drag is more effective than an increase in power: Reducing drag improves speed at an increasing rate while adding power improves speed at a declining rate.

4. The level curves of $f(x,y) = \left(\dfrac{1+x}{1+y}\right)^{1/3} - 1$ are

$$\left(\frac{1+x}{1+y}\right)^{1/3} - 1 = c \quad\Rightarrow\quad \frac{1+x}{1+y} = (1+c)^3 \quad\Rightarrow$$

$$y = \frac{1+x}{(1+c)^3} - 1.$$

From the level curves, we see that increasing x (from 0) by a small amount has a similar effect on the value of f as decreasing y by a small amount. However, for larger changes, a decrease in y gives greater values of f than a similar increase in x.



14.5 The Chain Rule

1. $z = xy^3 - x^2y,\quad x = t^2+1,\quad y = t^2-1 \quad\Rightarrow$

$$\frac{dz}{dt} = \frac{\partial z}{\partial x}\frac{dx}{dt} + \frac{\partial z}{\partial y}\frac{dy}{dt} = (y^3 - 2xy)(2t) + (3xy^2 - x^2)(2t) = 2t(y^3 - 2xy + 3xy^2 - x^2)$$

2. $z = \dfrac{x-y}{x+2y},\quad x = e^{\pi t},\quad y = e^{-\pi t} \quad\Rightarrow$

$$\begin{aligned}\frac{dz}{dt} &= \frac{\partial z}{\partial x}\frac{dx}{dt} + \frac{\partial z}{\partial y}\frac{dy}{dt} = \frac{(x+2y)(1)-(x-y)(1)}{(x+2y)^2}(\pi e^{\pi t}) + \frac{(x+2y)(-1)-(x-y)(2)}{(x+2y)^2}(-\pi e^{-\pi t})\\ &= \frac{3y}{(x+2y)^2}(\pi e^{\pi t}) + \frac{-3x}{(x+2y)^2}(-\pi e^{-\pi t}) = \frac{3\pi}{(x+2y)^2}\left(ye^{\pi t} + xe^{-\pi t}\right)\end{aligned}$$

3. $z = \sin x \cos y,\quad x = \sqrt{t},\quad y = 1/t \quad\Rightarrow$

$$\frac{dz}{dt} = \frac{\partial z}{\partial x}\frac{dx}{dt} + \frac{\partial z}{\partial y}\frac{dy}{dt} = (\cos x\cos y)\left(\tfrac{1}{2}t^{-1/2}\right) + (-\sin x\sin y)\left(-t^{-2}\right) = \frac{1}{2\sqrt{t}}\cos x\cos y + \frac{1}{t^2}\sin x\sin y$$

4. $z = \sqrt{1+xy},\quad x = \tan t,\quad y = \arctan t \quad\Rightarrow$

$$\begin{aligned}\frac{dz}{dt} &= \frac{\partial z}{\partial x}\frac{dx}{dt} + \frac{\partial z}{\partial y}\frac{dy}{dt} = \tfrac{1}{2}(1+xy)^{-1/2}(y)\cdot\sec^2 t + \tfrac{1}{2}(1+xy)^{-1/2}(x)\cdot\frac{1}{1+t^2}\\ &= \frac{1}{2\sqrt{1+xy}}\left(y\sec^2 t + \frac{x}{1+t^2}\right)\end{aligned}$$

5. $w = xe^{y/z},\ x = t^2,\ y = 1-t,\ z = 1+2t \quad\Rightarrow$

$$\frac{dw}{dt} = \frac{\partial w}{\partial x}\frac{dx}{dt} + \frac{\partial w}{\partial y}\frac{dy}{dt} + \frac{\partial w}{\partial z}\frac{dz}{dt} = e^{y/z}\cdot 2t + xe^{y/z}\left(\frac{1}{z}\right)\cdot(-1) + xe^{y/z}\left(-\frac{y}{z^2}\right)\cdot 2 = e^{y/z}\left(2t - \frac{x}{z} - \frac{2xy}{z^2}\right)$$

6. $w = \ln\sqrt{x^2+y^2+z^2} = \frac{1}{2}\ln(x^2+y^2+z^2),\quad x = \sin t,\quad y = \cos t,\quad z = \tan t \quad\Rightarrow$

$$\begin{aligned}\frac{dw}{dt} &= \frac{\partial w}{\partial x}\frac{dx}{dt} + \frac{\partial w}{\partial y}\frac{dy}{dt} + \frac{\partial w}{\partial z}\frac{dz}{dt} = \frac{1}{2}\cdot\frac{2x}{x^2+y^2+z^2}\cdot\cos t + \frac{1}{2}\cdot\frac{2y}{x^2+y^2+z^2}\cdot(-\sin t) + \frac{1}{2}\cdot\frac{2z}{x^2+y^2+z^2}\cdot\sec^2 t\\ &= \frac{x\cos t - y\sin t + z\sec^2 t}{x^2+y^2+z^2}\end{aligned}$$

7. $z = (x-y)^5,\quad x = s^2t,\quad y = st^2 \quad\Rightarrow$

$$\frac{\partial z}{\partial s} = \frac{\partial z}{\partial x}\frac{\partial x}{\partial s} + \frac{\partial z}{\partial y}\frac{\partial y}{\partial s} = 5(x-y)^4(1)\cdot 2st + 5(x-y)^4(-1)\cdot t^2 = 5(x-y)^4\left(2st - t^2\right)$$

$$\frac{\partial z}{\partial t} = \frac{\partial z}{\partial x}\frac{\partial x}{\partial t} + \frac{\partial z}{\partial y}\frac{\partial y}{\partial t} = 5(x-y)^4(1)\cdot s^2 + 5(x-y)^4(-1)\cdot 2st = 5(x-y)^4\left(s^2 - 2st\right)$$

8. $z = \tan^{-1}(x^2+y^2),\quad x = s\ln t,\quad y = te^s \quad\Rightarrow$

$$\frac{\partial z}{\partial s} = \frac{\partial z}{\partial x}\frac{\partial x}{\partial s} + \frac{\partial z}{\partial y}\frac{\partial y}{\partial s} = \frac{2x}{1+(x^2+y^2)^2}\cdot \ln t + \frac{2y}{1+(x^2+y^2)^2}\cdot te^s$$

$$= \frac{2}{1+(x^2+y^2)^2}\left(x\ln t + yte^s\right)$$

$$\frac{\partial z}{\partial t} = \frac{\partial z}{\partial x}\frac{\partial x}{\partial t} + \frac{\partial z}{\partial y}\frac{\partial y}{\partial t} = \frac{2x}{1+(x^2+y^2)^2}\cdot \frac{s}{t} + \frac{2y}{1+(x^2+y^2)^2}\cdot e^s$$

$$= \frac{2}{1+(x^2+y^2)^2}\left(\frac{xs}{t} + ye^s\right)$$

9. $z = \ln(3x+2y),\quad x = s\sin t,\quad y = t\cos s \quad\Rightarrow$

$$\frac{\partial z}{\partial s} = \frac{\partial z}{\partial x}\frac{\partial x}{\partial s} + \frac{\partial z}{\partial y}\frac{\partial y}{\partial s} = \frac{3}{3x+2y}(\sin t) + \frac{2}{3x+2y}(-t\sin s) = \frac{3\sin t - 2t\sin s}{3x+2y}$$

$$\frac{\partial z}{\partial t} = \frac{\partial z}{\partial x}\frac{\partial x}{\partial t} + \frac{\partial z}{\partial y}\frac{\partial y}{\partial t} = \frac{3}{3x+2y}(s\cos t) + \frac{2}{3x+2y}(\cos s) = \frac{3s\cos t + 2\cos s}{3x+2y}$$

10. $z = \sqrt{x}\,e^{xy},\quad x = 1+st,\quad y = s^2 - t^2 \quad\Rightarrow$

$$\frac{\partial z}{\partial s} = \frac{\partial z}{\partial x}\frac{\partial x}{\partial s} + \frac{\partial z}{\partial y}\frac{\partial y}{\partial s} = \left(\sqrt{x}\cdot e^{xy}(y) + e^{xy}\cdot \tfrac{1}{2}x^{-1/2}\right)(t) + \sqrt{x}\,e^{xy}(x)\,(2s) = \left(yt\sqrt{x} + \frac{t}{2\sqrt{x}} + 2x^{3/2}s\right)e^{xy}$$

$$\frac{\partial z}{\partial t} = \frac{\partial z}{\partial x}\frac{\partial x}{\partial t} + \frac{\partial z}{\partial y}\frac{\partial y}{\partial t} = \left(\sqrt{x}\cdot e^{xy}(y) + e^{xy}\cdot \tfrac{1}{2}x^{-1/2}\right)(s) + \sqrt{x}\,e^{xy}(x)\,(-2t) = \left(ys\sqrt{x} + \frac{s}{2\sqrt{x}} - 2x^{3/2}t\right)e^{xy}$$

11. $z = e^r\cos\theta,\ r = st,\ \theta = \sqrt{s^2+t^2} \quad\Rightarrow$

$$\frac{\partial z}{\partial s} = \frac{\partial z}{\partial r}\frac{\partial r}{\partial s} + \frac{\partial z}{\partial \theta}\frac{\partial \theta}{\partial s} = e^r\cos\theta\cdot t + e^r(-\sin\theta)\cdot\tfrac{1}{2}(s^2+t^2)^{-1/2}(2s) = te^r\cos\theta - e^r\sin\theta\cdot\frac{s}{\sqrt{s^2+t^2}}$$

$$= e^r\left(t\cos\theta - \frac{s}{\sqrt{s^2+t^2}}\sin\theta\right)$$

$$\frac{\partial z}{\partial t} = \frac{\partial z}{\partial r}\frac{\partial r}{\partial t} + \frac{\partial z}{\partial \theta}\frac{\partial \theta}{\partial t} = e^r\cos\theta\cdot s + e^r(-\sin\theta)\cdot\tfrac{1}{2}(s^2+t^2)^{-1/2}(2t) = se^r\cos\theta - e^r\sin\theta\cdot\frac{t}{\sqrt{s^2+t^2}}$$

$$= e^r\left(s\cos\theta - \frac{t}{\sqrt{s^2+t^2}}\sin\theta\right)$$

12. $z = \tan(u/v),\ u = 2s+3t,\ \ v = 3s-2t \quad\Rightarrow$

$$\frac{\partial z}{\partial s} = \frac{\partial z}{\partial u}\frac{\partial u}{\partial s} + \frac{\partial z}{\partial v}\frac{\partial v}{\partial s} = \sec^2(u/v)(1/v)\cdot 2 + \sec^2(u/v)(-uv^{-2})\cdot 3$$

$$= \frac{2}{v}\sec^2\left(\frac{u}{v}\right) - \frac{3u}{v^2}\sec^2\left(\frac{u}{v}\right) = \frac{2v-3u}{v^2}\sec^2\left(\frac{u}{v}\right)$$

$$\frac{\partial z}{\partial t} = \frac{\partial z}{\partial u}\frac{\partial u}{\partial t} + \frac{\partial z}{\partial v}\frac{\partial v}{\partial t} = \sec^2(u/v)(1/v)\cdot 3 + \sec^2(u/v)(-uv^{-2})\cdot(-2)$$
$$= \frac{3}{v}\sec^2\left(\frac{u}{v}\right) + \frac{2u}{v^2}\sec^2\left(\frac{u}{v}\right) = \frac{2u+3v}{v^2}\sec^2\left(\frac{u}{v}\right)$$

13. Let $x = g(t)$ and $y = h(t)$. Then $p(t) = f(x, y)$ and the Chain Rule (2) gives $\dfrac{dp}{dt} = \dfrac{\partial f}{\partial x}\dfrac{dx}{dt} + \dfrac{\partial f}{\partial y}\dfrac{dy}{dt}$. When $t = 2$,

$x = g(2) = 4$ and $y = h(2) = 5$, so $p'(2) = f_x(4,5)\,g'(2) + f_y(4,5)\,h'(2) = (2)(-3) + (8)(6) = 42$.

14. $R(s,t) = G\left(u(s,t), v(s,t)\right) \quad\Rightarrow\quad \dfrac{\partial R}{\partial s} = \dfrac{\partial R}{\partial u}\dfrac{\partial u}{\partial s} + \dfrac{\partial R}{\partial v}\dfrac{\partial v}{\partial s}$ and $\dfrac{\partial R}{\partial t} = \dfrac{\partial R}{\partial u}\dfrac{\partial u}{\partial t} + \dfrac{\partial R}{\partial v}\dfrac{\partial v}{\partial t}$ by the

Chain Rule (3). When $s = 1$ and $t = 2$, $u(1,2) = 5$ and $v(1,2) = 7$.

Thus $R_s(1,2) = G_u(5,7)\,u_s(1,2) + G_v(5,7)\,v_s(1,2) = (9)(4) + (-2)(2) = 32$ and

$R_t(1,2) = G_u(5,7)\,u_t(1,2) + G_v(5,7)\,v_t(1,2) = (9)(-3) + (-2)(6) = -39$.

15. $g(u,v) = f(x(u,v), y(u,v))$ where $x = e^u + \sin v$, $y = e^u + \cos v \quad\Rightarrow$

$\dfrac{\partial x}{\partial u} = e^u$, $\dfrac{\partial x}{\partial v} = \cos v$, $\dfrac{\partial y}{\partial u} = e^u$, $\dfrac{\partial y}{\partial v} = -\sin v$. By the Chain Rule (3), $\dfrac{\partial g}{\partial u} = \dfrac{\partial f}{\partial x}\dfrac{\partial x}{\partial u} + \dfrac{\partial f}{\partial y}\dfrac{\partial y}{\partial u}$. Then

$g_u(0,0) = f_x(x(0,0), y(0,0))\,x_u(0,0) + f_y(x(0,0), y(0,0))\,y_u(0,0) = f_x(1,2)(e^0) + f_y(1,2)(e^0) = 2(1) + 5(1) = 7$.

Similarly, $\dfrac{\partial g}{\partial v} = \dfrac{\partial f}{\partial x}\dfrac{\partial x}{\partial v} + \dfrac{\partial f}{\partial y}\dfrac{\partial y}{\partial v}$. Then

$$g_v(0,0) = f_x(x(0,0), y(0,0))\,x_v(0,0) + f_y(x(0,0), y(0,0))\,y_v(0,0) = f_x(1,2)(\cos 0) + f_y(1,2)(-\sin 0)$$
$$= 2(1) + 5(0) = 2$$

16. $g(r,s) = f(x(r,s), y(r,s))$ where $x = 2r - s$, $y = s^2 - 4r \quad\Rightarrow\quad \dfrac{\partial x}{\partial r} = 2$, $\dfrac{\partial x}{\partial s} = -1$, $\dfrac{\partial y}{\partial r} = -4$, $\dfrac{\partial y}{\partial s} = 2s$.

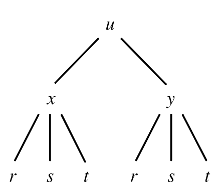
By the Chain Rule (3) $\dfrac{\partial g}{\partial r} = \dfrac{\partial f}{\partial x}\dfrac{\partial x}{\partial r} + \dfrac{\partial f}{\partial y}\dfrac{\partial y}{\partial r}$. Then

$$g_r(1,2) = f_x(x(1,2), y(1,2))\,x_r(1,2) + f_y(x(1,2), y(1,2))\,y_r(1,2) = f_x(0,0)(2) + f_y(0,0)(-4)$$
$$= 4(2) + 8(-4) = -24$$

Similarly, $\dfrac{\partial g}{\partial s} = \dfrac{\partial f}{\partial x}\dfrac{\partial x}{\partial s} + \dfrac{\partial f}{\partial y}\dfrac{\partial y}{\partial s}$. Then

$$g_s(1,2) = f_x(x(1,2), y(1,2))\,x_s(1,2) + f_y(x(1,2), y(1,2))\,y_s(1,2) = f_x(0,0)(-1) + f_y(0,0)(4)$$
$$= 4(-1) + 8(4) = 28$$

17.

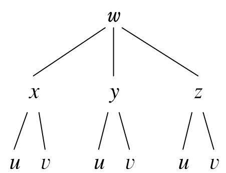


$u = f(x,y)$, $x = x(r,s,t)$, $y = y(r,s,t) \quad\Rightarrow$

$$\frac{\partial u}{\partial r} = \frac{\partial u}{\partial x}\frac{\partial x}{\partial r} + \frac{\partial u}{\partial y}\frac{\partial y}{\partial r}, \quad \frac{\partial u}{\partial s} = \frac{\partial u}{\partial x}\frac{\partial x}{\partial s} + \frac{\partial u}{\partial y}\frac{\partial y}{\partial s},$$

$$\frac{\partial u}{\partial t} = \frac{\partial u}{\partial x}\frac{\partial x}{\partial t} + \frac{\partial u}{\partial y}\frac{\partial y}{\partial t}$$

18.

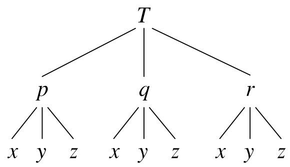


$w = f(x, y, z),\ \ x = x(u, v),\ \ y = y(u, v),\ z = z(u, v) \quad \Rightarrow$

$$\frac{\partial w}{\partial u} = \frac{\partial w}{\partial x}\frac{\partial x}{\partial u} + \frac{\partial w}{\partial y}\frac{\partial y}{\partial u} + \frac{\partial w}{\partial z}\frac{\partial z}{\partial u},$$

$$\frac{\partial w}{\partial v} = \frac{\partial w}{\partial x}\frac{\partial x}{\partial v} + \frac{\partial w}{\partial y}\frac{\partial y}{\partial v} + \frac{\partial w}{\partial z}\frac{\partial z}{\partial v}$$

19.



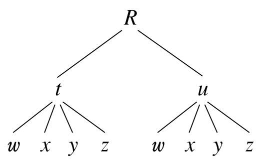
$T = F(p, q, r),\ p = p(x, y, z),\ \ q = q(x, y, z),\ r = r(x, y, z) \quad \Rightarrow$

$$\frac{\partial T}{\partial x} = \frac{\partial T}{\partial p}\frac{\partial p}{\partial x} + \frac{\partial T}{\partial q}\frac{\partial q}{\partial x} + \frac{\partial T}{\partial r}\frac{\partial r}{\partial x},$$

$$\frac{\partial T}{\partial y} = \frac{\partial T}{\partial p}\frac{\partial p}{\partial y} + \frac{\partial T}{\partial q}\frac{\partial q}{\partial y} + \frac{\partial T}{\partial r}\frac{\partial r}{\partial y},$$

$$\frac{\partial T}{\partial z} = \frac{\partial T}{\partial p}\frac{\partial p}{\partial z} + \frac{\partial T}{\partial q}\frac{\partial q}{\partial z} + \frac{\partial T}{\partial r}\frac{\partial r}{\partial z}$$

20.



$R = F(t, u),\ \ t = t(w, x, y, z),\ \ u = u(w, x, y, z) \quad \Rightarrow$

$$\frac{\partial R}{\partial w} = \frac{\partial R}{\partial t}\frac{\partial t}{\partial w} + \frac{\partial R}{\partial u}\frac{\partial u}{\partial w},\quad \frac{\partial R}{\partial x} = \frac{\partial R}{\partial t}\frac{\partial t}{\partial x} + \frac{\partial R}{\partial u}\frac{\partial u}{\partial x},$$

$$\frac{\partial R}{\partial y} = \frac{\partial R}{\partial t}\frac{\partial t}{\partial y} + \frac{\partial R}{\partial u}\frac{\partial u}{\partial y},\quad \frac{\partial R}{\partial z} = \frac{\partial R}{\partial t}\frac{\partial t}{\partial z} + \frac{\partial R}{\partial u}\frac{\partial u}{\partial z}$$

21. $z = x^4 + x^2 y,\ x = s + 2t - u,\ y = stu^2 \quad \Rightarrow$

$$\frac{\partial z}{\partial s} = \frac{\partial z}{\partial x}\frac{\partial x}{\partial s} + \frac{\partial z}{\partial y}\frac{\partial y}{\partial s} = (4x^3 + 2xy)(1) + (x^2)(tu^2),$$

$$\frac{\partial z}{\partial t} = \frac{\partial z}{\partial x}\frac{\partial x}{\partial t} + \frac{\partial z}{\partial y}\frac{\partial y}{\partial t} = (4x^3 + 2xy)(2) + (x^2)(su^2),$$

$$\frac{\partial z}{\partial u} = \frac{\partial z}{\partial x}\frac{\partial x}{\partial u} + \frac{\partial z}{\partial y}\frac{\partial y}{\partial u} = (4x^3 + 2xy)(-1) + (x^2)(2stu).$$

When $s = 4$, $t = 2$, and $u = 1$ we have $x = 7$ and $y = 8$,

so $\dfrac{\partial z}{\partial s} = (1484)(1) + (49)(2) = 1582,\ \dfrac{\partial z}{\partial t} = (1484)\,(2) + (49)(4) = 3164,\ \dfrac{\partial z}{\partial u} = (1484)(-1) + (49)(16) = -700.$

22. $T = v/(2u + v) = v(2u + v)^{-1},\ u = pq\sqrt{r},\ v = p\sqrt{q}\,r \quad \Rightarrow$

$$\frac{\partial T}{\partial p} = \frac{\partial T}{\partial u}\frac{\partial u}{\partial p} + \frac{\partial T}{\partial v}\frac{\partial v}{\partial p} = [-v(2u + v)^{-2}(2)](q\sqrt{r}) + \frac{(2u + v)(1) - v(1)}{(2u + v)^2}\,(\sqrt{q}\,r)$$

$$= \frac{-2v}{(2u + v)^2}\,(q\sqrt{r}) + \frac{2u}{(2u + v)^2}\,(\sqrt{q}\,r),$$

$$\frac{\partial T}{\partial q} = \frac{\partial T}{\partial u}\frac{\partial u}{\partial q} + \frac{\partial T}{\partial v}\frac{\partial v}{\partial q} = \frac{-2v}{(2u + v)^2}\,(p\sqrt{r}) + \frac{2u}{(2u + v)^2}\,\frac{pr}{2\sqrt{q}},$$

$$\frac{\partial T}{\partial r} = \frac{\partial T}{\partial u}\frac{\partial u}{\partial r} + \frac{\partial T}{\partial v}\frac{\partial v}{\partial r} = \frac{-2v}{(2u + v)^2}\,\frac{pq}{2\sqrt{r}} + \frac{2u}{(2u + v)^2}\,(p\sqrt{q}).$$

When $p = 2$, $q = 1$, and $r = 4$ we have $u = 4$ and $v = 8$,

so $\dfrac{\partial T}{\partial p} = \left(-\frac{1}{16}\right)(2) + \left(\frac{1}{32}\right)(4) = 0,\ \dfrac{\partial T}{\partial q} = \left(-\frac{1}{16}\right)(4) + \left(\frac{1}{32}\right)(4) = -\frac{1}{8},\ \dfrac{\partial T}{\partial r} = \left(-\frac{1}{16}\right)\left(\frac{1}{2}\right) + \left(\frac{1}{32}\right)(2) = \frac{1}{32}.$

23. $w = xy + yz + zx,\ x = r\cos\theta,\ y = r\sin\theta,\ z = r\theta \quad \Rightarrow$

$$\frac{\partial w}{\partial r} = \frac{\partial w}{\partial x}\frac{\partial x}{\partial r} + \frac{\partial w}{\partial y}\frac{\partial y}{\partial r} + \frac{\partial w}{\partial z}\frac{\partial z}{\partial r} = (y+z)(\cos\theta) + (x+z)(\sin\theta) + (y+x)(\theta),$$

$$\frac{\partial w}{\partial \theta} = \frac{\partial w}{\partial x}\frac{\partial x}{\partial \theta} + \frac{\partial w}{\partial y}\frac{\partial y}{\partial \theta} + \frac{\partial w}{\partial z}\frac{\partial z}{\partial \theta} = (y+z)(-r\sin\theta) + (x+z)(r\cos\theta) + (y+x)(r).$$

When $r = 2$ and $\theta = \pi/2$ we have $x = 0$, $y = 2$, and $z = \pi$, so $\frac{\partial w}{\partial r} = (2+\pi)(0) + (0+\pi)(1) + (2+0)(\pi/2) = 2\pi$ and

$$\frac{\partial w}{\partial \theta} = (2+\pi)(-2) + (0+\pi)(0) + (2+0)(2) = -2\pi.$$

24. $P = \sqrt{u^2+v^2+w^2} = (u^2+v^2+w^2)^{1/2},\ u = xe^y,\ v = ye^x,\ w = e^{xy} \quad \Rightarrow$

$$\begin{aligned}\frac{\partial P}{\partial x} &= \frac{\partial P}{\partial u}\frac{\partial u}{\partial x} + \frac{\partial P}{\partial v}\frac{\partial v}{\partial x} + \frac{\partial P}{\partial w}\frac{\partial w}{\partial x} \\ &= \tfrac{1}{2}(u^2+v^2+w^2)^{-1/2}(2u)(e^y) + \tfrac{1}{2}(u^2+v^2+w^2)^{-1/2}(2v)(ye^x) + \tfrac{1}{2}(u^2+v^2+w^2)^{-1/2}(2w)(ye^{xy}) \\ &= \frac{ue^y + vye^x + wye^{xy}}{\sqrt{u^2+v^2+w^2}},\end{aligned}$$

$$\begin{aligned}\frac{\partial P}{\partial y} &= \frac{\partial P}{\partial u}\frac{\partial u}{\partial y} + \frac{\partial P}{\partial v}\frac{\partial v}{\partial y} + \frac{\partial P}{\partial w}\frac{\partial w}{\partial y} = \frac{u}{\sqrt{u^2+v^2+w^2}}(xe^y) + \frac{v}{\sqrt{u^2+v^2+w^2}}(e^x) + \frac{w}{\sqrt{u^2+v^2+w^2}}(xe^{xy}) \\ &= \frac{uxe^y + ve^x + wxe^{xy}}{\sqrt{u^2+v^2+w^2}}.\end{aligned}$$

When $x = 0$ and $y = 2$ we have $u = 0$, $v = 2$, and $w = 1$, so $\frac{\partial P}{\partial x} = \frac{0+4+2}{\sqrt{5}} = \frac{6}{\sqrt{5}}$ and $\frac{\partial P}{\partial y} = \frac{0+2+0}{\sqrt{5}} = \frac{2}{\sqrt{5}}$.

25. $N = \frac{p+q}{p+r},\ p = u + vw,\ q = v + uw,\ r = w + uv \quad \Rightarrow$

$$\begin{aligned}\frac{\partial N}{\partial u} &= \frac{\partial N}{\partial p}\frac{\partial p}{\partial u} + \frac{\partial N}{\partial q}\frac{\partial q}{\partial u} + \frac{\partial N}{\partial r}\frac{\partial r}{\partial u} \\ &= \frac{(p+r)(1)-(p+q)(1)}{(p+r)^2}(1) + \frac{(p+r)(1)-(p+q)(0)}{(p+r)^2}(w) + \frac{(p+r)(0)-(p+q)(1)}{(p+r)^2}(v) \\ &= \frac{(r-q)+(p+r)w-(p+q)v}{(p+r)^2},\end{aligned}$$

$$\frac{\partial N}{\partial v} = \frac{\partial N}{\partial p}\frac{\partial p}{\partial v} + \frac{\partial N}{\partial q}\frac{\partial q}{\partial v} + \frac{\partial N}{\partial r}\frac{\partial r}{\partial v} = \frac{r-q}{(p+r)^2}(w) + \frac{p+r}{(p+r)^2}(1) + \frac{-(p+q)}{(p+r)^2}(u) = \frac{(r-q)w+(p+r)-(p+q)u}{(p+r)^2},$$

$$\frac{\partial N}{\partial w} = \frac{\partial N}{\partial p}\frac{\partial p}{\partial w} + \frac{\partial N}{\partial q}\frac{\partial q}{\partial w} + \frac{\partial N}{\partial r}\frac{\partial r}{\partial w} = \frac{r-q}{(p+r)^2}(v) + \frac{p+r}{(p+r)^2}(u) + \frac{-(p+q)}{(p+r)^2}(1) = \frac{(r-q)v+(p+r)u-(p+q)}{(p+r)^2}.$$

When $u = 2$, $v = 3$, and $w = 4$ we have $p = 14$, $q = 11$, and $r = 10$, so $\frac{\partial N}{\partial u} = \frac{-1+(24)(4)-(25)(3)}{(24)^2} = \frac{20}{576} = \frac{5}{144}$,

$$\frac{\partial N}{\partial v} = \frac{(-1)(4)+24-(25)(2)}{(24)^2} = \frac{-30}{576} = -\frac{5}{96}, \text{ and } \frac{\partial N}{\partial w} = \frac{(-1)(3)+(24)(2)-25}{(24)^2} = \frac{20}{576} = \frac{5}{144}.$$

26. $u = xe^{ty},\ x = \alpha^2\beta,\ y = \beta^2\gamma,\ t = \gamma^2\alpha \quad \Rightarrow$

$$\frac{\partial u}{\partial \alpha} = \frac{\partial u}{\partial x}\frac{\partial x}{\partial \alpha} + \frac{\partial u}{\partial y}\frac{\partial y}{\partial \alpha} + \frac{\partial u}{\partial t}\frac{\partial t}{\partial \alpha} = e^{ty}(2\alpha\beta) + xte^{ty}(0) + xye^{ty}(\gamma^2) = e^{ty}(2\alpha\beta + xy\gamma^2),$$

$$\frac{\partial u}{\partial \beta} = \frac{\partial u}{\partial x}\frac{\partial x}{\partial \beta} + \frac{\partial u}{\partial y}\frac{\partial y}{\partial \beta} + \frac{\partial u}{\partial t}\frac{\partial t}{\partial \beta} = e^{ty}(\alpha^2) + xte^{ty}(2\beta\gamma) + xye^{ty}(0) = e^{ty}(\alpha^2 + 2xt\beta\gamma),$$

$$\frac{\partial u}{\partial \gamma} = \frac{\partial u}{\partial x}\frac{\partial x}{\partial \gamma} + \frac{\partial u}{\partial y}\frac{\partial y}{\partial \gamma} + \frac{\partial u}{\partial t}\frac{\partial t}{\partial \gamma} = e^{ty}(0) + xte^{ty}(\beta^2) + xye^{ty}(2\gamma\alpha) = e^{ty}(xt\beta^2 + 2xy\alpha\gamma).$$

When $\alpha = -1$, $\beta = 2$, and $\gamma = 1$ we have $x = 2$, $y = 4$, and $t = -1$, so $\dfrac{\partial u}{\partial \alpha} = e^{-4}(-4+8) = 4e^{-4}$,

$\dfrac{\partial u}{\partial \beta} = e^{-4}(1-8) = -7e^{-4}$, and $\dfrac{\partial u}{\partial \gamma} = e^{-4}(-8-16) = -24e^{-4}$.

27. $y\cos x = x^2 + y^2$, so let $F(x,y) = y\cos x - x^2 - y^2 = 0$. Then by Equation 6

$$\frac{dy}{dx} = -\frac{F_x}{F_y} = -\frac{-y\sin x - 2x}{\cos x - 2y} = \frac{2x + y\sin x}{\cos x - 2y}.$$

28. $\cos(xy) = 1 + \sin y$, so let $F(x,y) = \cos(xy) - 1 - \sin y = 0$. Then by Equation 6

$$\frac{dy}{dx} = -\frac{F_x}{F_y} = -\frac{-\sin(xy)(y)}{-\sin(xy)(x) - \cos y} = -\frac{y\sin(xy)}{\cos y + x\sin(xy)}.$$

29. $\tan^{-1}(x^2 y) = x + xy^2$, so let $F(x,y) = \tan^{-1}(x^2y) - x - xy^2 = 0$. Then

$$F_x(x,y) = \frac{1}{1+(x^2y)^2}\,(2xy) - 1 - y^2 = \frac{2xy}{1+x^4y^2} - 1 - y^2 = \frac{2xy - (1+y^2)(1+x^4y^2)}{1+x^4y^2},$$

$$F_y(x,y) = \frac{1}{1+(x^2y)^2}\,(x^2) - 2xy = \frac{x^2}{1+x^4y^2} - 2xy = \frac{x^2 - 2xy(1+x^4y^2)}{1+x^4y^2}$$

and

$$\frac{dy}{dx} = -\frac{F_x}{F_y} = -\frac{[2xy - (1+y^2)(1+x^4y^2)]/(1+x^4y^2)}{[x^2 - 2xy(1+x^4y^2)]/(1+x^4y^2)} = \frac{(1+y^2)(1+x^4y^2) - 2xy}{x^2 - 2xy(1+x^4y^2)}$$

$$= \frac{1 + x^4y^2 + y^2 + x^4y^4 - 2xy}{x^2 - 2xy - 2x^5y^3}$$

30. $e^y \sin x = x + xy$, so let $F(x,y) = e^y\sin x - x - xy = 0$. Then $\dfrac{dy}{dx} = -\dfrac{F_x}{F_y} = -\dfrac{e^y\cos x - 1 - y}{e^y \sin x - x} = \dfrac{1 + y - e^y\cos x}{e^y\sin x - x}$.

31. $x^2 + 2y^2 + 3z^2 = 1$, so let $F(x,y,z) = x^2 + 2y^2 + 3z^2 - 1 = 0$. Then by Equations 7

$$\frac{\partial z}{\partial x} = -\frac{F_x}{F_z} = -\frac{2x}{6z} = -\frac{x}{3z} \quad \text{and} \quad \frac{\partial z}{\partial y} = -\frac{F_y}{F_z} = -\frac{4y}{6z} = -\frac{2y}{3z}.$$

32. $x^2 - y^2 + z^2 - 2z = 4$, so let $F(x,y,z) = x^2 - y^2 + z^2 - 2z - 4 = 0$. Then by Equations 7

$$\frac{\partial z}{\partial x} = -\frac{F_x}{F_z} = -\frac{2x}{2z-2} = \frac{x}{1-z} \quad \text{and} \quad \frac{\partial z}{\partial y} = -\frac{F_y}{F_z} = -\frac{-2y}{2z-2} = \frac{y}{z-1}.$$

33. $e^z = xyz$, so let $F(x, y, z) = e^z - xyz = 0$. Then $\dfrac{\partial z}{\partial x} = -\dfrac{F_x}{F_z} = -\dfrac{-yz}{e^z - xy} = \dfrac{yz}{e^z - xy}$ and

$\dfrac{\partial z}{\partial y} = -\dfrac{F_y}{F_z} = -\dfrac{-xz}{e^z - xy} = \dfrac{xz}{e^z - xy}$.

34. $yz + x\ln y = z^2$, so let $F(x, y, z) = yz + x\ln y - z^2 = 0$. Then $\dfrac{\partial z}{\partial x} = -\dfrac{F_x}{F_z} = -\dfrac{\ln y}{y - 2z} = \dfrac{\ln y}{2z - y}$ and

$\dfrac{\partial z}{\partial y} = -\dfrac{F_y}{F_z} = -\dfrac{z + (x/y)}{y - 2z} = \dfrac{x + yz}{2yz - y^2}$.

35. Since x and y are each functions of t, $T(x, y)$ is a function of t, so by the Chain Rule, $\dfrac{dT}{dt} = \dfrac{\partial T}{\partial x}\dfrac{dx}{dt} + \dfrac{\partial T}{\partial y}\dfrac{dy}{dt}$. After 3 seconds, $x = \sqrt{1 + t} = \sqrt{1 + 3} = 2$, $y = 2 + \frac{1}{3}t = 2 + \frac{1}{3}(3) = 3$, $\dfrac{dx}{dt} = \dfrac{1}{2\sqrt{1 + t}} = \dfrac{1}{2\sqrt{1 + 3}} = \dfrac{1}{4}$, and $\dfrac{dy}{dt} = \dfrac{1}{3}$.

Then $\dfrac{dT}{dt} = T_x(2, 3)\dfrac{dx}{dt} + T_y(2, 3)\dfrac{dy}{dt} = 4\left(\frac{1}{4}\right) + 3\left(\frac{1}{3}\right) = 2$. Thus the temperature is rising at a rate of 2°C/s.

36. (a) Since $\partial W/\partial T$ is negative, a rise in average temperature (while annual rainfall remains constant) causes a decrease in wheat production at the current production levels. Since $\partial W/\partial R$ is positive, an increase in annual rainfall (while the average temperature remains constant) causes an increase in wheat production.

(b) Since the average temperature is rising at a rate of 0.15°C/year, we know that $dT/dt = 0.15$. Since rainfall is decreasing at a rate of 0.1 cm/year, we know $dR/dt = -0.1$. Then, by the Chain Rule,

$\dfrac{dW}{dt} = \dfrac{\partial W}{\partial T}\dfrac{dT}{dt} + \dfrac{\partial W}{\partial R}\dfrac{dR}{dt} = (-2)(0.15) + (8)(-0.1) = -1.1$. Thus we estimate that wheat production will decrease at a rate of 1.1 units/year.

37. $C = 1449.2 + 4.6T - 0.055T^2 + 0.00029T^3 + 0.016D$, so $\dfrac{\partial C}{\partial T} = 4.6 - 0.11T + 0.00087T^2$ and $\dfrac{\partial C}{\partial D} = 0.016$.

According to the graph, the diver is experiencing a temperature of approximately 12.5°C at $t = 20$ minutes, so

$\dfrac{\partial C}{\partial T} = 4.6 - 0.11(12.5) + 0.00087(12.5)^2 \approx 3.36$. By sketching tangent lines at $t = 20$ to the graphs given, we estimate

$\dfrac{dD}{dt} \approx \dfrac{1}{2}$ and $\dfrac{dT}{dt} \approx -\dfrac{1}{10}$. Then, by the Chain Rule, $\dfrac{dC}{dt} = \dfrac{\partial C}{\partial T}\dfrac{dT}{dt} + \dfrac{\partial C}{\partial D}\dfrac{dD}{dt} \approx (3.36)\left(-\frac{1}{10}\right) + (0.016)\left(\frac{1}{2}\right) \approx -0.33$.

Thus the speed of sound experienced by the diver is decreasing at a rate of approximately 0.33 m/s per minute.

38. $V = \pi r^2 h/3$, so $\dfrac{dV}{dt} = \dfrac{\partial V}{\partial r}\dfrac{dr}{dt} + \dfrac{\partial V}{\partial h}\dfrac{dh}{dt} = \dfrac{2\pi rh}{3}\,1.8 + \dfrac{\pi r^2}{3}(-2.5) = 20{,}160\pi - 12{,}000\pi = 8160\pi \text{ in}^3/\text{s}$.

39. (a) $V = \ell wh$, so by the Chain Rule,

$$\frac{dV}{dt} = \frac{\partial V}{\partial \ell}\frac{d\ell}{dt} + \frac{\partial V}{\partial w}\frac{dw}{dt} + \frac{\partial V}{\partial h}\frac{dh}{dt} = wh\frac{d\ell}{dt} + \ell h\frac{dw}{dt} + \ell w\frac{dh}{dt} = 2\cdot 2\cdot 2 + 1\cdot 2\cdot 2 + 1\cdot 2\cdot(-3) = 6 \text{ m}^3/\text{s}.$$

(b) $S = 2(\ell w + \ell h + wh)$, so by the Chain Rule,

$$\begin{aligned}\frac{dS}{dt} &= \frac{\partial S}{\partial \ell}\frac{d\ell}{dt} + \frac{\partial S}{\partial w}\frac{dw}{dt} + \frac{\partial S}{\partial h}\frac{dh}{dt} = 2(w+h)\,\frac{d\ell}{dt} + 2(\ell+h)\,\frac{dw}{dt} + 2(\ell+w)\,\frac{dh}{dt}\\ &= 2(2+2)2 + 2(1+2)2 + 2(1+2)(-3) = 10\ \text{m}^2/\text{s}\end{aligned}$$

(c) $L^2 = \ell^2 + w^2 + h^2 \quad\Rightarrow\quad 2L\,\frac{dL}{dt} = 2\ell\,\frac{d\ell}{dt} + 2w\,\frac{dw}{dt} + 2h\,\frac{dh}{dt} = 2(1)(2) + 2(2)(2) + 2(2)(-3) = 0 \quad\Rightarrow$

$dL/dt = 0$ m/s.

40. $I = \dfrac{V}{R} \quad\Rightarrow$

$$\frac{dI}{dt} = \frac{\partial I}{\partial V}\frac{dV}{dt} + \frac{\partial I}{\partial R}\frac{dR}{dt} = \frac{1}{R}\frac{dV}{dt} - \frac{V}{R^2}\frac{dR}{dt} = \frac{1}{R}\frac{dV}{dt} - \frac{I}{R}\frac{dR}{dt} = \frac{1}{400}(-0.01) - \frac{0.08}{400}(0.03) = -0.000031\ \text{A/s}$$

41. $\dfrac{dP}{dt} = 0.05$, $\dfrac{dT}{dt} = 0.15$, $V = 8.31\dfrac{T}{P}$ and $\dfrac{dV}{dt} = \dfrac{8.31}{P}\dfrac{dT}{dt} - 8.31\dfrac{T}{P^2}\dfrac{dP}{dt}$. Thus when $P = 20$ and $T = 320$,

$$\frac{dV}{dt} = 8.31\left[\frac{0.15}{20} - \frac{(0.05)(320)}{400}\right] \approx -0.27\ \text{L/s}.$$

42. $P = 1.47L^{0.65}K^{0.35}$ and considering P, L, and K as functions of time t we have

$\dfrac{dP}{dt} = \dfrac{\partial P}{\partial L}\dfrac{dL}{dt} + \dfrac{\partial P}{\partial K}\dfrac{dK}{dt} = 1.47(0.65)L^{-0.35}K^{0.35}\dfrac{dL}{dt} + 1.47(0.35)L^{0.65}K^{-0.65}\dfrac{dK}{dt}$. We are given that $\dfrac{dL}{dt} = -2$ and $\dfrac{dK}{dt} = 0.5$, so when $L = 30$ and $K = 8$, the rate of change of production $\dfrac{dP}{dt}$ is $1.47(0.65)(30)^{-0.35}(8)^{0.35}(-2) + 1.47(0.35)(30)^{0.65}(8)^{-0.65}(0.5) \approx -0.596$. Thus production at that time is decreasing at a rate of about \$596,000 per year.

43. Let x be the length of the first side of the triangle and y the length of the second side. The area A of the triangle is given by $A = \frac{1}{2}xy\sin\theta$ where θ is the angle between the two sides. Thus A is a function of x, y, and θ, and x, y, and θ are each in turn functions of time t. We are given that $\dfrac{dx}{dt} = 3$, $\dfrac{dy}{dt} = -2$, and because A is constant, $\dfrac{dA}{dt} = 0$. By the Chain Rule,

$\dfrac{dA}{dt} = \dfrac{\partial A}{\partial x}\dfrac{dx}{dt} + \dfrac{\partial A}{\partial y}\dfrac{dy}{dt} + \dfrac{\partial A}{\partial \theta}\dfrac{d\theta}{dt} \quad\Rightarrow\quad \dfrac{dA}{dt} = \frac{1}{2}y\sin\theta\cdot\dfrac{dx}{dt} + \frac{1}{2}x\sin\theta\cdot\dfrac{dy}{dt} + \frac{1}{2}xy\cos\theta\cdot\dfrac{d\theta}{dt}$. When $x = 20$, $y = 30$, and $\theta = \pi/6$ we have

$$\begin{aligned}0 &= \tfrac{1}{2}(30)\left(\sin\tfrac{\pi}{6}\right)(3) + \tfrac{1}{2}(20)\left(\sin\tfrac{\pi}{6}\right)(-2) + \tfrac{1}{2}(20)(30)\left(\cos\tfrac{\pi}{6}\right)\frac{d\theta}{dt}\\ &= 45\cdot\tfrac{1}{2} - 20\cdot\tfrac{1}{2} + 300\cdot\frac{\sqrt{3}}{2}\cdot\frac{d\theta}{dt} = \tfrac{25}{2} + 150\sqrt{3}\,\frac{d\theta}{dt}\end{aligned}$$

Solving for $\dfrac{d\theta}{dt}$ gives $\dfrac{d\theta}{dt} = \dfrac{-25/2}{150\sqrt{3}} = -\dfrac{1}{12\sqrt{3}}$, so the angle between the sides is decreasing at a rate of $1/\left(12\sqrt{3}\right) \approx 0.048\ \text{rad/s}$.

44. $f_o = \left(\dfrac{c+v_o}{c-v_s}\right) f_s = \left(\frac{332+34}{332-40}\right) 460 \approx 576.6$ Hz. v_o and v_s are functions of time t, so

$$\begin{aligned}\frac{df_o}{dt} &= \frac{\partial f_o}{\partial v_o}\frac{dv_o}{dt} + \frac{\partial f_o}{\partial v_s}\frac{dv_s}{dt} = \left(\frac{1}{c-v_s}\right) f_s \cdot \frac{dv_o}{dt} + \frac{c+v_o}{(c-v_s)^2} f_s \cdot \frac{dv_s}{dt} \\ &= \left(\tfrac{1}{332-40}\right)(460)(1.2) + \tfrac{332+34}{(332-40)^2}(460)(1.4) \approx 4.65 \text{ Hz/s}\end{aligned}$$

45. (a) By the Chain Rule, $\dfrac{\partial z}{\partial r} = \dfrac{\partial z}{\partial x}\cos\theta + \dfrac{\partial z}{\partial y}\sin\theta$, $\dfrac{\partial z}{\partial \theta} = \dfrac{\partial z}{\partial x}(-r\sin\theta) + \dfrac{\partial z}{\partial y} r\cos\theta$.

(b) $\left(\dfrac{\partial z}{\partial r}\right)^2 = \left(\dfrac{\partial z}{\partial x}\right)^2 \cos^2\theta + 2\dfrac{\partial z}{\partial x}\dfrac{\partial z}{\partial y}\cos\theta\,\sin\theta + \left(\dfrac{\partial z}{\partial y}\right)^2 \sin^2\theta$,

$\left(\dfrac{\partial z}{\partial \theta}\right)^2 = \left(\dfrac{\partial z}{\partial x}\right)^2 r^2\sin^2\theta - 2\dfrac{\partial z}{\partial x}\dfrac{\partial z}{\partial y} r^2\cos\theta\,\sin\theta + \left(\dfrac{\partial z}{\partial y}\right)^2 r^2\cos^2\theta$. Thus

$\left(\dfrac{\partial z}{\partial r}\right)^2 + \dfrac{1}{r^2}\left(\dfrac{\partial z}{\partial \theta}\right)^2 = \left[\left(\dfrac{\partial z}{\partial x}\right)^2 + \left(\dfrac{\partial z}{\partial y}\right)^2\right](\cos^2\theta + \sin^2\theta) = \left(\dfrac{\partial z}{\partial x}\right)^2 + \left(\dfrac{\partial z}{\partial y}\right)^2$.

46. By the Chain Rule, $\dfrac{\partial u}{\partial s} = \dfrac{\partial u}{\partial x} e^s\cos t + \dfrac{\partial u}{\partial y} e^s \sin t$, $\dfrac{\partial u}{\partial t} = \dfrac{\partial u}{\partial x}(-e^s\sin t) + \dfrac{\partial u}{\partial y} e^s\cos t$. Then

$\left(\dfrac{\partial u}{\partial s}\right)^2 = \left(\dfrac{\partial u}{\partial x}\right)^2 e^{2s}\cos^2 t + 2\dfrac{\partial u}{\partial x}\dfrac{\partial u}{\partial y} e^{2s}\cos t\,\sin t + \left(\dfrac{\partial u}{\partial y}\right)^2 e^{2s}\sin^2 t$ and

$\left(\dfrac{\partial u}{\partial t}\right)^2 = \left(\dfrac{\partial u}{\partial x}\right)^2 e^{2s}\sin^2 t - 2\dfrac{\partial u}{\partial x}\dfrac{\partial u}{\partial y} e^{2s}\cos t\,\sin t + \left(\dfrac{\partial u}{\partial y}\right)^2 e^{2s}\cos^2 t$. Thus

$\left[\left(\dfrac{\partial u}{\partial s}\right)^2 + \left(\dfrac{\partial u}{\partial t}\right)^2\right] e^{-2s} = \left(\dfrac{\partial u}{\partial x}\right)^2 + \left(\dfrac{\partial u}{\partial y}\right)^2$.

47. Let $u = x - y$ and $v = x + y$. Then $z = \dfrac{1}{x}[f(u) + g(v)]$ and

$$\begin{aligned}\frac{\partial z}{\partial x} &= \frac{1}{x}\left[\frac{df}{du}\frac{\partial u}{\partial x} + \frac{dg}{dv}\frac{\partial v}{\partial x}\right] + [f(u)+g(v)]\left(-\frac{1}{x^2}\right) \\ &= \frac{1}{x}[f'(u)(1) + g'(v)(1)] - \frac{1}{x^2}[f(u)+g(v)] = \frac{1}{x}[f'(u)+g'(v)] - \frac{1}{x^2}[f(u)+g(v)]\end{aligned}$$

$$\frac{\partial z}{\partial y} = \frac{1}{x}\left[\frac{df}{du}\frac{\partial u}{\partial y} + \frac{dg}{dv}\frac{\partial v}{\partial y}\right] = \frac{1}{x}[f'(u)(-1) + g'(v)(1)] = \frac{1}{x}[-f'(u) + g'(v)]$$

$$\frac{\partial^2 z}{\partial y^2} = \frac{1}{x}\left[\frac{d}{du}[-f'(u)]\frac{\partial u}{\partial y} + \frac{d}{dv}[g'(v)]\frac{\partial v}{\partial y}\right] = \frac{1}{x}[-f''(u)(-1) + g''(v)(1)] = \frac{1}{x}[f''(u) + g''(v)]$$

Thus

$$\begin{aligned}\frac{\partial}{\partial x}\left(x^2\frac{\partial z}{\partial x}\right) &= \frac{\partial}{\partial x}(x[f'(u)+g'(v)] - [f(u)+g(v)]) \\ &= x[f''(u)(1) + g''(v)(1)] + [f'(u)+g'(v)](1) - [f'(u)(1) + g'(v)(1)] \\ &= x[f''(u)+g''(v)] + f'(u) + g'(v) - f'(u) - g'(v) = x[f''(u)+g''(v)] \\ &= x^2\cdot\frac{1}{x}[f''(u)+g''(v)] = x^2\frac{\partial^2 z}{\partial y^2}\end{aligned}$$

48. Let $u = ax + y$ and $v = ax - y$. Then $z = \frac{1}{y}\left[f(u) + g(v)\right]$ and

$$\frac{\partial z}{\partial x} = \frac{1}{y}\left[\frac{df}{du}\frac{\partial u}{\partial x} + \frac{dg}{dv}\frac{\partial v}{\partial x}\right] = \frac{1}{y}\left[f'(u)(a) + g'(v)(a)\right] = \frac{a}{y}\left[f'(u) + g'(v)\right]$$

$$\frac{\partial^2 z}{\partial x^2} = \frac{a}{y}\left[\frac{d}{du}\left[f'(u)\right]\frac{\partial u}{\partial x} + \frac{d}{dv}\left[g'(v)\right]\frac{\partial v}{\partial x}\right] = \frac{a}{y}\left[f''(u)(a) + g''(v)(a)\right] = \frac{a^2}{y}\left[f''(u) + g''(v)\right]$$

$$\frac{\partial z}{\partial y} = \frac{1}{y}\left[\frac{df}{du}\frac{\partial u}{\partial y} + \frac{dg}{dv}\frac{\partial v}{\partial y}\right] + \left[f(u) + g(v)\right]\left(-\frac{1}{y^2}\right)$$

$$= \frac{1}{y}\left[f'(u)(1) + g'(v)(-1)\right] - \frac{1}{y^2}\left[f(u) + g(v)\right] = \frac{1}{y}\left[f'(u) - g'(v)\right] - \frac{1}{y^2}\left[f(u) + g(v)\right]$$

$$\frac{\partial}{\partial y}\left(y^2\frac{\partial z}{\partial y}\right) = \frac{\partial}{\partial y}\left(y\left[f'(u) - g'(v)\right] - \left[f(u) + g(v)\right]\right)$$

$$= y\left[f''(u)(1) - g''(v)(-1)\right] + \left[f'(u) - g'(v)\right](1) - \left[f'(u)(1) + g'(v)(-1)\right]$$

$$= y\left[f''(u) + g''(v)\right] + f'(u) - g'(v) - f'(u) + g'(v) = y\left[f''(u) + g''(v)\right]$$

Thus $\frac{\partial^2 z}{\partial x^2} = \frac{a^2}{y}\left[f''(u) + g''(v)\right] = \frac{a^2}{y^2} \cdot y\left[f''(u) + g''(v)\right] = \frac{a^2}{y^2}\frac{\partial}{\partial y}\left(y^2\frac{\partial z}{\partial y}\right)$.

49. Let $u = x + at,\ v = x - at$. Then $z = f(u) + g(v)$, so $\partial z/\partial u = f'(u)$ and $\partial z/\partial v = g'(v)$.

Thus $\frac{\partial z}{\partial t} = \frac{\partial z}{\partial u}\frac{\partial u}{\partial t} + \frac{\partial z}{\partial v}\frac{\partial v}{\partial t} = af'(u) - ag'(v)$ and

$$\frac{\partial^2 z}{\partial t^2} = a\frac{\partial}{\partial t}\left[f'(u) - g'(v)\right] = a\left(\frac{df'(u)}{du}\frac{\partial u}{\partial t} - \frac{dg'(v)}{dv}\frac{\partial v}{\partial t}\right) = a^2 f''(u) + a^2 g''(v).$$

Similarly, $\frac{\partial z}{\partial x} = f'(u) + g'(v)$ and $\frac{\partial^2 z}{\partial x^2} = f''(u) + g''(v)$. Thus $\frac{\partial^2 z}{\partial t^2} = a^2\,\frac{\partial^2 z}{\partial x^2}$.

50. By the Chain Rule, $\frac{\partial u}{\partial s} = e^s\cos t\,\frac{\partial u}{\partial x} + e^s\sin t\,\frac{\partial u}{\partial y}$ and $\frac{\partial u}{\partial t} = -e^s\sin t\,\frac{\partial u}{\partial x} + e^s\cos t\,\frac{\partial u}{\partial y}$.

Then $\frac{\partial^2 u}{\partial s^2} = e^s\cos t\,\frac{\partial u}{\partial x} + e^s\cos t\,\frac{\partial}{\partial s}\left(\frac{\partial u}{\partial x}\right) + e^s\sin t\,\frac{\partial u}{\partial y} + e^s\sin t\,\frac{\partial}{\partial s}\left(\frac{\partial u}{\partial y}\right)$. But

$$\frac{\partial}{\partial s}\left(\frac{\partial u}{\partial x}\right) = \frac{\partial^2 u}{\partial x^2}\frac{\partial x}{\partial s} + \frac{\partial^2 u}{\partial y\,\partial x}\frac{\partial y}{\partial s} = e^s\cos t\,\frac{\partial^2 u}{\partial x^2} + e^s\sin t\,\frac{\partial^2 u}{\partial y\,\partial x}$$ and

$$\frac{\partial}{\partial s}\left(\frac{\partial u}{\partial y}\right) = \frac{\partial^2 u}{\partial y^2}\frac{\partial y}{\partial s} + \frac{\partial^2 u}{\partial x\,\partial y}\frac{\partial x}{\partial s} = e^s\sin t\,\frac{\partial^2 u}{\partial y^2} + e^s\cos t\,\frac{\partial^2 u}{\partial x\,\partial y}.$$

Also, by continuity of the partials, $\frac{\partial^2 u}{\partial x\,\partial y} = \frac{\partial^2 u}{\partial y\,\partial x}$. Thus

$$\frac{\partial^2 u}{\partial s^2} = e^s\cos t\,\frac{\partial u}{\partial x} + e^s\cos t\left(e^s\cos t\,\frac{\partial^2 u}{\partial x^2} + e^s\sin t\,\frac{\partial^2 u}{\partial x\,\partial y}\right) + e^s\sin t\,\frac{\partial u}{\partial y} + e^s\sin t\left(e^s\sin t\,\frac{\partial^2 u}{\partial y^2} + e^s\cos t\,\frac{\partial^2 u}{\partial x\,\partial y}\right)$$

$$= e^s\cos t\frac{\partial u}{\partial x} + e^s\sin t\,\frac{\partial u}{\partial y} + e^{2s}\cos^2 t\,\frac{\partial^2 u}{\partial x^2} + 2e^{2s}\cos t\sin t\,\frac{\partial^2 u}{\partial x\,\partial y} + e^{2s}\sin^2 t\,\frac{\partial^2 u}{\partial y^2}$$

Similarly

$$\begin{aligned}\frac{\partial^2 u}{\partial t^2} &= -e^s \cos t \,\frac{\partial u}{\partial x} - e^s \sin t \,\frac{\partial}{\partial t}\left(\frac{\partial u}{\partial x}\right) - e^s \sin t \,\frac{\partial u}{\partial y} + e^s \cos t \,\frac{\partial}{\partial t}\left(\frac{\partial u}{\partial y}\right) \\ &= -e^s \cos t \,\frac{\partial u}{\partial x} - e^s \sin t \left(-e^s \sin t \,\frac{\partial^2 u}{\partial x^2} + e^s \cos t \,\frac{\partial^2 u}{\partial x\,\partial y}\right) \\ &\qquad -e^s \sin t \,\frac{\partial u}{\partial y} + e^s \cos t \left(e^s \cos t \,\frac{\partial^2 u}{\partial y^2} - e^s \sin t \,\frac{\partial^2 u}{\partial x\,\partial y}\right) \\ &= -e^s \cos t \,\frac{\partial u}{\partial x} - e^s \sin t \,\frac{\partial u}{\partial y} + e^{2s} \sin^2 t \,\frac{\partial^2 u}{\partial x^2} - 2e^{2s} \cos t \sin t \,\frac{\partial^2 u}{\partial x\,\partial y} + e^{2s} \cos^2 t \,\frac{\partial^2 u}{\partial y^2}\end{aligned}$$

Thus $e^{-2s}\left(\dfrac{\partial^2 u}{\partial s^2} + \dfrac{\partial^2 u}{\partial t^2}\right) = (\cos^2 t + \sin^2 t)\left(\dfrac{\partial^2 u}{\partial x^2} + \dfrac{\partial^2 u}{\partial y^2}\right) = \dfrac{\partial^2 u}{\partial x^2} + \dfrac{\partial^2 u}{\partial y^2}$, as desired.

51. $\dfrac{\partial z}{\partial s} = \dfrac{\partial z}{\partial x}\,2s + \dfrac{\partial z}{\partial y}\,2r$. Then

$$\begin{aligned}\frac{\partial^2 z}{\partial r\,\partial s} &= \frac{\partial}{\partial r}\left(\frac{\partial z}{\partial x} 2s\right) + \frac{\partial}{\partial r}\left(\frac{\partial z}{\partial y} 2r\right) \\ &= \frac{\partial^2 z}{\partial x^2}\frac{\partial x}{\partial r}\,2s + \frac{\partial}{\partial y}\left(\frac{\partial z}{\partial x}\right)\frac{\partial y}{\partial r}\,2s + \frac{\partial z}{\partial x}\frac{\partial}{\partial r}\,2s + \frac{\partial^2 z}{\partial y^2}\frac{\partial y}{\partial r}\,2r + \frac{\partial}{\partial x}\left(\frac{\partial z}{\partial y}\right)\frac{\partial x}{\partial r}\,2r + \frac{\partial z}{\partial y}\,2 \\ &= 4rs\,\frac{\partial^2 z}{\partial x^2} + \frac{\partial^2 z}{\partial y\,\partial x}\,4s^2 + 0 + 4rs\,\frac{\partial^2 z}{\partial y^2} + \frac{\partial^2 z}{\partial x\,\partial y}\,4r^2 + 2\,\frac{\partial z}{\partial y}\end{aligned}$$

By the continuity of the partials, $\dfrac{\partial^2 z}{\partial r \partial s} = 4rs\,\dfrac{\partial^2 z}{\partial x^2} + 4rs\,\dfrac{\partial^2 z}{\partial y^2} + (4r^2 + 4s^2)\,\dfrac{\partial^2 z}{\partial x\,\partial y} + 2\dfrac{\partial z}{\partial y}$.

52. By the Chain Rule,

(a) $\dfrac{\partial z}{\partial r} = \dfrac{\partial z}{\partial x}\cos\theta + \dfrac{\partial z}{\partial y}\sin\theta$

(b) $\dfrac{\partial z}{\partial \theta} = -\dfrac{\partial z}{\partial x}\,r\sin\theta + \dfrac{\partial z}{\partial y}\,r\cos\theta$

(c)
$$\begin{aligned}\frac{\partial^2 z}{\partial r\,\partial\theta} &= \frac{\partial^2 z}{\partial\theta\,\partial r} = \frac{\partial}{\partial\theta}\left(\frac{\partial z}{\partial x}\cos\theta + \frac{\partial z}{\partial y}\sin\theta\right) = -\sin\theta\,\frac{\partial z}{\partial x} + \cos\theta\,\frac{\partial}{\partial\theta}\left(\frac{\partial z}{\partial x}\right) + \cos\theta\,\frac{\partial z}{\partial y} + \sin\theta\,\frac{\partial}{\partial\theta}\left(\frac{\partial z}{\partial y}\right) \\ &= -\sin\theta\,\frac{\partial z}{\partial x} + \cos\theta\left(\frac{\partial^2 z}{\partial x^2}\frac{\partial x}{\partial\theta} + \frac{\partial^2 z}{\partial y\,\partial x}\frac{\partial y}{\partial\theta}\right) + \cos\theta\,\frac{\partial z}{\partial y} + \sin\theta\,\frac{\partial^2 z}{\partial y^2}\frac{\partial y}{\partial\theta} + \frac{\partial^2 z}{\partial x\,\partial y}\frac{\partial x}{\partial\theta} \\ &= -\sin\theta\,\frac{\partial z}{\partial x} + \cos\theta\left(-r\sin\theta\,\frac{\partial^2 z}{\partial x^2} + r\cos\theta\,\frac{\partial^2 z}{\partial y\,\partial x}\right) + \cos\theta\,\frac{\partial z}{\partial y} + \sin\theta\left(r\cos\theta\,\frac{\partial^2 z}{\partial y^2} - r\sin\theta\,\frac{\partial^2 z}{\partial x\,\partial y}\right) \\ &= -\sin\theta\,\frac{\partial z}{\partial x} - r\cos\theta\,\sin\theta\,\frac{\partial^2 z}{\partial x^2} + r\cos^2\theta\,\frac{\partial^2 z}{\partial y\,\partial x} + \cos\theta\,\frac{\partial z}{\partial y} + r\cos\theta\sin\theta\,\frac{\partial^2 z}{\partial y^2} - r\sin^2\theta\,\frac{\partial^2 z}{\partial y\,\partial x} \\ &= \cos\theta\,\frac{\partial z}{\partial y} - \sin\theta\,\frac{\partial z}{\partial x} + r\cos\theta\sin\theta\left(\frac{\partial^2 z}{\partial y^2} - \frac{\partial^2 z}{\partial x^2}\right) + r(\cos^2\theta - \sin^2\theta)\,\frac{\partial^2 z}{\partial y\,\partial x}\end{aligned}$$

53. $\dfrac{\partial z}{\partial r} = \dfrac{\partial z}{\partial x}\cos\theta + \dfrac{\partial z}{\partial y}\sin\theta$ and $\dfrac{\partial z}{\partial \theta} = -\dfrac{\partial z}{\partial x}\,r\sin\theta + \dfrac{\partial z}{\partial y}\,r\cos\theta$. Then

$$\begin{aligned}\frac{\partial^2 z}{\partial r^2} &= \cos\theta\left(\frac{\partial^2 z}{\partial x^2}\cos\theta + \frac{\partial^2 z}{\partial y\,\partial x}\sin\theta\right) + \sin\theta\left(\frac{\partial^2 z}{\partial y^2}\sin\theta + \frac{\partial^2 z}{\partial x\,\partial y}\cos\theta\right) \\ &= \cos^2\theta\,\frac{\partial^2 z}{\partial x^2} + 2\cos\theta\,\sin\theta\,\frac{\partial^2 z}{\partial x\,\partial y} + \sin^2\theta\,\frac{\partial^2 z}{\partial y^2}\end{aligned}$$

and

$$\begin{aligned}\frac{\partial^2 z}{\partial \theta^2} &= -r\cos\theta\,\frac{\partial z}{\partial x} + (-r\sin\theta)\left(\frac{\partial^2 z}{\partial x^2}(-r\sin\theta) + \frac{\partial^2 z}{\partial y\,\partial x}\,r\cos\theta\right)\\ &\qquad -r\sin\theta\,\frac{\partial z}{\partial y} + r\cos\theta\left(\frac{\partial^2 z}{\partial y^2}\,r\cos\theta + \frac{\partial^2 z}{\partial x\,\partial y}(-r\sin\theta)\right)\\ &= -r\cos\theta\,\frac{\partial z}{\partial x} - r\sin\theta\,\frac{\partial z}{\partial y} + r^2\sin^2\theta\,\frac{\partial^2 z}{\partial x^2} - 2r^2\cos\theta\,\sin\theta\,\frac{\partial^2 z}{\partial x\,\partial y} + r^2\cos^2\theta\,\frac{\partial^2 z}{\partial y^2}\end{aligned}$$

Thus

$$\begin{aligned}\frac{\partial^2 z}{\partial r^2} + \frac{1}{r^2}\frac{\partial^2 z}{\partial \theta^2} + \frac{1}{r}\frac{\partial z}{\partial r} &= (\cos^2\theta + \sin^2\theta)\,\frac{\partial^2 z}{\partial x^2} + (\sin^2\theta + \cos^2\theta)\,\frac{\partial^2 z}{\partial y^2}\\ &\qquad -\frac{1}{r}\cos\theta\,\frac{\partial z}{\partial x} - \frac{1}{r}\sin\theta\,\frac{\partial z}{\partial y} + \frac{1}{r}\left(\cos\theta\,\frac{\partial z}{\partial x} + \sin\theta\,\frac{\partial z}{\partial y}\right)\\ &= \frac{\partial^2 z}{\partial x^2} + \frac{\partial^2 z}{\partial y^2} \text{ as desired.}\end{aligned}$$

54. (a) $\dfrac{\partial z}{\partial t} = \dfrac{\partial z}{\partial x}\dfrac{\partial x}{\partial t} + \dfrac{\partial z}{\partial y}\dfrac{\partial y}{\partial t}$. Then

$$\begin{aligned}\frac{\partial^2 z}{\partial t^2} &= \frac{\partial}{\partial t}\left(\frac{\partial z}{\partial x}\frac{\partial x}{\partial t}\right) + \frac{\partial}{\partial t}\left(\frac{\partial z}{\partial y}\frac{\partial y}{\partial t}\right) = \frac{\partial}{\partial t}\left(\frac{\partial z}{\partial x}\right)\frac{\partial x}{\partial t} + \frac{\partial^2 x}{\partial t^2}\frac{\partial z}{\partial x} + \frac{\partial}{\partial t}\left(\frac{\partial z}{\partial y}\right)\frac{\partial y}{\partial t} + \frac{\partial^2 y}{\partial t^2}\frac{\partial z}{\partial y}\\ &= \frac{\partial^2 z}{\partial x^2}\left(\frac{\partial x}{\partial t}\right)^2 + \frac{\partial^2 z}{\partial y\,\partial x}\frac{\partial x}{\partial t}\frac{\partial y}{\partial t} + \frac{\partial^2 x}{\partial t^2}\frac{\partial z}{\partial x} + \frac{\partial^2 z}{\partial y^2}\left(\frac{\partial y}{\partial t}\right)^2 + \frac{\partial^2 z}{\partial x\,\partial y}\frac{\partial y}{\partial t}\frac{\partial x}{\partial t} + \frac{\partial^2 y}{\partial t^2}\frac{\partial z}{\partial y}\\ &= \frac{\partial^2 z}{\partial x^2}\left(\frac{\partial x}{\partial t}\right)^2 + 2\,\frac{\partial^2 z}{\partial x\,\partial y}\frac{\partial x}{\partial t}\frac{\partial y}{\partial t} + \frac{\partial^2 z}{\partial y^2}\left(\frac{\partial y}{\partial t}\right)^2 + \frac{\partial^2 x}{\partial t^2}\frac{\partial z}{\partial x} + \frac{\partial^2 y}{\partial t^2}\frac{\partial z}{\partial y}\end{aligned}$$

(b) $\dfrac{\partial^2 z}{\partial s\,\partial t} = \dfrac{\partial}{\partial s}\left(\dfrac{\partial z}{\partial x}\dfrac{\partial x}{\partial t} + \dfrac{\partial z}{\partial y}\dfrac{\partial y}{\partial t}\right)$

$$\begin{aligned}&= \left(\frac{\partial^2 z}{\partial x^2}\frac{\partial x}{\partial s} + \frac{\partial^2 z}{\partial y\,\partial x}\frac{\partial y}{\partial s}\right)\frac{\partial x}{\partial t} + \frac{\partial z}{\partial x}\frac{\partial^2 x}{\partial s\,\partial t} + \left(\frac{\partial^2 z}{\partial y^2}\frac{\partial y}{\partial s} + \frac{\partial^2 z}{\partial x\,\partial y}\frac{\partial x}{\partial s}\right)\frac{\partial y}{\partial t} + \frac{\partial z}{\partial y}\frac{\partial^2 y}{\partial s\,\partial t}\\ &= \frac{\partial^2 z}{\partial x^2}\frac{\partial x}{\partial s}\frac{\partial x}{\partial t} + \frac{\partial^2 z}{\partial x\,\partial y}\left(\frac{\partial y}{\partial s}\frac{\partial x}{\partial t} + \frac{\partial y}{\partial t}\frac{\partial x}{\partial s}\right) + \frac{\partial z}{\partial x}\frac{\partial^2 x}{\partial s\,\partial t} + \frac{\partial z}{\partial y}\frac{\partial^2 y}{\partial s\,\partial t} + \frac{\partial^2 z}{\partial y^2}\frac{\partial y}{\partial s}\frac{\partial y}{\partial t}\end{aligned}$$

55. (a) Since f is a polynomial, it has continuous second-order partial derivatives, and

$f(tx, ty) = (tx)^2(ty) + 2(tx)(ty)^2 + 5(ty)^3 = t^3x^2y + 2t^3xy^2 + 5t^3y^3 = t^3(x^2y + 2xy^2 + 5y^3) = t^3 f(x, y)$.

Thus, f is homogeneous of degree 3.

(b) Differentiating both sides of $f(tx, ty) = t^n f(x, y)$ with respect to t using the Chain Rule, we get

$\dfrac{\partial}{\partial t} f(tx, ty) = \dfrac{\partial}{\partial t}\left[t^n f(x, y)\right] \quad \Leftrightarrow$

$\dfrac{\partial}{\partial(tx)} f(tx, ty)\cdot\dfrac{\partial(tx)}{\partial t} + \dfrac{\partial}{\partial(ty)} f(tx, ty)\cdot\dfrac{\partial(ty)}{\partial t} = x\,\dfrac{\partial}{\partial(tx)} f(tx, ty) + y\,\dfrac{\partial}{\partial(ty)} f(tx, ty) = nt^{n-1} f(x, y)$.

Setting $t = 1$: $x\,\dfrac{\partial}{\partial x} f(x, y) + y\,\dfrac{\partial}{\partial y} f(x, y) = nf(x, y)$.

56. Differentiating both sides of $f(tx, ty) = t^n f(x, y)$ with respect to t using the Chain Rule, we get

$$\frac{\partial}{\partial(tx)} f(tx, ty) \cdot \frac{\partial(tx)}{\partial t} + \frac{\partial}{\partial(ty)} f(tx, ty) \cdot \frac{\partial(ty)}{\partial t} = x \frac{\partial}{\partial(tx)} f(tx, ty) + y \frac{\partial}{\partial(ty)} f(tx, ty) = nt^{n-1} f(x, y) \text{ and}$$

differentiating again with respect to t gives

$$x\left[\frac{\partial^2}{\partial\,(tx)^2} f(tx, ty) \cdot \frac{\partial\,(tx)}{\partial t} + \frac{\partial^2}{\partial\,(ty)\,\partial\,(tx)} f(tx, ty) \cdot \frac{\partial\,(ty)}{\partial t}\right]$$

$$+\, y\left[\frac{\partial^2}{\partial\,(tx)\,\partial\,(ty)} f(tx, ty) \cdot \frac{\partial\,(tx)}{\partial t} + \frac{\partial^2}{\partial\,(ty)^2} f(tx, ty) \cdot \frac{\partial\,(ty)}{\partial t}\right] = n(n-1)t^{n-1} f(x, y).$$

Setting $t = 1$ and using the fact that $f_{yx} = f_{xy}$, we have $x^2 f_{xx} + 2xy f_{xy} + y^2 f_{yy} = n(n-1) f(x, y)$.

57. Differentiating both sides of $f(tx, ty) = t^n f(x, y)$ with respect to x using the Chain Rule, we get

$$\frac{\partial}{\partial x} f(tx, ty) = \frac{\partial}{\partial x} [t^n f(x, y)] \quad \Leftrightarrow$$

$$\frac{\partial}{\partial\,(tx)} f(tx, ty) \cdot \frac{\partial\,(tx)}{\partial x} + \frac{\partial}{\partial\,(ty)} f(tx, ty) \cdot \frac{\partial\,(ty)}{\partial x} = t^n \frac{\partial}{\partial x} f(x, y) \quad \Leftrightarrow \quad t f_x(tx, ty) = t^n f_x(x, y).$$

Thus $f_x(tx, ty) = t^{n-1} f_x(x, y)$.

58. $F(x, y, z) = 0$ is assumed to define z as a function of x and y, that is, $z = f(x, y)$. So by (7), $\dfrac{\partial z}{\partial x} = -\dfrac{F_x}{F_z}$ since $F_z \neq 0$.

Similarly, it is assumed that $F(x, y, z) = 0$ defines x as a function of y and z, that is $x = h(x, z)$. Then $F(h(y, z), y, z) = 0$

and by the Chain Rule, $F_x \dfrac{\partial x}{\partial y} + F_y \dfrac{\partial y}{\partial y} + F_z \dfrac{\partial z}{\partial y} = 0$. But $\dfrac{\partial z}{\partial y} = 0$ and $\dfrac{\partial y}{\partial y} = 1$, so $F_x \dfrac{\partial x}{\partial y} + F_y = 0 \quad \Rightarrow \quad \dfrac{\partial x}{\partial y} = -\dfrac{F_y}{F_x}$.

A similar calculation shows that $\dfrac{\partial y}{\partial z} = -\dfrac{F_z}{F_y}$. Thus $\dfrac{\partial z}{\partial x}\dfrac{\partial x}{\partial y}\dfrac{\partial y}{\partial z} = \left(-\dfrac{F_x}{F_z}\right)\left(-\dfrac{F_y}{F_x}\right)\left(-\dfrac{F_z}{F_y}\right) = -1$.

59. Given a function defined implicitly by $F(x, y) = 0$, where F is differentiable and $F_y \neq 0$, we know that $\dfrac{dy}{dx} = -\dfrac{F_x}{F_y}$. Let

$G(x, y) = -\dfrac{F_x}{F_y}$ so $\dfrac{dy}{dx} = G(x, y)$. Differentiating both sides with respect to x and using the Chain Rule gives

$$\frac{d^2y}{dx^2} = \frac{\partial G}{\partial x}\frac{dx}{dx} + \frac{\partial G}{\partial y}\frac{dy}{dx} \text{ where } \frac{\partial G}{\partial x} = \frac{\partial}{\partial x}\left(-\frac{F_x}{F_y}\right) = -\frac{F_y F_{xx} - F_x F_{yx}}{F_y^2},\ \frac{\partial G}{\partial y} = \frac{\partial}{\partial y}\left(-\frac{F_x}{F_y}\right) = -\frac{F_y F_{xy} - F_x F_{yy}}{F_y^2}.$$

Thus

$$\begin{aligned}\frac{d^2y}{dx^2} &= \left(-\frac{F_y F_{xx} - F_x F_{yx}}{F_y^2}\right)(1) + \left(-\frac{F_y F_{xy} - F_x F_{yy}}{F_y^2}\right)\left(-\frac{F_x}{F_y}\right) \\ &= -\frac{F_{xx} F_y^2 - F_{yx} F_x F_y - F_{xy} F_y F_x + F_{yy} F_x^2}{F_y^3}\end{aligned}$$

But F has continuous second derivatives, so by Clauraut's Theorem, $F_{yx} = F_{xy}$ and we have

$$\frac{d^2y}{dx^2} = -\frac{F_{xx} F_y^2 - 2F_{xy} F_x F_y + F_{yy} F_x^2}{F_y^3} \text{ as desired.}$$

14.6 Directional Derivatives and the Gradient Vector

1. We can approximate the directional derivative of the pressure function at K in the direction of S by the average rate of change of pressure between the points where the red line intersects the contour lines closest to K (extend the red line slightly at the left). In the direction of S, the pressure changes from 1000 millibars to 996 millibars and we estimate the distance between these two points to be approximately 50 km (using the fact that the distance from K to S is 300 km). Then the rate of change of pressure in the direction given is approximately $\frac{996-1000}{50} = -0.08$ millibar/km.

2. First we draw a line passing through Dubbo and Sydney. We approximate the directional derivative at Dubbo in the direction of Sydney by the average rate of change of temperature between the points where the line intersects the contour lines closest to Dubbo. In the direction of Sydney, the temperature changes from 30°C to 27°C. We estimate the distance between these two points to be approximately 120 km, so the rate of change of maximum temperature in the direction given is approximately $\frac{27-30}{120} = -0.025^\circ\text{C/km}$.

3. $D_{\mathbf{u}}\, f(-20,30) = \nabla f\,(-20,30)\cdot \mathbf{u} = f_T(-20,30)\left(\frac{1}{\sqrt{2}}\right) + f_v(-20,30)\left(\frac{1}{\sqrt{2}}\right)$.

$f_T(-20,30) = \lim\limits_{h\to 0} \dfrac{f(-20+h,30)-f(-20,30)}{h}$, so we can approximate $f_T(-20,30)$ by considering $h=\pm 5$ and using the values given in the table: $f_T(-20,30) \approx \dfrac{f(-15,30)-f(-20,30)}{5} = \dfrac{-26-(-33)}{5} = 1.4$,

$f_T(-20,30) \approx \dfrac{f(-25,30)-f(-20,30)}{-5} = \dfrac{-39-(-33)}{-5} = 1.2$. Averaging these values gives $f_T(-20,30)\approx 1.3$.

Similarly, $f_v(-20,30) = \lim\limits_{h\to 0} \dfrac{f(-20,30+h)-f(-20,30)}{h}$, so we can approximate $f_v(-20,30)$ with $h=\pm 10$:

$f_v(-20,30) \approx \dfrac{f(-20,40)-f(-20,30)}{10} = \dfrac{-34-(-33)}{10} = -0.1$,

$f_v(-20,30) \approx \dfrac{f(-20,20)-f(-20,30)}{-10} = \dfrac{-30-(-33)}{-10} = -0.3$. Averaging these values gives $f_v(-20,30)\approx -0.2$.

Then $D_{\mathbf{u}} f(-20,30) \approx 1.3\left(\frac{1}{\sqrt{2}}\right) + (-0.2)\left(\frac{1}{\sqrt{2}}\right) \approx 0.778$.

4. $f(x,y) = xy^3 - x^2 \quad\Rightarrow\quad f_x(x,y) = y^3 - 2x$ and $f_y(x,y) = 3xy^2$. If $\mathbf{u}$ is a unit vector in the direction of $\theta = \pi/3$, then from Equation 6, $D_{\mathbf{u}} f(1,2) = f_x(1,2)\cos\left(\frac{\pi}{3}\right) + f_y(1,2)\sin\left(\frac{\pi}{3}\right) = 6\cdot\frac{1}{2} + 12\cdot\frac{\sqrt{3}}{2} = 3 + 6\sqrt{3}$.

5. $f(x,y) = y\cos(xy) \quad\Rightarrow\quad f_x(x,y) = y[-\sin(xy)](y) = -y^2\sin(xy)$ and

$f_y(x,y) = y[-\sin(xy)](x) + [\cos(xy)](1) = \cos(xy) - xy\sin(xy)$. If $\mathbf{u}$ is a unit vector in the direction of $\theta = \pi/4$, then from Equation 6, $D_{\mathbf{u}} f(0,1) = f_x(0,1)\cos\left(\frac{\pi}{4}\right) + f_y(0,1)\sin\left(\frac{\pi}{4}\right) = 0\cdot\frac{\sqrt{2}}{2} + 1\cdot\frac{\sqrt{2}}{2} = \frac{\sqrt{2}}{2}$.

6. $f(x,y) = \sqrt{2x+3y} \quad\Rightarrow\quad f_x(x,y) = \frac{1}{2}(2x+3y)^{-1/2}(2) = 1/\sqrt{2x+3y}$ and

$f_y(x,y) = \frac{1}{2}(2x+3y)^{-1/2}(3) = 3/\left(2\sqrt{2x+3y}\right)$. If $\mathbf{u}$ is a unit vector in the direction of $\theta = -\pi/6$, then from Equation 6, $D_{\mathbf{u}} f(3,1) = f_x(3,1)\cos\left(-\frac{\pi}{6}\right) + f_y(3,1)\sin\left(-\frac{\pi}{6}\right) = \frac{1}{3}\cdot\frac{\sqrt{3}}{2} + \frac{1}{2}\cdot\left(-\frac{1}{2}\right) = \frac{\sqrt{3}}{6} - \frac{1}{4}$.

7. $f(x,y) = x/y = xy^{-1}$

(a) $\nabla f(x,y) = \dfrac{\partial f}{\partial x}\,\mathbf{i} + \dfrac{\partial f}{\partial y}\,\mathbf{j} = y^{-1}\,\mathbf{i} + (-xy^{-2})\,\mathbf{j} = \dfrac{1}{y}\,\mathbf{i} - \dfrac{x}{y^2}\,\mathbf{j}$

(b) $\nabla f(2,1) = \dfrac{1}{1}\,\mathbf{i} - \dfrac{2}{1^2}\,\mathbf{j} = \mathbf{i} - 2\,\mathbf{j}$

(c) By Equation 9, $D_{\mathbf{u}}\,f(2,1) = \nabla f(2,1)\cdot\mathbf{u} = (\mathbf{i} - 2\,\mathbf{j})\,\cdot\left(\frac{3}{5}\,\mathbf{i} + \frac{4}{5}\,\mathbf{j}\right) = \frac{3}{5} - \frac{8}{5} = -1.$

8. $f(x,y) = x^2 \ln y$

(a) $\nabla f(x,y) = \dfrac{\partial f}{\partial x}\,\mathbf{i} + \dfrac{\partial f}{\partial y}\,\mathbf{j} = 2x\ln y\,\mathbf{i} + (x^2/y)\,\mathbf{j}$

(b) $\nabla f(3,1) = 0\,\mathbf{i} + (9/1)\,\mathbf{j} = 9\,\mathbf{j}$

(c) By Equation 9, $D_{\mathbf{u}}\,f(3,1) = \nabla f(3,1)\cdot\mathbf{u} = 9\,\mathbf{j}\,\cdot\left(-\frac{5}{13}\,\mathbf{i} + \frac{12}{13}\,\mathbf{j}\right) = 0 + \frac{108}{13} = \frac{108}{13}.$

9. $f(x,y,z) = x^2yz - xyz^3$

(a) $\nabla f(x,y,z) = \langle f_x(x,y,z), f_y(x,y,z), f_z(x,y,z)\rangle = \left\langle 2xyz - yz^3, x^2z - xz^3, x^2y - 3xyz^2\right\rangle$

(b) $\nabla f(2,-1,1) = \langle -4+1, 4-2, -4+6\rangle = \langle -3, 2, 2\rangle$

(c) By Equation 14, $D_{\mathbf{u}}f(2,-1,1) = \nabla f(2,-1,1)\cdot\mathbf{u} = \langle -3,2,2\rangle\cdot\left\langle 0, \frac{4}{5}, -\frac{3}{5}\right\rangle = 0 + \frac{8}{5} - \frac{6}{5} = \frac{2}{5}.$

10. $f(x,y,z) = y^2e^{xyz}$

(a) $$\begin{aligned}\nabla f(x,y,z) &= \langle f_x(x,y,z), f_y(x,y,z), f_z(x,y,z)\rangle = \left\langle y^2e^{xyz}(yz), y^2\cdot e^{xyz}(xz) + e^{xyz}\cdot 2y, y^2e^{xyz}(xy)\right\rangle \\ &= \left\langle y^3ze^{xyz}, (xy^2z+2y)e^{xyz}, xy^3e^{xyz}\right\rangle\end{aligned}$$

(b) $\nabla f(0,1,-1) = \langle -1, 2, 0\rangle$

(c) $D_{\mathbf{u}}f(0,1,-1) = \nabla f(0,1,-1)\cdot\mathbf{u} = \langle -1,2,0\rangle\cdot\left\langle \frac{3}{13}, \frac{4}{13}, \frac{12}{13}\right\rangle = -\frac{3}{13} + \frac{8}{13} + 0 = \frac{5}{13}$

11. $f(x,y) = e^x\sin y \quad\Rightarrow\quad \nabla f(x,y) = \langle e^x\sin y, e^x\cos y\rangle$, $\nabla f(0,\pi/3) = \left\langle \frac{\sqrt{3}}{2}, \frac{1}{2}\right\rangle$, and a unit vector in the direction of $\mathbf{v}$ is $\mathbf{u} = \frac{1}{\sqrt{(-6)^2+8^2}}\,\langle -6,8\rangle = \frac{1}{10}\,\langle -6,8\rangle = \left\langle -\frac{3}{5}, \frac{4}{5}\right\rangle$, so

$D_{\mathbf{u}}\,f(0,\pi/3) = \nabla f(0,\pi/3)\cdot\mathbf{u} = \left\langle \frac{\sqrt{3}}{2}, \frac{1}{2}\right\rangle\cdot\left\langle -\frac{3}{5}, \frac{4}{5}\right\rangle = -\frac{3\sqrt{3}}{10} + \frac{4}{10} = \frac{4-3\sqrt{3}}{10}.$

12. $f(x,y) = \dfrac{x}{x^2+y^2} \quad\Rightarrow\quad \nabla f(x,y) = \left\langle \dfrac{(x^2+y^2)(1) - x(2x)}{(x^2+y^2)^2}, \dfrac{0 - x(2y)}{(x^2+y^2)^2}\right\rangle = \left\langle \dfrac{y^2-x^2}{(x^2+y^2)^2}, -\dfrac{2xy}{(x^2+y^2)^2}\right\rangle,$

$\nabla f(1,2) = \left\langle \frac{3}{25}, -\frac{4}{25}\right\rangle$, and a unit vector in the direction of $\mathbf{v} = \langle 3,5\rangle$ is $\mathbf{u} = \frac{1}{\sqrt{9+25}}\,\langle 3,5\rangle = \left\langle \frac{3}{\sqrt{34}}, \frac{5}{\sqrt{34}}\right\rangle$, so

$D_{\mathbf{u}}\,f(1,2) = \nabla f(1,2)\cdot\mathbf{u} = \left\langle \frac{3}{25}, -\frac{4}{25}\right\rangle\cdot\left\langle \frac{3}{\sqrt{34}}, \frac{5}{\sqrt{34}}\right\rangle = \frac{9}{25\sqrt{34}} - \frac{20}{25\sqrt{34}} = -\frac{11}{25\sqrt{34}}.$

13. $g(s,t) = s\sqrt{t} \quad\Rightarrow\quad \nabla g(s,t) = \left(\sqrt{t}\right)\mathbf{i} + \left(s/(2\sqrt{t})\right)\mathbf{j}$, $\nabla g(2,4) = 2\,\mathbf{i} + \frac{1}{2}\,\mathbf{j}$, and a unit vector in the direction of $\mathbf{v}$ is $\mathbf{u} = \frac{1}{\sqrt{2^2+(-1)^2}}(2\,\mathbf{i} - \mathbf{j}) = \frac{1}{\sqrt{5}}(2\,\mathbf{i} - \mathbf{j})$, so $D_{\mathbf{u}}\,g(2,4) = \nabla g(2,4)\cdot\mathbf{u} = (2\,\mathbf{i} + \frac{1}{2}\,\mathbf{j})\cdot\frac{1}{\sqrt{5}}(2\,\mathbf{i} - \mathbf{j}) = \frac{1}{\sqrt{5}}\left(4 - \frac{1}{2}\right) = \frac{7}{2\sqrt{5}}$ or $\frac{7\sqrt{5}}{10}$.

14. $g(u,v) = u^2e^{-v} \quad\Rightarrow\quad \nabla g(u,v) = \left(2ue^{-v}\right)\mathbf{i} + \left(-u^2e^{-v}\right)\mathbf{j}$, $\nabla g(3,0) = 6\,\mathbf{i} - 9\,\mathbf{j}$, and a unit vector in the direction of $\mathbf{v}$ is $\mathbf{u} = \frac{1}{\sqrt{3^2+4^2}}(3\,\mathbf{i} + 4\,\mathbf{j}) = \frac{1}{5}(3\,\mathbf{i}+4\,\mathbf{j})$, so $D_\mathbf{u}\,g(3,0) = \nabla g(3,0)\cdot\mathbf{u} = (6\,\mathbf{i} - 9\,\mathbf{j})\cdot\frac{1}{5}(3\,\mathbf{i}+4\,\mathbf{j}) = \frac{1}{5}(18-36) = -\frac{18}{5}$.

15. $f(x,y,z) = x^2y + y^2z \quad\Rightarrow\quad \nabla f(x,y,z) = \left\langle 2xy, x^2+2yz, y^2\right\rangle$, $\nabla f(1,2,3) = \langle 4,13,4\rangle$, and a unit vector in the direction of $\mathbf{v}$ is $\mathbf{u} = \frac{1}{\sqrt{4+1+4}}\langle 2,-1,2\rangle = \frac{1}{3}\langle 2,-1,2\rangle$, so

$D_\mathbf{u}\,f(1,2,3) = \nabla f(1,2,3)\cdot\mathbf{u} = \langle 4,13,4\rangle\cdot\frac{1}{3}\langle 2,-1,2\rangle = \frac{1}{3}(8-13+8) = \frac{3}{3} = 1.$

16. $f(x,y,z) = xy^2\tan^{-1}z \quad\Rightarrow\quad \nabla f(x,y,z) = \left\langle y^2\tan^{-1}z, 2xy\tan^{-1}z, \dfrac{xy^2}{1+z^2}\right\rangle$,

$\nabla f(2,1,1) = \left\langle 1\cdot\frac{\pi}{4}, 4\cdot\frac{\pi}{4}, \frac{2}{1+1}\right\rangle = \left\langle\frac{\pi}{4},\pi,1\right\rangle$, and a unit vector in the direction of $\mathbf{v}$ is $\mathbf{u} = \frac{1}{\sqrt{1+1+1}}\langle 1,1,1\rangle = \frac{1}{\sqrt{3}}\langle 1,1,1\rangle$,

so $D_\mathbf{u}\,f(2,1,1) = \nabla f(2,1,1)\cdot\mathbf{u} = \left\langle\frac{\pi}{4},\pi,1\right\rangle\cdot\frac{1}{\sqrt{3}}\langle 1,1,1\rangle = \frac{1}{\sqrt{3}}\left(\frac{\pi}{4}+\pi+1\right) = \frac{1}{\sqrt{3}}\left(\frac{5\pi}{4}+1\right)$.

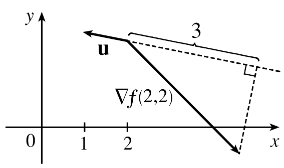
17. $h(r,s,t) = \ln(3r+6s+9t) \quad\Rightarrow\quad \nabla h(r,s,t) = \langle 3/(3r+6s+9t), 6/(3r+6s+9t), 9/(3r+6s+9t)\rangle$,

$\nabla h(1,1,1) = \left\langle\frac{1}{6},\frac{1}{3},\frac{1}{2}\right\rangle$, and a unit vector in the direction of $\mathbf{v} = 4\,\mathbf{i} + 12\,\mathbf{j} + 6\,\mathbf{k}$

is $\mathbf{u} = \frac{1}{\sqrt{16+144+36}}\,(4\,\mathbf{i}+12\,\mathbf{j}+6\,\mathbf{k}) = \frac{2}{7}\,\mathbf{i} + \frac{6}{7}\,\mathbf{j} + \frac{3}{7}\,\mathbf{k}$, so

$D_\mathbf{u}\,h(1,1,1) = \nabla h(1,1,1)\cdot\mathbf{u} = \left\langle\frac{1}{6},\frac{1}{3},\frac{1}{2}\right\rangle\cdot\left\langle\frac{2}{7},\frac{6}{7},\frac{3}{7}\right\rangle = \frac{1}{21}+\frac{2}{7}+\frac{3}{14} = \frac{23}{42}$.

18. $D_\mathbf{u}f(2,2) = \nabla f(2,2)\cdot\mathbf{u}$, the scalar projection of $\nabla f(2,2)$ onto $\mathbf{u}$, so we draw a perpendicular from the tip of $\nabla f(2,2)$ to the line containing $\mathbf{u}$. We can use the point $(2,2)$ to determine the scale of the axes, and we estimate the length of the projection to be approximately 3.0 units. Since the angle between $\nabla f(2,2)$ and $\mathbf{u}$ is greater than 90°, the scalar projection is negative. Thus $D_\mathbf{u}\,f(2,2) \approx -3$.



19. $f(x,y) = \sqrt{xy} \quad\Rightarrow\quad \nabla f(x,y) = \left\langle\frac{1}{2}(xy)^{-1/2}(y), \frac{1}{2}(xy)^{-1/2}(x)\right\rangle = \left\langle\dfrac{y}{2\sqrt{xy}}, \dfrac{x}{2\sqrt{xy}}\right\rangle$, so $\nabla f(2,8) = \left\langle 1,\frac{1}{4}\right\rangle$.

The unit vector in the direction of $\overrightarrow{PQ} = \langle 5-2, 4-8\rangle = \langle 3,-4\rangle$ is $\mathbf{u} = \left\langle\frac{3}{5},-\frac{4}{5}\right\rangle$, so

$D_\mathbf{u}\,f(2,8) = \nabla f(2,8)\cdot\mathbf{u} = \left\langle 1,\frac{1}{4}\right\rangle\cdot\left\langle\frac{3}{5},-\frac{4}{5}\right\rangle = \frac{2}{5}$.

20. $f(x,y,z) = xy^2z^3 \quad\Rightarrow\quad \nabla f(x,y,z) = \left\langle y^2z^3, 2xyz^3, 3xy^2z^2\right\rangle$, so $\nabla f(2,1,1) = \langle 1,4,6\rangle$. The unit vector in the direction of $\overrightarrow{PQ} = \langle -2,-4,4\rangle$ is $\mathbf{u} = \frac{1}{\sqrt{4+16+16}}\langle -2,-4,4\rangle = \frac{1}{6}\langle -2,-4,4\rangle$, so

$D_\mathbf{u}\,f(2,1,1) = \nabla f(2,1,1)\cdot\mathbf{u} = \langle 1,4,6\rangle\cdot\frac{1}{6}\langle -2,-4,4\rangle = \frac{1}{6}(-2-16+24) = 1$.

21. $f(x,y) = 4y\sqrt{x} \quad\Rightarrow\quad \nabla f(x,y) = \left\langle 4y\cdot\frac{1}{2}x^{-1/2}, 4\sqrt{x}\right\rangle = \langle 2y/\sqrt{x}, 4\sqrt{x}\,\rangle$.

$\nabla f(4,1) = \langle 1,8\rangle$ is the direction of maximum rate of change, and the maximum rate is $|\nabla f(4,1)| = \sqrt{1+64} = \sqrt{65}$.

22. $f(s,t) = te^{st} \quad\Rightarrow\quad \nabla f(s,t) = \left\langle te^{st}(t), te^{st}(s) + e^{st}(1)\right\rangle = \left\langle t^2e^{st}, (st+1)e^{st}\right\rangle$.

$\nabla f(0,2) = \langle 4,1\rangle$ is the direction of maximum rate of change, and the maximum rate is $|\nabla f(0,2)| = \sqrt{16+1} = \sqrt{17}$.

23. $f(x,y) = \sin(xy) \Rightarrow \nabla f(x,y) = \langle y\cos(xy), x\cos(xy)\rangle$, $\nabla f(1,0) = \langle 0,1\rangle$. Thus the maximum rate of change is $|\nabla f(1,0)| = 1$ in the direction $\langle 0,1\rangle$.

24. $f(x,y,z) = x\ln(yz) \Rightarrow \nabla f(x,y,z) = \left\langle \ln(yz), x\cdot\dfrac{z}{yz}, x\cdot\dfrac{y}{yz}\right\rangle = \left\langle \ln(yz), \dfrac{x}{y}, \dfrac{x}{z}\right\rangle$, $\nabla f(1,2,\frac{1}{2}) = \langle 0, \frac{1}{2}, 2\rangle$. Thus the maximum rate of change is $\left|\nabla f(1,2,\frac{1}{2})\right| = \sqrt{0+\frac{1}{4}+4} = \sqrt{\frac{17}{4}} = \frac{\sqrt{17}}{2}$ in the direction $\langle 0,\frac{1}{2},2\rangle$ or equivalently $\langle 0,1,4\rangle$.

25. $f(x,y,z) = x/(y+z) = x(y+z)^{-1} \Rightarrow$

$\nabla f(x,y,z) = \langle 1/(y+z), -x(y+z)^{-2}(1), -x(y+z)^{-2}(1)\rangle = \left\langle \dfrac{1}{y+z}, -\dfrac{x}{(y+z)^2}, -\dfrac{x}{(y+z)^2}\right\rangle$,

$\nabla f(8,1,3) = \langle \frac{1}{4}, -\frac{8}{4^2}, -\frac{8}{4^2}\rangle = \langle \frac{1}{4}, -\frac{1}{2}, -\frac{1}{2}\rangle$. Thus the maximum rate of change is

$|\nabla f(8,1,3)| = \sqrt{\frac{1}{16}+\frac{1}{4}+\frac{1}{4}} = \sqrt{\frac{9}{16}} = \frac{3}{4}$ in the direction $\langle \frac{1}{4}, -\frac{1}{2}, -\frac{1}{2}\rangle$ or equivalently $\langle 1,-2,-2\rangle$.

26. $f(p,q,r) = \arctan(pqr) \Rightarrow \nabla f(p,q,r) = \left\langle \dfrac{qr}{1+(pqr)^2}, \dfrac{pr}{1+(pqr)^2}, \dfrac{pq}{1+(pqr)^2}\right\rangle$, $\nabla f(1,2,1) = \langle \frac{2}{5}, \frac{1}{5}, \frac{2}{5}\rangle$. Thus the maximum rate of change is $|\nabla f(1,2,1)| = \sqrt{\frac{4}{25}+\frac{1}{25}+\frac{4}{25}} = \sqrt{\frac{9}{25}} = \frac{3}{5}$ in the direction $\langle \frac{2}{5}, \frac{1}{5}, \frac{2}{5}\rangle$ or equivalently $\langle 2,1,2\rangle$.

27. (a) As in the proof of Theorem 15, $D_{\mathbf{u}} f = |\nabla f|\cos\theta$. Since the minimum value of $\cos\theta$ is -1 occurring when $\theta = \pi$, the minimum value of $D_{\mathbf{u}} f$ is $-|\nabla f|$ occurring when $\theta = \pi$, that is when $\mathbf{u}$ is in the opposite direction of ∇f (assuming $\nabla f \neq \mathbf{0}$).

(b) $f(x,y) = x^4y - x^2y^3 \Rightarrow \nabla f(x,y) = \langle 4x^3y - 2xy^3, x^4 - 3x^2y^2\rangle$, so f decreases fastest at the point $(2,-3)$ in the direction $-\nabla f(2,-3) = -\langle 12,-92\rangle = \langle -12, 92\rangle$.

28. $f(x,y) = x^2 + xy^3 \Rightarrow \nabla f(x,y) = \langle 2x+y^3, 3xy^2\rangle$ so $\nabla f(2,1) = \langle 5,6\rangle$. If $\mathbf{u} = \langle a,b\rangle$ is a unit vector in the desired direction then $D_{\mathbf{u}}f(2,1) = 2 \Leftrightarrow \langle 5,6\rangle\cdot\langle a,b\rangle = 2 \Leftrightarrow 5a+6b=2 \Leftrightarrow b = \frac{1}{3} - \frac{5}{6}a$. But $a^2+b^2=1 \Leftrightarrow$ $a^2 + \left(\frac{1}{3}-\frac{5}{6}a\right)^2 = 1 \Leftrightarrow \frac{61}{36}a^2 - \frac{5}{9}a + \frac{1}{9} = 1 \Leftrightarrow 61a^2 - 20a - 32 = 0$. By the quadratic formula, the solutions are $a = \dfrac{-(-20)\pm\sqrt{(-20)^2-4(61)(-32)}}{2(61)} = \dfrac{20\pm\sqrt{8208}}{122} = \dfrac{10\pm 6\sqrt{57}}{61}$. If $a = \dfrac{10+6\sqrt{57}}{61} \approx 0.9065$ then $b = \dfrac{1}{3} - \dfrac{5}{6}\left(\dfrac{10+6\sqrt{57}}{61}\right) \approx -0.4221$, and if $a = \dfrac{10-6\sqrt{57}}{61} \approx -0.5787$ then $b = \dfrac{1}{3} - \dfrac{5}{6}\left(\dfrac{10-6\sqrt{57}}{61}\right) \approx 0.8156$.
Thus the two directions giving a directional derivative of 2 are approximately $\langle 0.9065, -0.4221\rangle$ and $\langle -0.5787, 0.8156\rangle$.

29. The direction of fastest change is $\nabla f(x,y) = (2x-2)\,\mathbf{i} + (2y-4)\,\mathbf{j}$, so we need to find all points (x,y) where $\nabla f(x,y)$ is parallel to $\mathbf{i}+\mathbf{j} \Leftrightarrow (2x-2)\,\mathbf{i} + (2y-4)\,\mathbf{j} = k\,(\mathbf{i}+\mathbf{j}) \Leftrightarrow k = 2x-2$ and $k = 2y-4$. Then $2x-2 = 2y-4 \Rightarrow$ $y = x+1$, so the direction of fastest change is $\mathbf{i}+\mathbf{j}$ at all points on the line $y = x+1$.

30. The fisherman is traveling in the direction $\langle -80, -60\rangle$. A unit vector in this direction is $\mathbf{u} = \frac{1}{100}\langle -80, -60\rangle = \left\langle -\frac{4}{5}, -\frac{3}{5}\right\rangle$, and if the depth of the lake is given by $f(x,y) = 200 + 0.02x^2 - 0.001y^3$, then $\nabla f(x,y) = \left\langle 0.04x, -0.003y^2\right\rangle$.

$D_{\mathbf{u}}\, f(80,60) = \nabla f(80,60)\cdot\mathbf{u} = \langle 3.2, -10.8\rangle \cdot \left\langle -\frac{4}{5}, -\frac{3}{5}\right\rangle = 3.92$. Since $D_{\mathbf{u}}\, f(80,60)$ is positive, the depth of the lake is increasing near $(80,60)$ in the direction toward the buoy.

31. $T = \dfrac{k}{\sqrt{x^2+y^2+z^2}}$ and $120 = T(1,2,2) = \dfrac{k}{3}$ so $k = 360$.

(a) $\mathbf{u} = \dfrac{\langle 1,-1,1\rangle}{\sqrt{3}}$,

$$D_{\mathbf{u}}T(1,2,2) = \nabla T(1,2,2)\cdot\mathbf{u} = \left[-360\left(x^2+y^2+z^2\right)^{-3/2}\langle x,y,z\rangle\right]_{(1,2,2)}\cdot\mathbf{u} = -\tfrac{40}{3}\langle 1,2,2\rangle\cdot\tfrac{1}{\sqrt{3}}\langle 1,-1,1\rangle = -\tfrac{40}{3\sqrt{3}}$$

(b) From (a), $\nabla T = -360\left(x^2+y^2+z^2\right)^{-3/2}\langle x,y,z\rangle$, and since $\langle x,y,z\rangle$ is the position vector of the point (x,y,z), the vector $-\langle x,y,z\rangle$, and thus ∇T, always points toward the origin.

32. $\nabla T = -400e^{-x^2-3y^2-9z^2}\langle x, 3y, 9z\rangle$

(a) $\mathbf{u} = \frac{1}{\sqrt{6}}\langle 1,-2,1\rangle$, $\nabla T(2,-1,2) = -400e^{-43}\langle 2,-3,18\rangle$ and

$$D_{\mathbf{u}}\,T(2,-1,2) = \left(-\frac{400e^{-43}}{\sqrt{6}}\right)(26) = -\frac{5200\sqrt{6}}{3e^{43}}\ {}^\circ\text{C/m}.$$

(b) $\nabla T(2,-1,2) = 400e^{-43}\langle -2,3,-18\rangle$ or equivalently $\langle -2,3,-18\rangle$.

(c) $|\nabla T| = 400e^{-x^2-3y^2-9z^2}\sqrt{x^2+9y^2+81z^2}\ {}^\circ\text{C/m}$ is the maximum rate of increase. At $(2,-1,2)$ the maximum rate of increase is $400e^{-43}\sqrt{337}\ {}^\circ\text{C/m}$.

33. $\nabla V(x,y,z) = \langle 10x-3y+yz, xz-3x, xy\rangle$, $\nabla V(3,4,5) = \langle 38,6,12\rangle$

(a) $D_{\mathbf{u}}\,V(3,4,5) = \langle 38,6,12\rangle\cdot\frac{1}{\sqrt{3}}\langle 1,1,-1\rangle = \frac{32}{\sqrt{3}}$

(b) $\nabla V(3,4,5) = \langle 38,6,12\rangle$, or equivalently, $\langle 19,3,6\rangle$.

(c) $|\nabla V(3,4,5)| = \sqrt{38^2+6^2+12^2} = \sqrt{1624} = 2\sqrt{406}$

34. $z = f(x,y) = 1000 - 0.005x^2 - 0.01y^2 \quad\Rightarrow\quad \nabla f(x,y) = \langle -0.01x, -0.02y\rangle$ and $\nabla f(60,40) = \langle -0.6, -0.8\rangle$.

(a) Due south is in the direction of the unit vector $\mathbf{u} = -\mathbf{j}$ and

$D_{\mathbf{u}}f(60,40) = \nabla f\,(60,40)\cdot\langle 0,-1\rangle = \langle -0.6,-0.8\rangle\cdot\langle 0,-1\rangle = 0.8$. Thus, if you walk due south from $(60,40,966)$ you will ascend at a rate of 0.8 vertical meters per horizontal meter.

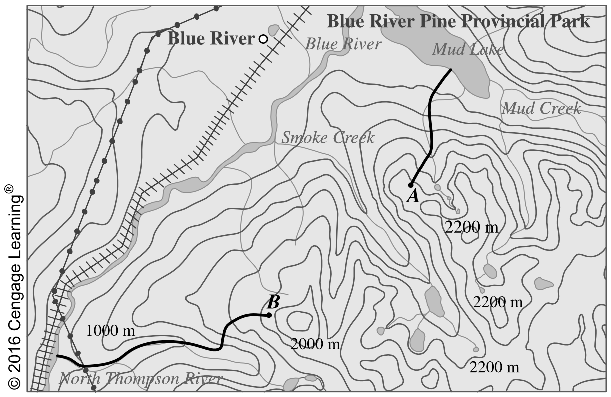
(b) Northwest is in the direction of the unit vector $\mathbf{u} = \frac{1}{\sqrt{2}}\langle -1,1\rangle$ and

$D_{\mathbf{u}}f(60,40) = \nabla f\,(60,40)\cdot\frac{1}{\sqrt{2}}\langle -1,1\rangle = \langle -0.6,-0.8\rangle\cdot\frac{1}{\sqrt{2}}\langle -1,1\rangle = -\frac{0.2}{\sqrt{2}} \approx -0.14$. Thus, if you walk northwest from $(60,40,966)$ you will descend at a rate of approximately 0.14 vertical meters per horizontal meter.

(c) $\nabla f(60,40) = \langle -0.6, -0.8 \rangle$ is the direction of largest slope with a rate of ascent given by $|\nabla f(60,40)| = \sqrt{(-0.6)^2 + (-0.8)^2} = 1$. The angle above the horizontal in which the path begins is given by $\tan\theta = 1 \;\Rightarrow\; \theta = 45°$.

35. A unit vector in the direction of $\overrightarrow{AB}$ is $\mathbf{i}$ and a unit vector in the direction of $\overrightarrow{AC}$ is $\mathbf{j}$. Thus $D_{\overrightarrow{AB}}\, f(1,3) = f_x(1,3) = 3$ and $D_{\overrightarrow{AC}}\, f(1,3) = f_y(1,3) = 26$. Therefore $\nabla f(1,3) = \langle f_x(1,3), f_y(1,3)\rangle = \langle 3, 26\rangle$, and by definition, $D_{\overrightarrow{AD}}\, f(1,3) = \nabla f \cdot \mathbf{u}$ where $\mathbf{u}$ is a unit vector in the direction of $\overrightarrow{AD}$, which is $\left\langle \frac{5}{13}, \frac{12}{13} \right\rangle$. Therefore, $D_{\overrightarrow{AD}}\, f(1,3) = \langle 3, 26\rangle \cdot \left\langle \frac{5}{13}, \frac{12}{13}\right\rangle = 3 \cdot \frac{5}{13} + 26 \cdot \frac{12}{13} = \frac{327}{13}$.

36. The curves of steepest ascent or descent are perpendicular to all of the contour lines (see Figure 12) so we sketch curves beginning at A and B that head toward lower elevations, crossing each contour line at a right angle.



37. (a) $\nabla(au+bv) = \left\langle \dfrac{\partial(au+bv)}{\partial x}, \dfrac{\partial(au+bv)}{\partial y}\right\rangle = \left\langle a\dfrac{\partial u}{\partial x} + b\dfrac{\partial v}{\partial x}, a\dfrac{\partial u}{\partial y} + b\dfrac{\partial v}{\partial y}\right\rangle = a\left\langle \dfrac{\partial u}{\partial x}, \dfrac{\partial u}{\partial y}\right\rangle + b\left\langle \dfrac{\partial v}{\partial x}, \dfrac{\partial v}{\partial y}\right\rangle$

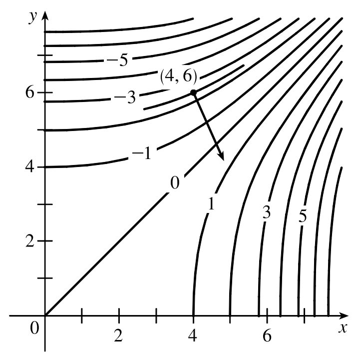
$= a\,\nabla u + b\,\nabla v$

(b) $\nabla(uv) = \left\langle v\dfrac{\partial u}{\partial x} + u\dfrac{\partial v}{\partial x}, v\dfrac{\partial u}{\partial y} + u\dfrac{\partial v}{\partial y}\right\rangle = v\left\langle \dfrac{\partial u}{\partial x}, \dfrac{\partial u}{\partial y}\right\rangle + u\left\langle \dfrac{\partial v}{\partial x}, \dfrac{\partial v}{\partial y}\right\rangle = v\,\nabla u + u\,\nabla v$

(c) $\nabla\left(\dfrac{u}{v}\right) = \left\langle \dfrac{v\dfrac{\partial u}{\partial x} - u\dfrac{\partial v}{\partial x}}{v^2}, \dfrac{v\dfrac{\partial u}{\partial y} - u\dfrac{\partial v}{\partial y}}{v^2}\right\rangle = \dfrac{v\left\langle \dfrac{\partial u}{\partial x}, \dfrac{\partial u}{\partial y}\right\rangle - u\left\langle \dfrac{\partial v}{\partial x}, \dfrac{\partial v}{\partial y}\right\rangle}{v^2} = \dfrac{v\,\nabla u - u\,\nabla v}{v^2}$

(d) $\nabla u^n = \left\langle \dfrac{\partial(u^n)}{\partial x}, \dfrac{\partial(u^n)}{\partial y}\right\rangle = \left\langle nu^{n-1}\dfrac{\partial u}{\partial x}, nu^{n-1}\dfrac{\partial u}{\partial y}\right\rangle = nu^{n-1}\,\nabla u$

38. If we place the initial point of the gradient vector $\nabla f(4,6)$ at $(4,6)$, the vector is perpendicular to the level curve of f that includes $(4,6)$, so we sketch a portion of the level curve through $(4,6)$ (using the nearby level curves as a guideline) and draw a line perpendicular to the curve at $(4,6)$. The gradient vector is parallel to this line, pointing in the direction of increasing function values, and with length equal to the maximum value of the directional derivative of f at $(4,6)$. We can estimate this length by finding the average rate of change in the direction of the gradient. The line intersects the contour lines corresponding to -2 and -3 with an estimated distance of 0.5 units. Thus the rate of change is approximately $\dfrac{-2-(-3)}{0.5} = 2$, and we sketch the gradient vector with length 2.



39. $f(x,y) = x^3 + 5x^2y + y^3 \quad\Rightarrow$

$D_{\mathbf{u}}f(x,y) = \nabla f(x,y)\cdot\mathbf{u} = \left\langle 3x^2+10xy, 5x^2+3y^2\right\rangle \cdot \left\langle \frac{3}{5}, \frac{4}{5}\right\rangle = \frac{9}{5}x^2 + 6xy + 4x^2 + \frac{12}{5}y^2 = \frac{29}{5}x^2 + 6xy + \frac{12}{5}y^2$. Then

$$D^2_{\mathbf{u}}f(x,y) = D_{\mathbf{u}}\left[D_{\mathbf{u}}f(x,y)\right] = \nabla\left[D_{\mathbf{u}}f(x,y)\right]\cdot\mathbf{u} = \left\langle \tfrac{58}{5}x + 6y, 6x + \tfrac{24}{5}y\right\rangle \cdot \left\langle \tfrac{3}{5}, \tfrac{4}{5}\right\rangle$$
$$= \tfrac{174}{25}x + \tfrac{18}{5}y + \tfrac{24}{5}x + \tfrac{96}{25}y = \tfrac{294}{25}x + \tfrac{186}{25}y$$

and $D^2_{\mathbf{u}}f(2,1) = \frac{294}{25}(2) + \frac{186}{25}(1) = \frac{774}{25}$.

40. (a) From Equation 9 we have $D_{\mathbf{u}}f = \nabla f\cdot\mathbf{u} = \langle f_x, f_y\rangle\cdot\langle a,b\rangle = f_x a + f_y b$ and from Exercise 39 we have

$D^2_{\mathbf{u}}f = D_{\mathbf{u}}\left[D_{\mathbf{u}}f\right] = \nabla\left[D_{\mathbf{u}}f\right]\cdot\mathbf{u} = \langle f_{xx}a + f_{yx}b, f_{xy}a + f_{yy}b\rangle\cdot\langle a,b\rangle = f_{xx}a^2 + f_{yx}ab + f_{xy}ab + f_{yy}b^2$.

But $f_{yx} = f_{xy}$ by Clairaut's Theorem, so $D^2_{\mathbf{u}}f = f_{xx}a^2 + 2f_{xy}ab + f_{yy}b^2$.

(b) $f(x,y) = xe^{2y} \quad\Rightarrow\quad f_x = e^{2y}$, $f_y = 2xe^{2y}$, $f_{xx} = 0$, $f_{xy} = 2e^{2y}$, $f_{yy} = 4xe^{2y}$ and a unit vector in the direction of $\mathbf{v}$ is $\mathbf{u} = \frac{1}{\sqrt{4^2+6^2}}\langle 4,6\rangle = \left\langle \frac{2}{\sqrt{13}}, \frac{3}{\sqrt{13}}\right\rangle = \langle a,b\rangle$. Then

$$D^2_{\mathbf{u}}f = f_{xx}a^2 + 2f_{xy}ab + f_{yy}b^2 = 0\cdot\left(\tfrac{2}{\sqrt{13}}\right)^2 + 2\cdot 2e^{2y}\left(\tfrac{2}{\sqrt{13}}\right)\left(\tfrac{3}{\sqrt{13}}\right) + 4xe^{2y}\left(\tfrac{3}{\sqrt{13}}\right)^2 = \tfrac{24}{13}e^{2y} + \tfrac{36}{13}xe^{2y}.$$

41. Let $F(x,y,z) = 2(x-2)^2 + (y-1)^2 + (z-3)^2$. Then $2(x-2)^2 + (y-1)^2 + (z-3)^2 = 10$ is a level surface of F.

$F_x(x,y,z) = 4(x-2) \quad\Rightarrow\quad F_x(3,3,5) = 4$, $F_y(x,y,z) = 2(y-1) \quad\Rightarrow\quad F_y(3,3,5) = 4$, and

$F_z(x,y,z) = 2(z-3) \quad\Rightarrow\quad F_z(3,3,5) = 4$.

(a) Equation 19 gives an equation of the tangent plane at $(3,3,5)$ as $4(x-3) + 4(y-3) + 4(z-5) = 0 \quad\Leftrightarrow$

$4x + 4y + 4z = 44$ or equivalently $x + y + z = 11$.

(b) By Equation 20, the normal line has symmetric equations $\dfrac{x-3}{4} = \dfrac{y-3}{4} = \dfrac{z-5}{4}$ or equivalently

$x - 3 = y - 3 = z - 5$. Corresponding parametric equations are $x = 3 + t$, $y = 3 + t$, $z = 5 + t$.

42. Let $F(x,y,z) = y^2 + z^2 - x$. Then $x = y^2 + z^2 + 1 \quad \Leftrightarrow \quad y^2 + z^2 - x = -1$ is a level surface of F.

$F_x(x,y,z) = -1 \quad \Rightarrow \quad F_x(3,1,-1) = -1, \quad F_y(x,y,z) = 2y \quad \Rightarrow \quad F_y(3,1,-1) = 2,$ and $F_z(x,y,z) = 2z \quad \Rightarrow$ $F_z(3,1,-1) = -2$.

(a) By Equation 19, an equation of the tangent plane at $(3,1,-1)$ is $(-1)(x-3) + 2(y-1) + (-2)[z-(-1)] = 0$ or $-x + 2y - 2z = 1$ or $x - 2y + 2z = -1$.

(b) By Equation 20, the normal line has symmetric equations $\dfrac{x-3}{-1} = \dfrac{y-1}{2} = \dfrac{z-(-1)}{-2}$ or equivalently $x - 3 = \dfrac{y-1}{-2} = \dfrac{z+1}{2}$ and parametric equations $x = 3 - t$, $y = 1 + 2t$, $z = -1 - 2t$.

43. Let $F(x,y,z) = xy^2z^3$. Then $xy^2z^3 = 8$ is a level surface of F and $\nabla F(x,y,z) = \langle y^2z^3, 2xyz^3, 3xy^2z^2 \rangle$.

(a) $\nabla F(2,2,1) = \langle 4,8,24 \rangle$ is a normal vector for the tangent plane at $(2,2,1)$, so an equation of the tangent plane is $4(x-2) + 8(y-2) + 24(z-1) = 0$ or $4x + 8y + 24z = 48$ or equivalently $x + 2y + 6z = 12$.

(b) The normal line has direction $\nabla F(2,2,1) = \langle 4,8,24 \rangle$ or equivalently $\langle 1,2,6 \rangle$, so parametric equations are $x = 2 + t$, $y = 2 + 2t$, $z = 1 + 6t$, and symmetric equations are $x - 2 = \dfrac{y-2}{2} = \dfrac{z-1}{6}$.

44. Let $F(x,y,z) = xy + yz + zx$. Then $xy + yz + zx = 5$ is a level surface of F and $\nabla F(x,y,z) = \langle y+z, x+z, x+y \rangle$.

(a) $\nabla F(1,2,1) = \langle 3,2,3 \rangle$ is a normal vector for the tangent plane at $(1,2,1)$, so an equation of the tangent plane is $3(x-1) + 2(y-2) + 3(z-1) = 0$ or $3x + 2y + 3z = 10$.

(b) The normal line has direction $\langle 3,2,3 \rangle$, so parametric equations are $x = 1 + 3t$, $y = 2 + 2t$, $z = 1 + 3t$, and symmetric equations are $\dfrac{x-1}{2} = \dfrac{y-2}{1} = \dfrac{z-1}{3}$.

45. Let $F(x,y,z) = x + y + z - e^{xyz}$. Then $x + y + z = e^{xyz}$ is the level surface $F(x,y,z) = 0$, and $\nabla F(x,y,z) = \langle 1 - yze^{xyz}, 1 - xze^{xyz}, 1 - xye^{xyz} \rangle$.

(a) $\nabla F(0,0,1) = \langle 1,1,1 \rangle$ is a normal vector for the tangent plane at $(0,0,1)$, so an equation of the tangent plane is $1(x-0) + 1(y-0) + 1(z-1) = 0$ or $x + y + z = 1$.

(b) The normal line has direction $\langle 1,1,1 \rangle$, so parametric equations are $x = t$, $y = t$, $z = 1 + t$, and symmetric equations are $x = y = z - 1$.

46. Let $F(x,y,z) = x^4 + y^4 + z^4 - 3x^2y^2z^2$. Then $x^4 + y^4 + z^4 = 3x^2y^2z^2$ is the level surface $F(x,y,z) = 0$, and $\nabla F(x,y,z) = \langle 4x^3 - 6xy^2z^2, 4y^3 - 6x^2yz^2, 4z^3 - 6x^2y^2z \rangle$.

(a) $\nabla F(1,1,1) = \langle -2,-2,-2 \rangle$ or equivalently $\langle 1,1,1 \rangle$ is a normal vector for the tangent plane at $(1,1,1)$, so an equation of the tangent plane is $1(x-1) + 1(y-1) + 1(z-1) = 0$ or $x + y + z = 3$.

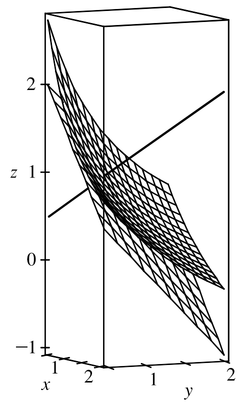
(b) The normal line has direction $\langle 1,1,1 \rangle$, so parametric equations are $x = 1 + t$, $y = 1 + t$, $z = 1 + t$, and symmetric equations are $x - 1 = y - 1 = z - 1$ or equivalently $x = y = z$.

47. $F(x,y,z) = xy + yz + zx$,

$\nabla F(x,y,z) = \langle y+z, x+z, y+x \rangle$,

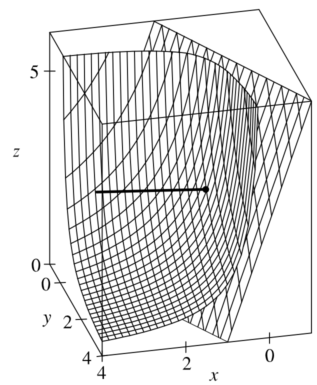
$\nabla F(1,1,1) = \langle 2,2,2 \rangle$, so an equation of the tangent plane is $2x + 2y + 2z = 6$ or $x + y + z = 3$, and the normal line is given by $x - 1 = y - 1 = z - 1$ or $x = y = z$. To graph the surface we solve for z:

$z = \dfrac{3 - xy}{x + y}$.

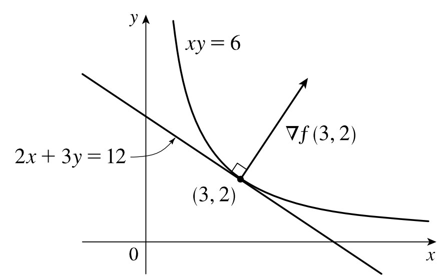


48. $F(x,y,z) = xyz$, $\nabla F(x,y,z) = \langle yz, xz, yx \rangle$,

$\nabla F(1,2,3) = \langle 6,3,2 \rangle$, so an equation of the tangent plane is $6x + 3y + 2z = 18$, and the normal line is given by $\dfrac{x-1}{6} = \dfrac{y-2}{3} = \dfrac{z-3}{2}$ or $x = 1 + 6t$, $y = 2 + 3t$, $z = 3 + 2t$. To graph the surface we solve for z: $z = \dfrac{6}{xy}$.

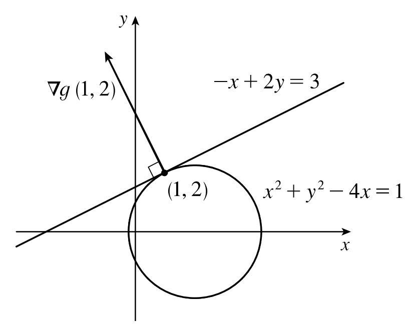


49. $f(x,y) = xy \quad \Rightarrow \quad \nabla f(x,y) = \langle y, x \rangle$, $\nabla f(3,2) = \langle 2,3 \rangle$. $\nabla f(3,2)$ is perpendicular to the tangent line, so the tangent line has equation $\nabla f(3,2) \cdot \langle x-3, y-2 \rangle = 0 \quad \Rightarrow \quad \langle 2,3 \rangle \cdot \langle x-3, x-2 \rangle = 0 \quad \Rightarrow$ $2(x-3) + 3(y-2) = 0$ or $2x + 3y = 12$.



50. $g(x,y) = x^2 + y^2 - 4x \quad \Rightarrow \quad \nabla g(x,y) = \langle 2x-4, 2y \rangle$,

$\nabla g(1,2) = \langle -2,4 \rangle$. $\nabla g(1,2)$ is perpendicular to the tangent line, so the tangent line has equation $\nabla g(1,2) \cdot \langle x-1, y-2 \rangle = 0 \quad \Rightarrow$ $\langle -2,4 \rangle \cdot \langle x-1, y-2 \rangle = 0 \quad \Rightarrow \quad -2(x-1) + 4(y-2) = 0 \quad \Leftrightarrow$ $-2x + 4y = 6$ or equivalently $-x + 2y = 3$.



51. $\nabla F(x_0,y_0,z_0) = \left\langle \dfrac{2x_0}{a^2}, \dfrac{2y_0}{b^2}, \dfrac{2z_0}{c^2} \right\rangle$. Thus an equation of the tangent plane at (x_0,y_0,z_0) is

$\dfrac{2x_0}{a^2}\,x + \dfrac{2y_0}{b^2}\,y + \dfrac{2z_0}{c^2}\,z = 2\left(\dfrac{x_0^2}{a^2} + \dfrac{y_0^2}{b^2} + \dfrac{z_0^2}{c^2}\right) = 2(1) = 2$ since (x_0,y_0,z_0) is a point on the ellipsoid. Hence

$\dfrac{x_0}{a^2}\,x + \dfrac{y_0}{b^2}\,y + \dfrac{z_0}{c^2}\,z = 1$ is an equation of the tangent plane.

52. $\nabla F(x_0, y_0, z_0) = \left\langle \dfrac{2x_0}{a^2}, \dfrac{2y_0}{b^2}, \dfrac{-2z_0}{c^2} \right\rangle$, so an equation of the tangent plane at (x_0, y_0, z_0) is

$$\frac{2x_0}{a^2}\,x + \frac{2y_0}{b^2}\,y - \frac{2z_0}{c^2}\,z = 2\left(\frac{x_0^2}{a^2} + \frac{y_0^2}{b^2} - \frac{z_0^2}{c^2}\right) = 2 \text{ or } \frac{x_0}{a^2}\,x + \frac{y_0}{b^2}\,y - \frac{z_0}{c^2}\,z = 1.$$

53. $\nabla F(x_0, y_0, z_0) = \left\langle \dfrac{2x_0}{a^2}, \dfrac{2y_0}{b^2}, \dfrac{-1}{c} \right\rangle$, so an equation of the tangent plane is $\dfrac{2x_0}{a^2}\,x + \dfrac{2y_0}{b^2}\,y - \dfrac{1}{c}\,z = \dfrac{2x_0^2}{a^2} + \dfrac{2y_0^2}{b^2} - \dfrac{z_0}{c}$

or $\dfrac{2x_0}{a^2}\,x + \dfrac{2y_0}{b^2}\,y = \dfrac{z}{c} + 2\left(\dfrac{x_0^2}{a^2} + \dfrac{y_0^2}{b^2}\right) - \dfrac{z_0}{c}$. But $\dfrac{z_0}{c} = \dfrac{x_0^2}{a^2} + \dfrac{y_0^2}{b^2}$, so the equation can be written as

$$\frac{2x_0}{a^2}\,x + \frac{2y_0}{b^2}\,y = \frac{z + z_0}{c}.$$

54. Let $F(x, y, z) = x^2 + y^2 + 2z^2$; then the ellipsoid $x^2 + y^2 + 2z^2 = 1$ is a level surface of F. $\nabla F(x, y, z) = \langle 2x, 2y, 4z \rangle$ is a normal vector to the surface at (x, y, z) and so it is a normal vector for the tangent plane there. The tangent plane is parallel to the plane $x + 2y + z = 1$ when the normal vectors of the planes are parallel, so we need a point (x_0, y_0, z_0) on the ellipsoid where $\langle 2x_0, 2y_0, 4z_0 \rangle = k\,\langle 1, 2, 1 \rangle$ for some $k \neq 0$. Comparing components we have $2x_0 = k \;\Rightarrow\; x_0 = k/2$, $2y_0 = 2k \;\Rightarrow\; y_0 = k$, $4z_0 = k \;\Rightarrow\; z_0 = k/4$. $(x_0, y_0, z_0) = (k/2, k, k/4)$ lies on the ellipsoid, so $(k/2)^2 + k^2 + 2(k/4)^2 = 1 \;\Rightarrow\; \frac{11}{8}k^2 = 1 \;\Rightarrow\; k^2 = \frac{8}{11} \;\Rightarrow\; k = \pm 2\sqrt{\frac{2}{11}}$. Thus the tangent planes at the points $\left(\sqrt{\frac{2}{11}}, 2\sqrt{\frac{2}{11}}, \frac{1}{2}\sqrt{\frac{2}{11}}\right)$ and $\left(-\sqrt{\frac{2}{11}}, -2\sqrt{\frac{2}{11}}, -\frac{1}{2}\sqrt{\frac{2}{11}}\right)$ are parallel to the given plane.

55. The hyperboloid $x^2 - y^2 - z^2 = 1$ is a level surface of $F(x, y, z) = x^2 - y^2 - z^2$ and $\nabla F(x, y, z) = \langle 2x, -2y, -2z \rangle$ is a normal vector to the surface and hence a normal vector for the tangent plane at (x, y, z). The tangent plane is parallel to the plane $z = x + y$ or $x + y - z = 0$ if and only if the corresponding normal vectors are parallel, so we need a point (x_0, y_0, z_0) on the hyperboloid where $\langle 2x_0, -2y_0, -2z_0 \rangle = c\,\langle 1, 1, -1 \rangle$ or equivalently $\langle x_0, -y_0, -z_0 \rangle = k\,\langle 1, 1, -1 \rangle$ for some $k \neq 0$. Then we must have $x_0 = k$, $y_0 = -k$, $z_0 = k$ and substituting into the equation of the hyperboloid gives $k^2 - (-k)^2 - k^2 = 1 \;\Leftrightarrow\; -k^2 = 1$, an impossibility. Thus there is no such point on the hyperboloid.

56. First note that the point $(1, 1, 2)$ is on both surfaces. The ellipsoid is a level surface of $F(x, y, z) = 3x^2 + 2y^2 + z^2$ and $\nabla F(x, y, z) = \langle 6x, 4y, 2z \rangle$. A normal vector to the surface at $(1, 1, 2)$ is $\nabla F(1, 1, 2) = \langle 6, 4, 4 \rangle$ and an equation of the tangent plane there is $6(x - 1) + 4(y - 1) + 4(z - 2) = 0$ or $6x + 4y + 4z = 18$ or $3x + 2y + 2z = 9$. The sphere is a level surface of $G(x, y, z) = x^2 + y^2 + z^2 - 8x - 6y - 8z + 24$ and $\nabla G(x, y, z) = \langle 2x - 8, 2y - 6, 2z - 8 \rangle$. A normal vector to the sphere at $(1, 1, 2)$ is $\nabla G(1, 1, 2) = \langle -6, -4, -4 \rangle$ and the tangent plane there is $-6(x - 1) - 4(y - 1) - 4(z - 2) = 0$ or $3x + 2y + 2z = 9$. Since these tangent planes are identical, the surfaces are tangent to each other at the point $(1, 1, 2)$.

57. Let (x_0, y_0, z_0) be a point on the cone [other than $(0, 0, 0)$]. The cone is a level surface of $F(x, y, z) = x^2 + y^2 - z^2$ and $\nabla F(x, y, z) = \langle 2x, 2y, -2z \rangle$, so $\nabla F(x_0, y_0, z_0) = \langle 2x_0, 2y_0, -2z_0 \rangle$ is a normal vector to the cone at this point and an equation of the tangent plane there is $2x_0(x-x_0)+2y_0(y-y_0)-2z_0(z-z_0)=0$ or $x_0x+y_0y-z_0z=x_0^2+y_0^2-z_0^2$. But $x_0^2+y_0^2=z_0^2$ so the tangent plane is given by $x_0x+y_0y-z_0z=0$, a plane which always contains the origin.

58. Let (x_0,y_0,z_0) be a point on the sphere. Then the normal line is given by $\dfrac{x-x_0}{2x_0}=\dfrac{y-y_0}{2y_0}=\dfrac{z-z_0}{2z_0}$. For the center $(0,0,0)$ to be on the line, we need $-\dfrac{x_0}{2x_0}=-\dfrac{y_0}{2y_0}=-\dfrac{z_0}{2z_0}$ or equivalently $1=1=1$, which is true.

59. Let $F(x,y,z)=x^2+y^2-z$. Then the paraboloid is the level surface $F(x,y,z)=0$ and $\nabla F(x,y,z)=\langle 2x,2y,-1\rangle$, so $\nabla F(1,1,2)=\langle 2,2,-1\rangle$ is a normal vector to the surface. Thus the normal line at $(1,1,2)$ is given by $x=1+2t$, $y=1+2t$, $z=2-t$. Substitution into the equation of the paraboloid $z=x^2+y^2$ gives $2-t=(1+2t)^2+(1+2t)^2 \quad\Leftrightarrow\quad 2-t=2+8t+8t^2 \quad\Leftrightarrow\quad 8t^2+9t=0 \quad\Leftrightarrow\quad t(8t+9)=0$. Thus the line intersects the paraboloid when $t=0$, corresponding to the given point $(1,1,2)$, or when $t=-\frac{9}{8}$, corresponding to the point $\left(-\frac{5}{4},-\frac{5}{4},\frac{25}{8}\right)$.

60. The ellipsoid is a level surface of $F(x,y,z)=4x^2+y^2+4z^2$ and $\nabla F(x,y,z)=\langle 8x,2y,8z\rangle$, so $\nabla F(1,2,1)=\langle 8,4,8\rangle$ or equivalently $\langle 2,1,2\rangle$ is a normal vector to the surface. Thus the normal line to the ellipsoid at $(1,2,1)$ is given by $x=1+2t$, $y=2+t$, $z=1+2t$. Substitution into the equation of the sphere gives $(1+2t)^2+(2+t)^2+(1+2t)^2=102 \quad\Leftrightarrow\quad 6+12t+9t^2=102 \quad\Leftrightarrow\quad 9t^2+12t-96=0 \quad\Leftrightarrow\quad 3(t+4)(3t-8)=0$. Thus the line intersects the sphere when $t=-4$, corresponding to the point $(-7,-2,-7)$, and when $t=\frac{8}{3}$, corresponding to the point $\left(\frac{19}{3},\frac{14}{3},\frac{19}{3}\right)$.

61. Let (x_0,y_0,z_0) be a point on the surface. Then an equation of the tangent plane at the point is $\dfrac{x}{2\sqrt{x_0}}+\dfrac{y}{2\sqrt{y_0}}+\dfrac{z}{2\sqrt{z_0}}=\dfrac{\sqrt{x_0}+\sqrt{y_0}+\sqrt{z_0}}{2}$. But $\sqrt{x_0}+\sqrt{y_0}+\sqrt{z_0}=\sqrt{c}$, so the equation is $\dfrac{x}{\sqrt{x_0}}+\dfrac{y}{\sqrt{y_0}}+\dfrac{z}{\sqrt{z_0}}=\sqrt{c}$. The x-, y-, and z-intercepts are $\sqrt{cx_0}$, $\sqrt{cy_0}$ and $\sqrt{cz_0}$ respectively. (The x-intercept is found by setting $y=z=0$ and solving the resulting equation for x, and the y- and z-intercepts are found similarly.) So the sum of the intercepts is $\sqrt{c}\left(\sqrt{x_0}+\sqrt{y_0}+\sqrt{z_0}\right)=c$, a constant.

62. The surface $xyz=1$ is a level surface of $F(x,y,z)=xyz$ and $\nabla F(x,y,z)=\langle yz,xz,xy\rangle$ is normal to the surface, so a normal vector for the tangent plane to the surface at (x_0,y_0,z_0) is $\langle y_0z_0,x_0z_0,x_0y_0\rangle$. An equation for the tangent plane there is $y_0z_0(x-x_0)+x_0z_0(y-y_0)+x_0y_0(z-z_0)=0 \quad\Rightarrow\quad y_0z_0x+x_0z_0y+x_0y_0z=3x_0y_0z_0$ or $\dfrac{x}{x_0}+\dfrac{y}{y_0}+\dfrac{z}{z_0}=3$. If (x_0,y_0,z_0) is in the first octant, then the tangent plane cuts off a pyramid in the first octant with vertices $(0,0,0)$, $(3x_0,0,0)$, $(0,3y_0,0)$, $(0,0,3z_0)$. The base in the xy-plane is a triangle with area $\frac{1}{2}(3x_0)(3y_0)$ and the height (along the z-axis) of the pyramid is $3z_0$. The volume of the pyramid for any point (x_0,y_0,z_0) on the surface $xyz=1$ in the first octant is $\frac{1}{3}\,(\text{base})\,(\text{height})=\frac{1}{3}\cdot\frac{1}{2}(3x_0)(3y_0)\cdot 3z_0=\frac{9}{2}x_0y_0z_0=\frac{9}{2}$ since $x_0y_0z_0=1$.

63. If $f(x,y,z) = z - x^2 - y^2$ and $g(x,y,z) = 4x^2 + y^2 + z^2$, then the tangent line is perpendicular to both ∇f and ∇g at $(-1,1,2)$. The vector $\mathbf{v} = \nabla f \times \nabla g$ will therefore be parallel to the tangent line.

We have $\nabla f(x,y,z) = \langle -2x, -2y, 1\rangle \Rightarrow \nabla f(-1,1,2) = \langle 2,-2,1\rangle$, and $\nabla g(x,y,z) = \langle 8x, 2y, 2z\rangle \Rightarrow$

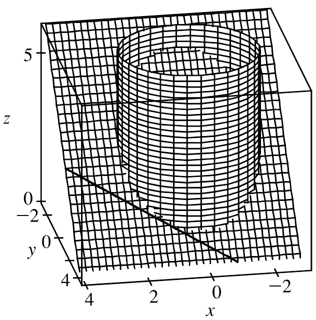
$\nabla g(-1,1,2) = \langle -8,2,4\rangle$. Hence $\mathbf{v} = \nabla f \times \nabla g = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 2 & -2 & 1 \\ -8 & 2 & 4 \end{vmatrix} = -10\,\mathbf{i} - 16\,\mathbf{j} - 12\,\mathbf{k}$.

Parametric equations are: $x = -1 - 10t,\ y = 1 - 16t,\ z = 2 - 12t$.

64. (a) Let $f(x,y,z) = y + z$ and $g(x,y,z) = x^2 + y^2$. Then the required tangent line is perpendicular to both ∇f and ∇g at $(1,2,1)$ and the vector $\mathbf{v} = \nabla f \times \nabla g$ is parallel to the tangent line. We have $\nabla f(x,y,z) = \langle 0,1,1\rangle \Rightarrow \nabla f(1,2,1) = \langle 0,1,1\rangle$, and $\nabla g(x,y,z) = \langle 2x, 2y, 0\rangle \Rightarrow \nabla g(1,2,1) = \langle 2,4,0\rangle$. Hence

$\mathbf{v} = \nabla f \times \nabla g = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 0 & 1 & 1 \\ 2 & 4 & 0 \end{vmatrix} = -4\,\mathbf{i} + 2\,\mathbf{j} - 2\,\mathbf{k}$. So parametric equations of the desired tangent line are $x = 1 - 4t,\ y = 2 + 2t,\ z = 1 - 2t$.

(b)



65. Parametric equations for the helix are $x = \cos \pi t,\ \ y = \sin \pi t,\ \ z = t$, and substituting into the equation of the paraboloid gives $t = \cos^2 \pi t + \sin^2 \pi t \Rightarrow t = 1$. Thus the helix intersects the surface at the point $(\cos \pi, \sin \pi, 1) = (-1,0,1)$. Here $\mathbf{r}'(t) = \langle -\pi \sin \pi t, \pi \cos \pi t, 1\rangle$, so the tangent vector to the helix at that point is $\mathbf{r}'(1) = \langle -\pi \sin \pi, \pi \cos \pi, 1\rangle = \langle 0, -\pi, 1\rangle$. The paraboloid $z = x^2 + y^2 \Leftrightarrow x^2 + y^2 - z = 0$ is a level surface of $F(x,y,z) = x^2 + y^2 - z$ and $\nabla F(x,y,z) = \langle 2x, 2y, -1\rangle$, so a normal vector to the tangent plane at $(-1,0,1)$ is $\nabla F(-1,0,1) = \langle -2,0,-1\rangle$. The angle θ between $\mathbf{r}'(1)$ and $\nabla F(-1,0,1)$ is given by

$$\cos\theta = \frac{\langle 0,-\pi,1\rangle \cdot \langle -2,0,-1\rangle}{|\langle 0,-\pi,1\rangle|\ |\langle -2,0,-1\rangle|} = \frac{0+0-1}{\sqrt{0+\pi^2+1}\,\sqrt{4+0+1}} = \frac{-1}{\sqrt{5(\pi^2+1)}} \quad\Rightarrow$$

$\theta = \cos^{-1} \dfrac{-1}{\sqrt{5(\pi^2+1)}} \approx 97.8^\circ$. Because $\nabla F(-1,0,1)$ is perpendicular to the tangent plane, the angle of intersection between the helix and the paraboloid is approximately $97.8^\circ - 90^\circ = 7.8^\circ$.

66. Parametric equations for the helix are $x = \cos(\pi t/2),\ \ y = \sin(\pi t/2),\ \ z = t$, and substituting into the equation of the sphere gives $\cos^2(\pi t/2) + \sin^2(\pi t/2) + t^2 = 2 \Rightarrow 1 + t^2 = 2 \Rightarrow t = \pm 1$. Thus the helix intersects the sphere at two points: $(\cos(\pi/2), \sin(\pi/2), 1) = (0,1,1)$, when $t = 1$, and $(\cos(-\pi/2), \sin(-\pi/2), -1) = (0,-1,-1)$, when $t = -1$. Here $\mathbf{r}'(t) = \left\langle -\frac{\pi}{2}\sin(\pi t/2), \frac{\pi}{2}\cos(\pi t/2), 1\right\rangle$, so the tangent vector to the helix at $(0,1,1)$ is $\mathbf{r}'(1) = \langle -\pi/2, 0, 1\rangle$. The sphere $x^2 + y^2 + z^2 = 2$ is a level surface of $F(x,y,z) = x^2 + y^2 + z^2$ and $\nabla F(x,y,z) = \langle 2x, 2y, 2z\rangle$, so a normal vector to the tangent plane at $(0,1,1)$ is $\nabla F(0,1,1) = \langle 0,2,2\rangle$. As in Exercise 65, the angle of intersection between the helix and the sphere is the angle between the tangent vector to the helix and the tangent plane to the sphere. The angle θ between $\mathbf{r}'(1)$ and $\nabla F(0,1,1)$ is given by

$$\cos\theta = \frac{\langle -\pi/2,0,1\rangle\cdot\langle 0,2,2\rangle}{|\langle -\pi/2,0,1\rangle|\,|\langle 0,2,2\rangle|} = \frac{2}{\sqrt{(\pi^2/4)+1}\,\sqrt{8}} = \frac{2}{\sqrt{2\pi^2+8}} \quad\Rightarrow\quad \theta = \cos^{-1}\frac{2}{\sqrt{2\pi^2+8}} \approx 67.7^\circ$$

Because $\nabla F(0,1,1)$ is perpendicular to the tangent plane, the angle between $\mathbf{r}'(1)$ and the tangent plane is approximately $90^\circ - 67.7^\circ = 22.3^\circ$.

At $(0,-1,-1)$, $\mathbf{r}'(-1) = \langle \pi/2,0,1\rangle$ and $\nabla F(0,-1,-1) = \langle 0,-2,-2\rangle$, and the angle ϕ between these vectors is given by $\cos\phi = \dfrac{\langle \pi/2,0,1\rangle\cdot\langle 0,-2,-2\rangle}{|\langle \pi/2,0,1\rangle|\,|\langle 0,-2,-2\rangle|} = \dfrac{-2}{\sqrt{2\pi^2+8}} \quad\Rightarrow\quad \phi = \cos^{-1}\dfrac{-2}{\sqrt{2\pi^2+8}} \approx 112.3^\circ$. Thus the angle between the helix and the sphere at $(0,-1,-1)$ is approximately $112.3^\circ - 90^\circ = 22.3^\circ$. (By symmetry, we would expect the angles to be identical.)

67. (a) The direction of the normal line of F is given by ∇F, and that of G by ∇G. Assuming that $\nabla F \neq 0 \neq \nabla G$, the two normal lines are perpendicular at P if $\nabla F\cdot\nabla G = 0$ at $P \quad\Leftrightarrow$ $\langle \partial F/\partial x, \partial F/\partial y, \partial F/\partial z\rangle\cdot\langle \partial G/\partial x, \partial G/\partial y, \partial G/\partial z\rangle = 0$ at $P \quad\Leftrightarrow\quad F_xG_x + F_yG_y + F_zG_z = 0$ at P.

(b) Here $F = x^2+y^2-z^2$ and $G = x^2+y^2+z^2-r^2$, so $\nabla F\cdot\nabla G = \langle 2x,2y,-2z\rangle\cdot\langle 2x,2y,2z\rangle = 4x^2+4y^2-4z^2 = 4F = 0$, since the point (x,y,z) lies on the graph of $F=0$. To see that this is true without using calculus, note that $G=0$ is the equation of a sphere centered at the origin and $F=0$ is the equation of a right circular cone with vertex at the origin (which is generated by lines through the origin). At any point of intersection, the sphere's normal line (which passes through the origin) lies on the cone, and thus is perpendicular to the cone's normal line. So the surfaces with equations $F=0$ and $G=0$ are everywhere orthogonal.

68. (a) The function $f(x,y) = (xy)^{1/3}$ is continuous on $\mathbb{R}^2$ since it is a composition of a polynomial and the cube root function, both of which are continuous. (See the text just after Example 14.2.8.)

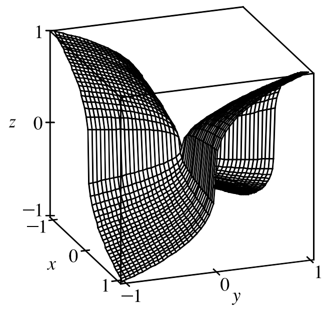
$$f_x(0,0) = \lim_{h\to 0}\frac{f(0+h,0)-f(0,0)}{h} = \lim_{h\to 0}\frac{(h\cdot 0)^{1/3}-0}{h} = 0,$$

$$f_y(0,0) = \lim_{h\to 0}\frac{f(0,0+h)-f(0,0)}{h} = \lim_{h\to 0}\frac{(0\cdot h)^{1/3}-0}{h} = 0.$$

Therefore, $f_x(0,0)$ and $f_y(0,0)$ do exist and are equal to 0. Now let $\mathbf{u}$ be any unit vector other than $\mathbf{i}$ and $\mathbf{j}$ (these correspond to f_x and f_y respectively.) Then $\mathbf{u} = a\,\mathbf{i} + b\,\mathbf{j}$ where $a\neq 0$ and $b\neq 0$. Thus

$D_{\mathbf{u}}\,f(0,0) = \lim\limits_{h\to 0}\dfrac{f(0+ha,0+hb)-f(0,0)}{h} = \lim\limits_{h\to 0}\dfrac{\sqrt[3]{(ha)(hb)}}{h} = \lim\limits_{h\to 0}\dfrac{\sqrt[3]{ab}}{h^{1/3}}$ and this limit does not exist, so $D_{\mathbf{u}}\,f(0,0)$ does not exist.

(b)



Notice that if we start at the origin and proceed in the direction of the x- or y-axis, then the graph is flat. But if we proceed in any other direction, then the graph is extremely steep.

69. Let $\mathbf{u} = \langle a, b\rangle$ and $\mathbf{v} = \langle c, d\rangle$. Then we know that at the given point, $D_{\mathbf{u}}\, f = \nabla f \cdot \mathbf{u} = af_x + bf_y$ and $D_{\mathbf{v}}\, f = \nabla f \cdot \mathbf{v} = cf_x + df_y$. But these are just two linear equations in the two unknowns f_x and f_y, and since $\mathbf{u}$ and $\mathbf{v}$ are not parallel, we can solve the equations to find $\nabla f = \langle f_x, f_y\rangle$ at the given point. In fact,

$$\nabla f = \left\langle \frac{d\, D_{\mathbf{u}}\, f - b\, D_{\mathbf{v}}\, f}{ad - bc}, \frac{a\, D_{\mathbf{v}}\, f - c\, D_{\mathbf{u}}\, f}{ad - bc} \right\rangle.$$

70. Since $z = f(x, y)$ is differentiable at $\mathbf{x}_0 = (x_0, y_0)$, by Definition 14.4.7 we have $\Delta z = f_x(x_0, y_0)\,\Delta x + f_y(x_0, y_0)\,\Delta y + \varepsilon_1\,\Delta x + \varepsilon_2\,\Delta y$ where $\varepsilon_1, \varepsilon_2 \to 0$ as $(\Delta x, \Delta y) \to (0, 0)$. Now $\Delta z = f(\mathbf{x}) - f(\mathbf{x}_0)$, $\langle \Delta x, \Delta y\rangle = \mathbf{x} - \mathbf{x}_0$ so $(\Delta x, \Delta y) \to (0, 0)$ is equivalent to $\mathbf{x} \to \mathbf{x}_0$ and $\langle f_x(x_0, y_0)\,, f_y(x_0, y_0)\rangle = \nabla f(\mathbf{x}_0)$. Substituting into 14.4.7 gives $f(\mathbf{x}) - f(\mathbf{x}_0) = \nabla f(\mathbf{x}_0) \cdot (\mathbf{x} - \mathbf{x}_0) + \langle \varepsilon_1, \varepsilon_2\rangle \cdot \langle \Delta x, \Delta y\rangle$ or $\langle \varepsilon_1, \varepsilon_2\rangle \cdot (\mathbf{x} - \mathbf{x}_0) = f(\mathbf{x}) - f(\mathbf{x}_0) - \nabla f(\mathbf{x}_0) \cdot (\mathbf{x} - \mathbf{x}_0)$,

and so $\dfrac{f(\mathbf{x}) - f(\mathbf{x}_0) - \nabla f(\mathbf{x}_0) \cdot (\mathbf{x} - \mathbf{x}_0)}{|\mathbf{x} - \mathbf{x}_0|} = \dfrac{\langle \varepsilon_1, \varepsilon_2\rangle \cdot (\mathbf{x} - \mathbf{x}_0)}{|\mathbf{x} - \mathbf{x}_0|}$. But $\dfrac{\mathbf{x} - \mathbf{x}_0}{|\mathbf{x} - \mathbf{x}_0|}$ is a unit vector so

$\displaystyle\lim_{\mathbf{x} \to \mathbf{x}_0} \frac{\langle \varepsilon_1, \varepsilon_2\rangle \cdot (\mathbf{x} - \mathbf{x}_0)}{|\mathbf{x} - \mathbf{x}_0|} = 0$ since $\varepsilon_1, \varepsilon_2 \to 0$ as $\mathbf{x} \to \mathbf{x}_0$. Hence $\displaystyle\lim_{\mathbf{x} \to \mathbf{x}_0} \frac{f(\mathbf{x}) - f(\mathbf{x}_0) - \nabla f(\mathbf{x}_0) \cdot (\mathbf{x} - \mathbf{x}_0)}{|\mathbf{x} - \mathbf{x}_0|} = 0$.

14.7 Maximum and Minimum Values

1. (a) First we compute $D(1, 1) = f_{xx}(1, 1)\, f_{yy}(1, 1) - [f_{xy}(1, 1)]^2 = (4)(2) - (1)^2 = 7$. Since $D(1, 1) > 0$ and $f_{xx}(1, 1) > 0$, f has a local minimum at $(1, 1)$ by the Second Derivatives Test.

(b) $D(1, 1) = f_{xx}(1, 1)\, f_{yy}(1, 1) - [f_{xy}(1, 1)]^2 = (4)(2) - (3)^2 = -1$. Since $D(1, 1) < 0$, f has a saddle point at $(1, 1)$ by the Second Derivatives Test.

2. (a) $D = g_{xx}(0, 2)\, g_{yy}(0, 2) - [g_{xy}(0, 2)]^2 = (-1)(1) - (6)^2 = -37$. Since $D < 0$, g has a saddle point at $(0, 2)$ by the Second Derivatives Test.

(b) $D = g_{xx}(0, 2)\, g_{yy}(0, 2) - [g_{xy}(0, 2)]^2 = (-1)(-8) - (2)^2 = 4$. Since $D > 0$ and $g_{xx}(0, 2) < 0$, g has a local maximum at $(0, 2)$ by the Second Derivatives Test.

(c) $D = g_{xx}(0, 2)\, g_{yy}(0, 2) - [g_{xy}(0, 2)]^2 = (4)(9) - (6)^2 = 0$. In this case the Second Derivatives Test gives no information about g at the point $(0, 2)$.

3. In the figure, a point at approximately $(1,1)$ is enclosed by level curves which are oval in shape and indicate that as we move away from the point in any direction the values of f are increasing. Hence we would expect a local minimum at or near $(1,1)$. The level curves near $(0,0)$ resemble hyperbolas, and as we move away from the origin, the values of f increase in some directions and decrease in others, so we would expect to find a saddle point there.

To verify our predictions, we have $f(x,y) = 4 + x^3 + y^3 - 3xy \quad \Rightarrow \quad f_x(x,y) = 3x^2 - 3y$, $f_y(x,y) = 3y^2 - 3x$. We have critical points where these partial derivatives are equal to 0: $3x^2 - 3y = 0$, $3y^2 - 3x = 0$. Substituting $y = x^2$ from the first equation into the second equation gives $3(x^2)^2 - 3x = 0 \quad \Rightarrow \quad 3x(x^3 - 1) = 0 \quad \Rightarrow \quad x = 0$ or $x = 1$. Then we have two critical points, $(0,0)$ and $(1,1)$. The second partial derivatives are $f_{xx}(x,y) = 6x$, $f_{xy}(x,y) = -3$, and $f_{yy}(x,y) = 6y$, so $D(x,y) = f_{xx}(x,y)\,f_{yy}(x,y) - [f_{xy}(x,y)]^2 = (6x)(6y) - (-3)^2 = 36xy - 9$. Then $D(0,0) = 36(0)(0) - 9 = -9$, and $D(1,1) = 36(1)(1) - 9 = 27$. Since $D(0,0) < 0$, f has a saddle point at $(0,0)$ by the Second Derivatives Test. Since $D(1,1) > 0$ and $f_{xx}(1,1) > 0$, f has a local minimum at $(1,1)$.

4. In the figure, points at approximately $(-1,1)$ and $(-1,-1)$ are enclosed by oval-shaped level curves which indicate that as we move away from either point in any direction, the values of f are increasing. Hence we would expect local minima at or near $(-1,\pm 1)$. Similarly, the point $(1,0)$ appears to be enclosed by oval-shaped level curves which indicate that as we move away from the point in any direction the values of f are decreasing, so we should have a local maximum there. We also show hyperbola-shaped level curves near the points $(-1,0)$, $(1,1)$, and $(1,-1)$. The values of f increase along some paths leaving these points and decrease in others, so we should have a saddle point at each of these points.

To confirm our predictions, we have $f(x,y) = 3x - x^3 - 2y^2 + y^4 \quad \Rightarrow \quad f_x(x,y) = 3 - 3x^2, \quad f_y(x,y) = -4y + 4y^3$. Setting these partial derivatives equal to 0, we have $3 - 3x^2 = 0 \quad \Rightarrow \quad x = \pm 1$ and $-4y + 4y^3 = 0 \quad \Rightarrow$ $y(y^2 - 1) = 0 \quad \Rightarrow \quad y = 0, \pm 1$. So our critical points are $(\pm 1, 0)$, $(\pm 1, 1)$, $(\pm 1, -1)$.

The second partial derivatives are $f_{xx}(x,y) = -6x$, $f_{xy}(x,y) = 0$, and $f_{yy}(x,y) = 12y^2 - 4$, so

$D(x,y) = f_{xx}(x,y)\,f_{yy}(x,y) - [f_{xy}(x,y)]^2 = (-6x)(12y^2 - 4) - (0)^2 = -72xy^2 + 24x$.

We use the Second Derivatives Test to classify the 6 critical points:

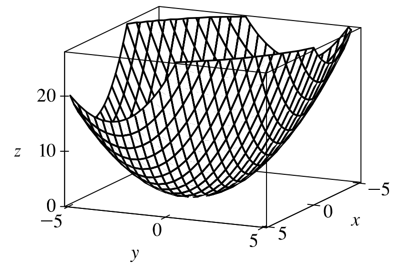
Critical Point	D	f_{xx}	Conclusion
$(1,0)$	24	-6	$D > 0$, $f_{xx} < 0 \Rightarrow f$ has a local maximum at $(1,0)$
$(1,1)$	-48		$D < 0 \Rightarrow f$ has a saddle point at $(1,1)$
$(1,-1)$	-48		$D < 0 \Rightarrow f$ has a saddle point at $(1,-1)$
$(-1,0)$	-24		$D < 0 \Rightarrow f$ has a saddle point at $(-1,0)$
$(-1,1)$	48	6	$D > 0$, $f_{xx} > 0 \Rightarrow f$ has a local minimum at $(-1,1)$
$(-1,-1)$	48	6	$D > 0$, $f_{xx} > 0 \Rightarrow f$ has a local minimum at $(-1,-1)$

5. $f(x,y) = x^2 + xy + y^2 + y \quad \Rightarrow \quad f_x = 2x + y, \; f_y = x + 2y + 1, \; f_{xx} = 2, \; f_{xy} = 1, \; f_{yy} = 2$. Then $f_x = 0$ implies $y = -2x$, and substitution into $f_y = x + 2y + 1 = 0$ gives $x + 2(-2x) + 1 = 0 \quad \Rightarrow \quad -3x = -1 \quad \Rightarrow \quad x = \frac{1}{3}$.

Then $y = -\frac{2}{3}$ and the only critical point is $\left(\frac{1}{3}, -\frac{2}{3}\right)$.

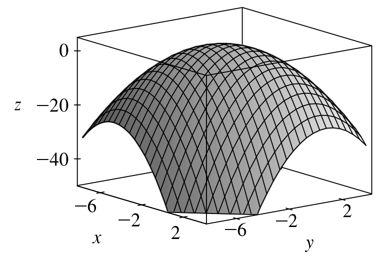
$D(x, y) = f_{xx}f_{yy} - (f_{xy})^2 = (2)(2) - (1)^2 = 3$, and since

$D\left(\frac{1}{3}, -\frac{2}{3}\right) = 3 > 0$ and $f_{xx}\left(\frac{1}{3}, -\frac{2}{3}\right) = 2 > 0$, $f\left(\frac{1}{3}, -\frac{2}{3}\right) = -\frac{1}{3}$ is a local minimum by the Second Derivatives Test.

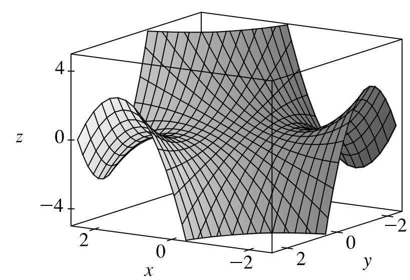


6. $f(x, y) = xy - 2x - 2y - x^2 - y^2 \quad \Rightarrow \quad f_x = y - 2 - 2x$,

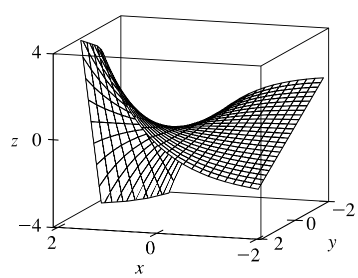
$f_y = x - 2 - 2y$, $f_{xx} = -2$, $f_{xy} = 1$, $f_{yy} = -2$. Then $f_x = 0$ implies $y = 2x + 2$, and substitution into $f_y = 0$ gives $x - 2 - 2(2x + 2) = 0 \quad \Rightarrow$ $-3x = 6 \quad \Rightarrow \quad x = -2$. Then $y = -2$ and the only critical point is $(-2, -2)$. $D(x, y) = f_{xx}f_{yy} - (f_{xy})^2 = (-2)(-2) - 1^2 = 3$, and since $D(-2, -2) = 3 > 0$ and $f_{xx}(-2, -2) = -2 < 0$, $f(-2, -2) = 4$ is a local maximum by the Second Derivatives Test.



7. $f(x, y) = (x - y)(1 - xy) = x - y - x^2y + xy^2 \quad \Rightarrow \quad f_x = 1 - 2xy + y^2$, $f_y = -1 - x^2 + 2xy$, $f_{xx} = -2y$, $f_{xy} = -2x + 2y$, $f_{yy} = 2x$. Then $f_x = 0$ implies $1 - 2xy + y^2 = 0$ and $f_y = 0$ implies $-1 - x^2 + 2xy = 0$. Adding the two equations gives $1 + y^2 - 1 - x^2 = 0 \quad \Rightarrow \quad y^2 = x^2 \quad \Rightarrow \quad y = \pm x$, but if $y = -x$ then $f_x = 0$ implies $1 + 2x^2 + x^2 = 0 \quad \Rightarrow \quad 3x^2 = -1$ which has no real solution. If $y = x$ then substitution into $f_x = 0$ gives $1 - 2x^2 + x^2 = 0 \quad \Rightarrow \quad x^2 = 1 \quad \Rightarrow$ $x = \pm 1$, so the critical points are $(1, 1)$ and $(-1, -1)$. Now $D(1, 1) = (-2)(2) - 0^2 = -4 < 0$ and $D(-1, -1) = (2)(-2) - 0^2 = -4 < 0$, so $(1, 1)$ and $(-1, -1)$ are saddle points.



8. $f(x, y) = y(e^x - 1) \quad \Rightarrow \quad f_x = ye^x$, $f_y = e^x - 1$, $f_{xx} = ye^x$, $f_{xy} = e^x$, $f_{yy} = 0$. Because e^x is never zero, $f_x = 0$ only when $y = 0$, and $f_y = 0$ when $e^x = 1 \quad \Rightarrow \quad x = 0$, so the only critical point is $(0, 0)$. $D(x, y) = f_{xx}f_{yy} - (f_{xy})^2 = (ye^x)(0) - (e^x)^2 = -e^{2x}$, and since $D(0, 0) = -1 < 0$, $(0, 0)$ is a saddle point.



9. $f(x, y) = x^2 + y^4 + 2xy \quad \Rightarrow \quad f_x = 2x + 2y$, $f_y = 4y^3 + 2x$, $f_{xx} = 2$, $f_{xy} = 2$, $f_{yy} = 12y^2$. Then $f_x = 0$ implies $y = -x$, and substitution into $f_y = 4y^3 + 2x = 0$ gives $-4x^3 + 2x = 0 \quad \Rightarrow \quad 2x\left(1 - 2x^2\right) = 0 \quad \Rightarrow \quad x = 0$ or $x = \pm\frac{1}{\sqrt{2}}$. Thus the critical points are $(0, 0)$, $\left(\frac{1}{\sqrt{2}}, -\frac{1}{\sqrt{2}}\right)$, and $\left(-\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}\right)$. Now

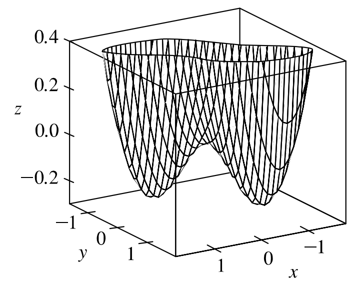
$D(x,y) = f_{xx}f_{yy} - (f_{xy})^2 = (2)(12y^2) - (2)^2 = 24y^2 - 4$,

so $D(0,0) = -4 < 0$ and $(0,0)$ is a saddle point.

$D\left(\frac{1}{\sqrt{2}}, -\frac{1}{\sqrt{2}}\right) = D\left(-\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}\right) = 24\left(\frac{1}{2}\right) - 4 = 8 > 0$ and

$f_{xx}\left(\frac{1}{\sqrt{2}}, -\frac{1}{\sqrt{2}}\right) = f_{xx}\left(-\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}\right) = 2 > 0$, so $f\left(\frac{1}{\sqrt{2}}, -\frac{1}{\sqrt{2}}\right) = -\frac{1}{4}$

and $f\left(-\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}\right) = -\frac{1}{4}$ are local minima.



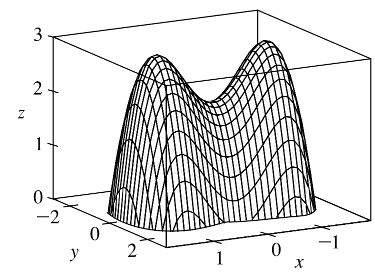
10. $f(x,y) = 2 - x^4 + 2x^2 - y^2 \quad\Rightarrow\quad f_x = -4x^3 + 4x,\ f_y = -2y,\ f_{xx} = -12x^2 + 4,\ f_{xy} = 0,\ f_{yy} = -2$. Then $f_x = 0$ implies $-4x(x^2 - 1) = 0$, so $x = 0$ or $x = \pm 1$, and $f_y = 0$ implies $y = 0$. Thus the critical points are $(0,0)$, $(\pm 1, 0)$.

$D(0,0) = (4)(-2) - 0^2 = -8 < 0$, so $(0,0)$ is a saddle point.

$D(1,0) = D(-1,0) = (-8)(-2) - (0)^2 = 16 > 0$, and

$f_{xx}(1,0) = f_{xx}(-1,0) = -8 < 0$, so $f(1,0) = 3$ and $f(-1,0) = 3$

are local maxima.

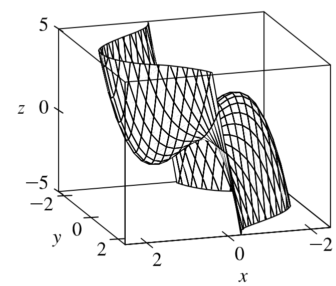


11. $f(x,y) = x^3 - 3x + 3xy^2 \quad\Rightarrow\quad f_x = 3x^2 - 3 + 3y^2,\ f_y = 6xy,\ f_{xx} = 6x,\ f_{xy} = 6y,\ f_{yy} = 6x$. Then $f_y = 0$ implies $x = 0$ or $y = 0$. If $x = 0$, substitution into $f_x = 0$ gives $3y^2 = 3 \quad\Rightarrow\quad y = \pm 1$, and if $y = 0$, substitution into $f_x = 0$ gives $x = \pm 1$. Thus the critical points are $(0, \pm 1)$ and $(\pm 1, 0)$.

$D(0, \pm 1) = 0 - 36 < 0$, so $(0, \pm 1)$ are saddle points.

$D(\pm 1, 0) = 36 - 0 > 0$, $f_{xx}(1,0) = 6 > 0$, and $f_{xx}(-1,0) = -6 < 0$,

so $f(1,0) = -2$ is a local minimum and $f(-1,0) = 2$ is a local maximum.



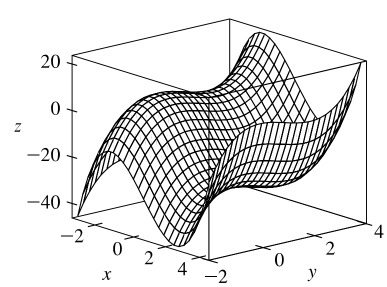
12. $f(x,y) = x^3 + y^3 - 3x^2 - 3y^2 - 9x \quad\Rightarrow\quad f_x = 3x^2 - 6x - 9,\ f_y = 3y^2 - 6y,\ f_{xx} = 6x - 6,\ f_{xy} = 0,\ f_{yy} = 6y - 6$. Then $f_x = 0$ implies $3(x+1)(x-3) = 0 \quad\Rightarrow\quad x = -1$ or $x = 3$, and $f_y = 0$ implies $3y(y-2) = 0 \quad\Rightarrow\quad y = 0$ or $y = 2$. Thus the critical points are $(-1,0)$, $(-1,2)$, $(3,0)$, and $(3,2)$. $\quad D(-1,2) = (-12)(6) - (0)^2 = -72 < 0$ and

$D(3,0) = (12)(-6) - (0)^2 = -72 < 0$, so $(-1,2)$ and $(3,0)$ are saddle points. $\quad D(-1,0) = (-12)(-6) - (0)^2 = 72 > 0$ and

$f_{xx}(-1,0) = -12 < 0$, so $f(-1,0) = 5$ is a local maximum.

$D(3,2) = (12)(6) - (0)^2 = 72 > 0$ and $f_{xx}(3,2) = 12 > 0$, so

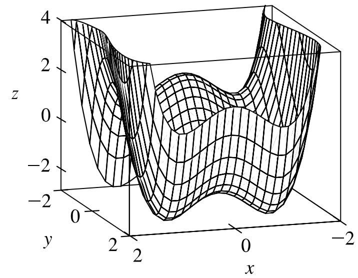
$f(3,2) = -31$ is a local minimum.



13. $f(x,y) = x^4 - 2x^2 + y^3 - 3y \quad \Rightarrow \quad f_x = 4x^3 - 4x,\ f_y = 3y^2 - 3,\ f_{xx} = 12x^2 - 4,\ f_{xy} = 0,\ f_{yy} = 6y.$

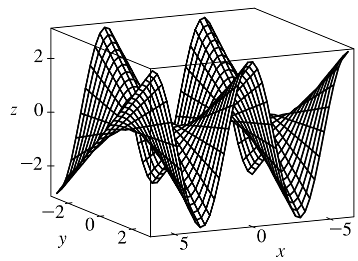
Then $f_x = 0$ implies $4x(x^2 - 1) = 0 \quad \Rightarrow \quad x = 0$ or $x = \pm 1$, and $f_y = 0$ implies $3(y^2 - 1) = 0 \quad \Rightarrow \quad y = \pm 1$.

Thus there are six critical points: $(0, \pm 1)$, $(\pm 1, 1)$, and $(\pm 1, -1)$.
$D(0,1) = (-4)(6) - (0)^2 = -24 < 0$ and
$D(\pm 1, -1) = (8)(-6) = -48 < 0$, so $(0,1)$ and $(\pm 1, -1)$ are saddle points. $D(0,-1) = (-4)(-6) = 24 > 0$ and $f_{xx}(0,-1) = -4 < 0$, so $f(0,-1) = 2$ is a local maximum. $D(\pm 1, 1) = (8)(6) = 48 > 0$ and $f_{xx}(\pm 1, 1) = 8 > 0$, so $f(\pm 1, 1) = -3$ are local minima.



14. $f(x,y) = y \cos x \quad \Rightarrow \quad f_x = -y \sin x$, $f_y = \cos x$, $f_{xx} = -y \cos x$, $f_{xy} = -\sin x$, $f_{yy} = 0$. Then $f_y = 0$ if and only if $x = \frac{\pi}{2} + n\pi$ for n an integer. But $\sin\left(\frac{\pi}{2} + n\pi\right) \neq 0$, so $f_x = 0 \quad \Rightarrow \quad y = 0$ and the critical points are $\left(\frac{\pi}{2} + n\pi, 0\right)$, n an integer.

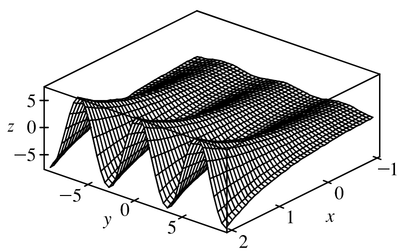
$D\left(\frac{\pi}{2} + n\pi, 0\right) = (0)(0) - (\pm 1)^2 = -1 < 0$, so each critical point is a saddle point.



15. $f(x,y) = e^x \cos y \quad \Rightarrow \quad f_x = e^x \cos y,\ f_y = -e^x \sin y.$

Now $f_x = 0$ implies $\cos y = 0$ or $y = \frac{\pi}{2} + n\pi$ for n an integer.

But $\sin\left(\frac{\pi}{2} + n\pi\right) \neq 0$, so there are no critical points.



16. $f(x,y) = xye^{-(x^2+y^2)/2} \quad \Rightarrow \quad f_x = xy \cdot e^{-(x^2+y^2)/2}(-x) + e^{-(x^2+y^2)/2} \cdot y = y(1 - x^2)e^{-(x^2+y^2)/2},$

$f_y = xy \cdot e^{-(x^2+y^2)/2}(-y) + e^{-(x^2+y^2)/2} \cdot x = x(1 - y^2)e^{-(x^2+y^2)/2},$

$f_{xx} = y\left[(1 - x^2) \cdot e^{-(x^2+y^2)/2}(-x) + e^{-(x^2+y^2)/2}(-2x)\right] = xy(x^2 - 3)e^{-(x^2+y^2)/2},$

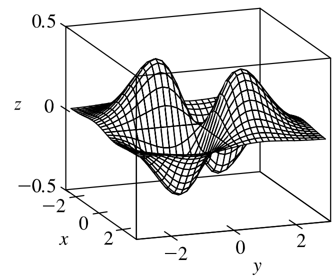
$f_{xy} = (1 - x^2)\left[y \cdot e^{-(x^2+y^2)/2}(-y) + e^{-(x^2+y^2)/2}(1)\right] = (1 - x^2)(1 - y^2)e^{-(x^2+y^2)/2},$

$f_{yy} = x\left[(1 - y^2) \cdot e^{-(x^2+y^2)/2}(-y) + e^{-(x^2+y^2)/2}(-2y)\right] = xy(y^2 - 3)e^{-(x^2+y^2)/2}.$

Then $f_x = 0$ implies $y(1 - x^2) = 0 \quad \Rightarrow \quad y = 0$ or $x = \pm 1$. Substituting $y = 0$ into $f_y = 0$ gives $xe^{-x^2/2} = 0 \quad \Rightarrow$ $x = 0$, and substituting $x = \pm 1$ into $f_y = 0$ gives $\pm(1 - y^2)e^{-(1+y^2)/2} = 0 \quad \Rightarrow \quad y = \pm 1$, so the critical points are $(0,0)$, $(1, \pm 1)$, and $(-1, \pm 1)$. $D(0,0) = (0)(0) - (1)^2 = -1 < 0$, so $(0,0)$ is a saddle point.

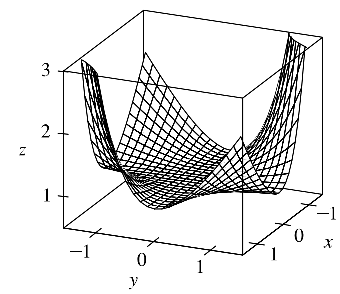
[continued]

$D(1,1) = D(-1,-1) = (-2e^{-1})(-2e^{-1}) - (0)^2 = 4e^{-2} > 0$ and $f_{xx}(1,1) = f_{xx}(-1,-1) = -2e^{-1} < 0$, so $f(1,1) = f(-1,-1) = e^{-1}$ are local maxima.
$D(1,-1) = D(-1,1) = (2e^{-1})(2e^{-1}) - (0)^2 = 4e^{-2} > 0$ and $f_{xx}(1,-1) = f_{xx}(-1,1) = 2e^{-1} > 0$, so $f(1,-1) = f(-1,1) = -e^{-1}$ are local minima.

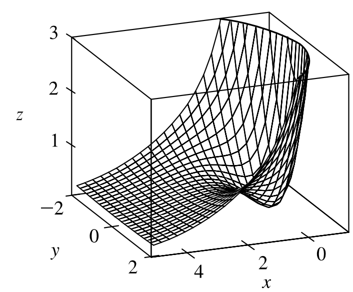


17. $f(x,y) = xy + e^{-xy} \quad\Rightarrow\quad f_x = y - ye^{-xy},\ f_y = x - xe^{-xy},\ f_{xx} = y^2e^{-xy}$, $f_{xy} = 1 - \left[y(-xe^{-xy}) + e^{-xy}(1)\right] = 1 + (xy-1)e^{-xy},\ f_{yy} = x^2e^{-xy}$. Then $f_x = 0$ implies $y(1 - e^{-xy}) = 0 \quad\Rightarrow$ $y = 0$ or $e^{-xy} = 1 \quad\Rightarrow\quad x = 0$ or $y = 0$. If $x = 0$ then $f_y = 0$ for any y-value, so all points of the form $(0, y_0)$ are critical points. If $y = 0$, then $f_y = x - xe^0 = 0$ for any x-value, so all points of the form $(x_0, 0)$ are critical points. We have $D(x_0, 0) = (0)(x_0^2) - (0)^2 = 0$ and $D(0, y_0) = (y_0^2)(0) - (0)^2 = 0$, so the Second Derivatives Test gives no information.

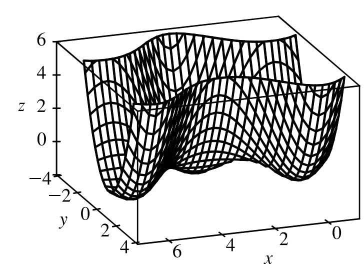
Notice that if we let $t = xy$, then $f(x,y) = g(t) = t + e^{-t} \quad\Rightarrow$ $g'(t) = 1 - e^{-t}$. Now $g'(t) = 0$ only for $t = 0$, and $g'(t) < 0$ for $t < 0$, $g'(t) > 0$ for $t > 0$. Thus $g(0) = 1$ is a local and absolute minimum, so $f(x,y) = xy + e^{-xy} \geq 1$ for all (x,y) with equality if and only if $x = 0$ or $y = 0$. Hence all points on the x- and y-axes are local (and absolute) minima, where $f(x,y) = 1$.



18. $f(x,y) = (x^2 + y^2)e^{-x} \quad\Rightarrow\quad f_x = (x^2+y^2)(-e^{-x}) + e^{-x}(2x) = (2x - x^2 - y^2)e^{-x},\quad f_y = 2ye^{-x}$, $f_{xx} = (2x - x^2 - y^2)(-e^{-x}) + e^{-x}(2 - 2x) = (x^2 + y^2 - 4x + 2)e^{-x},\quad f_{xy} = -2ye^{-x},\quad f_{yy} = 2e^{-x}$. Then $f_y = 0$ implies $y = 0$ and substituting into $f_x = 0$ gives $(2x - x^2)e^{-x} = 0 \quad\Rightarrow$ $x(2 - x) = 0 \quad\Rightarrow\quad x = 0$ or $x = 2$, so the critical points are $(0,0)$ and $(2,0)$. $D(0,0) = (2)(2) - (0)^2 = 4 > 0$ and $f_{xx}(0,0) = 2 > 0$, so $f(0,0) = 0$ is a local minimum.
$D(2,0) = (-2e^{-2})(2e^{-2}) - (0)^2 = -4e^{-4} < 0$ so $(2,0)$ is a saddle point.



19. $f(x,y) = y^2 - 2y\cos x \quad\Rightarrow\quad f_x = 2y\sin x$, $f_y = 2y - 2\cos x$, $f_{xx} = 2y\cos x$, $f_{xy} = 2\sin x$, $f_{yy} = 2$. Then $f_x = 0$ implies $y = 0$ or $\sin x = 0 \quad\Rightarrow\quad x = 0, \pi$, or 2π for $-1 \leq x \leq 7$. Substituting $y = 0$ into $f_y = 0$ gives $\cos x = 0 \quad\Rightarrow\quad x = \frac{\pi}{2}$ or $\frac{3\pi}{2}$, substituting $x = 0$ or $x = 2\pi$ into $f_y = 0$ gives $y = 1$, and substituting $x = \pi$ into $f_y = 0$ gives $y = -1$. Thus the critical points are $(0,1)$, $\left(\frac{\pi}{2}, 0\right)$, $(\pi, -1)$, $\left(\frac{3\pi}{2}, 0\right)$, and $(2\pi, 1)$.



$D\left(\frac{\pi}{2},0\right)=D\left(\frac{3\pi}{2},0\right)=-4<0$ so $\left(\frac{\pi}{2},0\right)$ and $\left(\frac{3\pi}{2},0\right)$ are saddle points. $D(0,1)=D(\pi,-1)=D(2\pi,1)=4>0$ and $f_{xx}(0,1)=f_{xx}(\pi,-1)=f_{xx}(2\pi,1)=2>0$, so $f(0,1)=f(\pi,-1)=f(2\pi,1)=-1$ are local minima.

20. $f(x,y)=\sin x\,\sin y \quad\Rightarrow\quad f_x=\cos x\,\sin y$, $f_y=\sin x\,\cos y$, $f_{xx}=-\sin x\,\sin y$, $f_{xy}=\cos x\,\cos y$, $f_{yy}=-\sin x\,\sin y$. Here we have $-\pi<x<\pi$ and $-\pi<y<\pi$, so $f_x=0$ implies $\cos x=0$ or $\sin y=0$. If $\cos x=0$ then $x=-\frac{\pi}{2}$ or $\frac{\pi}{2}$, and if $\sin y=0$ then $y=0$. Substituting $x=\pm\frac{\pi}{2}$ into $f_y=0$ gives $\cos y=0 \quad\Rightarrow\quad y=-\frac{\pi}{2}$ or $\frac{\pi}{2}$, and substituting $y=0$ into $f_y=0$ gives $\sin x=0 \quad\Rightarrow\quad x=0$. Thus the critical points are $\left(-\frac{\pi}{2},\pm\frac{\pi}{2}\right)$, $\left(\frac{\pi}{2},\pm\frac{\pi}{2}\right)$, and $(0,0)$.

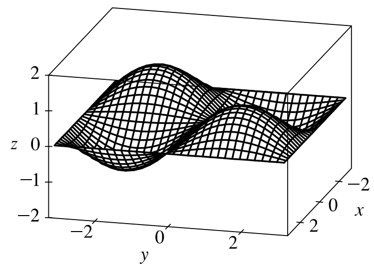
$D(0,0)=-1<0$ so $(0,0)$ is a saddle point.

$D\left(-\frac{\pi}{2},\pm\frac{\pi}{2}\right)=D\left(\frac{\pi}{2},\pm\frac{\pi}{2}\right)=1>0$ and

$f_{xx}\left(-\frac{\pi}{2},-\frac{\pi}{2}\right)=f_{xx}\left(\frac{\pi}{2},\frac{\pi}{2}\right)=-1<0$ while

$f_{xx}\left(-\frac{\pi}{2},\frac{\pi}{2}\right)=f_{xx}\left(\frac{\pi}{2},-\frac{\pi}{2}\right)=1>0$, so $f\left(-\frac{\pi}{2},-\frac{\pi}{2}\right)=f\left(\frac{\pi}{2},\frac{\pi}{2}\right)=1$

are local maxima and $f\left(-\frac{\pi}{2},\frac{\pi}{2}\right)=f\left(\frac{\pi}{2},-\frac{\pi}{2}\right)=1$ are local minima.



21. $f(x,y)=x^2+4y^2-4xy+2 \quad\Rightarrow\quad f_x=2x-4y$, $f_y=8y-4x$, $f_{xx}=2$, $f_{xy}=-4$, $f_{yy}=8$. Then $f_x=0$ and $f_y=0$ each implies $y=\frac{1}{2}x$, so all points of the form $\left(x_0,\frac{1}{2}x_0\right)$ are critical points and for each of these we have $D\left(x_0,\frac{1}{2}x_0\right)=(2)(8)-(-4)^2=0$. The Second Derivatives Test gives no information, but $f(x,y)=x^2+4y^2-4xy+2=(x-2y)^2+2\geq 2$ with equality if and only if $y=\frac{1}{2}x$. Thus $f\left(x_0,\frac{1}{2}x_0\right)=2$ are all local (and absolute) minima.

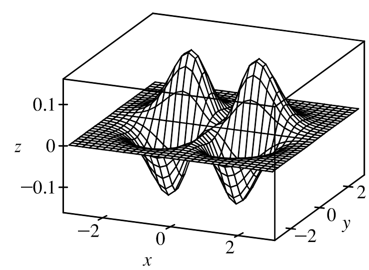
22. $f(x,y)=x^2ye^{-x^2-y^2} \quad\Rightarrow$

$f_x=x^2ye^{-x^2-y^2}(-2x)+2xye^{-x^2-y^2}=2xy(1-x^2)e^{-x^2-y^2}$,

$f_y=x^2ye^{-x^2-y^2}(-2y)+x^2e^{-x^2-y^2}=x^2(1-2y^2)e^{-x^2-y^2}$,

$f_{xx}=2y(2x^4-5x^2+1)e^{-x^2-y^2}$,

$f_{xy}=2x(1-x^2)(1-2y^2)e^{-x^2-y^2}$, $f_{yy}=2x^2y(2y^2-3)e^{-x^2-y^2}$.



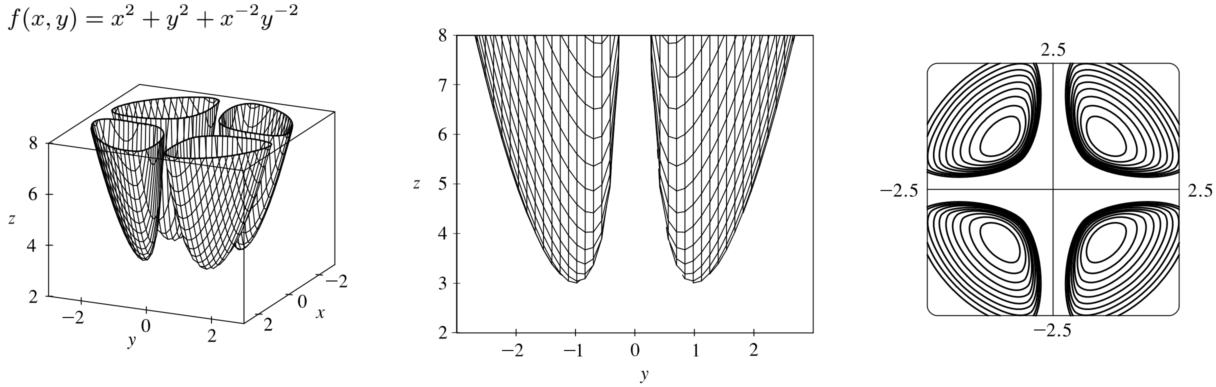
$f_x=0$ implies $x=0$, $y=0$, or $x=\pm1$. If $x=0$ then $f_y=0$ for any y-value, so all points of the form $(0,y)$ are critical points. If $y=0$ then $f_y=0 \quad\Rightarrow\quad x^2e^{-x^2}=0 \quad\Rightarrow\quad x=0$, so $(0,0)$ (already included above) is a critical point. If $x=\pm1$ then $(1-2y^2)e^{-1-y^2}=0 \quad\Rightarrow\quad y=\pm\frac{1}{\sqrt{2}}$, so $\left(\pm1,\frac{1}{\sqrt{2}}\right)$ and $\left(\pm1,-\frac{1}{\sqrt{2}}\right)$ are critical points. Now

$D\left(\pm1,\frac{1}{\sqrt{2}}\right)=8e^{-3}>0$, $f_{xx}\left(\pm1,\frac{1}{\sqrt{2}}\right)=-2\sqrt{2}\,e^{-3/2}<0$ and $D\left(\pm1,-\frac{1}{\sqrt{2}}\right)=8e^{-3}>0$,

$f_{xx}\left(\pm1,-\frac{1}{\sqrt{2}}\right)=2\sqrt{2}\,e^{-3/2}>0$, so $f\left(\pm1,\frac{1}{\sqrt{2}}\right)=\frac{1}{\sqrt{2}}e^{-3/2}$ are local maximum points while

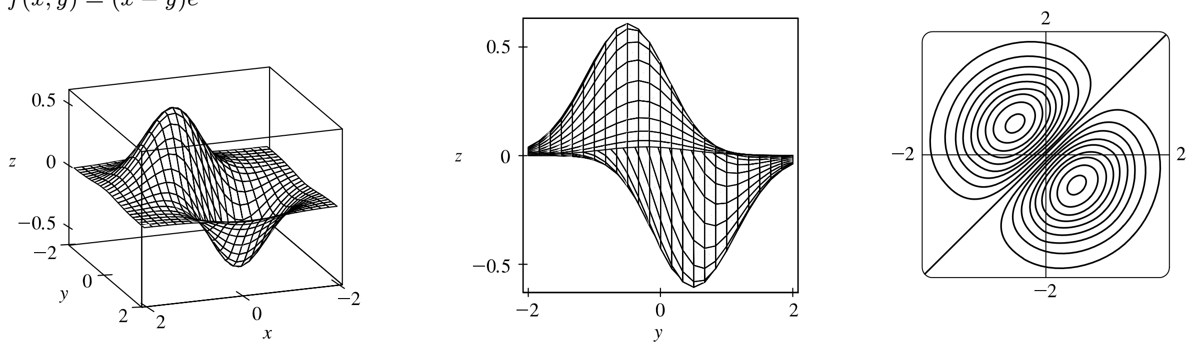
$f\left(\pm1,-\frac{1}{\sqrt{2}}\right)=-\frac{1}{\sqrt{2}}e^{-3/2}$ are local minimum points. At all critical points $(0,y)$ we have $D(0,y)=0$, so the Second Derivatives Test gives no information. However, if $y>0$ then $x^2ye^{-x^2-y^2}\geq 0$ with equality only when $x=0$, so we have local minimum values $f(0,y)=0$, $y>0$. Similarly, if $y<0$ then $x^2ye^{-x^2-y^2}\leq 0$ with equality when $x=0$ so $f(0,y)=0$, $y<0$ are local maximum values, and $(0,0)$ is a saddle point.

23. $f(x,y) = x^2 + y^2 + x^{-2}y^{-2}$



From the graphs, there appear to be local minima of about $f(1,\pm1) = f(-1,\pm1) \approx 3$ (and no local maxima or saddle points). $f_x = 2x - 2x^{-3}y^{-2}$, $f_y = 2y - 2x^{-2}y^{-3}$, $f_{xx} = 2 + 6x^{-4}y^{-2}$, $f_{xy} = 4x^{-3}y^{-3}$, $f_{yy} = 2 + 6x^{-2}y^{-4}$. Then $f_x = 0$ implies $2x^4y^2 - 2 = 0$ or $x^4y^2 = 1$ or $y^2 = x^{-4}$. Note that neither x nor y can be zero. Now $f_y = 0$ implies $2x^2y^4 - 2 = 0$, and with $y^2 = x^{-4}$ this implies $2x^{-6} - 2 = 0$ or $x^6 = 1$. Thus $x = \pm1$ and if $x = 1$, $y = \pm1$; if $x = -1$, $y = \pm1$. So the critical points are $(1,1)$, $(1,-1)$,$(-1,1)$ and $(-1,-1)$. Now $D(1,\pm1) = D(-1,\pm1) = 64 - 16 > 0$ and $f_{xx} > 0$ always, so $f(1,\pm1) = f(-1,\pm1) = 3$ are local minima.

24. $f(x,y) = (x-y)e^{-x^2-y^2}$



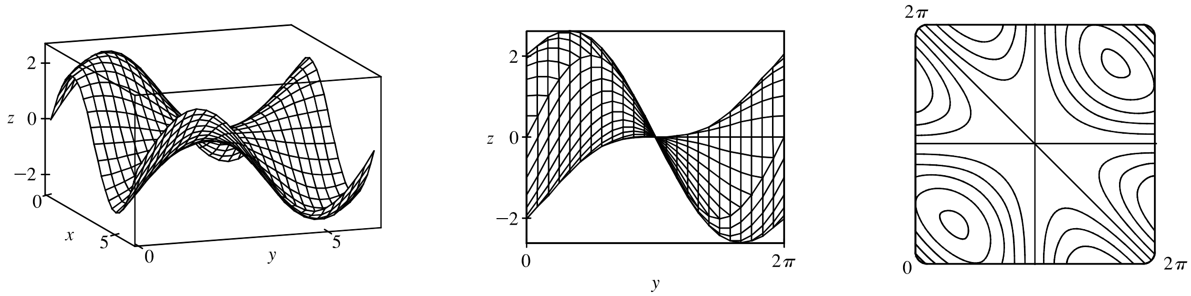
From the graphs, there appears to be a local maximum of about $f(0.5,-0.5) \approx 0.6$ and a local minimum of about $f(-0.5,0.5) \approx -0.6$.

$f_x = (x-y)e^{-x^2-y^2}(-2x) + e^{-x^2-y^2}(1) = e^{-x^2-y^2}(1 - 2x^2 + 2xy)$,

$f_y = (x-y)e^{-x^2-y^2}(-2y) + e^{-x^2-y^2}(-1) = -e^{-x^2-y^2}(1 - 2y^2 + 2xy)$, $f_{xx} = 2e^{-x^2-y^2}(2x^3 - 3x + y - 2x^2y)$,

$f_{xy} = 2e^{-x^2-y^2}(x - y + 2x^2y - 2xy^2)$, $f_{yy} = -2e^{-x^2-y^2}(2y^3 - 3y + x - 2xy^2)$. Then $f_x = 0$ implies $1 - 2x^2 + 2xy = 0$ and $f_y = 0$ implies $1 - 2y^2 + 2xy = 0$. Subtracting these two equations gives $-2x^2 + 2y^2 = 0 \quad\Rightarrow\quad y = \pm x$. If $y = x$ then substituting into $f_x = 0$ gives $1 - 2x^2 + 2x^2 = 0$, an impossibility. Substituting $y = -x$ gives $1 - 2x^2 - 2x^2 = 0 \quad\Rightarrow\quad x^2 = \frac{1}{4} \quad\Rightarrow\quad x = \pm\frac{1}{2}$. Thus the critical points are $\left(\frac{1}{2},-\frac{1}{2}\right)$ and $\left(-\frac{1}{2},\frac{1}{2}\right)$. Now $D\left(\frac{1}{2},-\frac{1}{2}\right) = (-3e^{-1/2})(-3e^{-1/2}) - (e^{-1/2})^2 = 8e^{-1} > 0$ with $f_{xx}\left(\frac{1}{2},-\frac{1}{2}\right) = -3e^{-1/2} < 0$, so $f\left(\frac{1}{2},-\frac{1}{2}\right) = e^{-1/2} \approx 0.607$ is a local maximum, and $D\left(-\frac{1}{2},\frac{1}{2}\right) = (3e^{-1/2})(3e^{-1/2}) - (-e^{-1/2})^2 = 8e^{-1} > 0$ with $f_{xx}\left(-\frac{1}{2},\frac{1}{2}\right) = 3e^{-1/2} > 0$, so $f\left(-\frac{1}{2},\frac{1}{2}\right) = -e^{-1/2} \approx -0.607$ is a local minimum.

25. $f(x,y) = \sin x + \sin y + \sin(x+y),\ 0 \le x \le 2\pi,\ 0 \le y \le 2\pi$

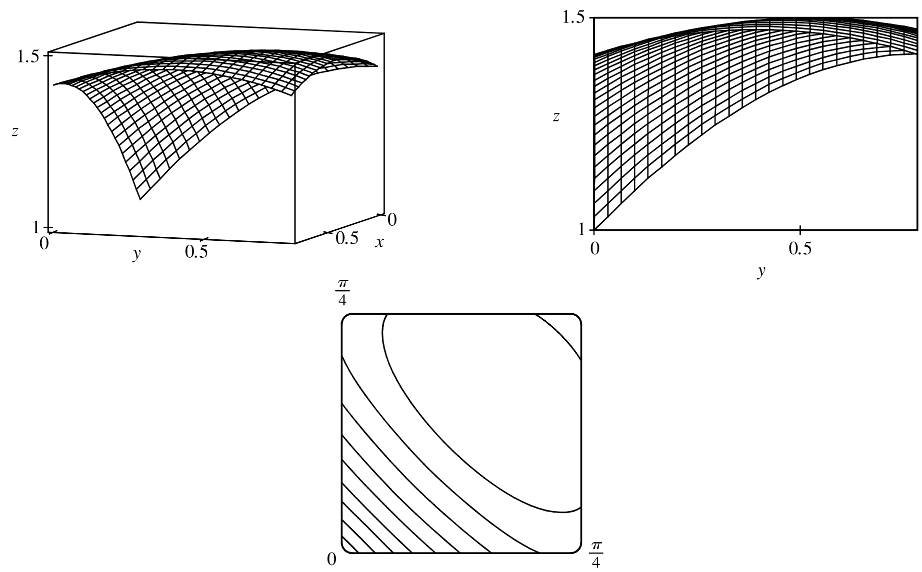


From the graphs it appears that f has a local maximum at about $(1,1)$ with value approximately 2.6, a local minimum at about $(5,5)$ with value approximately -2.6, and a saddle point at about $(3,3)$.

$f_x = \cos x + \cos(x+y)$, $f_y = \cos y + \cos(x+y)$, $f_{xx} = -\sin x - \sin(x+y)$, $f_{yy} = -\sin y - \sin(x+y)$, $f_{xy} = -\sin(x+y)$. Setting $f_x = 0$ and $f_y = 0$ and subtracting gives $\cos x - \cos y = 0$ or $\cos x = \cos y$. Thus $x = y$ or $x = 2\pi - y$. If $x = y$, $f_x = 0$ becomes $\cos x + \cos 2x = 0$ or $2\cos^2 x + \cos x - 1 = 0$, a quadratic in $\cos x$. Thus $\cos x = -1$ or $\frac{1}{2}$ and $x = \pi$, $\frac{\pi}{3}$, or $\frac{5\pi}{3}$, giving the critical points (π,π), $\left(\frac{\pi}{3},\frac{\pi}{3}\right)$ and $\left(\frac{5\pi}{3},\frac{5\pi}{3}\right)$. Similarly if $x = 2\pi - y$, $f_x = 0$ becomes $(\cos x) + 1 = 0$ and the resulting critical point is (π,π). Now $D(x,y) = \sin x\ \sin y + \sin x\ \sin(x+y) + \sin y\ \sin(x+y)$. So $D(\pi,\pi) = 0$ and the Second Derivatives Test doesn't apply. However, along the line $y = x$ we have $f(x,x) = 2\sin x + \sin 2x = 2\sin x + 2\sin x\ \cos x = 2\sin x(1+\cos x)$, and $f(x,x) > 0$ for $0 < x < \pi$ while $f(x,x) < 0$ for $\pi < x < 2\pi$. Thus every disk with center (π,π) contains points where f is positive as well as points where f is negative, so the graph crosses its tangent plane ($z = 0$) there and (π,π) is a saddle point.

$D\left(\frac{\pi}{3},\frac{\pi}{3}\right) = \frac{9}{4} > 0$ and $f_{xx}\left(\frac{\pi}{3},\frac{\pi}{3}\right) < 0$ so $f\left(\frac{\pi}{3},\frac{\pi}{3}\right) = \frac{3\sqrt{3}}{2}$ is a local maximum while $D\left(\frac{5\pi}{3},\frac{5\pi}{3}\right) = \frac{9}{4} > 0$ and $f_{xx}\left(\frac{5\pi}{3},\frac{5\pi}{3}\right) > 0$, so $f\left(\frac{5\pi}{3},\frac{5\pi}{3}\right) = -\frac{3\sqrt{3}}{2}$ is a local minimum.

26. $f(x,y) = \sin x + \sin y + \cos(x+y),\ 0 \le x \le \frac{\pi}{4},\ 0 \le y \le \frac{\pi}{4}$

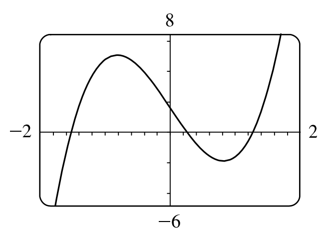


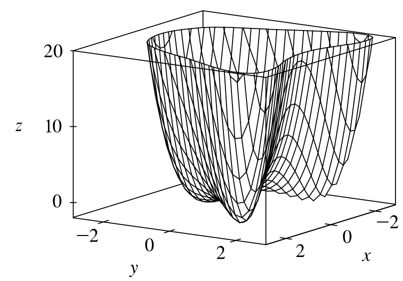
[continued]

From the graphs, it seems that f has a local maximum at about $(0.5, 0.5)$.

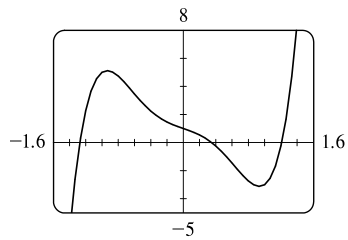
$f_x = \cos x - \sin(x + y)$, $f_y = \cos y - \sin(x + y)$, $f_{xx} = -\sin x - \cos(x + y)$, $f_{yy} = -\sin y - \cos(x + y)$, $f_{xy} = -\cos(x + y)$. Setting $f_x = 0$ and $f_y = 0$ and subtracting gives $\cos x = \cos y$. Thus $x = y$. Substituting $x = y$ into $f_x = 0$ gives $\cos x - \sin 2x = 0$ or $\cos x(1 - 2\sin x) = 0$. But $\cos x \neq 0$ for $0 \leq x \leq \frac{\pi}{4}$ and $1 - 2\sin x = 0$ implies $x = \frac{\pi}{6}$, so the only critical point is $\left(\frac{\pi}{6}, \frac{\pi}{6}\right)$. Here $f_{xx}\left(\frac{\pi}{6}, \frac{\pi}{6}\right) = -1 < 0$ and $D\left(\frac{\pi}{6}, \frac{\pi}{6}\right) = (-1)^2 - \frac{1}{4} > 0$. Thus $f\left(\frac{\pi}{6}, \frac{\pi}{6}\right) = \frac{3}{2}$ is a local maximum.

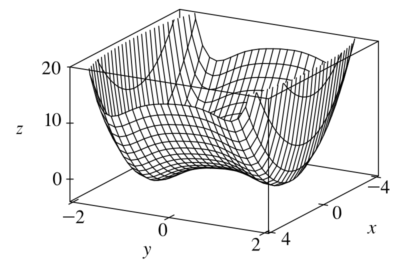
27. $f(x, y) = x^4 + y^4 - 4x^2y + 2y \quad \Rightarrow \quad f_x(x, y) = 4x^3 - 8xy$ and $f_y(x, y) = 4y^3 - 4x^2 + 2$. $f_x = 0 \quad \Rightarrow$ $4x(x^2 - 2y) = 0$, so $x = 0$ or $x^2 = 2y$. If $x = 0$ then substitution into $f_y = 0$ gives $4y^3 = -2 \quad \Rightarrow \quad y = -\frac{1}{\sqrt[3]{2}}$, so $\left(0, -\frac{1}{\sqrt[3]{2}}\right)$ is a critical point. Substituting $x^2 = 2y$ into $f_y = 0$ gives $4y^3 - 8y + 2 = 0$. Using a graph, solutions are approximately $y = -1.526$, 0.259, and 1.267. (Alternatively, we could have used a calculator or a CAS to find these roots.) We have $x^2 = 2y \quad \Rightarrow \quad x = \pm\sqrt{2y}$, so $y = -1.526$ gives no real-valued solution for x, but $y = 0.259 \quad \Rightarrow \quad x \approx \pm 0.720$ and $y = 1.267 \quad \Rightarrow \quad x \approx \pm 1.592$. Thus to three decimal places, the critical points are $\left(0, -\frac{1}{\sqrt[3]{2}}\right) \approx (0, -0.794)$, $(\pm 0.720, 0.259)$, and $(\pm 1.592, 1.267)$. Now since $f_{xx} = 12x^2 - 8y$, $f_{xy} = -8x$, $f_{yy} = 12y^2$, and $D = (12x^2 - 8y)(12y^2) - 64x^2$, we have $D(0, -0.794) > 0$, $f_{xx}(0, -0.794) > 0$, $D(\pm 0.720, 0.259) < 0$, $D(\pm 1.592, 1.267) > 0$, and $f_{xx}(\pm 1.592, 1.267) > 0$. Therefore $f(0, -0.794) \approx -1.191$ and $f(\pm 1.592, 1.267) \approx -1.310$ are local minima, and $(\pm 0.720, 0.259)$ are saddle points. There is no highest point on the graph, but the lowest points are approximately $(\pm 1.592, 1.267, -1.310)$.



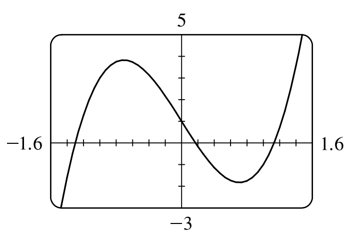


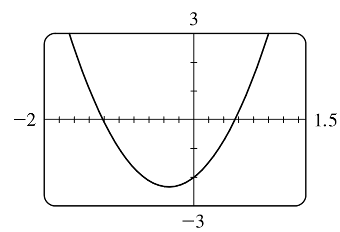
28. $f(x, y) = y^6 - 2y^4 + x^2 - y^2 + y \quad \Rightarrow \quad f_x(x, y) = 2x$ and $f_y(x, y) = 6y^5 - 8y^3 - 2y + 1$. $f_x = 0$ implies $x = 0$, and the graph of f_y shows that the roots of $f_y = 0$ are approximately $y = -1.273$, 0.347, and 1.211. (Alternatively, we could have found the roots of $f_y = 0$ directly, using a calculator or CAS.) So to three decimal places, the critical points are $(0, -1.273)$, $(0, 0.347)$, and $(0, 1.211)$. Now since $f_{xx} = 2$, $f_{xy} = 0$, $f_{yy} = 30y^4 - 24y^2 - 2$, and $D = 60y^4 - 48y^2 - 4$, we have $D(0, -1.273) > 0$, $f_{xx}(0, -1.273) > 0$, $D(0, 0.347) < 0$, $D(0, 1.211) > 0$, and $f_{xx}(0, 1.211) > 0$, so $f(0, -1.273) \approx -3.890$ and $f(0, 1.211) \approx -1.403$ are local minima, and $(0, 0.347)$ is a saddle point. The lowest point on the graph is approximately $(0, -1.273, -3.890)$.

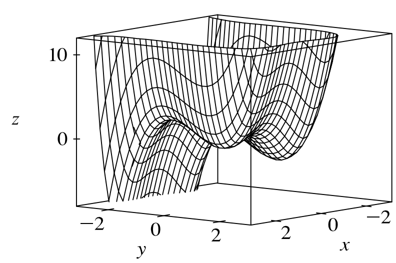




29. $f(x,y) = x^4 + y^3 - 3x^2 + y^2 + x - 2y + 1 \quad \Rightarrow \quad f_x(x,y) = 4x^3 - 6x + 1$ and $f_y(x,y) = 3y^2 + 2y - 2$. From the graphs, we see that to three decimal places, $f_x = 0$ when $x \approx -1.301$, 0.170, or 1.131, and $f_y = 0$ when $y \approx -1.215$ or x 0.549. (Alternatively, we could have used a calculator or a CAS to find these roots. We could also use the quadratic formula to find the solutions of $f_y = 0$.) So, to three decimal places, f has critical points at $(-1.301, -1.215)$, $(-1.301, 0.549)$, $(0.170, -1.215)$, $(0.170, 0.549)$, $(1.131, -1.215)$, and $(1.131, 0.549)$. Now since $f_{xx} = 12x^2 - 6$, $f_{xy} = 0$, $f_{yy} = 6y + 2$, and $D = (12x^2 - 6)(6y + 2)$, we have $D(-1.301, -1.215) < 0$, $D(-1.301, 0.549) > 0$, $f_{xx}(-1.301, 0.549) > 0$, $D(0.170, -1.215) > 0$, $f_{xx}(0.170, -1.215) < 0$, $D(0.170, 0.549) < 0$, $D(1.131, -1.215) < 0$, $D(1.131, 0.549) > 0$, and $f_{xx}(1.131, 0.549) > 0$. Therefore, to three decimal places, $f(-1.301, 0.549) \approx -3.145$ and $f(1.131, 0.549) \approx -0.701$ are local minima, $f(0.170, -1.215) \approx 3.197$ is a local maximum, and $(-1.301, -1.215)$, $(0.170, 0.549)$, and $(1.131, -1.215)$ are saddle points. There is no highest or lowest point on the graph.







30. $f(x,y) = 20e^{-x^2-y^2} \sin 3x \cos 3y \quad \Rightarrow$

$$\begin{aligned} f_x(x,y) &= 20 \cos 3y \left[e^{-x^2-y^2}(3 \cos 3x) + (\sin 3x) e^{-x^2-y^2}(-2x) \right] \\ &= 20e^{-x^2-y^2} \cos 3y \,(3 \cos 3x - 2x \sin 3x) \\ f_y(x,y) &= 20 \sin 3x \left[e^{-x^2-y^2}(-3 \sin 3y) + (\cos 3y) e^{-x^2-y^2}(-2y) \right] \\ &= -20e^{-x^2-y^2} \sin 3x \,(3 \sin 3y + 2y \cos 3y) \end{aligned}$$

Now $f_x = 0$ implies $\cos 3y = 0$ or $3 \cos 3x - 2x \sin 3x = 0$. For $|y| \le 1$, the solutions to $\cos 3y = 0$ are $y = \pm\frac{\pi}{6} \approx \pm 0.524$. Using a graph (or a calculator or CAS), we estimate the roots of $3 \cos 3x - 2x \sin 3x$ for $|x| \le 1$ to be

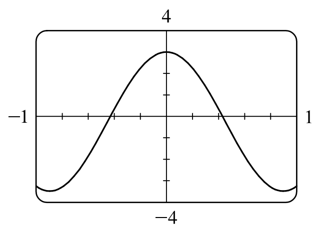
$x \approx \pm 0.430$. $f_y = 0$ implies $\sin 3x = 0$, so $x = 0$, or $3\sin 3y + 2y\cos 3y = 0$. From a graph (or calculator or CAS), the roots of $3\sin 3y + 2y\cos 3y$ between -1 and 1 are approximately 0 and ± 0.872. So to three decimal places, f has critical points at $(\pm 0.430, 0)$, $(0.430, \pm 0.872)$, $(-0.430, \pm 0.872)$, and $(0, \pm 0.524)$. Now

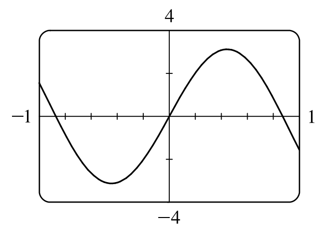
$$f_{xx} = 20e^{-x^2-y^2}\cos 3y[(4x^2 - 11)\sin 3x - 12x\cos 3x]$$

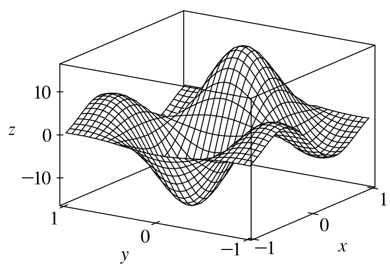
$$f_{xy} = -20e^{-x^2-y^2}(3\cos 3x - 2x\sin 3x)(3\sin 3y + 2y\cos 3y)$$

$$f_{yy} = 20e^{-x^2-y^2}\sin 3x[(4y^2 - 11)\cos 3y - 12y\sin 3y]$$

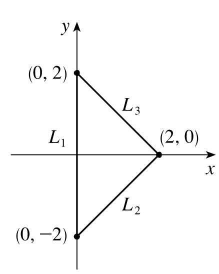
and $D = f_{xx}f_{yy} - f_{xy}^2$. Then $D(\pm 0.430, 0) > 0$, $f_{xx}(0.430, 0) < 0$, $f_{xx}(-0.430, 0) > 0$, $D(0.430, \pm 0.872) > 0$, $f_{xx}(0.430, \pm 0.872) > 0$, $D(-0.430, \pm 0.872) > 0$, $f_{xx}(-0.430, \pm 0.872) < 0$, and $D(0, \pm 0.524) < 0$, so $f(0.430, 0) \approx 15.973$ and $f(-0.430, \pm 0.872) \approx 6.459$ are local maxima, $f(-0.430, 0) \approx -15.973$ and $f(0.430, \pm 0.872) \approx -6.459$ are local minima, and $(0, \pm 0.524)$ are saddle points. The highest point on the graph is approximately $(0.430, 0, 15.973)$ and the lowest point is approximately $(-0.430, 0, -15.973)$.





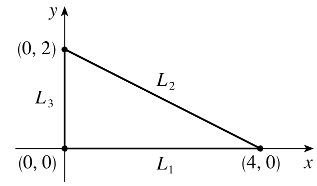


31. Since f is a polynomial it is continuous on D, so an absolute maximum and minimum exist. Here $f_x = 2x - 2$, $f_y = 2y$, and setting $f_x = f_y = 0$ gives $(1, 0)$ as the only critical point (which is inside D), where $f(1, 0) = -1$. Along L_1: $x = 0$ and $f(0, y) = y^2$ for $-2 \le y \le 2$, a quadratic function which attains its minimum at $y = 0$, where $f(0, 0) = 0$, and its maximum at $y = \pm 2$, where $f(0, \pm 2) = 4$. Along L_2: $y = x - 2$ for $0 \le x \le 2$, and $f(x, x - 2) = 2x^2 - 6x + 4 = 2\left(x - \frac{3}{2}\right)^2 - \frac{1}{2}$, a quadratic which attains its minimum at $x = \frac{3}{2}$, where $f\left(\frac{3}{2}, -\frac{1}{2}\right) = -\frac{1}{2}$, and its maximum at $x = 0$, where $f(0, -2) = 4$. Along L_3: $y = 2 - x$ for $0 \le x \le 2$, and $f(x, 2 - x) = 2x^2 - 6x + 4 = 2\left(x - \frac{3}{2}\right)^2 - \frac{1}{2}$, a quadratic which attains its minimum at $x = \frac{3}{2}$, where $f\left(\frac{3}{2}, \frac{1}{2}\right) = -\frac{1}{2}$, and its maximum at $x = 0$, where $f(0, 2) = 4$. Thus the absolute maximum of f on D is $f(0, \pm 2) = 4$ and the absolute minimum is $f(1, 0) = -1$.



32. Since f is a polynomial it is continuous on D, so an absolute maximum and minimum exist. $f_x = 1 - y$, $f_y = 1 - x$, and setting $f_x = f_y = 0$ gives $(1,1)$ as the only critical point (which is inside D), where $f(1,1) = 1$. Along L_1: $y = 0$ and $f(x,0) = x$ for $0 \le x \le 4$, an increasing function in x, so the maximum value is $f(4,0) = 4$ and the minimum value is $f(0,0) = 0$. Along L_2: $y = 2 - \frac{1}{2}x$ and $f\left(x, 2 - \frac{1}{2}x\right) = \frac{1}{2}x^2 - \frac{3}{2}x + 2 = \frac{1}{2}\left(x - \frac{3}{2}\right)^2 + \frac{7}{8}$ for $0 \le x \le 4$, a quadratic function which has a minimum at $x = \frac{3}{2}$, where $f\left(\frac{3}{2}, \frac{5}{4}\right) = \frac{7}{8}$, and a maximum at $x = 4$, where $f(4,0) = 4$.

Along L_3: $x = 0$ and $f(0,y) = y$ for $0 \le y \le 2$, an increasing function in y, so the maximum value is $f(0,2) = 2$ and the minimum value is $f(0,0) = 0$. Thus the absolute maximum of f on D is $f(4,0) = 4$ and the absolute minimum is $f(0,0) = 0$.



33. $f_x(x,y) = 2x + 2xy$, $f_y(x,y) = 2y + x^2$, and setting $f_x = f_y = 0$ gives $(0,0)$ as the only critical point in D, with $f(0,0) = 4$.

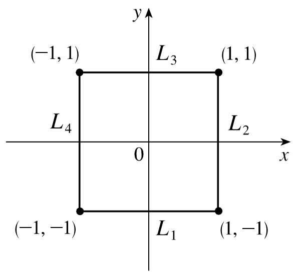
On L_1: $y = -1$, $f(x,-1) = 5$, a constant.

On L_2: $x = 1$, $f(1,y) = y^2 + y + 5$, a quadratic in y which attains its maximum at $(1,1)$, $f(1,1) = 7$ and its minimum at $\left(1, -\frac{1}{2}\right)$, $f\left(1, -\frac{1}{2}\right) = \frac{19}{4}$.

On L_3: $f(x,1) = 2x^2 + 5$ which attains its maximum at $(-1,1)$ and $(1,1)$ with $f(\pm 1, 1) = 7$ and its minimum at $(0,1)$, $f(0,1) = 5$.

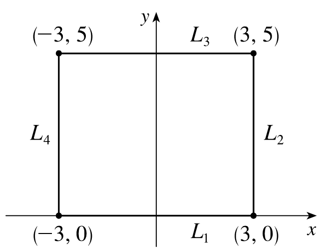
On L_4: $f(-1,y) = y^2 + y + 5$ with maximum at $(-1,1)$, $f(-1,1) = 7$ and minimum at $\left(-1, -\frac{1}{2}\right)$, $f\left(-1, -\frac{1}{2}\right) = \frac{19}{4}$.

Thus the absolute maximum is attained at both $(\pm 1, 1)$ with $f(\pm 1, 1) = 7$ and the absolute minimum on D is attained at $(0,0)$ with $f(0,0) = 4$.

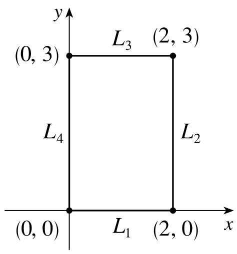


34. $f(x,y) = x^2 + xy + y^2 - 6y \quad \Rightarrow \quad f_x = 2x + y, \quad f_y = x + 2y - 6$. Then $f_x = 0$ implies $y = -2x$, and substituting into $f_y = 0$ gives $x - 4x - 6 = 0 \quad \Rightarrow \quad x = -2$, so the only critical point is $(-2,4)$ (which is in D) where $f(-2,4) = -12$. Along L_1: $y = 0$, so $f(x,0) = x^2$, $-3 \le x \le 3$, which has a maximum value at $x = \pm 3$ where $f(\pm 3, 0) = 9$ and a minimum value at $x = 0$, where $f(0,0) = 0$. Along L_2: $x = 3$, so $f(3,y) = 9 - 3y + y^2 = \left(y - \frac{3}{2}\right)^2 + \frac{27}{4}$, $0 \le y \le 5$, which has a maximum value at $y = 5$ where $f(3,5) = 19$ and a minimum value at $y = \frac{3}{2}$ where $f(3, \frac{3}{2}) = \frac{27}{4}$.

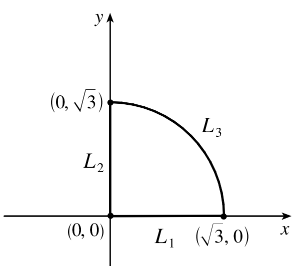
Along L_3: $y = 5$, so $f(x,5) = x^2 + 5x - 5 = \left(x + \frac{5}{2}\right)^2 - \frac{45}{4}$, $-3 \le x \le 3$, which has a maximum value at $x = 3$ where $f(3,5) = 19$ and a minimum value at $x = -\frac{5}{2}$, where $f\left(-\frac{5}{2}, 5\right) = -\frac{45}{4}$. Along L_4: $x = -3$, so $f(-3,y) = 9 - 9y + y^2 = \left(y - \frac{9}{2}\right)^2 - \frac{45}{4}$, $0 \le y \le 5$, which has a maximum value at $y = 0$ where $f(-3,0) = 9$ and a minimum value at $y = \frac{9}{2}$ where $f\left(-3, \frac{9}{2}\right) = -\frac{45}{4}$. Thus the absolute maximum of f on D is $f(3,5) = 19$ and the absolute minimum is $f(-2,4) = -12$.



35. $f(x,y) = x^2 + 2y^2 - 2x - 4y + 1 \quad \Rightarrow \quad f_x = 2x - 2,\ f_y = 4y - 4$. Setting $f_x = 0$ and $f_y = 0$ gives $(1,1)$ as the only critical point (which is inside D), where $f(1,1) = -2$. Along L_1: $y = 0$, so $f(x,0) = x^2 - 2x + 1 = (x-1)^2$, $0 \le x \le 2$, which has a maximum value both at $x = 0$ and $x = 2$ where $f(0,0) = f(2,0) = 1$ and a minimum value at $x = 1$, where $f(1,0) = 0$. Along L_2: $x = 2$, so $f(2,y) = 2y^2 - 4y + 1 = 2(y-1)^2 - 1$, $0 \le y \le 3$, which has a maximum value at $y = 3$ where $f(2,3) = 7$ and a minimum value at $y = 1$ where $f(2,1) = -1$. Along L_3: $y = 3$, so $f(x,3) = x^2 - 2x + 7 = (x-1)^2 + 6$, $0 \le x \le 2$, which has a maximum value both at $x = 0$ and $x = 2$ where $f(0,3) = f(2,3) = 7$ and a minimum value at $x = 1$, where $f(1,3) = 6$. Along L_4: $x = 0$, so $f(0,y) = 2y^2 - 4y + 1 = 2(y-1)^2 - 1$, $0 \le y \le 3$, which has a maximum value at $y = 3$ where $f(0,3) = 7$ and a minimum value at $y = 1$ where $f(0,1) = -1$. Thus the absolute maximum is attained at both $(0,3)$ and $(2,3)$, where $f(0,3) = f(2,3) = 7$, and the absolute minimum is $f(1,1) = -2$.



36. $f_x = y^2$ and $f_y = 2xy$, and since $f_x = 0 \quad \Leftrightarrow \quad y = 0$, there are no critical points in the interior of D. Along L_1: $y = 0$ and $f(x,0) = 0$. Along L_2: $x = 0$ and $f(0,y) = 0$. Along L_3: $y = \sqrt{3 - x^2}$, so let $g(x) = f\left(x, \sqrt{3 - x^2}\right) = 3x - x^3$ for $0 \le x \le \sqrt{3}$. Then $g'(x) = 3 - 3x^2 = 0 \quad \Leftrightarrow \quad x = 1$. The maximum value is $f\left(1, \sqrt{2}\right) = 2$ and the minimum occurs both at $x = 0$ and $x = \sqrt{3}$ where $f\left(0, \sqrt{3}\right) = f\left(\sqrt{3}, 0\right) = 0$. Thus the absolute maximum of f on D is $f\left(1, \sqrt{2}\right) = 2$, and the absolute minimum is 0 which occurs at all points along L_1 and L_2.

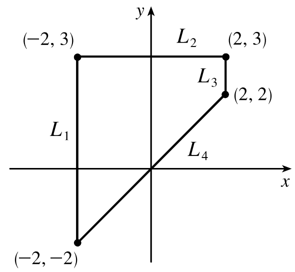


37. $f_x(x,y) = 6x^2$ and $f_y(x,y) = 4y^3$. And so $f_x = 0$ and $f_y = 0$ only occur when $x = y = 0$. Hence, the only critical point inside the disk is at $x = y = 0$ where $f(0,0) = 0$. Now on the circle $x^2 + y^2 = 1$, $y^2 = 1 - x^2$ so let $g(x) = f(x,y) = 2x^3 + (1 - x^2)^2 = x^4 + 2x^3 - 2x^2 + 1,\ -1 \le x \le 1$. Then $g'(x) = 4x^3 + 6x^2 - 4x = 0 \quad \Rightarrow \quad x = 0$, -2, or $\frac{1}{2}$. $f(0, \pm 1) = g(0) = 1$, $f\left(\frac{1}{2}, \pm\frac{\sqrt{3}}{2}\right) = g\left(\frac{1}{2}\right) = \frac{13}{16}$, and $(-2,-3)$ is not in D. Checking the endpoints, we get $f(-1,0) = g(-1) = -2$ and $f(1,0) = g(1) = 2$. Thus the absolute maximum and minimum of f on D are $f(1,0) = 2$ and $f(-1,0) = -2$.

Another method: On the boundary $x^2 + y^2 = 1$ we can write $x = \cos\theta$, $y = \sin\theta$, so $f(\cos\theta, \sin\theta) = 2\cos^3\theta + \sin^4\theta$, $0 \le \theta \le 2\pi$.

38. $f_x(x,y) = 3x^2 - 3$ and $f_y(x,y) = -3y^2 + 12$ and the critical points are $(1,2)$, $(1,-2)$, $(-1,2)$, and $(-1,-2)$. But only $(1,2)$ and $(-1,2)$ are in D and $f(1,2) = 14$, $f(-1,2) = 18$. Along L_1: $x = -2$ and $f(-2,y) = -2 - y^3 + 12y$,

$-2 \leq y \leq 3$, which has a maximum at $y = 2$ where $f(-2, 2) = 14$ and a minimum at $y = -2$ where $f(-2, -2) = -18$. Along L_2: $x = 2$ and $f(2, y) = 2 - y^3 + 12y$, $2 \leq y \leq 3$, which has a maximum at $y = 2$ where $f(2, 2) = 18$ and a minimum at $y = 3$ where $f(2, 3) = 11$. Along L_3: $y = 3$ and $f(x, 3) = x^3 - 3x + 9$, $-2 \leq x \leq 2$, which has a maximum at $x = -1$ and $x = 2$ where $f(-1, 3) = f(2, 3) = 11$ and a minimum at $x = 1$ and $x = -2$ where $f(1, 3) = f(-2, 3) = 7$. Along L_4: $y = x$ and $f(x, x) = 9x$, $-2 \leq x \leq 2$, which has a maximum at $x = 2$ where $f(2, 2) = 18$ and a minimum at $x = -2$ where $f(-2, -2) = -18$. So the absolute maximum value of f on D is $f(2, 2) = 18$ and the minimum is $f(-2, -2) = -18$.



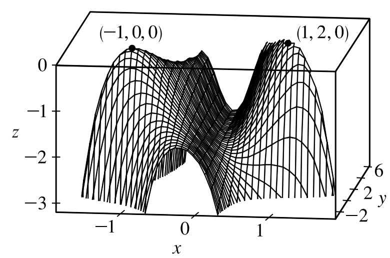
39. $f(x, y) = -(x^2 - 1)^2 - (x^2y - x - 1)^2 \quad \Rightarrow \quad f_x(x, y) = -2(x^2 - 1)(2x) - 2(x^2y - x - 1)(2xy - 1)$ and $f_y(x, y) = -2(x^2y - x - 1)x^2$. Setting $f_y(x, y) = 0$ gives either $x = 0$ or $x^2y - x - 1 = 0$.

There are no critical points for $x = 0$, since $f_x(0, y) = -2$, so we set $x^2y - x - 1 = 0 \quad \Leftrightarrow \quad y = \dfrac{x + 1}{x^2} \quad [x \neq 0]$,

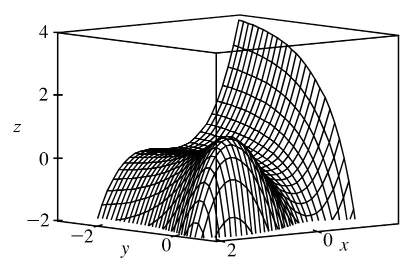
so $f_x\left(x, \dfrac{x+1}{x^2}\right) = -2(x^2 - 1)(2x) - 2\left(x^2 \dfrac{x+1}{x^2} - x - 1\right)\left(2x \dfrac{x+1}{x^2} - 1\right) = -4x(x^2 - 1)$. Therefore $f_x(x, y) = f_y(x, y) = 0$ at the points $(1, 2)$ and $(-1, 0)$. To classify these critical points, we calculate

$f_{xx}(x, y) = -12x^2 - 12x^2y^2 + 12xy + 4y + 2$, $f_{yy}(x, y) = -2x^4$, and $f_{xy}(x, y) = -8x^3y + 6x^2 + 4x$. In order to use the Second Derivatives Test we calculate

$D(-1, 0) = f_{xx}(-1, 0)\, f_{yy}(-1, 0) - [f_{xy}(-1, 0)]^2 = 16 > 0$, $f_{xx}(-1, 0) = -10 < 0$, $D(1, 2) = 16 > 0$, and $f_{xx}(1, 2) = -26 < 0$, so both $(-1, 0)$ and $(1, 2)$ give local maxima.



40. $f(x, y) = 3xe^y - x^3 - e^{3y}$ is differentiable everywhere, so the requirement for critical points is that $f_x = 3e^y - 3x^2 = 0$ **(1)** and $f_y = 3xe^y - 3e^{3y} = 0$ **(2)**. From **(1)** we obtain $e^y = x^2$, and then **(2)** gives $3x^3 - 3x^6 = 0 \quad \Rightarrow \quad x = 1$ or 0, but only $x = 1$ is valid, since $x = 0$ makes **(1)** impossible. So substituting $x = 1$ into **(1)** gives $y = 0$, and the only critical point is $(1, 0)$.



The Second Derivatives Test shows that this gives a local maximum, since $D(1, 0) = \left[-6x(3xe^y - 9e^{3y}) - (3e^y)^2\right]_{(1,0)} = 27 > 0$ and $f_{xx}(1, 0) = [-6x]_{(1,0)} = -6 < 0$. But $f(1, 0) = 1$ is not an absolute maximum because, for instance, $f(-3, 0) = 17$. This can also be seen from the graph.

41. Let d be the distance from $(2, 0, -3)$ to any point (x, y, z) on the plane $x + y + z = 1$, so $d = \sqrt{(x - 2)^2 + y^2 + (z + 3)^2}$ where $z = 1 - x - y$, and we minimize $d^2 = f(x, y) = (x - 2)^2 + y^2 + (4 - x - y)^2$. Then

$f_x(x,y) = 2(x-2) + 2(4-x-y)(-1) = 4x + 2y - 12$, $f_y(x,y) = 2y + 2(4-x-y)(-1) = 2x + 4y - 8$. Solving $4x + 2y - 12 = 0$ and $2x + 4y - 8 = 0$ simultaneously gives $x = \frac{8}{3}$, $y = \frac{2}{3}$, so the only critical point is $\left(\frac{8}{3}, \frac{2}{3}\right)$. An absolute minimum exists (since there is a minimum distance from the point to the plane) and it must occur at a critical point, so the shortest distance occurs for $x = \frac{8}{3}$, $y = \frac{2}{3}$ for which $d = \sqrt{\left(\frac{8}{3}-2\right)^2 + \left(\frac{2}{3}\right)^2 + \left(4 - \frac{8}{3} - \frac{2}{3}\right)^2} = \sqrt{\frac{4}{3}} = \frac{2}{\sqrt{3}}$.

42. Here the distance d from a point on the plane to the point $(0,1,1)$ is $d = \sqrt{x^2 + (y-1)^2 + (z-1)^2}$, where $z = 2 - \frac{1}{3}x + \frac{2}{3}y$. We can minimize $d^2 = f(x,y) = x^2 + (y-1)^2 + \left(1 - \frac{1}{3}x + \frac{2}{3}y\right)^2$, so

$f_x(x,y) = 2x + 2\left(1 - \frac{1}{3}x + \frac{2}{3}y\right)\left(-\frac{1}{3}\right) = \frac{20}{9}x - \frac{4}{9}y - \frac{2}{3}$ and

$f_y(x,y) = 2(y-1) + 2\left(1 - \frac{1}{3}x + \frac{2}{3}y\right)\left(\frac{2}{3}\right) = -\frac{4}{9}x + \frac{26}{9}y - \frac{2}{3}$. Solving $\frac{20}{9}x - \frac{4}{9}y - \frac{2}{3} = 0$ and $-\frac{4}{9}x + \frac{26}{9}y - \frac{2}{3} = 0$ simultaneously gives $x = \frac{5}{14}$ and $y = \frac{2}{7}$, so the only critical point is $\left(\frac{5}{14}, \frac{2}{7}\right)$.

This point must correspond to the minimum distance, so the point on the plane closest to $(0,1,1)$ is $\left(\frac{5}{14}, \frac{2}{7}, \frac{29}{14}\right)$.

43. Let d be the distance from the point $(4,2,0)$ to any point (x,y,z) on the cone, so $d = \sqrt{(x-4)^2 + (y-2)^2 + z^2}$ where $z^2 = x^2 + y^2$, and we minimize $d^2 = (x-4)^2 + (y-2)^2 + x^2 + y^2 = f(x,y)$. Then

$f_x(x,y) = 2(x-4) + 2x = 4x - 8$, $f_y(x,y) = 2(y-2) + 2y = 4y - 4$, and the critical points occur when $f_x = 0 \Rightarrow x = 2$, $f_y = 0 \Rightarrow y = 1$. Thus the only critical point is $(2,1)$. An absolute minimum exists (since there is a minimum distance from the cone to the point) which must occur at a critical point, so the points on the cone closest to $(4,2,0)$ are $\left(2, 1, \pm\sqrt{5}\right)$.

44. The distance from the origin to a point (x,y,z) on the surface is $d = \sqrt{x^2 + y^2 + z^2}$ where $y^2 = 9 + xz$, so we minimize $d^2 = x^2 + 9 + xz + z^2 = f(x,z)$. Then $f_x = 2x + z$, $f_z = x + 2z$, and $f_x = 0$, $f_z = 0 \Rightarrow x = 0, z = 0$, so the only critical point is $(0,0)$. $D(0,0) = (2)(2) - 1 = 3 > 0$ with $f_{xx}(0,0) = 2 > 0$, so this is a minimum. Thus $y^2 = 9 + 0 \Rightarrow y = \pm 3$ and the points on the surface closest to the origin are $(0, \pm 3, 0)$.

45. Let x, y, z be the positive numbers. Then $x + y + z = 100 \Rightarrow z = 100 - x - y$, and we want to maximize $xyz = xy(100 - x - y) = 100xy - x^2y - xy^2 = f(x,y)$ for $0 < x, y, z < 100$. $f_x = 100y - 2xy - y^2$, $f_y = 100x - x^2 - 2xy$, $f_{xx} = -2y$, $f_{yy} = -2x$, $f_{xy} = 100 - 2x - 2y$. Then $f_x = 0$ implies $y(100 - 2x - y) = 0 \Rightarrow y = 100 - 2x$ (since $y > 0$). Substituting into $f_y = 0$ gives $x[100 - x - 2(100 - 2x)] = 0 \Rightarrow 3x - 100 = 0$ (since $x > 0$) $\Rightarrow x = \frac{100}{3}$. Then $y = 100 - 2\left(\frac{100}{3}\right) = \frac{100}{3}$, and the only critical point is $\left(\frac{100}{3}, \frac{100}{3}\right)$. $D\left(\frac{100}{3}, \frac{100}{3}\right) = \left(-\frac{200}{3}\right)\left(-\frac{200}{3}\right) - \left(-\frac{100}{3}\right)^2 = \frac{10{,}000}{3} > 0$ and $f_{xx}\left(\frac{100}{3}, \frac{100}{3}\right) = -\frac{200}{3} < 0$. Thus $f\left(\frac{100}{3}, \frac{100}{3}\right)$ is a local maximum. It is also the absolute maximum (compare to the values of f as x, y, or $z \to 0$ or 100), so the numbers are $x = y = z = \frac{100}{3}$.

46. Let x, y, z, be the positive numbers. Then $x + y + z = 12$ and we want to minimize $x^2 + y^2 + z^2 = x^2 + y^2 + (12 - x - y)^2 = f(x,y)$ for $0 < x, y < 12$. $f_x = 2x + 2(12 - x - y)(-1) = 4x + 2y - 24$,

$f_y = 2y + 2(12 - x - y)(-1) = 2x + 4y - 24$, $f_{xx} = 4$, $f_{xy} = 2$, $f_{yy} = 4$. Then $f_x = 0$ implies $4x + 2y = 24$ or $y = 12 - 2x$ and substituting into $f_y = 0$ gives $2x + 4(12 - 2x) = 24 \quad \Rightarrow \quad 6x = 24 \quad \Rightarrow \quad x = 4$ and then $y = 4$, so the only critical point is $(4, 4)$. $D(4, 4) = 16 - 4 > 0$ and $f_{xx}(4, 4) = 4 > 0$, so $f(4, 4)$ is a local minimum. $f(4, 4)$ is also the absolute minimum [compare to the values of f as $x, y \to 0$ or 12] so the numbers are $x = y = z = 4$.

47. Center the sphere at the origin so that its equation is $x^2 + y^2 + z^2 = r^2$, and orient the inscribed rectangular box so that its edges are parallel to the coordinate axes. Any vertex of the box satisfies $x^2 + y^2 + z^2 = r^2$, so take (x, y, z) to be the vertex in the first octant. Then the box has length $2x$, width $2y$, and height $2z = 2\sqrt{r^2 - x^2 - y^2}$ with volume given by

$V(x, y) = (2x)(2y)\left(2\sqrt{r^2 - x^2 - y^2}\right) = 8xy\sqrt{r^2 - x^2 - y^2}$ for $0 < x < r$, $0 < y < r$. Then

$V_x = (8xy) \cdot \frac{1}{2}(r^2 - x^2 - y^2)^{-1/2}(-2x) + \sqrt{r^2 - x^2 - y^2} \cdot 8y = \dfrac{8y(r^2 - 2x^2 - y^2)}{\sqrt{r^2 - x^2 - y^2}}$ and $V_y = \dfrac{8x(r^2 - x^2 - 2y^2)}{\sqrt{r^2 - x^2 - y^2}}$.

Setting $V_x = 0$ gives $y = 0$ or $2x^2 + y^2 = r^2$, but $y > 0$ so only the latter solution applies. Similarly, $V_y = 0$ with $x > 0$ implies $x^2 + 2y^2 = r^2$. Substituting, we have $2x^2 + y^2 = x^2 + 2y^2 \quad \Rightarrow \quad x^2 = y^2 \quad \Rightarrow \quad y = x$. Then $x^2 + 2y^2 = r^2 \quad \Rightarrow$ $3x^2 = r^2 \quad \Rightarrow \quad x = \sqrt{r^2/3} = r/\sqrt{3} = y$. Thus the only critical point is $\left(r/\sqrt{3}, r/\sqrt{3}\right)$. There must be a maximum volume and here it must occur at a critical point, so the maximum volume occurs when $x = y = r/\sqrt{3}$ and the maximum volume is $V\left(\frac{r}{\sqrt{3}}, \frac{r}{\sqrt{3}}\right) = 8\left(\frac{r}{\sqrt{3}}\right)\left(\frac{r}{\sqrt{3}}\right)\sqrt{r^2 - \left(\frac{r}{\sqrt{3}}\right)^2 - \left(\frac{r}{\sqrt{3}}\right)^2} = \dfrac{8}{3\sqrt{3}}\, r^3$.

48. Let x, y, and z be the dimensions of the box. We wish to minimize surface area $= 2xy + 2xz + 2yz$, but we have volume $= xyz = 1000 \quad \Rightarrow \quad z = \dfrac{1000}{xy}$ so we minimize

$f(x, y) = 2xy + 2x\left(\dfrac{1000}{xy}\right) + 2y\left(\dfrac{1000}{xy}\right) = 2xy + \dfrac{2000}{y} + \dfrac{2000}{x}$. Then $f_x = 2y - \dfrac{2000}{x^2}$ and $f_y = 2x - \dfrac{2000}{y^2}$. Setting $f_x = 0$ implies $y = \dfrac{1000}{x^2}$ and substituting into $f_y = 0$ gives $x - \dfrac{x^4}{1000} = 0 \quad \Rightarrow \quad x^3 = 1000$ [since $x \neq 0$] $\Rightarrow \quad x = 10$. The surface area has a minimum but no maximum and it must occur at a critical point, so the minimal surface area occurs for a box with dimensions $x = 10$ cm, $y = 1000/10^2 = 10$ cm, $z = 1000/10^2 = 10$ cm.

49. Maximize $f(x, y) = \dfrac{xy}{3}(6 - x - 2y)$, then the maximum volume is $V = xyz$.

$f_x = \frac{1}{3}(6y - 2xy - y^2) = \frac{1}{3}y(6 - 2x - 2y)$ and $f_y = \frac{1}{3}x\,(6 - x - 4y)$. Setting $f_x = 0$ and $f_y = 0$ gives the critical point $(2, 1)$ which geometrically must give a maximum. Thus the volume of the largest such box is $V = (2)(1)\left(\frac{2}{3}\right) = \frac{4}{3}$.

50. Surface area $= 2(xy + xz + yz) = 64$ cm^2, so $xy + xz + yz = 32$ or $z = \dfrac{32 - xy}{x + y}$. Maximize the volume

$f(x, y) = xy\,\dfrac{32 - xy}{x + y}$. Then $f_x = \dfrac{32y^2 - 2xy^3 - x^2y^2}{(x + y)^2} = y^2\,\dfrac{32 - 2xy - x^2}{(x + y)^2}$ and $f_y = x^2\,\dfrac{32 - 2xy - y^2}{(x + y)^2}$. Setting

$f_x = 0$ implies $y = \dfrac{32 - x^2}{2x}$ and substituting into $f_y = 0$ gives $32(4x^2) - (32 - x^2)(4x^2) - (32 - x^2)^2 = 0$ or $3x^4 + 64x^2 - (32)^2 = 0$. Thus $x^2 = \frac{64}{6}$ or $x = \frac{8}{\sqrt{6}}$, $y = \frac{64/3}{16/\sqrt{6}} = \frac{8}{\sqrt{6}}$ and $z = \frac{8}{\sqrt{6}}$. Thus the box is a cube with edge length $\frac{8}{\sqrt{6}}$ cm.

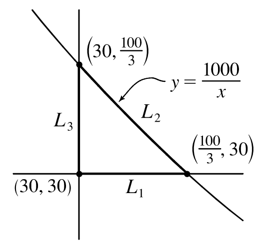
51. Let the dimensions be x, y, and z; then $4x + 4y + 4z = c$ and the volume is $V = xyz = xy\left(\frac{1}{4}c - x - y\right) = \frac{1}{4}cxy - x^2y - xy^2$, $x > 0$, $y > 0$. Then $V_x = \frac{1}{4}cy - 2xy - y^2$ and $V_y = \frac{1}{4}cx - x^2 - 2xy$, so $V_x = 0 = V_y$ when $2x + y = \frac{1}{4}c$ and $x + 2y = \frac{1}{4}c$. Solving, we get $x = \frac{1}{12}c$, $y = \frac{1}{12}c$ and $z = \frac{1}{4}c - x - y = \frac{1}{12}c$. From the geometrical nature of the problem, this critical point must give an absolute maximum. Thus the box is a cube with edge length $\frac{1}{12}c$.

52. The cost equals $5xy + 2(xz + yz)$ and $xyz = V$, so $C(x, y) = 5xy + 2V(x + y)/(xy) = 5xy + 2V(x^{-1} + y^{-1})$. Then $C_x = 5y - 2Vx^{-2}$, $C_y = 5x - 2\,Vy^{-2}$, $C_x = 0$ implies $y = 2\,V/(5x^2)$, $C_y = 0$ implies $x = \sqrt[3]{\frac{2}{5}V} = y$. Thus the dimensions of the aquarium which minimize the cost are $x = y = \sqrt[3]{\frac{2}{5}V}$ units, $z = V^{1/3}\left(\frac{5}{2}\right)^{2/3}$.

53. Let the dimensions be x, y and z, then minimize $xy + 2(xz + yz)$ if $xyz = 32{,}000\text{ cm}^3$. Then $f(x, y) = xy + [64{,}000(x + y)/xy] = xy + 64{,}000(x^{-1} + y^{-1})$, $f_x = y - 64{,}000x^{-2}$, $f_y = x - 64{,}000y^{-2}$. And $f_x = 0$ implies $y = 64{,}000/x^2$; substituting into $f_y = 0$ implies $x^3 = 64{,}000$ or $x = 40$ and then $y = 40$. Now $D(x, y) = [(2)(64{,}000)]^2x^{-3}y^{-3} - 1 > 0$ for $(40, 40)$ and $f_{xx}(40, 40) > 0$ so this is indeed a minimum. Thus the dimensions of the box are $x = y = 40$ cm, $z = 20$ cm.

54. Let x be the length of the north and south walls, y the length of the east and west walls, and z the height of the building. The heat loss is given by $h = 10(2yz) + 8(2xz) + 1(xy) + 5(xy) = 6xy + 16xz + 20yz$. The volume is 4000 m^3, so $xyz = 4000$, and we substitute $z = \frac{4000}{xy}$ to obtain the heat loss function $h(x, y) = 6xy + 80{,}000/x + 64{,}000/y$.

(a) Since $z = \frac{4000}{xy} \geq 4$, $xy \leq 1000 \quad \Rightarrow \quad y \leq 1000/x$. Also $x \geq 30$ and $y \geq 30$, so the domain of h is $D = \{(x, y) \mid x \geq 30, 30 \leq y \leq 1000/x\}$.



(b) $h(x, y) = 6xy + 80{,}000x^{-1} + 64{,}000y^{-1} \quad \Rightarrow$
$h_x = 6y - 80{,}000x^{-2}$, $h_y = 6x - 64{,}000y^{-2}$.
$h_x = 0$ implies $6x^2y = 80{,}000 \quad \Rightarrow \quad y = \dfrac{80{,}000}{6x^2}$ and substituting into

$h_y = 0$ gives $6x = 64{,}000\left(\dfrac{6x^2}{80{,}000}\right)^2 \quad \Rightarrow \quad x^3 = \dfrac{80{,}000^2}{6 \cdot 64{,}000} = \dfrac{50{,}000}{3}$, so

$x = \sqrt[3]{\dfrac{50{,}000}{3}} = 10\sqrt[3]{\dfrac{50}{3}} \quad \Rightarrow \quad y = \dfrac{80}{\sqrt[3]{60}}$, and the only critical point of h is $\left(10\sqrt[3]{\dfrac{50}{3}}, \dfrac{80}{\sqrt[3]{60}}\right) \approx (25.54, 20.43)$

which is not in D. Next we check the boundary of D.

On L_1: $y = 30$, $h(x, 30) = 180x + 80{,}000/x + 6400/3$, $30 \le x \le \frac{100}{3}$. Since $h'(x, 30) = 180 - 80{,}000/x^2 > 0$ for $30 \le x \le \frac{100}{3}$, $h(x, 30)$ is an increasing function with minimum $h(30, 30) = 10{,}200$ and maximum $h\left(\frac{100}{3}, 30\right) \approx 10{,}533$.

On L_2: $y = 1000/x$, $h(x, 1000/x) = 6000 + 64x + 80{,}000/x$, $30 \le x \le \frac{100}{3}$.

Since $h'(x, 1000/x) = 64 - 80{,}000/x^2 < 0$ for $30 \le x \le \frac{100}{3}$, $h(x, 1000/x)$ is a decreasing function with minimum $h\left(\frac{100}{3}, 30\right) \approx 10{,}533$ and maximum $h\left(30, \frac{100}{3}\right) \approx 10{,}587$.

On L_3: $x = 30$, $h(30, y) = 180y + 64{,}000/y + 8000/3$, $30 \le y \le \frac{100}{3}$. $h'(30, y) = 180 - 64{,}000/y^2 > 0$ for $30 \le y \le \frac{100}{3}$, so $h(30, y)$ is an increasing function of y with minimum $h(30, 30) = 10{,}200$ and maximum $h\left(30, \frac{100}{3}\right) \approx 10{,}587$.

Thus the absolute minimum of h is $h(30, 30) = 10{,}200$, and the dimensions of the building that minimize heat loss are walls 30 m in length and height $\frac{4000}{30^2} = \frac{40}{9} \approx 4.44$ m.

(c) From part (b), the only critical point of h, which gives a local (and absolute) minimum, is approximately $h(25.54, 20.43) \approx 9396$. So a building of volume 4000 m^2 with dimensions $x \approx 25.54$ m, $y \approx 20.43$ m, $z \approx \frac{4000}{(25.54)(20.43)} \approx 7.67$ m has the least amount of heat loss.

55. Let x, y, z be the dimensions of the rectangular box. Then the volume of the box is xyz and

$L = \sqrt{x^2 + y^2 + z^2} \quad \Rightarrow \quad L^2 = x^2 + y^2 + z^2 \quad \Rightarrow \quad z = \sqrt{L^2 - x^2 - y^2}$.

Substituting, we have volume $V(x, y) = xy\sqrt{L^2 - x^2 - y^2}$ $(x, y > 0)$.

$$V_x = xy \cdot \tfrac{1}{2}(L^2 - x^2 - y^2)^{-1/2}(-2x) + y\sqrt{L^2 - x^2 - y^2} = y\sqrt{L^2 - x^2 - y^2} - \frac{x^2 y}{\sqrt{L^2 - x^2 - y^2}},$$

$V_y = x\sqrt{L^2 - x^2 - y^2} - \dfrac{xy^2}{\sqrt{L^2 - x^2 - y^2}}$. $V_x = 0$ implies $y(L^2 - x^2 - y^2) = x^2 y \quad \Rightarrow \quad y(L^2 - 2x^2 - y^2) = 0 \quad \Rightarrow$ $2x^2 + y^2 = L^2$ (since $y > 0$), and $V_y = 0$ implies $x(L^2 - x^2 - y^2) = xy^2 \quad \Rightarrow \quad x(L^2 - x^2 - 2y^2) = 0 \quad \Rightarrow$ $x^2 + 2y^2 = L^2$ (since $x > 0$). Substituting $y^2 = L^2 - 2x^2$ into $x^2 + 2y^2 = L^2$ gives $x^2 + 2L^2 - 4x^2 = L^2 \quad \Rightarrow$ $3x^2 = L^2 \quad \Rightarrow \quad x = L/\sqrt{3}$ (since $x > 0$) and then $y = \sqrt{L^2 - 2\left(L/\sqrt{3}\right)^2} = L/\sqrt{3}$.

So the only critical point is $\left(L/\sqrt{3}, L/\sqrt{3}\right)$ which, from the geometrical nature of the problem, must give an absolute maximum. Thus the maximum volume is $V\left(L/\sqrt{3}, L/\sqrt{3}\right) = \left(L/\sqrt{3}\right)^2 \sqrt{L^2 - \left(L/\sqrt{3}\right)^2 - \left(L/\sqrt{3}\right)^2} = L^3/\left(3\sqrt{3}\right)$ cubic units.

56. $Y(N, P) = kNPe^{-N-P} \quad \Rightarrow \quad Y_N = kP\left[N\left(-e^{-N-P}\right) + e^{-N-P}(1)\right] = kP(1 - N)e^{-N-P}$,

$Y_P = kN\left[P\left(-e^{-N-P}\right) + e^{-N-P}(1)\right] = kN(1 - P)e^{-N-P}$. Here $N \ge 0$ and $P \ge 0$, but if either $N = 0$ or $P = 0$ then the yield is zero. Assuming that $N > 0$ and $P > 0$, $Y_N = 0$ implies $N = 1$ and $Y_P = 0$ implies $P = 1$, so the only critical point in $\{(N, P) \mid N > 0, P > 0\}$ is $(1, 1)$ where $Y(1, 1) = ke^{-2}$.

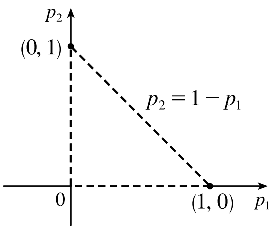
$D(N, P) = Y_{NN}Y_{PP} - (Y_{NP})^2 = \left[kP(N-2)e^{-N-P}\right]\left[kN(P-2)e^{-N-P}\right] - \left[k(1-N)(1-P)e^{-N-P}\right]^2 \quad \Rightarrow$

$D(1, 1) = \left(-ke^{-2}\right)\left(-ke^{-2}\right) - (0)^2 = k^2e^{-4} > 0$ and $Y_{NN}(1, 1) = -ke^{-2} < 0$, so $Y(1, 1) = ke^{-2}$ is a local maximum. $Y(1, 1)$ is also the absolute maximum (we have only one critical point, and $Y \to 0$ as $N \to 0$ or $P \to 0$ and $Y \to 0$ as N or P grow large) so the best yield is achieved when both the nitrogen and phosphorus levels are 1 (measured in appropriate units).

57. (a) We are given that $p_1 + p_2 + p_3 = 1 \quad \Rightarrow \quad p_3 = 1 - p_1 - p_2$, so

$H = -p_1 \ln p_1 - p_2 \ln p_2 - p_3 \ln p_3 = -p_1 \ln p_1 - p_2 \ln p_2 - (1 - p_1 - p_2) \ln (1 - p_1 - p_2)$.

(b) Because p_i is a proportion we have $0 \leq p_i \leq 1$, but H is undefined unless $p_1 > 0$, $p_2 > 0$, and $1 - p_1 - p_2 > 0 \quad \Leftrightarrow \quad p_1 + p_2 < 1$. This last restriction forces $p_1 < 1$ and $p_2 < 1$, so the domain of H is $\{(p_1, p_2) \mid 0 < p_1 < 1,\ p_2 < 1 - p_1\}$. It is the interior of the triangle drawn in the figure.



(c)
$$\begin{aligned} H_{p_1} &= -\left[p_1 \cdot (1/p_1) + (\ln p_1) \cdot 1\right] - \left[(1 - p_1 - p_2) \cdot (-1)/\left(1 - p_1 - p_2\right) + \ln (1 - p_1 - p_2) \cdot (-1)\right] \\ &= -1 - \ln p_1 + 1 + \ln (1 - p_1 - p_2) = \ln (1 - p_1 - p_2) - \ln p_1 \end{aligned}$$

Similarly $H_{p_2} = \ln (1 - p_1 - p_2) - \ln p_2$. Then $H_{p_1} = 0$ implies $\ln (1 - p_1 - p_2) = \ln p_1 \quad \Rightarrow \quad 1 - p_1 - p_2 = p_1 \quad \Rightarrow \quad p_2 = 1 - 2p_1$, and $H_{p_2} = 0$ implies $\ln (1 - p_1 - p_2) = \ln p_2 \quad \Rightarrow \quad p_1 = 1 - 2p_2$. Substituting, we have $p_1 = 1 - 2\,(1 - 2p_1) \quad \Rightarrow$ $3p_1 = 1 \quad \Rightarrow \quad p_1 = \frac{1}{3}$, and then $p_2 = 1 - 2\left(\frac{1}{3}\right) = \frac{1}{3}$. Thus the only critical point is $\left(\frac{1}{3}, \frac{1}{3}\right)$.

$D(p_1, p_2) = H_{p_1p_1}H_{p_2p_2} - (H_{p_1p_2})^2 = \left(\dfrac{-1}{1 - p_1 - p_2} - \dfrac{1}{p_1}\right)\left(\dfrac{-1}{1 - p_1 - p_2} - \dfrac{1}{p_2}\right) - \left(\dfrac{-1}{1 - p_1 - p_2}\right)^2$, so

$D\left(\frac{1}{3}, \frac{1}{3}\right) = (-6)\,(-6) - (-3)^2 = 27 > 0$ and $H_{p_1p_1}\left(\frac{1}{3}, \frac{1}{3}\right) = -6 < 0$. Thus $H\left(\frac{1}{3}, \frac{1}{3}\right) = -\frac{1}{3} \ln \frac{1}{3} - \frac{1}{3} \ln \frac{1}{3} - \frac{1}{3} \ln \frac{1}{3} = -\ln \frac{1}{3} = \ln 3$ is a local maximum. Here it is also the absolute maximum, so the maximum value of H is $\ln 3$, which occurs for $p_1 = p_2 = p_3 = \frac{1}{3}$ (all three species have equal proportion in the ecosystem).

58. Since $p + q + r = 1$ we can substitute $p = 1 - r - q$ into P giving

$P = P(q, r) = 2(1 - r - q)q + 2(1 - r - q)r + 2rq = 2q - 2q^2 + 2r - 2r^2 - 2rq$. Since p, q and r represent proportions and $p + q + r = 1$, we know $q \geq 0$, $r \geq 0$, and $q + r \leq 1$. Thus, we want to find the absolute maximum of the continuous function $P(q, r)$ on the closed set D enclosed by the lines $q = 0$, $r = 0$, and $q + r = 1$. To find any critical points, we set the partial derivatives equal to zero: $P_q(q,r) = 2 - 4q - 2r = 0$ and $P_r(q,r) = 2 - 4r - 2q = 0$. The first equation gives $r = 1 - 2q$, and substituting into the second equation we have $2 - 4(1-2q) - 2q = 0 \Rightarrow q = \frac{1}{3}$. Then we have one critical point, $\left(\frac{1}{3}, \frac{1}{3}\right)$, where $P\left(\frac{1}{3}, \frac{1}{3}\right) = \frac{2}{3}$. Next we find the maximum values of P on the boundary of D which consists of three line segments. For the segment given by $r = 0$, $0 \le q \le 1$, $P(q,r) = P(q,0) = 2q - 2q^2$, $0 \le q \le 1$. This represents a parabola with maximum value $P\left(\frac{1}{2}, 0\right) = \frac{1}{2}$. On the segment $q = 0$, $0 \le r \le 1$ we have $P(0,r) = 2r - 2r^2$, $0 \le r \le 1$. This represents a parabola with maximum value $P\left(0, \frac{1}{2}\right) = \frac{1}{2}$. Finally, on the segment $q + r = 1$, $0 \le q \le 1$, $P(q,r) = P(q, 1-q) = 2q - 2q^2$, $0 \le q \le 1$ which has a maximum value of $P\left(\frac{1}{2}, \frac{1}{2}\right) = \frac{1}{2}$. Comparing these values with the value of P at the critical point, we see that the absolute maximum value of $P(q,r)$ on D is $\frac{2}{3}$.

59. Note that here the variables are m and b, and $f(m,b) = \sum_{i=1}^{n} [y_i - (mx_i + b)]^2$. Then $f_m = \sum_{i=1}^{n} -2x_i[y_i - (mx_i + b)] = 0$ implies $\sum_{i=1}^{n} \left(x_i y_i - m x_i^2 - b x_i\right) = 0$ or $\sum_{i=1}^{n} x_i y_i = m \sum_{i=1}^{n} x_i^2 + b \sum_{i=1}^{n} x_i$ and $f_b = \sum_{i=1}^{n} -2[y_i - (mx_i + b)] = 0$ implies $\sum_{i=1}^{n} y_i = m \sum_{i=1}^{n} x_i + \sum_{i=1}^{n} b = m\left(\sum_{i=1}^{n} x_i\right) + nb$. Thus we have the two desired equations.

Now $f_{mm} = \sum_{i=1}^{n} 2x_i^2$, $f_{bb} = \sum_{i=1}^{n} 2 = 2n$ and $f_{mb} = \sum_{i=1}^{n} 2x_i$. And $f_{mm}(m,b) > 0$ always and $D(m,b) = 4n\left(\sum_{i=1}^{n} x_i^2\right) - 4\left(\sum_{i=1}^{n} x_i\right)^2 = 4\left[n\left(\sum_{i=1}^{n} x_i^2\right) - \left(\sum_{i=1}^{n} x_i\right)^2\right] > 0$ always so the solutions of these two equations do indeed minimize $\sum_{i=1}^{n} d_i^2$.

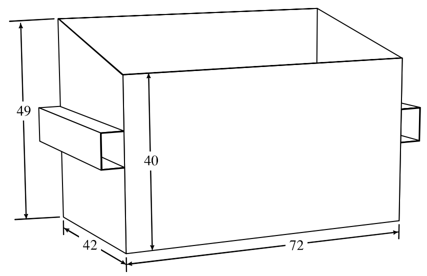
60. Any such plane must cut out a tetrahedron in the first octant. We need to minimize the volume of the tetrahedron that passes through the point $(1,2,3)$. Writing the equation of the plane as $\frac{x}{a} + \frac{y}{b} + \frac{z}{c} = 1$, the volume of the tetrahedron is given by $V = \frac{abc}{6}$. But $(1,2,3)$ must lie on the plane, so we need $\frac{1}{a} + \frac{2}{b} + \frac{3}{c} = 1$ $(\star)$ and thus can think of c as a function of a and b. Then $V_a = \frac{b}{6}\left(c + a\frac{\partial c}{\partial a}\right)$ and $V_b = \frac{a}{6}\left(c + b\frac{\partial c}{\partial b}\right)$. Differentiating $(\star)$ with respect to a we get $-a^{-2} - 3c^{-2}\frac{\partial c}{\partial a} = 0 \Rightarrow \frac{\partial c}{\partial a} = \frac{-c^2}{3a^2}$, and differentiating $(\star)$ with respect to b gives $-2b^{-2} - 3c^{-2}\frac{\partial c}{\partial b} = 0 \Rightarrow \frac{\partial c}{\partial b} = \frac{-2c^2}{3b^2}$. Then $V_a = \frac{b}{6}\left(c + a\frac{-c^2}{3a^2}\right) = 0 \Rightarrow c = 3a$, and $V_b = \frac{a}{6}\left(c + b\frac{-2c^2}{3b^2}\right) = 0 \Rightarrow c = \frac{3}{2}b$. Thus $3a = \frac{3}{2}b$ or $b = 2a$. Putting these into $(\star)$ gives $\frac{3}{a} = 1$ or $a = 3$ and then $b = 6$, $c = 9$. Thus the equation of the required plane is $\frac{x}{3} + \frac{y}{6} + \frac{z}{9} = 1$ or $6x + 3y + 2z = 18$.

APPLIED PROJECT Designing a Dumpster

Note: The difficulty and results of this project vary widely with the type of container studied. In addition to the variation of basic shapes of containers, dumpsters may include additional constructed parts such as supports, lift pockets, wheels, etc. Also, a CAS or graphing utility may be needed to solve the resulting equations.

Here we present a typical solution for one particular trash Dumpster.

1. The basic shape and dimensions (in inches) of an actual trash Dumpster are as shown in the figure.



The front and back, as well as both sides, have an extra one-inch-wide flap that is folded under and welded to the base. In addition, the side panels each fold over one inch onto the front and back pieces where they are welded. Each side has a rectangular lift pocket, with cross-section 5 by 8 inches, made of the same material. These are attached with an extra one-inch width of steel on both top and bottom where each pocket is welded to the side sheet. All four sides have a "lip" at the top; the front and back panels have an extra 5 inches of steel at the top which is folded outward in three creases to form a rectangular tube. The edge is then welded back to the main sheet. The two sides form a top lip with separate sheets of steel 5 inches wide, similarly bent into three sides and welded to the main sheets (requiring two welds each). These extend beyond the main side sheets by 1.5 inches at each end in order to join with the lips on the front and back panels. The container has a hinged lid, extra steel supports on the base at each corner, metal "fins" serving as extra support for the side lift pockets, and wheels underneath. The volume of the container is $V = \frac{1}{2}(40 + 49) \times 42 \times 72 = 134{,}568 \text{ in}^3$ or 77.875 ft^3.

2. First, we assume that some aspects of the construction do not change with different dimensions, so they may be considered fixed costs. This includes the lid (with hinges), wheels, and extra steel supports. Also, the upper "lip" we previously described extends beyond the side width to connect to the other pieces. We can safely assume that this extra portion, including any associated welds, costs the same regardless of the container's dimensions, so we will consider just the portion matching the measurement of the side panels in our calculations. We will further assume that the angle of the top of the container should be preserved. Then to compute the variable costs, let x be the width, y the length, and z the height of the front of the container. The back of the container is 9 inches, or $\frac{3}{4}$ ft, taller than the front, so using similar triangles we can say the back panel has height $z + \frac{3}{14}x$. Measuring in feet, we want the volume to remain constant, so $V = \frac{1}{2}\left(z + z + \frac{3}{14}x\right)(x)(y) = xyz + \frac{3}{28}x^2y = 77.875$. To determine a function for the variable cost, we first find the area of each sheet of metal needed. The base has area xy ft^2. The front panel has visible area yz plus $\frac{1}{12}y$ for the portion folded onto the base and $\frac{5}{12}y$ for the steel at the top used to form the lip, so $\left(yz + \frac{1}{2}y\right)$ ft^2 in total. Similarly, the back sheet has area $y\left(z + \frac{3}{14}x\right) + \frac{1}{12}y + \frac{5}{12}y = yz + \frac{3}{14}xy + \frac{1}{2}y$. Each side has visible area $\frac{1}{2}\left[z + \left(z + \frac{3}{14}x\right)\right](x)$, and the sheet includes one-inch flaps folding onto the front and back panels, so with area $\frac{1}{12}z$ and $\frac{1}{12}\left(z+\frac{3}{14}x\right)$, and a one-inch flap to fold onto the base with area $\frac{1}{12}x$. The lift pocket is constructed of a piece of steel 20 inches by x ft (including the 2 extra inches used by the welds). The additional metal used to make the lip at the top of the panel has width 5 inches and length that we can determine using the Pythagorean Theorem: $x^2+\left(\frac{3}{14}x\right)^2=\text{length}^2$, so length $=\frac{\sqrt{205}}{14}x\approx 1.0227x$. Thus the area of steel needed for each side panel is approximately

$$\tfrac{1}{2}\left[z+\left(z+\tfrac{3}{14}x\right)\right](x)+\tfrac{1}{12}z+\tfrac{1}{12}\left(z+\tfrac{3}{14}x\right)+\tfrac{1}{12}x+\tfrac{5}{3}x+\tfrac{5}{12}(1.0227x)\approx xz+\tfrac{3}{28}x^2+\tfrac{1}{6}z+2.194x$$

We also have the following welds:

Weld	Length
Front, back welded to base	$2y$
Sides welded to base	$2x$
Sides welded to front	$2z$
Sides welded to back	$2\left(z+\frac{3}{14}x\right)$
Weld on front and back lip	$2y$
Two welds on each side lip	$4(1.0227x)$
Two welds for each lift pocket	$4x$

Thus the total length of welds needed is

$$2y+2x+2z+2\left(z+\tfrac{3}{14}x\right)+2y+4(1.0227x)+4x\approx 10.519x+4y+4z$$

Finally, the total variable cost is approximately

$$\begin{aligned}0.90(xy)+0.70\left[\left(yz+\tfrac{1}{2}y\right)+\left(yz+\tfrac{3}{14}xy+\tfrac{1}{2}y\right)+2\left(xz+\tfrac{3}{28}x^2+\tfrac{1}{6}z+2.194x\right)\right]+\ 0.18(10.519x+4y+4z)\\ \approx 1.05xy+1.4yz+1.42y+1.4xz+0.15x^2+0.953z+4.965x\end{aligned}$$

We would like to minimize this function while keeping volume constant, so since $xyz+\frac{3}{28}x^2y=77.875$ we can substitute $z=\dfrac{77.875}{xy}-\dfrac{3}{28}x$ giving variable cost as a function of x and y:

$$C(x,y)\approx 0.9xy+\frac{109.0}{x}+1.42y+\frac{109.0}{y}+\frac{74.2}{xy}+4.86x$$

Using a CAS, we solve the system of equations $C_x(x,y)=0$ and $C_y(x,y)=0$; the only critical point within an appropriate domain is approximately $(3.58, 5.29)$. From the nature of the function C (or from a graph) we can determine that C has an absolute minimum at $(3.58, 5.29)$, and so the minimum cost is attained for $x\approx 3.58$ ft (or 43.0 in), $y\approx 5.29$ ft (or 63.5 in), and $z\approx\frac{77.875}{3.58(5.29)}-\frac{3}{28}(3.58)\approx 3.73$ ft (or 44.8 in).

3. The fixed cost aspects of the container which we did not include in our calculations, such as the wheels and lid, don't affect the validity of our results. Some of our other assumptions, however, may influence the accuracy of our findings. We simplified the price of the steel sheets to include cuts and bends, and we simplified the price of welding to include the labor and materials. This may not be accurate for areas of the container, such as the lip and lift pockets, that require several cuts, bends, and welds in a relatively small surface area. Consequently, increasing some dimensions of the container may not increase the cost in the same manner as our computations predict. If we do not assume that the angle of the sloped top of the container must be preserved, it is likely that we could further improve our cost. Finally, our results show that the length of the container should be changed to minimize cost; this may not be possible if the two lift pockets must remain a fixed distance apart for handling by machinery.

4. The minimum variable cost using our values found in Problem 2 is $C(3.58, 5.29) \approx \$96.95$, while the current dimensions give an estimated variable cost of $C(3.5, 6.0) \approx \$97.30$. If we determine that our assumptions and simplifications are acceptable, our work shows that a slight savings can be gained by adjusting the dimensions of the container. However, the difference in cost is modest, and may not justify changes in the manufacturing process.

DISCOVERY PROJECT Quadratic Approximations and Critical Points

1. $$Q(x,y) = f(a,b) + f_x(a,b)(x-a) + f_y(a,b)(y-b) + \tfrac{1}{2}f_{xx}(a,b)(x-a)^2 \\ + f_{xy}(a,b)(x-a)(y-b) + \tfrac{1}{2}f_{yy}(a,b)(y-b)^2,$$

so

$$Q_x(x,y) = f_x(a,b) + \tfrac{1}{2}f_{xx}(a,b)(2)(x-a) + f_{xy}(a,b)(y-b) = f_x(a,b) + f_{xx}(a,b)(x-a) + f_{xy}(a,b)(y-b)$$

At (a,b) we have $Q_x(a,b) = f_x(a,b) + f_{xx}(a,b)\,(a-a) + f_{xy}(a,b)(b-b) = f_x(a,b)$.

Similarly, $Q_y(x,y) = f_y(a,b) + f_{xy}(a,b)(x-a) + f_{yy}(a,b)(y-b) \quad \Rightarrow$

$Q_y(a,b) = f_y(a,b) + f_{xy}(a,b)(a-a) + f_{yy}(a,b)(b-b) = f_y(a,b)$.

For the second-order partial derivatives we have

$$Q_{xx}(x,y) = \frac{\partial}{\partial x}\left[f_x(a,b) + f_{xx}(a,b)(x-a) + f_{xy}(a,b)(y-b)\right] = f_{xx}(a,b) \quad \Rightarrow \quad Q_{xx}(a,b) = f_{xx}(a,b)$$

$$Q_{xy}(x,y) = \frac{\partial}{\partial y}\left[f_x(a,b) + f_{xx}(a,b)(x-a) + f_{xy}(a,b)(y-b)\right] = f_{xy}(a,b) \quad \Rightarrow \quad Q_{xy}(a,b) = f_{xy}(a,b)$$

$$Q_{yy}(x,y) = \frac{\partial}{\partial y}\left[f_y(a,b) + f_{xy}(a,b)(x-a) + f_{yy}(a,b)(y-b)\right] = f_{yy}(a,b) \quad \Rightarrow \quad Q_{yy}(a,b) = f_{yy}(a,b)$$

2. (a) First we find the partial derivatives and values that will be needed:

$$\begin{aligned} f(x,y) &= e^{-x^2-y^2} & f(0,0) &= 1 \\ f_x(x,y) &= -2xe^{-x^2-y^2} & f_x(0,0) &= 0 \\ f_y(x,y) &= -2ye^{-x^2-y^2} & f_y(0,0) &= 0 \\ f_{xx}(x,y) &= (4x^2-2)e^{-x^2-y^2} & f_{xx}(0,0) &= -2 \\ f_{xy}(x,y) &= 4xye^{-x^2-y^2} & f_{xy}(0,0) &= 0 \\ f_{yy}(x,y) &= (4y^2-2)e^{-x^2-y^2} & f_{yy}(0,0) &= -2 \end{aligned}$$

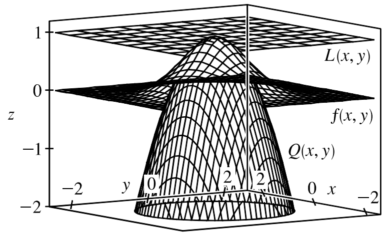
Then the first-degree Taylor polynomial of f at $(0,0)$ is

$$L(x,y) = f(0,0) + f_x(0,0)(x-0) + f_y(0,0)(y-0) = 1 + (0)(x-0) + (0)(y-0) = 1$$

The second-degree Taylor polynomial is given by

$$\begin{aligned} Q(x,y) &= f(0,0) + f_x(0,0)(x-0) + f_y(0,0)(y-0) + \tfrac{1}{2}f_{xx}(0,0)(x-0)^2 \\ &\qquad + f_{xy}(0,0)(x-0)(y-0) + \tfrac{1}{2}f_{yy}(0,0)(y-0)^2 \\ &= 1 - x^2 - y^2 \end{aligned}$$

(b)



As we see from the graph, L approximates f well only for points (x,y) extremely close to the origin. Q is a much better approximation; the shape of its graph looks similar to that of the graph of f near the origin, and the values of Q appear to be good estimates for the values of f within a significant radius of the origin.

3. (a) First we find the partial derivatives and values that will be needed:

$$\begin{array}{llll} f(x,y) = xe^y & f(1,0) = 1 & f_{xx}(x,y) = 0 & f_{xx}(1,0) = 0 \\ f_x(x,y) = e^y & f_x(1,0) = 1 & f_{xy}(x,y) = e^y & f_{xy}(1,0) = 1 \\ f_y(x,y) = xe^y & f_y(1,0) = 1 & f_{yy}(x,y) = xe^y & f_{yy}(1,0) = 1 \end{array}$$

Then the first-degree Taylor polynomial of f at $(1,0)$ is

$$L(x,y) = f(1,0) + f_x(1,0)(x-1) + f_y(1,0)(y-0) = 1 + (1)(x-1) + (1)(y-0) = x + y$$

The second-degree Taylor polynomial is given by

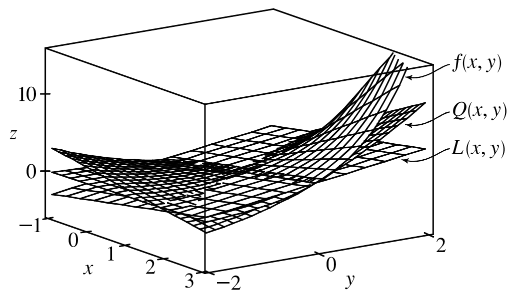
$$\begin{aligned} Q(x,y) &= f(1,0) + f_x(1,0)(x-1) + f_y(1,0)(y-0) + \tfrac{1}{2}f_{xx}(1,0)(x-1)^2 \\ &\qquad + f_{xy}(1,0)(x-1)(y-0) + \tfrac{1}{2}f_{yy}(1,0)(y-0)^2 \\ &= \tfrac{1}{2}y^2 + x + xy \end{aligned}$$

(b) $L(0.9, 0.1) = 0.9 + 0.1 = 1.0$

$Q(0.9, 0.1) = \frac{1}{2}(0.1)^2 + 0.9 + (0.9)(0.1) = 0.995$

$f(0.9, 0.1) = 0.9e^{0.1} \approx 0.9947$

(c)



As we see from the graph, L and Q both approximate f reasonably well near the point $(1,0)$. As we venture farther from the point, the graph of Q follows the shape of the graph of f more closely than L.

4. (a) $f(x,y) = ax^2 + bxy + cy^2 = a\left[x^2 + \frac{b}{a}\,xy + \frac{c}{a}\,y^2\right] = a\left[x^2 + \frac{b}{a}\,xy + \left(\frac{b}{2a}\,y\right)^2 - \left(\frac{b}{2a}\,y\right)^2 + \frac{c}{a}\,y^2\right]$

$$= a\left[\left(x + \frac{b}{2a}\,y\right)^2 - \frac{b^2}{4a^2}\,y^2 + \frac{c}{a}\,y^2\right] = a\left[\left(x + \frac{b}{2a}\,y\right)^2 + \left(\frac{4ac - b^2}{4a^2}\right)y^2\right]$$

(b) For $D = 4ac - b^2$, from part (a) we have $f(x,y) = a\left[\left(x + \frac{b}{2a}\,y\right)^2 + \left(\frac{D}{4a^2}\right)y^2\right]$. If $D > 0$,

$\left(\frac{D}{4a^2}\right)y^2 \geq 0$ and $\left(x + \frac{b}{2a}\,y\right)^2 \geq 0$, so $\left[\left(x + \frac{b}{2a}\,y\right)^2 + \left(\frac{D}{4a^2}\right)y^2\right] \geq 0$. Here $a > 0$, thus

$f(x,y) = a\left[\left(x + \frac{b}{2a}\,y\right)^2 + \left(\frac{D}{4a^2}\right)y^2\right] \geq 0$. We know $f(0,0) = 0$, so $f(0,0) \leq f(x,y)$ for all (x,y), and by definition f has a local minimum at $(0,0)$.

(c) As in part (b), $\left[\left(x + \frac{b}{2a}\,y\right)^2 + \left(\frac{D}{4a^2}\right)y^2\right] \geq 0$, and since $a < 0$ we have

$f(x,y) = a\left[\left(x + \frac{b}{2a}\,y\right)^2 + \left(\frac{D}{4a^2}\right)y^2\right] \leq 0$. Since $f(0,0) = 0$, we must have $f(0,0) \geq f(x,y)$ for all (x,y), so by definition f has a local maximum at $(0,0)$.

(d) $f(x,y) = ax^2 + bxy + cy^2$, so $f_x(x,y) = 2ax + by \;\Rightarrow\; f_x(0,0) = 0$ and $f_y(x,y) = bx + 2cy \;\Rightarrow\; f_y(0,0) = 0$. Since $f(0,0) = 0$ and f and its partial derivatives are continuous, we know from Equation 14.4.2 that the tangent plane to the graph of f at $(0,0)$ is the plane $z = 0$. Then f has a saddle point at $(0,0)$ if the graph of f crosses the tangent plane at $(0,0)$, or equivalently, if some paths to the origin have positive function values while other paths have negative function values. Suppose we approach the origin along the x-axis; then we have $y = 0 \;\Rightarrow\; f(x,0) = ax^2$ which has the same sign as a. We must now find at least one path to the origin where $f(x,y)$ gives values with sign opposite that of a. Since $f(x,y) = a\left[\left(x + \frac{b}{2a}\,y\right)^2 + \left(\frac{D}{4a^2}\right)y^2\right]$, if we approach the origin along the line $x = -\frac{b}{2a}\,y$, we have

$f\left(-\frac{b}{2a}\,y, y\right) = a\left[\left(-\frac{b}{2a}\,y + \frac{b}{2a}\,y\right)^2 + \left(\frac{D}{4a^2}\right)y^2\right] = \frac{D}{4a}\,y^2$. Since $D < 0$, these values have signs opposite that of a. Thus, f has a saddle point at $(0,0)$.

5. (a) Since the partial derivatives of f exist at $(0,0)$ and $(0,0)$ is a critical point, we know $f_x(0,0) = 0$ and $f_y(0,0) = 0$. Then the second-degree Taylor polynomial of f at $(0,0)$ can be expressed as

$$\begin{aligned} Q(x,y) &= f(0,0) + f_x(0,0)(x-0) + f_y(0,0)(y-0) + \tfrac{1}{2}f_{xx}(0,0)(x-0)^2 \\ &\qquad + f_{xy}(0,0)(x-0)(y-0) + \tfrac{1}{2}f_{yy}(0,0)(y-0)^2 \\ &= \tfrac{1}{2}f_{xx}(0,0)x^2 + f_{xy}(0,0)xy + \tfrac{1}{2}f_{yy}(0,0)y^2 \end{aligned}$$

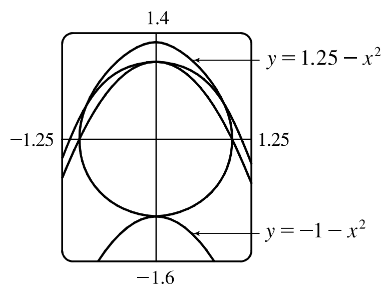
(b) $Q(x,y) = \frac{1}{2} f_{xx}(0,0)x^2 + f_{xy}(0,0)xy + \frac{1}{2} f_{yy}(0,0)y^2$ fits the form of the polynomial function in Problem 4 with $a = \frac{1}{2} f_{xx}(0,0)$, $b = f_{xy}(0,0)$, and $c = \frac{1}{2} f_{yy}(0,0)$. Then we know Q is a paraboloid, and that Q has a local maximum, local minimum, or saddle point at $(0,0)$. Here, $D = 4ac - b^2 = 4\left(\frac{1}{2}\right) f_{xx}(0,0) \left(\frac{1}{2}\right) f_{yy}(0,0) - [f_{xy}(0,0)]^2 = f_{xx}(0,0) f_{yy}(0,0) - [f_{xy}(0,0)]^2$, and if $D > 0$ with $a = \frac{1}{2} f_{xx}(0,0) > 0 \Rightarrow f_{xx}(0,0) > 0$, we know from Problem 4 that Q has a local minimum at $(0,0)$. Similarly, if $D > 0$ and $a < 0 \Rightarrow f_{xx}(0,0) < 0$, Q has a local maximum at $(0,0)$, and if $D < 0$, Q has a saddle point at $(0,0)$.

(c) Since $f(x,y) \approx Q(x,y)$ near $(0,0)$, part (b) suggests that for $D = f_{xx}(0,0) f_{yy}(0,0) - [f_{xy}(0,0)]^2$, if $D > 0$ and $f_{xx}(0,0) > 0$, f has a local minimum at $(0,0)$. If $D > 0$ and $f_{xx}(0,0) < 0$, f has a local maximum at $(0,0)$, and if $D < 0$, f has a saddle point at $(0,0)$. Together with the conditions given in part (a), this is precisely the Second Derivatives Test from Section 14.7.

14.8 Lagrange Multipliers

1. At the extreme values of f, the level curves of f just touch the curve $g(x,y) = 8$ with a common tangent line. (See Figure 1 and the accompanying discussion.) We can observe several such occurrences on the contour map, but the level curve $f(x,y) = c$ with the largest value of c which still intersects the curve $g(x,y) = 8$ is approximately $c = 59$, and the smallest value of c corresponding to a level curve which intersects $g(x,y) = 8$ appears to be $c = 30$. Thus we estimate the maximum value of f subject to the constraint $g(x,y) = 8$ to be about 59 and the minimum to be 30.

2. (a) The values $c = \pm 1$ and $c = 1.25$ seem to give curves which are tangent to the circle. These values represent possible extreme values of the function $x^2 + y$ subject to the constraint $x^2 + y^2 = 1$.



(b) $\nabla f = \langle 2x, 1 \rangle$, $\lambda \nabla g = \langle 2\lambda x, 2\lambda y \rangle$. So $2x = 2\lambda x \Rightarrow$ either $\lambda = 1$ or $x = 0$. If $\lambda = 1$, then $y = \frac{1}{2}$ and so $x = \pm\frac{\sqrt{3}}{2}$ (from the constraint). If $x = 0$, then $y = \pm 1$. Therefore f has possible extreme values at the points $(0, \pm 1)$ and $\left(\pm\frac{\sqrt{3}}{2}, \frac{1}{2}\right)$. We calculate $f\left(\pm\frac{\sqrt{3}}{2}, \frac{1}{2}\right) = \frac{5}{4}$ (the maximum value), $f(0,1) = 1$, and $f(0,-1) = -1$ (the minimum value). These are our answers from part (a).

3. We want to find the extreme values of $f(x,y) = x^2 - y^2$ subject to the constraint $g(x,y) = x^2 + y^2 = 1$. Then $\nabla f = \lambda \nabla g \Rightarrow \langle 2x, -2y \rangle = \lambda \langle 2x, 2y \rangle$, so we solve the equations $2x = 2\lambda x$, $-2y = 2\lambda y$, and $x^2 + y^2 = 1$. From the first equation we have $2x(\lambda - 1) = 0 \Rightarrow x = 0$ or $\lambda = 1$. If $x = 0$ then substitution into the constraint gives

$y^2 = 1 \Rightarrow y = \pm 1$. If $\lambda = 1$ then substitution into the second equation gives $-2y = 2y \Rightarrow y = 0$, and from the constraint we must have $x = \pm 1$. Thus the possible points for the extreme values of f are $(0, \pm 1)$ and $(\pm 1, 0)$. Evaluating f at these points, we see that the maximum value of f is $f(\pm 1, 0) = 1$ and the minimum is $f(0, \pm 1) = -1$.

4. $f(x, y) = 3x + y$, $g(x, y) = x^2 + y^2 = 10$, and $\nabla f = \lambda \nabla g \Rightarrow \langle 3, 1 \rangle = \langle 2\lambda x, 2\lambda y \rangle$, so $3 = 2\lambda x$, $1 = 2\lambda y$, and $x^2 + y^2 = 10$. From the first two equations we have $\dfrac{3}{2x} = \lambda = \dfrac{1}{2y} \Rightarrow x = 3y$ (note that the first two equations imply $x \neq 0$ and $y \neq 0$) and substitution into the third equation gives $9y^2 + y^2 = 10 \Rightarrow y^2 = 1 \Rightarrow y = \pm 1$. Then f has possible extreme values at the points $(3, 1)$ and $(-3, -1)$. We compute $f(3, 1) = 10$ and $f(-3, -1) = -10$, so the maximum value of f on $x^2 + y^2 = 10$ is $f(3, 1) = 10$ and the minimum value is $f(-3, -1) = -10$.

5. $f(x, y) = xy$, $g(x, y) = 4x^2 + y^2 = 8$, and $\nabla f = \lambda \nabla g \Rightarrow \langle y, x \rangle = \langle 8\lambda x, 2\lambda y \rangle$, so $y = 8\lambda x$, $x = 2\lambda y$, and $4x^2 + y^2 = 8$. First note that if $x = 0$ then $y = 0$ by the first equation, and if $y = 0$ then $x = 0$ by the second equation. But this contradicts the third equation, so $x \neq 0$ and $y \neq 0$. Then from the first two equations we have

$\dfrac{y}{8x} = \lambda = \dfrac{x}{2y} \Rightarrow 2y^2 = 8x^2 \Rightarrow y^2 = 4x^2$, and substitution into the third equation gives

$4x^2 + 4x^2 = 8 \Rightarrow x = \pm 1$. If $x = \pm 1$ then $y^2 = 4 \Rightarrow y = \pm 2$, so f has possible extreme values at $(1, \pm 2)$ and $(-1, \pm 2)$. Evaluating f at these points, we see that the maximum value is $f(1, 2) = f(-1, -2) = 2$ and the minimum is $f(1, -2) = f(-1, 2) = -2$.

6. $f(x, y) = xe^y$, $g(x, y) = x^2 + y^2 = 2$, and $\nabla f = \lambda \nabla g \Rightarrow \langle e^y, xe^y \rangle = \langle 2\lambda x, 2\lambda y \rangle$, so $e^y = 2\lambda x$, $xe^y = 2\lambda y$, and $x^2 + y^2 = 2$. First note that from the first equation $x \neq 0$. If $y = 0$, the second equation implies $x = 0$, so $y \neq 0$. Then from the first two equations we have $\dfrac{e^y}{2x} = \lambda = \dfrac{xe^y}{2y} \Rightarrow 2ye^y = 2x^2 e^y \Rightarrow y = x^2$, and substituting into the third equation gives $x^2 + (x^2)^2 = 2 \Rightarrow x^4 + x^2 - 2 = 0 \Rightarrow (x^2 + 2)(x^2 - 1) = 0 \Rightarrow x = \pm 1$. From $y = x^2$ we have $y = 1$, so f has possible extreme values at $(\pm 1, 1)$. Evaluating f at these points, we see that the maximum value is $f(1, 1) = e$ and the minimum is $f(-1, 1) = -e$.

7. $f(x, y, z) = 2x + 2y + z$, $g(x, y, z) = x^2 + y^2 + z^2 = 9$, and $\nabla f = \lambda \nabla g \Rightarrow \langle 2, 2, 1 \rangle = \langle 2\lambda x, 2\lambda y, 2\lambda z \rangle$, so $2\lambda x = 2$, $2\lambda y = 2$, $2\lambda z = 1$, and $x^2 + y^2 + z^2 = 9$. The first three equations imply $x = \dfrac{1}{\lambda}$, $y = \dfrac{1}{\lambda}$, and $z = \dfrac{1}{2\lambda}$. But substitution into the fourth equation gives $\left(\dfrac{1}{\lambda}\right)^2 + \left(\dfrac{1}{\lambda}\right)^2 + \left(\dfrac{1}{2\lambda}\right)^2 = 9 \Rightarrow \dfrac{9}{4\lambda^2} = 9 \Rightarrow \lambda = \pm\frac{1}{2}$, so f has possible extreme values at the points $(2, 2, 1)$ and $(-2, -2, -1)$. The maximum value of f on $x^2 + y^2 + z^2 = 9$ is $f(2, 2, 1) = 9$, and the minimum is $f(-2, -2, -1) = -9$.

8. $f(x,y,z)=e^{xyz}$, $g(x,y,z)=2x^2+y^2+z^2=24$, and $\nabla f=\lambda\nabla g \Rightarrow \langle yze^{xyz}, xze^{xyz}, xye^{xyz}\rangle=\langle 4\lambda x, 2\lambda y, 2\lambda z\rangle$. Then $yze^{xyz}=4\lambda x$, $xze^{xyz}=2\lambda y$, $xye^{xyz}=2\lambda z$, and $2x^2+y^2+z^2=24$. If any of x, y, z, or λ is zero, then the first three equations imply that two of the variables x, y, z must be zero. If $x=y=z=0$ it contradicts the fourth equation, so exactly two are zero, and from the fourth equation the possibilities are $(\pm 2\sqrt{3},0,0)$, $(0,\pm 2\sqrt{6},0)$, $(0,0,\pm 2\sqrt{6})$, all with an f-value of $e^0=1$. If none of x, y, z, λ is zero then from the first three equations we have $\dfrac{4\lambda x}{yz}=e^{xyz}=\dfrac{2\lambda y}{xz}=\dfrac{2\lambda z}{xy} \Rightarrow \dfrac{2x}{yz}=\dfrac{y}{xz}=\dfrac{z}{xy}$. This gives $2x^2z=y^2z \Rightarrow 2x^2=y^2$ and $xy^2=xz^2 \Rightarrow y^2=z^2$. Substituting into the fourth equation, we have $y^2+y^2+y^2=24 \Rightarrow y^2=8 \Rightarrow y=\pm 2\sqrt{2}$, so $x^2=4 \Rightarrow x=\pm 2$ and $z^2=y^2 \Rightarrow z=\pm 2\sqrt{2}$, giving possible points $(\pm 2,\pm 2\sqrt{2},\pm 2\sqrt{2})$ (all combinations). The value of f is e^{16} when all coordinates are positive or exactly two are negative, and the value is e^{-16} when all are negative or exactly one of the coordinates is negative. Thus the maximum of f subject to the constraint is e^{16} and the minimum is e^{-16}.

9. $f(x,y,z)=xy^2z$, $g(x,y,z)=x^2+y^2+z^2=4$, and $\nabla f=\lambda\nabla g \Rightarrow \langle y^2z, 2xyz, xy^2\rangle=\lambda\langle 2x,2y,2z\rangle$. Then $y^2z=2\lambda x$, $2xyz=2\lambda y$, $xy^2=2\lambda z$, and $x^2+y^2+z^2=4$.

Case 1: If $\lambda=0$, then the first equation implies that $y=0$ or $z=0$. If $y=0$, then any values of x and z satisfy the first three equations, so from the fourth equation all points $(x,0,z)$ such that $x^2+z^2=4$ are possible points. If $z=0$ then from the third equation $x=0$ or $y=0$, and from the fourth equation, the possible points are $(0,\pm 2,0)$, $(\pm 2,0,0)$. The f-value in all these cases is 0.

Case 2: If $\lambda\neq 0$ but any one of x, y, z is zero, the first three equations imply that all three coordinates must be zero, contradicting the fourth equation. Thus if $\lambda\neq 0$, none of x, y, z is zero and from the first three equations we have $\dfrac{y^2z}{2x}=\lambda=xz=\dfrac{xy^2}{2z}$. This gives $y^2z=2x^2z \Rightarrow y^2=2x^2$ and $2y^2z^2=2x^2y^2 \Rightarrow z^2=x^2$. Substituting into the fourth equation, we have $x^2+2x^2+x^2=4 \Rightarrow x^2=1 \Rightarrow x=\pm 1$, so $y=\pm\sqrt{2}$ and $z=\pm 1$, giving possible points $(\pm 1,\pm\sqrt{2},\pm 1)$ (all combinations). The value of f is 2 when x and z are the same sign and -2 when they are opposite. Thus the maximum of f subject to the constraint is $f(1,\pm\sqrt{2},1)=f(-1,\pm\sqrt{2},-1)=2$ and the minimum is $f(1,\pm\sqrt{2},-1)=f(-1,\pm\sqrt{2},1)=-2$.

10. $f(x,y,z)=\ln(x^2+1)+\ln(y^2+1)+\ln(z^2+1)$, $g(x,y,z)=x^2+y^2+z^2=12$. Then $\nabla f=\lambda\nabla g \Rightarrow$ $\left\langle \dfrac{2x}{x^2+1},\dfrac{2y}{y^2+1},\dfrac{2z}{z^2+1}\right\rangle=\lambda\langle 2x,2y,2z\rangle$, so $\dfrac{2x}{x^2+1}=2\lambda x$, $\dfrac{2y}{y^2+1}=2\lambda y$, $\dfrac{2z}{z^2+1}=2\lambda z$, and $x^2+y^2+z^2=12$.

First, if $\lambda=0$ then $x=y=z=0$ which contradicts the last equation, so we may assume that $\lambda\neq 0$.

Case 1: If $x\neq 0$, $y\neq 0$, and $z\neq 0$, then from the first three equations we have $\dfrac{1}{x^2+1}=\lambda=\dfrac{1}{y^2+1}=\dfrac{1}{z^2+1} \Rightarrow$

$x^2 = y^2 = z^2$, and substitution into the last equation gives $3x^2 = 12 \quad \Rightarrow \quad x = \pm 2$. Thus possible points are $(\pm 2, \pm 2, \pm 2)$ (all combinations), all of which have an f-value of $3 \ln 5$.

Case 2: If exactly one of x, y, z is zero, say $x = 0$, then from the second and third equations we have $y^2 = z^2$. Substitution into the last equation gives $2y^2 = 12 \quad \Rightarrow \quad y = \pm\sqrt{6}$. The situation is similar for $y = 0$ or $z = 0$, giving possible points $\left(0, \pm\sqrt{6}, \pm\sqrt{6}\right)$, $\left(\pm\sqrt{6}, 0, \pm\sqrt{6}\right)$, $\left(\pm\sqrt{6}, \pm\sqrt{6}, 0\right)$ (all combinations), all with an f-value of $2 \ln 7$.

Case 3: If exactly two of x, y, z are zero, then the square of the nonzero variable is 12, giving possible points $\left(0, 0, \pm 2\sqrt{3}\right)$, $\left(0, \pm 2\sqrt{3}, 0\right)$, $\left(\pm 2\sqrt{3}, 0, 0\right)$, all with an f-value of $\ln 13$.

Thus the maximum of f subject to the constraint is $3 \ln 5 \approx 4.83$ and the minimum is $\ln 13 \approx 2.56$.

11. $f(x, y, z) = x^2 + y^2 + z^2,\ g(x, y, z) = x^4 + y^4 + z^4 = 1 \quad \Rightarrow \quad \nabla f = \langle 2x, 2y, 2z \rangle,\ \lambda \nabla g = \left\langle 4\lambda x^3, 4\lambda y^3, 4\lambda z^3 \right\rangle$.

Case 1: If $x \neq 0$, $y \neq 0$, and $z \neq 0$, then $\nabla f = \lambda \nabla g$ implies $\lambda = 1/(2x^2) = 1/(2y^2) = 1/(2z^2)$ or $x^2 = y^2 = z^2$ and $3x^4 = 1$ or $x = \pm\frac{1}{\sqrt[4]{3}}$ giving the points $\left(\pm\frac{1}{\sqrt[4]{3}}, \frac{1}{\sqrt[4]{3}}, \frac{1}{\sqrt[4]{3}}\right)$, $\left(\pm\frac{1}{\sqrt[4]{3}}, -\frac{1}{\sqrt[4]{3}}, \frac{1}{\sqrt[4]{3}}\right)$, $\left(\pm\frac{1}{\sqrt[4]{3}}, \frac{1}{\sqrt[4]{3}}, -\frac{1}{\sqrt[4]{3}}\right)$, $\left(\pm\frac{1}{\sqrt[4]{3}}, -\frac{1}{\sqrt[4]{3}}, -\frac{1}{\sqrt[4]{3}}\right)$ all with an f-value of $\sqrt{3}$.

Case 2: If one of the variables equals zero and the other two are not zero, then the squares of the two nonzero coordinates are equal with common value $\frac{1}{\sqrt{2}}$ and corresponding f-value of $\sqrt{2}$.

Case 3: If exactly two of the variables are zero, then the third variable has value ± 1 with the corresponding f-value of 1.

Thus on $x^4 + y^4 + z^4 = 1$, the maximum value of f is $\sqrt{3}$ and the minimum value is 1.

12. $f(x, y, z) = x^4 + y^4 + z^4,\ g(x, y, z) = x^2 + y^2 + z^2 = 1 \quad \Rightarrow \quad \nabla f = \left\langle 4x^3, 4y^3, 4z^3 \right\rangle,\ \lambda \nabla g = \langle 2\lambda x, 2\lambda y, 2\lambda z \rangle$.

Case 1: If $x \neq 0$, $y \neq 0$, and $z \neq 0$ then $\nabla f = \lambda \nabla g$ implies $\lambda = 2x^2 = 2y^2 = 2z^2$ or $x^2 = y^2 = z^2 = \frac{1}{3}$ giving 8 points each with an f-value of $\frac{1}{3}$.

Case 2: If one of the variables is 0 and the other two are not, then the squares of the two nonzero coordinates are equal with common value $\frac{1}{2}$ and the corresponding f-value is $\frac{1}{2}$.

Case 3: If exactly two of the variables are 0, then the third variable has value ± 1 with corresponding f-value of 1.

Thus on $x^2 + y^2 + z^2 = 1$, the maximum value of f is 1 and the minimum value is $\frac{1}{3}$.

13. $f(x, y, z, t) = x + y + z + t,\ g(x, y, z, t) = x^2 + y^2 + z^2 + t^2 = 1 \quad \Rightarrow \quad \langle 1, 1, 1, 1 \rangle = \langle 2\lambda x, 2\lambda y, 2\lambda z, 2\lambda t \rangle$, so $\lambda = 1/(2x) = 1/(2y) = 1/(2z) = 1/(2t)$ and $x = y = z = t$. But $x^2 + y^2 + z^2 + t^2 = 1$, so the possible points are $\left(\pm\frac{1}{2}, \pm\frac{1}{2}, \pm\frac{1}{2}, \pm\frac{1}{2}\right)$. Thus the maximum value of f is $f\left(\frac{1}{2}, \frac{1}{2}, \frac{1}{2}, \frac{1}{2}\right) = 2$ and the minimum value is $f\left(-\frac{1}{2}, -\frac{1}{2}, -\frac{1}{2}, -\frac{1}{2}\right) = -2$.

14. $f(x_1, x_2, \ldots, x_n) = x_1 + x_2 + \cdots + x_n,\ g(x_1, x_2, \ldots, x_n) = x_1^2 + x_2^2 + \cdots + x_n^2 = 1 \quad \Rightarrow$
$\langle 1, 1, \ldots, 1 \rangle = \langle 2\lambda x_1, 2\lambda x_2, \ldots, 2\lambda x_n \rangle$, so $\lambda = 1/(2x_1) = 1/(2x_2) = \cdots = 1/(2x_n)$ and $x_1 = x_2 = \cdots = x_n$.

But $x_1^2 + x_2^2 + \cdots + x_n^2 = 1$, so $x_i = \pm 1/\sqrt{n}$ for $i = 1, \ldots, n$. Thus the maximum value of f is $f(1/\sqrt{n}, 1/\sqrt{n}, \ldots, 1/\sqrt{n}) = \sqrt{n}$ and the minimum value is $f(-1/\sqrt{n}, -1/\sqrt{n}, \ldots, -1/\sqrt{n}) = -\sqrt{n}$.

15. $f(x,y) = x^2 + y^2$, $g(x,y) = xy = 1$, and $\nabla f = \lambda \nabla g \Rightarrow \langle 2x, 2y\rangle = \langle \lambda y, \lambda x\rangle$, so $2x = \lambda y$, $2y = \lambda x$, and $xy = 1$. From the last equation, $x \neq 0$ and $y \neq 0$, so $2x = \lambda y \Rightarrow \lambda = 2x/y$. Substituting, we have $2y = (2x/y)\,x \Rightarrow y^2 = x^2 \Rightarrow y = \pm x$. But $xy = 1$, so $x = y = \pm 1$ and the possible points for the extreme values of f are $(1,1)$ and $(-1,-1)$. Here there is no maximum value, since the constraint $xy = 1 \Leftrightarrow y = 1/x$ allows x or y to become arbitrarily large, and hence $f(x,y) = x^2 + y^2$ can be made arbitrarily large. The minimum value is $f(1,1) = f(-1,-1) = 2$.

16. $f(x,y,z) = x^2 + 2y^2 + 3z^2$, $g(x,y) = x + 2y + 3z = 10$, and $\nabla f = \lambda \nabla g \Rightarrow \langle 2x, 4y, 6z\rangle = \langle \lambda, 2\lambda, 3\lambda\rangle$, so $2x = \lambda$, $4y = 2\lambda$, $6z = 3\lambda$, and $x + 2y + 3z = 10$. From the first three equations we have $2x = \lambda = 2y = 2z \Rightarrow x = y = z$, and substituting into the fourth equation gives $x + 2x + 3x = 10 \Rightarrow x = \frac{5}{3} = y = z$. Thus the only possible point for an extreme value of f is $\left(\frac{5}{3}, \frac{5}{3}, \frac{5}{3}\right)$. Notice here that the constraint $x + 2y + 3z = 10$ allows any of $|x|$, $|y|$, or $|z|$ to be arbitrarily large, and hence $f(x,y,z) = x^2 + 2y^2 + 3z^2$ can be made arbitrarily large. So f has no maximum value subject to the constraint. The minimum value is $f\left(\frac{5}{3}, \frac{5}{3}, \frac{5}{3}\right) = 6\left(\frac{5}{3}\right)^2 = \frac{50}{3}$.

17. $f(x,y,z) = x + y + z$, $g(x,y,z) = x^2 + z^2 = 2$, $h(x,y,z) = x + y = 1$, and $\nabla f = \lambda \nabla g + \mu \nabla h \Rightarrow \langle 1,1,1\rangle = \langle 2\lambda x, 0, 2\lambda z\rangle + \langle \mu, \mu, 0\rangle$. Then $1 = 2\lambda x + \mu$, $1 = \mu$, $1 = 2\lambda z$, $x^2 + z^2 = 2$, and $x + y = 1$. Substituting $\mu = 1$ into the first equation gives $\lambda = 0$ or $x = 0$. But $\lambda = 0$ contradicts $1 = 2\lambda z$, so $x = 0$. Then $x + y = 1 \Rightarrow y = 1$ and $x^2 + z^2 = 2 \Rightarrow z = \pm\sqrt{2}$, so the possible points are $\left(0, 1, \pm\sqrt{2}\right)$. The maximum value of f subject to the constraints is $f(0,1,\sqrt{2}) = 1 + \sqrt{2} \approx 2.41$ and the minimum is $f(0,1,-\sqrt{2}) = 1 - \sqrt{2} \approx -0.41$.

Note: Since $x + y = 1$ is one of the constraints, we could have solved the problem by solving $f(x,z) = 1 + z$ subject to $x^2 + z^2 = 2$.

18. $f(x,y,z) = z$, $g(x,y,z) = x^2 + y^2 - z^2 = 0$, $h(x,y,z) = x + y + z = 24$, and $\nabla f = \lambda \nabla g + \mu \nabla h \Rightarrow \langle 0,0,1\rangle = \langle 2\lambda x, 2\lambda y, -2\lambda z\rangle + \langle \mu, \mu, \mu\rangle$. Then $0 = 2\lambda x + \mu$, $0 = 2\lambda y + \mu$, $1 = -2\lambda z + \mu$, $x^2 + y^2 - z^2 = 0$, and $x + y + z = 24$. From the first two equations we have $-2\lambda x = \mu = -2\lambda y \Rightarrow \lambda = 0$ or $x = y$. But $\lambda = 0 \Rightarrow \mu = 0$ which contradicts the third equation, so $x = y$ and substitution into the last equation gives $z = 24 - 2x$. From the fourth equation we have $x^2 + x^2 - (24 - 2x)^2 = 0 \Rightarrow -2x^2 + 96x - 576 = 0 \Rightarrow x^2 - 48x + 288 = 0 \Rightarrow$

$$x = \frac{48 \pm \sqrt{1152}}{2} = 24 \pm 12\sqrt{2} = y.$$

Now $z = 24 - 2x$, so the possible points are $\left(24 + 12\sqrt{2}, 24 + 12\sqrt{2}, -24 - 24\sqrt{2}\right)$ and $\left(24 - 12\sqrt{2}, 24 - 12\sqrt{2}, -24 + 24\sqrt{2}\right)$. The maximum of f subject to the constraints is $f\left(24 - 12\sqrt{2}, 24 - 12\sqrt{2}, -24 + 24\sqrt{2}\right) = -24 + 24\sqrt{2} \approx 9.94$ and the minimum is $f\left(24 + 12\sqrt{2}, 24 + 12\sqrt{2}, -24 - 24\sqrt{2}\right) = -24 - 24\sqrt{2} \approx -57.94$.

19. $f(x,y,z) = yz + xy,\ g(x,y,z) = xy = 1,\ h(x,y,z) = y^2 + z^2 = 1 \quad\Rightarrow\quad \nabla f = \langle y, x+z, y\rangle, \lambda\nabla g = \langle \lambda y, \lambda x, 0\rangle,$ $\mu\nabla h = \langle 0, 2\mu y, 2\mu z\rangle$. Then $y = \lambda y$ implies $\lambda = 1$ [$y \neq 0$ since $g(x,y,z) = 1$], $x + z = \lambda x + 2\mu y$ and $y = 2\mu z$. Thus $\mu = z/(2y) = y/(2y)$ or $y^2 = z^2$, and so $y^2 + z^2 = 1$ implies $y = \pm\frac{1}{\sqrt{2}}$, $z = \pm\frac{1}{\sqrt{2}}$. Then $xy = 1$ implies $x = \pm\sqrt{2}$ and the possible points are $\left(\pm\sqrt{2}, \pm\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}\right)$, $\left(\pm\sqrt{2}, \pm\frac{1}{\sqrt{2}}, -\frac{1}{\sqrt{2}}\right)$. Hence the maximum of f subject to the constraints is $f\left(\pm\sqrt{2}, \pm\frac{1}{\sqrt{2}}, \pm\frac{1}{\sqrt{2}}\right) = \frac{3}{2}$ and the minimum is $f\left(\pm\sqrt{2}, \pm\frac{1}{\sqrt{2}}, \mp\frac{1}{\sqrt{2}}\right) = \frac{1}{2}$.

Note: Since $xy = 1$ is one of the constraints we could have solved the problem by solving $f(y,z) = yz + 1$ subject to $y^2 + z^2 = 1$.

20. $f(x,y,z) = x^2 + y^2 + z^2,\ g(x,y,z) = x - y = 1,\ h(x,y,z) = y^2 - z^2 = 1 \quad\Rightarrow\quad \nabla f = \langle 2x, 2y, 2z\rangle,$ $\lambda\nabla g = \langle \lambda, -\lambda, 0\rangle$, and $\mu\nabla h = \langle 0, 2\mu y, -2\mu z\rangle$. Then $2x = \lambda$, $2y = -\lambda + 2\mu y$, and $2z = -2\mu z \quad\Rightarrow\quad z = 0$ or $\mu = -1$. If $z = 0$ then $y^2 - z^2 = 1$ implies $y^2 = 1 \quad\Rightarrow\quad y = \pm 1$. If $y = 1$, $x - y = 1$ implies $x = 2$, and if $y = -1$ we have $x = 0$, so possible points are $(2, 1, 0)$ and $(0, -1, 0)$. If $\mu = -1$ then $2y = -\lambda + 2\mu y$ implies $4y = -\lambda$, but $\lambda = 2x$ so $4y = -2x \quad\Rightarrow\quad x = -2y$ and $x - y = 1$ implies $-3y = 1 \quad\Rightarrow\quad y = -\frac{1}{3}$. But then $y^2 - z^2 = 1$ implies $z^2 = -\frac{8}{9}$, an impossibility. Thus the maximum value of f subject to the constraints is $f(2,1,0) = 5$ and the minimum is $f(0,-1,0) = 1$.

Note: Since $x - y = 1 \quad\Rightarrow\quad x = y + 1$ is one of the constraints we could have solved the problem by solving $f(y,z) = (y+1)^2 + y^2 + z^2$ subject to $y^2 - z^2 = 1$.

21. $f(x,y) = x^2 + y^2 + 4x - 4y$. For the interior of the region, we find the critical points: $f_x = 2x + 4$, $f_y = 2y - 4$, so the only critical point is $(-2, 2)$ (which is inside the region) and $f(-2,2) = -8$. For the boundary, we use Lagrange multipliers. $g(x,y) = x^2 + y^2 = 9$, so $\nabla f = \lambda\nabla g \quad\Rightarrow\quad \langle 2x+4, 2y-4\rangle = \langle 2\lambda x, 2\lambda y\rangle$. Thus $2x + 4 = 2\lambda x$ and $2y - 4 = 2\lambda y$. Adding the two equations gives $2x + 2y = 2\lambda x + 2\lambda y \quad\Rightarrow\quad x + y = \lambda(x+y) \quad\Rightarrow\quad (x+y)(\lambda - 1) = 0$, so $x + y = 0 \quad\Rightarrow\quad y = -x$ or $\lambda - 1 = 0 \quad\Rightarrow\quad \lambda = 1$. But $\lambda = 1$ leads to a contradition in $2x + 4 = 2\lambda x$, so $y = -x$ and $x^2 + y^2 = 9$ implies $2y^2 = 9 \quad\Rightarrow\quad y = \pm\frac{3}{\sqrt{2}}$. We have $f\left(\frac{3}{\sqrt{2}}, -\frac{3}{\sqrt{2}}\right) = 9 + 12\sqrt{2} \approx 25.97$ and $f\left(-\frac{3}{\sqrt{2}}, \frac{3}{\sqrt{2}}\right) = 9 - 12\sqrt{2} \approx -7.97$, so the maximum value of f on the disk $x^2 + y^2 \leq 9$ is $f\left(\frac{3}{\sqrt{2}}, -\frac{3}{\sqrt{2}}\right) = 9 + 12\sqrt{2}$ and the minimum is $f(-2,2) = -8$.

22. $f(x,y) = 2x^2 + 3y^2 - 4x - 5 \quad\Rightarrow\quad \nabla f = \langle 4x - 4, 6y\rangle = \langle 0, 0\rangle \quad\Rightarrow\quad x = 1, y = 0$. Thus $(1,0)$ is the only critical point of f, and it lies in the region $x^2 + y^2 < 16$. On the boundary, $g(x,y) = x^2 + y^2 = 16 \quad\Rightarrow\quad \lambda\nabla g = \langle 2\lambda x, 2\lambda y\rangle$, so $6y = 2\lambda y \quad\Rightarrow\quad$ either $y = 0$ or $\lambda = 3$. If $y = 0$, then $x = \pm 4$; if $\lambda = 3$, then $4x - 4 = 2\lambda x \quad\Rightarrow\quad x = -2$ and $y = \pm 2\sqrt{3}$. Now $f(1,0) = -7$, $f(4,0) = 11$, $f(-4,0) = 43$, and $f\left(-2, \pm 2\sqrt{3}\right) = 47$. Thus the maximum value of $f(x,y)$ on the disk $x^2 + y^2 \leq 16$ is $f\left(-2, \pm 2\sqrt{3}\right) = 47$, and the minimum value is $f(1,0) = -7$.

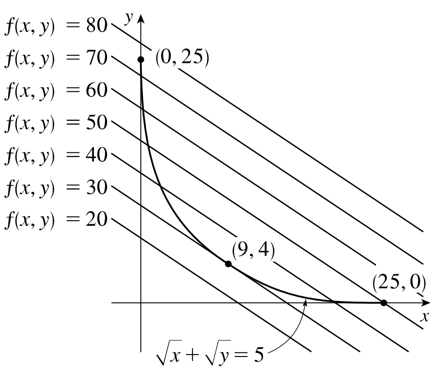
23. $f(x,y) = e^{-xy}$. For the interior of the region, we find the critical points: $f_x = -ye^{-xy}$, $f_y = -xe^{-xy}$, so the only critical point is $(0,0)$, and $f(0,0) = 1$. For the boundary, we use Lagrange multipliers. $g(x,y) = x^2 + 4y^2 = 1 \Rightarrow$ $\lambda\nabla g = \langle 2\lambda x, 8\lambda y\rangle$, so setting $\nabla f = \lambda\nabla g$ we get $-ye^{-xy} = 2\lambda x$ and $-xe^{-xy} = 8\lambda y$. The first of these gives $e^{-xy} = -2\lambda x/y$, and then the second gives $-x(-2\lambda x/y) = 8\lambda y \Rightarrow x^2 = 4y^2$. Solving this last equation with the constraint $x^2 + 4y^2 = 1$ gives $x = \pm\frac{1}{\sqrt{2}}$ and $y = \pm\frac{1}{2\sqrt{2}}$. Now $f\left(\pm\frac{1}{\sqrt{2}}, \mp\frac{1}{2\sqrt{2}}\right) = e^{1/4} \approx 1.284$ and $f\left(\pm\frac{1}{\sqrt{2}}, \pm\frac{1}{2\sqrt{2}}\right) = e^{-1/4} \approx 0.779$. The former are the maxima on the region and the latter are the minima.

24. (a) $f(x,y) = 2x + 3y$, $g(x,y) = \sqrt{x} + \sqrt{y} = 5 \Rightarrow \nabla f = \langle 2, 3\rangle = \lambda\nabla g = \lambda\left\langle \dfrac{1}{2\sqrt{x}}, \dfrac{1}{2\sqrt{y}}\right\rangle$. Then

$2 = \dfrac{\lambda}{2\sqrt{x}}$ and $3 = \dfrac{\lambda}{2\sqrt{y}}$ so $4\sqrt{x} = \lambda = 6\sqrt{y} \Rightarrow \sqrt{y} = \frac{2}{3}\sqrt{x}$. With $\sqrt{x} + \sqrt{y} = 5$ we have $\sqrt{x} + \frac{2}{3}\sqrt{x} = 5 \Rightarrow$ $\sqrt{x} = 3 \Rightarrow x = 9$. Substituting into $\sqrt{y} = \frac{2}{3}\sqrt{x}$ gives $\sqrt{y} = 2$ or $y = 4$. Thus the only possible extreme value subject to the constraint is $f(9,4) = 30$. (The question remains whether this is indeed the maximum of f.)

(b) $f(25,0) = 50$ which is larger than the result of part (a).

(c)



We can see from the level curves of f that the maximum occurs at the left endpoint $(0,25)$ of the constraint curve g. The maximum value is $f(0,25) = 75$.

(d) Here ∇g does not exist if $x = 0$ or $y = 0$, so the method will not locate any associated points. Also, the method of Lagrange multipliers identifies points where the level curves of f share a common tangent line with the constraint curve g. This normally does not occur at an endpoint, although an absolute maximum or minimum may occur there.

(e) Here $f(9,4)$ is the absolute *minimum* of f subject to g.

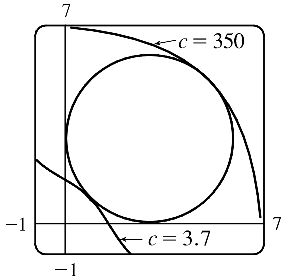
25. (a) $f(x,y) = x$, $g(x,y) = y^2 + x^4 - x^3 = 0 \Rightarrow \nabla f = \langle 1, 0\rangle = \lambda\nabla g = \lambda\left\langle 4x^3 - 3x^2, 2y\right\rangle$. Then

$1 = \lambda(4x^3 - 3x^2)$ **(1)** and $0 = 2\lambda y$ **(2)**. We have $\lambda \neq 0$ from **(1)**, so **(2)** gives $y = 0$. Then, from the constraint equation, $x^4 - x^3 = 0 \Rightarrow x^3(x-1) = 0 \Rightarrow x = 0$ or $x = 1$. But $x = 0$ contradicts **(1)**, so the only possible extreme value subject to the constraint is $f(1,0) = 1$. (The question remains whether this is indeed the minimum of f.)

(b) The constraint is $y^2 + x^4 - x^3 = 0 \quad \Leftrightarrow \quad y^2 = x^3 - x^4$. The left side is non-negative, so we must have $x^3 - x^4 \geq 0$ which is true only for $0 \leq x \leq 1$. Therefore the minimum possible value for $f(x, y) = x$ is 0 which occurs for $x = y = 0$. However, $\lambda \nabla g(0, 0) = \lambda \langle 0 - 0, 0 \rangle = \langle 0, 0 \rangle$ and $\nabla f(0, 0) = \langle 1, 0 \rangle$, so $\nabla f(0, 0) \neq \lambda \nabla g(0, 0)$ for all values of λ.

(c) Here $\nabla g(0, 0) = \mathbf{0}$ but the method of Lagrange multipliers requires that $\nabla g \neq \mathbf{0}$ everywhere on the constraint curve.

26. (a) The graphs of $f(x, y) = 3.7$ and $f(x, y) = 350$ seem to be tangent to the circle, and so 3.7 and 350 are the approximate minimum and maximum values of the function $f(x, y)$ subject to the constraint $(x - 3)^2 + (y - 3)^2 = 9$.



(b) Let $g(x, y) = (x - 3)^2 + (y - 3)^2$. We calculate $f_x(x, y) = 3x^2 + 3y$, $f_y(x, y) = 3y^2 + 3x$, $g_x(x, y) = 2x - 6$, and $g_y(x, y) = 2y - 6$, and use a CAS to search for solutions to the equations $g(x, y) = (x - 3)^2 + (y - 3)^2 = 9$, $f_x = \lambda g_x$, and $f_y = \lambda g_y$. The solutions are $(x, y) = \left(3 - \frac{3}{2}\sqrt{2}, 3 - \frac{3}{2}\sqrt{2}\right) \approx (0.879, 0.879)$ and $(x, y) = \left(3 + \frac{3}{2}\sqrt{2}, 3 + \frac{3}{2}\sqrt{2}\right) \approx (5.121, 5.121)$. These give $f\left(3 - \frac{3}{2}\sqrt{2}, 3 - \frac{3}{2}\sqrt{2}\right) = \frac{351}{2} - \frac{243}{2}\sqrt{2} \approx 3.673$ and $f\left(3 + \frac{3}{2}\sqrt{2}, 3 + \frac{3}{2}\sqrt{2}\right) = \frac{351}{2} + \frac{243}{2}\sqrt{2} \approx 347.33$, in accordance with part (a).

27. $P(L, K) = bL^\alpha K^{1-\alpha},\ g(L, K) = mL + nK = p \quad \Rightarrow \quad \nabla P = \left\langle \alpha b L^{\alpha - 1} K^{1-\alpha}, (1 - \alpha) b L^\alpha K^{-\alpha} \right\rangle,\ \lambda \nabla g = \langle \lambda m, \lambda n \rangle$. Then $\alpha b (K/L)^{1-\alpha} = \lambda m$ and $(1 - \alpha) b (L/K)^\alpha = \lambda n$ and $mL + nK = p$, so $\alpha b (K/L)^{1-\alpha}/m = (1 - \alpha) b (L/K)^\alpha / n$ or $n\alpha/[m(1 - \alpha)] = (L/K)^\alpha (L/K)^{1-\alpha}$ or $L = Kn\alpha/[m(1 - \alpha)]$. Substituting into $mL + nK = p$ gives $K = (1 - \alpha)p/n$ and $L = \alpha p/m$ for the maximum production.

28. $C(L, K) = mL + nK,\ g(L, K) = bL^\alpha K^{1-\alpha} = Q \quad \Rightarrow \quad \nabla C = \langle m, n \rangle,\ \lambda \nabla g = \left\langle \lambda \alpha b L^{\alpha - 1} K^{1-\alpha}, \lambda (1 - \alpha) b L^\alpha K^{-\alpha} \right\rangle$.

Then $\dfrac{m}{\alpha b}\left(\dfrac{L}{K}\right)^{1-\alpha} = \dfrac{n}{(1 - \alpha) b}\left(\dfrac{K}{L}\right)^\alpha$ and $bL^\alpha K^{1-\alpha} = Q \quad \Rightarrow \quad \dfrac{n\alpha}{m(1 - \alpha)} = \left(\dfrac{L}{K}\right)^{1-\alpha}\left(\dfrac{L}{K}\right)^\alpha \quad \Rightarrow$

$L = \dfrac{Kn\alpha}{m(1 - \alpha)}$ and so $b\left[\dfrac{Kn\alpha}{m(1 - \alpha)}\right]^\alpha K^{1-\alpha} = Q$. Hence $K = \dfrac{Q}{b\left(n\alpha/[m(1 - \alpha)]\right)^\alpha} = \dfrac{Qm^\alpha (1 - \alpha)^\alpha}{bn^\alpha \alpha^\alpha}$

and $L = \dfrac{Qm^{\alpha - 1}(1 - \alpha)^{\alpha - 1}}{bn^{\alpha - 1}\alpha^{\alpha - 1}} = \dfrac{Qn^{1-\alpha}\alpha^{1-\alpha}}{bm^{1-\alpha}(1 - \alpha)^{1-\alpha}}$ minimizes cost.

29. Let the sides of the rectangle be x and y. Then $f(x, y) = xy$, $g(x, y) = 2x + 2y = p \quad \Rightarrow \quad \nabla f(x, y) = \langle y, x \rangle$, $\lambda \nabla g = \langle 2\lambda, 2\lambda \rangle$. Then $\lambda = \frac{1}{2}y = \frac{1}{2}x$ implies $x = y$ and the rectangle with maximum area is a square with side length $\frac{1}{4}p$.

30. Let $f(x, y, z) = s(s - x)(s - y)(s - z)$, $g(x, y, z) = x + y + z$. Then $\nabla f = \langle -s(s - y)(s - z), -s(s - x)(s - z), -s(s - x)(s - y) \rangle$, $\lambda \nabla g = \langle \lambda, \lambda, \lambda \rangle$. Thus $(s - y)(s - z) = (s - x)(s - z)$ **(1)**, and $(s - x)(s - z) = (s - x)(s - y)$ **(2)**. **(1)** implies $x = y$ while **(2)** implies $y = z$, so $x = y = z = p/3$ and the triangle with maximum area is equilateral.

31. The distance from $(2,0,-3)$ to a point (x,y,z) on the plane is $d=\sqrt{(x-2)^2+y^2+(z+3)^2}$, so we seek to minimize $d^2=f(x,y,z)=(x-2)^2+y^2+(z+3)^2$ subject to the constraint that (x,y,z) lies on the plane $x+y+z=1$, that is, that $g(x,y,z)=x+y+z=1$. Then $\nabla f=\lambda\nabla g \;\Rightarrow\; \langle 2(x-2),2y,2(z+3)\rangle=\langle\lambda,\lambda,\lambda\rangle$, so $x=(\lambda+4)/2$, $y=\lambda/2$, $z=(\lambda-6)/2$. Substituting into the constraint equation gives $\dfrac{\lambda+4}{2}+\dfrac{\lambda}{2}+\dfrac{\lambda-6}{2}=1 \;\Rightarrow\; 3\lambda-2=2 \;\Rightarrow\; \lambda=\frac{4}{3}$, so $x=\frac{8}{3}$, $y=\frac{2}{3}$, and $z=-\frac{7}{3}$. This must correspond to a minimum, so the shortest distance is $d=\sqrt{\left(\frac{8}{3}-2\right)^2+\left(\frac{2}{3}\right)^2+\left(-\frac{7}{3}+3\right)^2}=\sqrt{\frac{4}{3}}=\frac{2}{\sqrt{3}}$.

32. The distance from $(0,1,1)$ to a point (x,y,z) on the plane is $d=\sqrt{x^2+(y-1)^2+(z-1)^2}$, so we minimize $d^2=f(x,y,z)=x^2+(y-1)^2+(z-1)^2$ subject to the constraint that (x,y,z) lies on the plane $x-2y+3z=6$, that is, $g(x,y,z)=x-2y+3z=6$. Then $\nabla f=\lambda\nabla g \;\Rightarrow\; \langle 2x,2(y-1),2(z-1)\rangle=\langle\lambda,-2\lambda,3\lambda\rangle$, so $x=\lambda/2$, $y=1-\lambda$, $z=(3\lambda+2)/2$. Substituting into the constraint equation gives $\dfrac{\lambda}{2}-2(1-\lambda)+3\cdot\dfrac{3\lambda+2}{2}=6 \;\Rightarrow\; \lambda=\frac{5}{7}$, so $x=\frac{5}{14}$, $y=\frac{2}{7}$, and $z=\frac{29}{14}$. This must correspond to a minimum, so the point on the plane closest to the point $(0,1,1)$ is $\left(\frac{5}{14},\frac{2}{7},\frac{29}{14}\right)$.

33. Let $f(x,y,z)=d^2=(x-4)^2+(y-2)^2+z^2$. Then we want to minimize f subject to the constraint $g(x,y,z)=x^2+y^2-z^2=0$. $\nabla f=\lambda\nabla g \;\Rightarrow\; \langle 2(x-4),2(y-2),2z\rangle=\langle 2\lambda x,2\lambda y,-2\lambda z\rangle$, so $x-4=\lambda x$, $y-2=\lambda y$, and $z=-\lambda z$. From the last equation we have $z+\lambda z=0 \;\Rightarrow\; z(1+\lambda)=0$, so either $z=0$ or $\lambda=-1$. But from the constraint equation we have $z=0 \;\Rightarrow\; x^2+y^2=0 \;\Rightarrow\; x=y=0$ which is not possible from the first two equations. So $\lambda=-1$ and $x-4=\lambda x \;\Rightarrow\; x=2$, $y-2=\lambda y \;\Rightarrow\; y=1$, and $x^2+y^2-z^2=0 \;\Rightarrow\; 4+1-z^2=0 \;\Rightarrow\; z=\pm\sqrt{5}$. This must correspond to a minimum, so the points on the cone closest to $(4,2,0)$ are $\left(2,1,\pm\sqrt{5}\right)$.

34. Let $f(x,y,z)=d^2=x^2+y^2+z^2$. Then we want to minimize f subject to the constraint $g(x,y,z)=y^2-xz=9$. $\nabla f=\lambda\nabla g \;\Rightarrow\; \langle 2x,2y,2z\rangle=\langle -\lambda z,2\lambda y,-\lambda x\rangle$, so $2x=-\lambda z$, $y=\lambda y$, and $2z=-\lambda x$. If $x=0$ then the last equation implies $z=0$, and from the constraint $y^2-xz=9$ we have $y=\pm 3$. If $x\neq 0$, then the first and third equations give $\lambda=-2x/z=-2z/x \;\Rightarrow\; x^2=z^2$. From the second equation we have $y=0$ or $\lambda=1$. If $y=0$ then $y^2-xz=9 \;\Rightarrow\; z=-9/x$ and $x^2=z^2 \;\Rightarrow\; x^2=81/x^2 \;\Rightarrow\; x=\pm 3$. Since $z=-9/x$, $x=3 \;\Rightarrow\; z=-3$ and $x=-3 \;\Rightarrow\; z=3$. If $\lambda=1$, then $2x=-z$ and $2z=-x$ which implies $x=z=0$, contradicting the assumption that $x\neq 0$. Thus the possible points are $(0,\pm 3,0)$, $(3,0,-3)$, $(-3,0,3)$. We have $f(0,\pm 3,0)=9$ and $f(3,0,-3)=f(-3,0,3)=18$, so the points on the surface that are closest to the origin are $(0,\pm 3,0)$.

35. $f(x,y,z)=xyz$, $g(x,y,z)=x+y+z=100 \;\Rightarrow\; \nabla f=\langle yz,xz,xy\rangle=\lambda\nabla g=\langle\lambda,\lambda,\lambda\rangle$. Then $\lambda=yz=xz=xy$ implies $x=y=z=\frac{100}{3}$.

36. Minimize $f(x,y,z) = x^2 + y^2 + z^2$ subject to $g(x,y,z) = x + y + z = 12$ with $x > 0$, $y > 0$, $z > 0$. Then $\nabla f = \lambda \nabla g \Rightarrow \langle 2x, 2y, 2z \rangle = \lambda \langle 1, 1, 1 \rangle \Rightarrow 2x = \lambda, 2y = \lambda, 2z = \lambda \Rightarrow x = y = z$, so $x + y + z = 12 \Rightarrow 3x = 12 \Rightarrow x = 4 = y = z$. By comparing nearby values we can confirm that this gives a minimum and not a maximum. Thus the three numbers are 4, 4, and 4.

37. If the dimensions are $2x$, $2y$, and $2z$, then maximize $f(x,y,z) = (2x)(2y)(2z) = 8xyz$ subject to $g(x,y,z) = x^2 + y^2 + z^2 = r^2$ ($x > 0$, $y > 0$, $z > 0$). Then $\nabla f = \lambda \nabla g \Rightarrow \langle 8yz, 8xz, 8xy \rangle = \lambda \langle 2x, 2y, 2z \rangle \Rightarrow 8yz = 2\lambda x$, $8xz = 2\lambda y$, and $8xy = 2\lambda z$, so $\lambda = \dfrac{4yz}{x} = \dfrac{4xz}{y} = \dfrac{4xy}{z}$. This gives $x^2 z = y^2 z \Rightarrow x^2 = y^2$ (since $z \neq 0$) and $xy^2 = xz^2 \Rightarrow z^2 = y^2$, so $x^2 = y^2 = z^2 \Rightarrow x = y = z$, and substituting into the constraint equation gives $3x^2 = r^2 \Rightarrow x = r/\sqrt{3} = y = z$. Thus the largest volume of such a box is

$f\left(\frac{r}{\sqrt{3}}, \frac{r}{\sqrt{3}}, \frac{r}{\sqrt{3}}\right) = 8\left(\frac{r}{\sqrt{3}}\right)\left(\frac{r}{\sqrt{3}}\right)\left(\frac{r}{\sqrt{3}}\right) = \dfrac{8}{3\sqrt{3}} r^3$.

38. If the dimensions of the box are x, y, and z then minimize $f(x,y,z) = 2xy + 2xz + 2yz$ subject to $g(x,y,z) = xyz = 1000$ ($x > 0$, $y > 0$, $z > 0$). Then $\nabla f = \lambda \nabla g \Rightarrow \langle 2y + 2z, 2x + 2z, 2x + 2y \rangle = \lambda \langle yz, xz, xy \rangle \Rightarrow 2y + 2z = \lambda yz$, $2x + 2z = \lambda xz$, $2x + 2y = \lambda xy$. Solving for λ in each equation gives $\lambda = \dfrac{2}{z} + \dfrac{2}{y} = \dfrac{2}{z} + \dfrac{2}{x} = \dfrac{2}{y} + \dfrac{2}{x} \Rightarrow x = y = z$. From $xyz = 1000$ we have $x^3 = 1000 \Rightarrow x = 10$ and the dimensions of the box are $x = y = z = 10$ cm.

39. $f(x,y,z) = xyz$, $g(x,y,z) = x + 2y + 3z = 6 \Rightarrow \nabla f = \langle yz, xz, xy \rangle = \lambda \nabla g = \langle \lambda, 2\lambda, 3\lambda \rangle$. Then $\lambda = yz = \frac{1}{2}xz = \frac{1}{3}xy$ implies $x = 2y$, $z = \frac{2}{3}y$. But $2y + 2y + 2y = 6$ so $y = 1$, $x = 2$, $z = \frac{2}{3}$ and the volume is $V = \frac{4}{3}$.

40. $f(x,y,z) = xyz$, $g(x,y,z) = xy + yz + xz = 32 \Rightarrow \nabla f = \langle yz, xz, xy \rangle = \lambda \nabla g = \langle \lambda(y+z), \lambda(x+z), \lambda(x+y) \rangle$. Then $\lambda(y+z) = yz$ **(1)**, $\lambda(x+z) = xz$ **(2)**, and $\lambda(x+y) = xy$ **(3)**. And **(1)** minus **(2)** implies $\lambda(y-x) = z(y-x)$ so $x = y$ or $\lambda = z$. If $\lambda = z$, then **(1)** implies $z(y+z) = yz$ or $z = 0$ which is false. Thus $x = y$. Similarly **(2)** minus **(3)** implies $\lambda(z-y) = x(z-y)$ so $y = z$ or $\lambda = x$. As above, $\lambda \neq x$, so $x = y = z$ and $3x^2 = 32$ or $x = y = z = \frac{8}{\sqrt{6}}$ cm.

41. $f(x,y,z) = xyz$, $g(x,y,z) = 4(x+y+z) = c \Rightarrow \nabla f = \langle yz, xz, xy \rangle$, $\lambda \nabla g = \langle 4\lambda, 4\lambda, 4\lambda \rangle$. Thus $4\lambda = yz = xz = xy$ or $x = y = z = \frac{1}{12}c$ are the dimensions giving the maximum volume.

42. $C(x,y,z) = 5xy + 2xz + 2yz$, $g(x,y,z) = xyz = V \Rightarrow \nabla C = \langle 5y + 2z, 5x + 2z, 2x + 2y \rangle = \lambda \nabla g = \langle \lambda yz, \lambda xz, \lambda xy \rangle$. Then $\lambda yz = 5y + 2z$ **(1)**, $\lambda xz = 5x + 2z$ **(2)**, $\lambda xy = 2(x+y)$ **(3)**, and $xyz = V$ **(4)**. Now **(1)** − **(2)** implies $\lambda z(y-x) = 5(y-x)$, so $x = y$ or $\lambda = 5/z$, but z can't be 0, so $x = y$. Then twice **(2)** minus five times **(3)** together with $x = y$ implies $\lambda y(2x - 5y) = 2(2z - 5y)$ which gives

$z = \frac{5}{2}y$ [again $\lambda \neq 2/y$ or else **(3)** implies $y = 0$]. Hence $\frac{5}{2}y^3 = V$ and the dimensions which minimize cost are $x = y = \sqrt[3]{\frac{2}{5}V}$ units, $z = V^{1/3}\left(\frac{5}{2}\right)^{2/3}$ units.

43. If the dimensions of the box are given by x, y, and z, then we need to find the maximum value of $f(x, y, z) = xyz$ $[x, y, z > 0]$ subject to the constraint $L = \sqrt{x^2 + y^2 + z^2}$ or $g(x, y, z) = x^2 + y^2 + z^2 = L^2$. $\nabla f = \lambda \nabla g \;\Rightarrow\; \langle yz, xz, xy \rangle = \lambda \langle 2x, 2y, 2z \rangle$, so $yz = 2\lambda x \;\Rightarrow\; \lambda = \dfrac{yz}{2x}$, $xz = 2\lambda y \;\Rightarrow\; \lambda = \dfrac{xz}{2y}$, and $xy = 2\lambda z \;\Rightarrow\; \lambda = \dfrac{xy}{2z}$.

Thus $\lambda = \dfrac{yz}{2x} = \dfrac{xz}{2y} \;\Rightarrow\; x^2 = y^2$ [since $z \neq 0$] $\Rightarrow\; x = y$ and $\lambda = \dfrac{yz}{2x} = \dfrac{xy}{2z} \;\Rightarrow\; x = z$ [since $y \neq 0$].

Substituting into the constraint equation gives $x^2 + x^2 + x^2 = L^2 \;\Rightarrow\; x^2 = L^2/3 \;\Rightarrow\; x = L/\sqrt{3} = y = z$ and the maximum volume is $\left(L/\sqrt{3}\right)^3 = L^3/\left(3\sqrt{3}\right)$.

44. Let the dimensions of the box be x, y, and z, so its volume is $f(x, y, z) = xyz$, its surface area is $2xy + 2yz + 2xz = 1500$ and its total edge length is $4x + 4y + 4z = 200$. We find the extreme values of $f(x, y, z)$ subject to the constraints $g(x, y, z) = xy + yz + xz = 750$ and $h(x, y, z) = x + y + z = 50$. Then $\nabla f = \langle yz, xz, xy \rangle = \lambda \nabla g + \mu \nabla h = \langle \lambda(y + z), \lambda(x + z), \lambda(x + y) \rangle + \langle \mu, \mu, \mu \rangle$. So $yz = \lambda(y + z) + \mu$ **(1)**, $xz = \lambda(x + z) + \mu$ **(2)**, and $xy = \lambda(x + y) + \mu$ **(3)**. Notice that the box can't be a cube or else $x = y = z = \frac{50}{3}$ but then $xy + yz + xz = \frac{2500}{3} \neq 750$. Assume x is the distinct side, that is, $x \neq y$, $x \neq z$. Then **(1)** minus **(2)** implies $z\,(y - x) = \lambda(y - x)$ or $\lambda = z$, and **(1)** minus **(3)** implies $y(z - x) = \lambda(z - x)$ or $\lambda = y$. So $y = z = \lambda$ and $x + y + z = 50$ implies $x = 50 - 2\lambda$; also $xy + yz + xz = 750$ implies $x(2\lambda) + \lambda^2 = 750$. Hence $50 - 2\lambda = \dfrac{750 - \lambda^2}{2\lambda}$ or $3\lambda^2 - 100\lambda + 750 = 0$ and $\lambda = \dfrac{50 \pm 5\sqrt{10}}{3}$, giving the points $\left(\frac{1}{3}\left(50 \mp 10\sqrt{10}\right), \frac{1}{3}\left(50 \pm 5\sqrt{10}\right), \frac{1}{3}\left(50 \pm 5\sqrt{10}\right)\right)$.

Thus the minimum of f is $f\left(\frac{1}{3}\left(50 - 10\sqrt{3}\right), \frac{1}{3}\left(50 + 5\sqrt{10}\right), \frac{1}{3}\left(50 + 5\sqrt{10}\right)\right) = \frac{1}{27}\left(87{,}500 - 2500\sqrt{10}\right)$, and its maximum is $f\left(\frac{1}{3}\left(50 + 10\sqrt{10}\right), \frac{1}{3}\left(50 - 5\sqrt{10}\right), \frac{1}{3}\left(50 - 5\sqrt{10}\right)\right) = \frac{1}{27}\left(87{,}500 + 2500\sqrt{10}\right)$.

Note: If either y or z is the distinct side, then symmetry gives the same result.

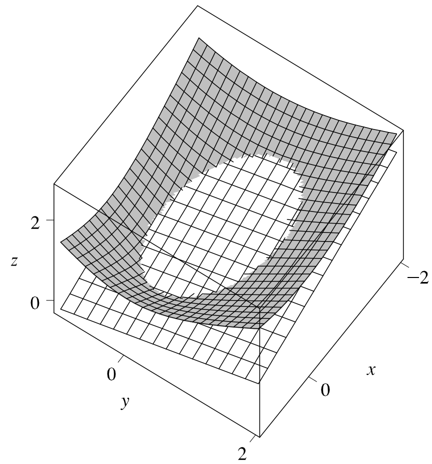
45. We need to find the extreme values of $f(x, y, z) = x^2 + y^2 + z^2$ subject to the two constraints $g(x, y, z) = x + y + 2z = 2$ and $h(x, y, z) = x^2 + y^2 - z = 0$. $\nabla f = \langle 2x, 2y, 2z \rangle$, $\lambda \nabla g = \langle \lambda, \lambda, 2\lambda \rangle$ and $\mu \nabla h = \langle 2\mu x, 2\mu y, -\mu \rangle$. Thus we need $2x = \lambda + 2\mu x$ **(1)**, $2y = \lambda + 2\mu y$ **(2)**, $2z = 2\lambda - \mu$ **(3)**, $x + y + 2z = 2$ **(4)**, and $x^2 + y^2 - z = 0$ **(5)**.

From **(1)** and **(2)**, $2(x - y) = 2\mu(x - y)$, so if $x \neq y$, $\mu = 1$. Putting this in **(3)** gives $2z = 2\lambda - 1$ or $\lambda = z + \frac{1}{2}$, but putting $\mu = 1$ into **(1)** says $\lambda = 0$. Hence $z + \frac{1}{2} = 0$ or $z = -\frac{1}{2}$. Then **(4)** and **(5)** become $x + y - 3 = 0$ and $x^2 + y^2 + \frac{1}{2} = 0$. The last equation cannot be true, so this case gives no solution. So we must have $x = y$. Then **(4)** and **(5)** become $2x + 2z = 2$ and $2x^2 - z = 0$ which imply $z = 1 - x$ and $z = 2x^2$. Thus $2x^2 = 1 - x$ or $2x^2 + x - 1 = (2x - 1)(x + 1) = 0$ so $x = \frac{1}{2}$ or

$x = -1$. The two points to check are $\left(\frac{1}{2}, \frac{1}{2}, \frac{1}{2}\right)$ and $(-1, -1, 2)$: $f\left(\frac{1}{2}, \frac{1}{2}, \frac{1}{2}\right) = \frac{3}{4}$ and $f(-1, -1, 2) = 6$. Thus $\left(\frac{1}{2}, \frac{1}{2}, \frac{1}{2}\right)$ is the point on the ellipse nearest the origin and $(-1, -1, 2)$ is the one farthest from the origin.

46. (a) After plotting $z = \sqrt{x^2 + y^2}$, the top half of the cone, and the plane $z = (5 - 4x + 3y)/8$ we see the ellipse formed by the intersection of the surfaces. The ellipse can be plotted explicitly using cylindrical coordinates (see Section 15.7): The cone is given by $z = r$, and the plane is $4r\cos\theta - 3r\sin\theta + 8z = 5$. Substituting $z = r$ into the plane equation gives $4r\cos\theta - 3r\sin\theta + 8r = 5 \quad\Rightarrow\quad r = \dfrac{5}{4\cos\theta - 3\sin\theta + 8}$.

Since $z = r$ on the ellipse, parametric equations (in cylindrical coordinates) are $\theta = t,\ r = z = \dfrac{5}{4\cos t - 3\sin t + 8},\ 0 \le t \le 2\pi$.



(b) We need to find the extreme values of $f(x, y, z) = z$ subject to the two constraints $g(x, y, z) = 4x - 3y + 8z = 5$ and $h(x, y, z) = x^2 + y^2 - z^2 = 0$.

$\nabla f = \lambda \nabla g + \mu \nabla h \quad\Rightarrow\quad \langle 0, 0, 1\rangle = \lambda\langle 4, -3, 8\rangle + \mu\langle 2x, 2y, -2z\rangle$, so we need $4\lambda + 2\mu x = 0 \quad\Rightarrow\quad x = -\frac{2\lambda}{\mu}$ **(1)**, $-3\lambda + 2\mu y = 0 \quad\Rightarrow\quad y = \frac{3\lambda}{2\mu}$ **(2)**, $8\lambda - 2\mu z = 1 \quad\Rightarrow\quad z = \frac{8\lambda - 1}{2\mu}$ **(3)**, $4x - 3y + 8z = 5$ **(4)**, and $x^2 + y^2 = z^2$ **(5)**. [Note that $\mu \neq 0$, else $\lambda = 0$ from **(1)**, but substitution into **(3)** gives a contradiction.]

Substituting **(1)**, **(2)**, and **(3)** into **(4)** gives $4\left(-\frac{2\lambda}{\mu}\right) - 3\left(\frac{3\lambda}{2\mu}\right) + 8\left(\frac{8\lambda - 1}{2\mu}\right) = 5 \quad\Rightarrow\quad \mu = \frac{39\lambda - 8}{10}$ and into **(5)** gives

$\left(-\frac{2\lambda}{\mu}\right)^2 + \left(\frac{3\lambda}{2\mu}\right)^2 = \left(\frac{8\lambda - 1}{2\mu}\right)^2 \quad\Rightarrow\quad 16\lambda^2 + 9\lambda^2 = (8\lambda - 1)^2 \quad\Rightarrow\quad 39\lambda^2 - 16\lambda + 1 = 0 \quad\Rightarrow\quad \lambda = \frac{1}{13}$ or $\lambda = \frac{1}{3}$.

If $\lambda = \frac{1}{13}$ then $\mu = -\frac{1}{2}$ and $x = \frac{4}{13}$, $y = -\frac{3}{13}$, $z = \frac{5}{13}$. If $\lambda = \frac{1}{3}$ then $\mu = \frac{1}{2}$ and $x = -\frac{4}{3}$, $y = 1$, $z = \frac{5}{3}$. Thus the highest point on the ellipse is $\left(-\frac{4}{3}, 1, \frac{5}{3}\right)$ and the lowest point is $\left(\frac{4}{13}, -\frac{3}{13}, \frac{5}{13}\right)$.

47. $f(x, y, z) = ye^{x-z},\ g(x, y, z) = 9x^2 + 4y^2 + 36z^2 = 36,\ h(x, y, z) = xy + yz = 1. \quad \nabla f = \lambda\nabla g + \mu\nabla h \quad\Rightarrow$ $\left\langle ye^{x-z}, e^{x-z}, -ye^{x-z}\right\rangle = \lambda\langle 18x, 8y, 72z\rangle + \mu\langle y, x + z, y\rangle$, so $ye^{x-z} = 18\lambda x + \mu y$, $e^{x-z} = 8\lambda y + \mu(x + z)$, $-ye^{x-z} = 72\lambda z + \mu y$, $9x^2 + 4y^2 + 36z^2 = 36$, $xy + yz = 1$. Using a CAS to solve these 5 equations simultaneously for x, y, z, λ, and μ (in Maple, use the `allvalues` command), we get 4 real-valued solutions:

$x \approx 0.222444,\quad y \approx -2.157012,\quad z \approx -0.686049,\quad \lambda \approx -0.200401,\quad \mu \approx 2.108584$

$x \approx -1.951921,\quad y \approx -0.545867,\quad z \approx 0.119973,\quad \lambda \approx 0.003141,\quad \mu \approx -0.076238$

$x \approx 0.155142,\quad y \approx 0.904622,\quad z \approx 0.950293,\quad \lambda \approx -0.012447,\quad \mu \approx 0.489938$

$x \approx 1.138731,\quad y \approx 1.768057,\quad z \approx -0.573138,\quad \lambda \approx 0.317141,\quad \mu \approx 1.862675$

Substituting these values into f gives $f(0.222444, -2.157012, -0.686049) \approx -5.3506$,

$f(-1.951921, -0.545867, 0.119973) \approx -0.0688$, $f(0.155142, 0.904622, 0.950293) \approx 0.4084$,

$f(1.138731, 1.768057, -0.573138) \approx 9.7938$. Thus the maximum is approximately 9.7938, and the minimum is approximately -5.3506.

48. $f(x, y, z) = x + y + z,\ g(x, y, z) = x^2 - y^2 - z = 0,\ h(x, y, z) = x^2 + z^2 = 4.$

$\nabla f = \lambda \nabla g + \mu \nabla h \quad \Rightarrow \quad \langle 1, 1, 1 \rangle = \lambda \langle 2x, -2y, -1 \rangle + \mu \langle 2x, 0, 2z \rangle$, so $1 = 2\lambda x + 2\mu x$, $1 = -2\lambda y$, $1 = -\lambda + 2\mu z$, $x^2 - y^2 = z$, $x^2 + z^2 = 4$. Using a CAS to solve these 5 equations simultaneously for x, y, z, λ, and μ, we get 4 real-valued solutions:

$$\begin{array}{lllll} x \approx -1.652878, & y \approx -1.964194, & z \approx -1.126052, & \lambda \approx 0.254557, & \mu \approx -0.557060 \\ x \approx -1.502800, & y \approx 0.968872, & z \approx 1.319694, & \lambda \approx -0.516064, & \mu \approx 0.183352 \\ x \approx -0.992513, & y \approx 1.649677, & z \approx -1.736352, & \lambda \approx -0.303090, & \mu \approx -0.200682 \\ x \approx 1.895178, & y \approx 1.718347, & z \approx 0.638984, & \lambda \approx -0.290977, & \mu \approx 0.554805 \end{array}$$

Substituting these values into f gives $f(-1.652878, -1.964194, -1.126052) \approx -4.7431$,

$f(-1.502800, 0.968872, 1.319694) \approx 0.7858$, $f(-0.992513, 1.649677, -1.736352) \approx -1.0792$,

$f(1.895178, 1.718347, 0.638984) \approx 4.2525$. Thus the maximum is approximately 4.2525, and the minimum is approximately -4.7431.

49. (a) We wish to maximize $f(x_1, x_2, \ldots, x_n) = \sqrt[n]{x_1 x_2 \cdots x_n}$ subject to

$g(x_1, x_2, \ldots, x_n) = x_1 + x_2 + \cdots + x_n = c$ and $x_i > 0$.

$\nabla f = \left\langle \frac{1}{n}(x_1 x_2 \cdots x_n)^{\frac{1}{n}-1}(x_2 \cdots x_n), \frac{1}{n}(x_1 x_2 \cdots x_n)^{\frac{1}{n}-1}(x_1 x_3 \cdots x_n), \ldots, \frac{1}{n}(x_1 x_2 \cdots x_n)^{\frac{1}{n}-1}(x_1 \cdots x_{n-1}) \right\rangle$

and $\lambda \nabla g = \langle \lambda, \lambda, \ldots, \lambda \rangle$, so we need to solve the system of equations

$$\begin{aligned} \tfrac{1}{n}(x_1 x_2 \cdots x_n)^{\frac{1}{n}-1}(x_2 \cdots x_n) = \lambda \quad &\Rightarrow \quad x_1^{1/n} x_2^{1/n} \cdots x_n^{1/n} = n\lambda x_1 \\ \tfrac{1}{n}(x_1 x_2 \cdots x_n)^{\frac{1}{n}-1}(x_1 x_3 \cdots x_n) = \lambda \quad &\Rightarrow \quad x_1^{1/n} x_2^{1/n} \cdots x_n^{1/n} = n\lambda x_2 \\ &\vdots \\ \tfrac{1}{n}(x_1 x_2 \cdots x_n)^{\frac{1}{n}-1}(x_1 \cdots x_{n-1}) = \lambda \quad &\Rightarrow \quad x_1^{1/n} x_2^{1/n} \cdots x_n^{1/n} = n\lambda x_n \end{aligned}$$

This implies $n\lambda x_1 = n\lambda x_2 = \cdots = n\lambda x_n$. Note $\lambda \neq 0$, otherwise we can't have all $x_i > 0$. Thus $x_1 = x_2 = \cdots = x_n$.

But $x_1 + x_2 + \cdots + x_n = c \quad \Rightarrow \quad n x_1 = c \quad \Rightarrow \quad x_1 = \dfrac{c}{n} = x_2 = x_3 = \cdots = x_n$. Then the only point where f can have an extreme value is $\left(\dfrac{c}{n}, \dfrac{c}{n}, \ldots, \dfrac{c}{n}\right)$. Since we can choose values for $(x_1, x_2, \ldots, x_n)$ that make f as close to zero (but not equal) as we like, f has no minimum value. Thus the maximum value is

$f\left(\dfrac{c}{n}, \dfrac{c}{n}, \ldots, \dfrac{c}{n}\right) = \sqrt[n]{\dfrac{c}{n} \cdot \dfrac{c}{n} \cdot \cdots \cdot \dfrac{c}{n}} = \dfrac{c}{n}$.

(b) From part (a), $\dfrac{c}{n}$ is the maximum value of f. Thus $f(x_1, x_2, \ldots, x_n) = \sqrt[n]{x_1 x_2 \cdots x_n} \le \dfrac{c}{n}$. But $x_1 + x_2 + \cdots + x_n = c$, so $\sqrt[n]{x_1 x_2 \cdots x_n} \le \dfrac{x_1 + x_2 + \cdots + x_n}{n}$. These two means are equal when f attains its maximum value $\dfrac{c}{n}$, but this can occur only at the point $\left(\dfrac{c}{n}, \dfrac{c}{n}, \ldots, \dfrac{c}{n}\right)$ we found in part (a). So the means are equal only when $x_1 = x_2 = x_3 = \cdots = x_n = \dfrac{c}{n}$.

50. (a) Let $f(x_1, \ldots, x_n, y_1, \ldots, y_n) = \sum\limits_{i=1}^{n} x_i y_i$, $g(x_1, \ldots, x_n) = \sum\limits_{i=1}^{n} x_i^2$, and $h(x_1, \ldots, x_n) = \sum\limits_{i=1}^{n} y_i^2$. Then $\nabla f = \nabla \sum\limits_{i=1}^{n} x_i y_i = \langle y_1, y_2, \ldots, y_n, x_1, x_2, \ldots, x_n \rangle$, $\nabla g = \nabla \sum\limits_{i=1}^{n} x_i^2 = \langle 2x_1, 2x_2, \ldots, 2x_n, 0, 0, \ldots, 0 \rangle$ and $\nabla h = \nabla \sum\limits_{i=1}^{n} y_i^2 = \langle 0, 0, \ldots, 0, 2y_1, 2y_2, \ldots, 2y_n \rangle$. So $\nabla f = \lambda \nabla g + \mu \nabla h \quad \Leftrightarrow \quad y_i = 2\lambda x_i$ and $x_i = 2\mu y_i$, $1 \le i \le n$. Then $1 = \sum\limits_{i=1}^{n} y_i^2 = \sum\limits_{i=1}^{n} 4\lambda^2 x_i^2 = 4\lambda^2 \sum\limits_{i=1}^{n} x_i^2 = 4\lambda^2 \quad \Rightarrow \quad \lambda = \pm\frac{1}{2}$. If $\lambda = \frac{1}{2}$ then $y_i = 2\left(\frac{1}{2}\right)x_i = x_i$, $1 \le i \le n$. Thus $\sum\limits_{i=1}^{n} x_i y_i = \sum\limits_{i=1}^{n} x_i^2 = 1$. Similarly if $\lambda = -\frac{1}{2}$ we get $y_i = -x_i$ and $\sum\limits_{i=1}^{n} x_i y_i = -1$. Similarly we get $\mu = \pm\frac{1}{2}$ giving $y_i = \pm x_i$, $1 \le i \le n$, and $\sum\limits_{i=1}^{n} x_i y_i = \pm 1$. Thus the maximum value of $\sum\limits_{i=1}^{n} x_i y_i$ is 1.

(b) Here we assume $\sum\limits_{i=1}^{n} a_i^2 \ne 0$ and $\sum\limits_{i=1}^{n} b_i^2 \ne 0$. (If $\sum\limits_{i=1}^{n} a_i^2 = 0$, then each $a_i = 0$ and so the inequality is trivially true.)

$x_i = \dfrac{a_i}{\sqrt{\sum a_j^2}} \quad \Rightarrow \quad \sum x_i^2 = \dfrac{\sum a_i^2}{\sum a_j^2} = 1$, and $y_i = \dfrac{b_i}{\sqrt{\sum b_j^2}} \quad \Rightarrow \quad \sum y_i^2 = \dfrac{\sum b_i^2}{\sum b_j^2} = 1$. Therefore, from part (a),

$\sum x_i y_i = \sum \dfrac{a_i b_i}{\sqrt{\sum a_j^2}\sqrt{\sum b_j^2}} \le 1 \quad \Leftrightarrow \quad \sum a_i b_i \le \sqrt{\sum a_j^2}\sqrt{\sum b_j^2}$.

APPLIED PROJECT Rocket Science

1. Initially the rocket engine has mass $M_r = M_1$ and payload mass $P = M_2 + M_3 + A$. Then the change in velocity resulting from the first stage is $\Delta V_1 = -c \ln\left(1 - \dfrac{(1-S)M_1}{M_2 + M_3 + A + M_1}\right)$. After the first stage is jettisoned we can consider the rocket engine to have mass $M_r = M_2$ and the payload to have mass $P = M_3 + A$. The resulting change in velocity from the second stage is $\Delta V_2 = -c \ln\left(1 - \dfrac{(1-S)M_2}{M_3 + A + M_2}\right)$. When only the third stage remains, we have $M_r = M_3$ and $P = A$, so the resulting change in velocity is $\Delta V_3 = -c \ln\left(1 - \dfrac{(1-S)M_3}{A + M_3}\right)$. Since the rocket started from rest, the final velocity attained is

$$\begin{aligned}
v_f &= \Delta V_1 + \Delta V_2 + \Delta V_3 \\
&= -c\ln\left(1 - \frac{(1-S)M_1}{M_2+M_3+A+M_1}\right) + (-c)\ln\left(1 - \frac{(1-S)M_2}{M_3+A+M_2}\right) + (-c)\ln\left(1 - \frac{(1-S)M_3}{A+M_3}\right) \\
&= -c\left[\ln\left(\frac{M_1+M_2+M_3+A-(1-S)M_1}{M_1+M_2+M_3+A}\right) + \ln\left(\frac{M_2+M_3+A-(1-S)M_2}{M_2+M_3+A}\right) \right. \\
&\qquad \left. + \ln\left(\frac{M_3+A-(1-S)M_3}{M_3+A}\right)\right] \\
&= c\left[\ln\left(\frac{M_1+M_2+M_3+A}{SM_1+M_2+M_3+A}\right) + \ln\left(\frac{M_2+M_3+A}{SM_2+M_3+A}\right) + \ln\left(\frac{M_3+A}{SM_3+A}\right)\right]
\end{aligned}$$

2. Define $N_1 = \dfrac{M_1+M_2+M_3+A}{SM_1+M_2+M_3+A}$, $N_2 = \dfrac{M_2+M_3+A}{SM_2+M_3+A}$, and $N_3 = \dfrac{M_3+A}{SM_3+A}$. Then

$$\begin{aligned}
\frac{(1-S)N_1}{1-SN_1} &= \frac{(1-S)\,\dfrac{M_1+M_2+M_3+A}{SM_1+M_2+M_3+A}}{1-S\,\dfrac{M_1+M_2+M_3+A}{SM_1+M_2+M_3+A}} = \frac{(1-S)(M_1+M_2+M_3+A)}{SM_1+M_2+M_3+A-S(M_1+M_2+M_3+A)} \\
&= \frac{(1-S)(M_1+M_2+M_3+A)}{(1-S)(M_2+M_3+A)} = \frac{M_1+M_2+M_3+A}{M_2+M_3+A}
\end{aligned}$$

as desired.

Similarly,

$$\frac{(1-S)N_2}{1-SN_2} = \frac{(1-S)(M_2+M_3+A)}{SM_2+M_3+A-S(M_2+M_3+A)} = \frac{(1-S)(M_2+M_3+A)}{(1-S)(M_3+A)} = \frac{M_2+M_3+A}{M_3+A}$$

and
$$\frac{(1-S)N_3}{1-SN_3} = \frac{(1-S)(M_3+A)}{SM_3+A-S(M_3+A)} = \frac{(1-S)(M_3+A)}{(1-S)(A)} = \frac{M_3+A}{A}$$

Then

$$\begin{aligned}
\frac{M+A}{A} &= \frac{M_1+M_2+M_3+A}{A} = \frac{M_1+M_2+M_3+A}{M_2+M_3+A}\cdot\frac{M_2+M_3+A}{M_3+A}\cdot\frac{M_3+A}{A} \\
&= \frac{(1-S)N_1}{1-SN_1}\cdot\frac{(1-S)N_2}{1-SN_2}\cdot\frac{(1-S)N_3}{1-SN_3} = \frac{(1-S)^3N_1N_2N_3}{(1-SN_1)(1-SN_2)(1-SN_3)}
\end{aligned}$$

3. Since $A > 0$, $M + A$ and consequently $\dfrac{M+A}{A}$ is minimized for the same values as M. $\ln x$ is a strictly increasing function, so $\ln\left(\dfrac{M+A}{A}\right)$ must give a minimum for the same values as $\dfrac{M+A}{A}$ and hence M. We then wish to minimize $\ln\left(\dfrac{M+A}{A}\right)$ subject to the constraint $c\,(\ln N_1 + \ln N_2 + \ln N_3) = v_f$. From Problem 2,

$$\begin{aligned}
\ln\left(\frac{M+A}{A}\right) &= \ln\left(\frac{(1-S)^3\,N_1N_2N_3}{(1-SN_1)\,(1-SN_2)\,(1-SN_3)}\right) \\
&= 3\ln(1-S) + \ln N_1 + \ln N_2 + \ln N_3 - \ln(1-SN_1) - \ln(1-SN_2) - \ln(1-SN_3)
\end{aligned}$$

Using the method of Lagrange multipliers, we need to solve $\nabla\left[\ln\left(\frac{M+A}{A}\right)\right] = \lambda\nabla[c(\ln N_1 + \ln N_2 + \ln N_3)]$ with $c(\ln N_1 + \ln N_2 + \ln N_3) = v_f$ in terms of N_1, N_2, and N_3. The resulting system is

$$\frac{1}{N_1} + \frac{S}{1-SN_1} = \lambda\frac{c}{N_1} \qquad \frac{1}{N_2} + \frac{S}{1-SN_2} = \lambda\frac{c}{N_2} \qquad \frac{1}{N_3} + \frac{S}{1-SN_3} = \lambda\frac{c}{N_3}$$

$$c\,(\ln N_1 + \ln N_2 + \ln N_3) = v_f$$

One approach to solving the system is isolating $c\lambda$ in the first three equations which gives

$1 + \frac{SN_1}{1-SN_1} = c\lambda = 1 + \frac{SN_2}{1-SN_2} = 1 + \frac{SN_3}{1-SN_3} \quad\Rightarrow\quad \frac{N_1}{1-SN_1} = \frac{N_2}{1-SN_2} = \frac{N_3}{1-SN_3} \quad\Rightarrow$

$N_1 = N_2 = N_3$ (Verify!). This says the fourth equation can be expressed as $c(\ln N_1 + \ln N_1 + \ln N_1) = v_f \quad\Rightarrow$

$3c\ln N_1 = v_f \quad\Rightarrow\quad \ln N_1 = \frac{v_f}{3c}$. Thus the minimum mass M of the rocket engine is attained for

$N_1 = N_2 = N_3 = e^{v_f/(3c)}$.

4. Using the previous results, $\frac{M+A}{A} = \frac{(1-S)^3 N_1 N_2 N_3}{(1-SN_1)(1-SN_2)(1-SN_3)} = \frac{(1-S)^3\left[e^{v_f/(3c)}\right]^3}{\left[1-Se^{v_f/(3c)}\right]^3} = \frac{(1-S)^3 e^{v_f/c}}{\left[1-Se^{v_f/(3c)}\right]^3}$.

Then $M = \frac{A(1-S)^3 e^{v_f/c}}{\left[1-Se^{v_f/(3c)}\right]^3} - A$.

5. (a) From Problem 4, $M = \frac{A(1-0.2)^3 e^{(17{,}500/6000)}}{\left(1-0.2e^{[17{,}500/(3\cdot 6000)]}\right)^3} - A \approx 90.4A - A = 89.4A$.

(b) First, $N_3 = \frac{M_3+A}{SM_3+A} \quad\Rightarrow\quad e^{[17{,}500/(3\cdot 6000)]} = \frac{M_3+A}{0.2M_3+A} \quad\Rightarrow\quad M_3 = \frac{A(1-e^{35/36})}{0.2e^{35/36}-1} \approx 3.49A$.

Then $N_2 = \frac{M_2+M_3+A}{SM_2+M_3+A} = \frac{M_2+3.49A+A}{0.2M_2+3.49A+A} \quad\Rightarrow\quad M_2 = \frac{4.49A(1-e^{35/36})}{0.2e^{35/36}-1} \approx 15.67A$ and

$N_3 = \frac{M_1+M_2+M_3+A}{SM_1+M_2+M_3+A} = \frac{M_1+15.67A+3.49A+A}{0.2M_1+15.67A+3.49A+A} \quad\Rightarrow\quad M_1 = \frac{20.16A(1-e^{35/36})}{0.2e^{35/36}-1} \approx 70.36A$.

6. As in Problem 5, $N_3 = \frac{M_3+A}{SM_3+A} \quad\Rightarrow\quad e^{24{,}700/(3\cdot 6000)} = \frac{M_3+A}{0.2M_3+A} \quad\Rightarrow\quad M_3 = \frac{A(1-e^{247/180})}{0.2e^{247/180}-1} \approx 13.9A$,

$N_2 = \frac{M_2+M_3+A}{SM_2+M_3+A} = \frac{M_2+13.9A+A}{0.2M_2+13.9A+A} \quad\Rightarrow\quad M_2 = \frac{14.9A(1-e^{247/180})}{0.2e^{247/180}-1} \approx 208A$, and

$N_3 = \frac{M_1+M_2+M_3+A}{SM_1+M_2+M_3+A} = \frac{M_1+208A+13.9A+A}{0.2M_1+208A+13.9A+A} \quad\Rightarrow\quad M_1 = \frac{222.9A(1-e^{247/180})}{0.2e^{247/180}-1} \approx 3110A$.

Here $A = 500$, so the mass of each stage of the rocket engine is approximately $M_1 = 3110(500) = 1{,}550{,}000$ lb, $M_2 = 208(500) = 104{,}000$ lb, and $M_3 = 13.9(500) = 6950$ lb.

APPLIED PROJECT Hydro-Turbine Optimization

1. We wish to maximize the total energy production for a given total flow, so we can say Q_T is fixed and we want to maximize $KW_1 + KW_2 + KW_3$. Notice each KW_i has a constant factor $\left(170 - 1.6 \cdot 10^{-6} Q_T^2\right)$, so to simplify the computations we can equivalently maximize

$$\begin{aligned} f(Q_1, Q_2, Q_3) &= \frac{KW_1 + KW_2 + KW_3}{170 - 1.6 \cdot 10^{-6} Q_T^2} \\ &= \left(-18.89 + 0.1277 Q_1 - 4.08 \cdot 10^{-5} Q_1^2\right) + \left(-24.51 + 0.1358 Q_2 - 4.69 \cdot 10^{-5} Q_2^2\right) \\ &\qquad + \left(-27.02 + 0.1380 Q_3 - 3.84 \cdot 10^{-5} Q_3^2\right) \end{aligned}$$

subject to the constraint $g(Q_1, Q_2, Q_3) = Q_1 + Q_2 + Q_3 = Q_T$. So first we find the values of Q_1, Q_2, Q_3 where $\nabla f(Q_1, Q_2, Q_3) = \lambda \nabla g(Q_1, Q_2, Q_3)$ and $Q_1 + Q_2 + Q_3 = Q_T$ which is equivalent to solving the system

$$\begin{aligned} 0.1277 - 2(4.08 \cdot 10^{-5}) Q_1 &= \lambda \\ 0.1358 - 2(4.69 \cdot 10^{-5}) Q_2 &= \lambda \\ 0.1380 - 2(3.84 \cdot 10^{-5}) Q_3 &= \lambda \\ Q_1 + Q_2 + Q_3 &= Q_T \end{aligned}$$

Comparing the first and third equations, we have $0.1277 - 2(4.08 \cdot 10^{-5}) Q_1 = 0.1380 - 2(3.84 \cdot 10^{-5}) Q_3 \quad \Rightarrow$ $Q_1 = -126.2255 + 0.9412 Q_3$. From the second and third equations, $0.1358 - 2(4.69 \cdot 10^{-5}) Q_2 = 0.1380 - 2(3.84 \cdot 10^{-5}) Q_3 \quad \Rightarrow \quad Q_2 = -23.4542 + 0.8188 Q_3$. Substituting into $Q_1 + Q_2 + Q_3 = Q_T$ gives $(-126.2255 + 0.9412 Q_3) + (-23.4542 + 0.8188 Q_3) + Q_3 = Q_T \quad \Rightarrow$ $2.76 Q_3 = Q_T + 149.6797 \quad \Rightarrow \quad Q_3 = 0.3623 Q_T + 54.23$. Then $Q_1 = -126.2255 + 0.9412 Q_3 = -126.2255 + 0.9412(0.3623 Q_T + 54.23) = 0.3410 Q_T - 75.18$ and $Q_2 = -23.4542 + 0.8188(0.3623 Q_T + 54.23) = 0.2967 Q_T + 20.95$. As long as we maintain $250 \le Q_1 \le 1110$, $250 \le Q_2 \le 1110$, and $250 \le Q_3 \le 1225$, we can reason from the nature of the functions KW_i that these values give a maximum of f, and hence a maximum energy production, and not a minimum.

2. From Problem 1, the value of Q_1 that maximizes energy production is $0.3410 Q_T - 75.18$, but since $250 \le Q_1 \le 1110$, we must have $250 \le 0.3410 Q_T - 75.18 \le 1110 \quad \Rightarrow \quad 325.18 \le 0.3410 Q_T \le 1185.18 \quad \Rightarrow \quad 953.6 \le Q_T \le 3475.6$. Similarly, $250 \le Q_2 \le 1110 \quad \Rightarrow \quad 250 \le 0.2967 Q_T + 20.95 \le 1110 \quad \Rightarrow \quad 772.0 \le Q_T \le 3670.5$, and $250 \le Q_3 \le 1225 \quad \Rightarrow \quad 250 \le 0.3623 Q_T + 54.23 \le 1225 \quad \Rightarrow \quad 540.4 \le Q_T \le 3231.5$. Consolidating these results, we see that the values from Problem 1 are applicable only for $953.6 \le Q_T \le 3231.5$.

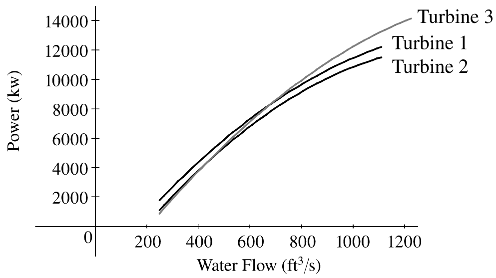
3. If $Q_T = 2500$, the results from Problem 1 show that the maximum energy production occurs for

$$\begin{aligned} Q_1 &= 0.3410 Q_T - 75.18 = 0.3410(2500) - 75.18 = 777.3 \\ Q_2 &= 0.2967 Q_T + 20.95 = 0.2967(2500) + 20.95 = 762.7 \\ Q_3 &= 0.3623 Q_T + 54.23 = 0.3623(2500) + 54.23 = 960.0 \end{aligned}$$

The energy produced for these values is $KW_1 + KW_2 + KW_3 \approx 8915.2 + 8285.1 + 11{,}211.3 \approx 28{,}411.6$.

We compute the energy production for a nearby distribution, $Q_1 = 770$, $Q_2 = 760$, and $Q_3 = 970$: $KW_1 + KW_2 + KW_3 \approx 8839.8 + 8257.4 + 11{,}313.5 = 28{,}410.7$. For another example, we take $Q_1 = 780$, $Q_2 = 765$, and $Q_3 = 955$: $KW_1 + KW_2 + KW_3 \approx 8942.9 + 8308.8 + 11{,}159.7 = 28{,}411.4$. These distributions are both close to the distribution from Problem 1 and both give slightly lower energy productions, suggesting that $Q_1 = 777.3$, $Q_2 = 762.7$, and $Q_3 = 960.0$ is indeed the optimal distribution.

4. First we graph each power function in its domain if all of the flow is directed to that turbine (so $Q_i = Q_T$). If we use only one turbine, the graph indicates that for a water flow of 1000 ft^3/s, Turbine 3 produces the most power, approximately 12,200 kW. In comparison, if we use all three turbines, the results of Problem 1 with $Q_T = 1000$ give $Q_1 = 265.8$, $Q_2 = 317.7$, and $Q_3 = 416.5$, resulting in a total energy production of $KW_1 + KW_2 + KW_3 \approx 8397.4$ kW. Here, using only one turbine produces significantly more energy! If the flow is only 600 ft^3/s, we do not have the option of using all three turbines, as the domain restrictions require a minimum of 250 ft^3/s in each turbine. We can use just one turbine, then, and from the graph Turbine 1 produces the most energy for a water flow of 600 ft^3.



5. If we examine the graph from Problem 4, we see that for water flows above approximately 450 ft^3/s, Turbine 2 produces the least amount of power. Therefore it seems reasonable to assume that we should distribute the incoming flow of 1500 ft^3/s between Turbines 1 and 3. (This can be verified by computing the power produced with the other pairs of turbines for comparison.) So now we wish to maximize $KW_1 + KW_3$ subject to the constraint $Q_1 + Q_3 = Q_T$ where $Q_T = 1500$.

As in Problem 1, we can equivalently maximize

$$\begin{aligned} f(Q_1, Q_3) &= \frac{KW_1 + KW_3}{170 - 1.6 \cdot 10^{-6} Q_T^2} \\ &= \left(-18.89 + 0.1277Q_1 - 4.08 \cdot 10^{-5} Q_1^2\right) + \left(-27.02 + 0.1380Q_3 - 3.84 \cdot 10^{-5} Q_3^2\right) \end{aligned}$$

subject to the constraint $g(Q_1, Q_3) = Q_1 + Q_3 = Q_T$.

Then we solve $\nabla f(Q_1, Q_3) = \lambda \nabla g(Q_1, Q_3) \quad \Rightarrow \quad 0.1277 - 2\left(4.08 \cdot 10^{-5}\right) Q_1 = \lambda$ and $0.1380 - 2(3.84 \cdot 10^{-5})Q_3 = \lambda$, thus $0.1277 - 2(4.08 \cdot 10^{-5})Q_1 = 0.1380 - 2(3.84 \cdot 10^{-5})Q_3 \quad \Rightarrow$ $Q_1 = -126.2255 + 0.9412Q_3$. Substituting into $Q_1 + Q_3 = Q_T$ gives $-126.2255 + 0.9412Q_3 + Q_3 = 1500 \quad \Rightarrow$ $Q_3 \approx 837.7$, and then $Q_1 = Q_T - Q_3 \approx 1500 - 837.7 = 662.3$. So we should apportion approximately 662.3 ft^3/s to Turbine 1 and the remaining 837.7 ft^3/s to Turbine 3. The resulting energy production is $KW_1 + KW_3 \approx 7952.1 + 10{,}256.2 = 18{,}208.3$ kW. (We can verify that this is indeed a maximum energy production by checking nearby distributions.) In comparison, if we use all three turbines with $Q_T = 1500$ we get $Q_1 = 436.3$, $Q_2 = 466.0$, and $Q_3 = 597.7$, resulting in a total energy production of $KW_1 + KW_2 + KW_3 \approx$ 16,538.7 kW. Clearly, for this flow level it is beneficial to use only two turbines.

6. Note that an incoming flow of 3400 ft^3/s is not within the domain we established in Problem 2, so we cannot simply use our previous work to give the optimal distribution. We will need to use all three turbines, due to the capacity limitations of each individual turbine, but 3400 is less than the maximum combined capacity of 3445 ft^3/s, so we still must decide how to distribute the flows. From the graph in Problem 4, Turbine 3 produces the most power for the higher flows, so it seems reasonable to use Turbine 3 at its maximum capacity of 1225 and distribute the remaining 2175 ft^3/s flow between Turbines 1 and 2. We can again use the technique of Lagrange multipliers to determine the optimal distribution. Following the procedure we used in Problem 5, we wish to maximize $KW_1 + KW_2$ subject to the constraint $Q_1 + Q_2 = Q_T$ where $Q_T = 2175$. We can equivalently maximize

$$f(Q_1, Q_2) = \frac{KW_1 + KW_2}{170 - 1.6 \cdot 10^{-6} Q_T^2}$$
$$= \left(-18.89 + 0.1277Q_1 - 4.08 \cdot 10^{-5} Q_1^2\right) + \left(-24.51 + 0.1358Q_2 - 4.69 \cdot 10^{-5} Q_2^2\right)$$

subject to the constraint $g(Q_1, Q_2) = Q_1 + Q_2 = Q_T$. Then we solve $\nabla f(Q_1, Q_2) = \lambda \nabla g(Q_1, Q_2) \quad \Rightarrow$
$0.1277 - 2(4.08 \cdot 10^{-5})Q_1 = \lambda$ and $0.1358 - 2(4.69 \cdot 10^{-5})Q_2 = \lambda$, thus
$0.1277 - 2(4.08 \cdot 10^{-5})Q_1 = 0.1358 - 2\left(4.69 \cdot 10^{-5}\right)Q_2 \quad \Rightarrow \quad Q_1 = -99.2647 + 1.1495Q_2$. Substituting into $Q_1 + Q_2 = Q_T$ gives $-99.2647 + 1.1495Q_2 + Q_2 = 2175 \quad \Rightarrow \quad Q_2 \approx 1058.0$, and then $Q_1 \approx 1117.0$. This value for Q_1 is larger than the allowable maximum flow to Turbine 1, but the result indicates that the flow to Turbine 1 should be maximized. Thus we should recommend that the company apportion the maximum allowable flows to Turbines 1 and 3, 1110 and 1225 ft^3/s, and the remaining 1065 ft^3/s to Turbine 2. Checking nearby distributions within the domain verifies that we have indeed found the optimal distribution.

14 Review

TRUE-FALSE QUIZ

1. True. $f_y(a, b) = \lim\limits_{h \to 0} \dfrac{f(a, b + h) - f(a, b)}{h}$ from Equation 14.3.3. Let $h = y - b$. As $h \to 0$, $y \to b$. Then by substituting, we get $f_y(a, b) = \lim\limits_{y \to b} \dfrac{f(a, y) - f(a, b)}{y - b}$.

2. False. If there were such a function, then $f_{xy} = 2y$ and $f_{yx} = 1$. So $f_{xy} \neq f_{yx}$, which contradicts Clairaut's Theorem.

3. False. $f_{xy} = \dfrac{\partial^2 f}{\partial y \, \partial x}$.

4. True. From Equation 14.6.14 we get $D_{\mathbf{k}}\, f(x, y, z) = \nabla f(x, y, z) \cdot \langle 0, 0, 1 \rangle = f_z(x, y, z)$.

5. False. See Example 14.2.3.

6. False. See Exercise 14.4.46(a).

7. True. If f has a local minimum and f is differentiable at (a, b) then by Theorem 14.7.2, $f_x(a, b) = 0$ and $f_y(a, b) = 0$, so $\nabla f(a, b) = \langle f_x(a, b), f_y(a, b) \rangle = \langle 0, 0 \rangle = \mathbf{0}$.

8. False. If f is not continuous at $(2, 5)$, then we can have $\lim_{(x,y)\to(2,5)} f(x, y) \neq f(2, 5)$. (See Example 14.2.7)

9. False. $\nabla f(x, y) = \langle 0, 1/y \rangle$.

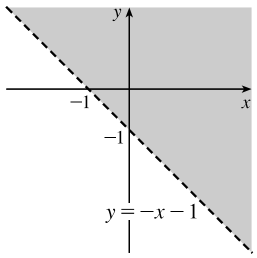
10. True. This is part (c) of the Second Derivatives Test (14.7.3).

11. True. $\nabla f = \langle \cos x, \cos y \rangle$, so $|\nabla f| = \sqrt{\cos^2 x + \cos^2 y}$. But $|\cos\theta| \leq 1$, so $|\nabla f| \leq \sqrt{2}$. Now $D_{\mathbf{u}}\, f(x, y) = \nabla f \cdot \mathbf{u} = |\nabla f|\, |\mathbf{u}| \cos\theta$, but $\mathbf{u}$ is a unit vector, so $|D_{\mathbf{u}}\, f(x, y)| \leq \sqrt{2} \cdot 1 \cdot 1 = \sqrt{2}$.

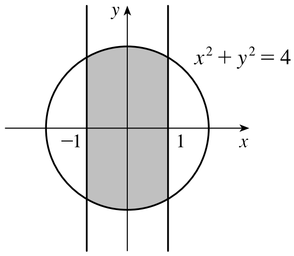
12. False. See Exercise 14.7.39.

EXERCISES

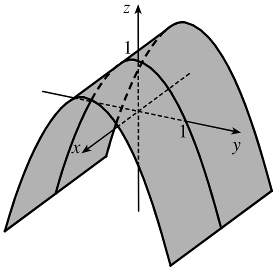
1. $\ln(x + y + 1)$ is defined only when $x + y + 1 > 0 \quad \Leftrightarrow \quad y > -x - 1$, so the domain of f is $\{(x, y) \mid y > -x - 1\}$, all those points above the line $y = -x - 1$.



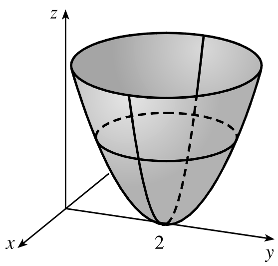
2. $\sqrt{4 - x^2 - y^2}$ is defined only when $4 - x^2 - y^2 \geq 0 \quad \Leftrightarrow \quad x^2 + y^2 \leq 4$, and $\sqrt{1 - x^2}$ is defined only when $1 - x^2 \geq 0 \quad \Leftrightarrow \quad -1 \leq x \leq 1$, so the domain of f is $\left\{(x, y) \mid -1 \leq x \leq 1, -\sqrt{4 - x^2} \leq y \leq \sqrt{4 - x^2}\right\}$, which consists of those points on or inside the circle $x^2 + y^2 = 4$ for $-1 \leq x \leq 1$.



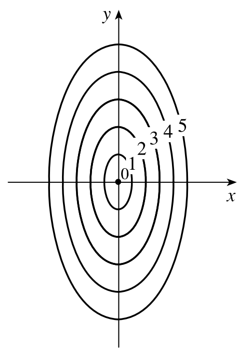
3. $z = f(x, y) = 1 - y^2$, a parabolic cylinder



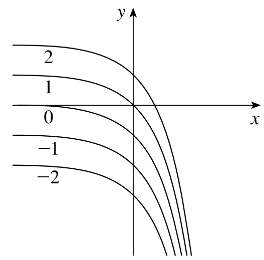
4. $z = f(x, y) = x^2 + (y - 2)^2$, a circular paraboloid with vertex $(0, 2, 0)$ and axis parallel to the z-axis



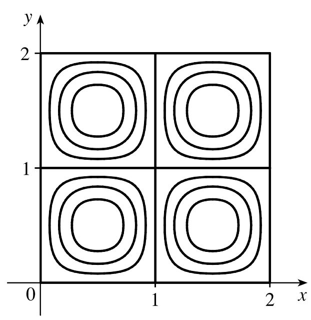
5. The level curves are $\sqrt{4x^2 + y^2} = k$ or $4x^2 + y^2 = k^2$, $k \geq 0$, a family of ellipses.



6. The level curves are $e^x + y = k$ or $y = -e^x + k$, a family of exponential curves.



7.



8. (a) The point $(3, 2)$ lies partway between the level curves with z-values 50 and 60, and it appears that $(3, 2)$ is about the same distance from either level curve. So we estimate that $f(3, 2) \approx 55$.

(b) At the point $(3, 2)$, if we fix y at $y = 2$ and allow x to vary, the level curves indicate that the z-values decrease as x increases, so $f_x(3, 2)$ is negative. In other words, if we start at $(3, 2)$ and move right (in the positive x-direction), the contours show that our path along the surface $z = f(x, y)$ is descending.

(c) Both $f_y(2, 1)$ and $f_y(2, 2)$ are positive, because if we start from either point and move in the positive y-direction, the contour map indicates that the path is ascending. But the level curves are closer together in the y-direction at $(2, 1)$ than at $(2, 2)$, so the path is steeper (the z-values increase more rapidly) at $(2, 1)$ and hence $f_y(2, 1) > f_y(2, 2)$.

9. f is a rational function, so it is continuous on its domain. Since f is defined at $(1, 1)$, we use direct substitution to evaluate the limit: $\displaystyle\lim_{(x,y)\to(1,1)} \frac{2xy}{x^2 + 2y^2} = \frac{2(1)(1)}{1^2 + 2(1)^2} = \frac{2}{3}$.

10. As $(x, y) \to (0, 0)$ along the x-axis, $f(x, 0) = 0/x^2 = 0$ for $x \neq 0$, so $f(x, y) \to 0$ along this line. But $f(x, x) = 2x^2/(3x^2) = \frac{2}{3}$, so as $(x, y) \to (0, 0)$ along the line $x = y$, $f(x, y) \to \frac{2}{3}$. Thus the limit doesn't exist.

11. (a) $T_x(6, 4) = \displaystyle\lim_{h\to 0} \frac{T(6 + h, 4) - T(6, 4)}{h}$, so we can approximate $T_x(6, 4)$ by considering $h = \pm 2$ and using the values given in the table: $T_x(6, 4) \approx \dfrac{T(8, 4) - T(6, 4)}{2} = \dfrac{86 - 80}{2} = 3$,

$T_x(6,4) \approx \dfrac{T(4,4)-T(6,4)}{-2} = \dfrac{72-80}{-2} = 4$. Averaging these values, we estimate $T_x(6,4)$ to be approximately 3.5°C/m. Similarly, $T_y(6,4) = \lim\limits_{h\to 0} \dfrac{T(6,4+h)-T(6,4)}{h}$, which we can approximate with $h = \pm 2$:

$T_y(6,4) \approx \dfrac{T(6,6)-T(6,4)}{2} = \dfrac{75-80}{2} = -2.5$, $T_y(6,4) \approx \dfrac{T(6,2)-T(6,4)}{-2} = \dfrac{87-80}{-2} = -3.5$. Averaging these values, we estimate $T_y(6,4)$ to be approximately -3.0°C/m.

(b) Here $\mathbf{u} = \left\langle \frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}} \right\rangle$, so by Equation 14.6.9, $D_{\mathbf{u}}\,T(6,4) = \nabla T(6,4)\cdot\mathbf{u} = T_x(6,4)\,\frac{1}{\sqrt{2}} + T_y(6,4)\,\frac{1}{\sqrt{2}}$. Using our estimates from part (a), we have $D_{\mathbf{u}}\,T(6,4) \approx (3.5)\,\frac{1}{\sqrt{2}} + (-3.0)\,\frac{1}{\sqrt{2}} = \frac{1}{2\sqrt{2}} \approx 0.35$. This means that as we move through the point $(6,4)$ in the direction of $\mathbf{u}$, the temperature increases at a rate of approximately 0.35°C/m.

Alternatively, we can use Definition 14.6.2: $D_{\mathbf{u}}\,T(6,4) = \lim\limits_{h\to 0} \dfrac{T\left(6 + h\,\frac{1}{\sqrt{2}}, 4 + h\,\frac{1}{\sqrt{2}}\right) - T(6,4)}{h}$,

which we can estimate with $h = \pm 2\sqrt{2}$. Then $D_{\mathbf{u}}\,T(6,4) \approx \dfrac{T(8,6)-T(6,4)}{2\sqrt{2}} = \dfrac{80-80}{2\sqrt{2}} = 0$,

$D_{\mathbf{u}}\,T(6,4) \approx \dfrac{T(4,2)-T(6,4)}{-2\sqrt{2}} = \dfrac{74-80}{-2\sqrt{2}} = \dfrac{3}{\sqrt{2}}$. Averaging these values, we have $D_{\mathbf{u}}\,T(6,4) \approx \frac{3}{2\sqrt{2}} \approx 1.1^\circ\text{C/m}$.

(c) $T_{xy}(x,y) = \dfrac{\partial}{\partial y}\left[T_x(x,y)\right] = \lim\limits_{h\to 0} \dfrac{T_x(x,y+h)-T_x(x,y)}{h}$, so $T_{xy}(6,4) = \lim\limits_{h\to 0} \dfrac{T_x(6,4+h)-T_x(6,4)}{h}$ which we can estimate with $h = \pm 2$. We have $T_x(6,4) \approx 3.5$ from part (a), but we will also need values for $T_x(6,6)$ and $T_x(6,2)$. If we use $h = \pm 2$ and the values given in the table, we have

$T_x(6,6) \approx \dfrac{T(8,6)-T(6,6)}{2} = \dfrac{80-75}{2} = 2.5$, $T_x(6,6) \approx \dfrac{T(4,6)-T(6,6)}{-2} = \dfrac{68-75}{-2} = 3.5$.

Averaging these values, we estimate $T_x(6,6) \approx 3.0$. Similarly,

$T_x(6,2) \approx \dfrac{T(8,2)-T_x(6,2)}{2} = \dfrac{90-87}{2} = 1.5$, $T_x(6,2) \approx \dfrac{T(4,2)-T(6,2)}{-2} = \dfrac{74-87}{-2} = 6.5$.

Averaging these values, we estimate $T_x(6,2) \approx 4.0$. Finally, we estimate $T_{xy}(6,4)$:

$T_{xy}(6,4) \approx \dfrac{T_x(6,6)-T_x(6,4)}{2} = \dfrac{3.0-3.5}{2} = -0.25$, $T_{xy}(6,4) \approx \dfrac{T_x(6,2)-T_x(6,4)}{-2} = \dfrac{4.0-3.5}{-2} = -0.25$.

Averaging these values, we have $T_{xy}(6,4) \approx -0.25$.

12. From the table, $T(6,4) = 80$, and from Exercise 11 we estimated $T_x(6,4) \approx 3.5$ and $T_y(6,4) \approx -3.0$. The linear approximation then is

$$T(x,y) \approx T(6,4) + T_x(6,4)(x-6) + T_y(6,4)(y-4) \approx 80 + 3.5(x-6) - 3(y-4) = 3.5x - 3y + 71$$

Thus at the point $(5,3.8)$, we can use the linear approximation to estimate $T(5,3.8) \approx 3.5(5) - 3(3.8) + 71 \approx 77.1^\circ\text{C}$.

13. $f(x,y) = (5y^3 + 2x^2y)^8 \quad\Rightarrow\quad f_x = 8(5y^3+2x^2y)^7(4xy) = 32xy(5y^3+2x^2y)^7$,

$f_y = 8(5y^3+2x^2y)^7(15y^2+2x^2) = (16x^2+120y^2)(5y^3+2x^2y)^7$

14. $g(u,v) = \dfrac{u+2v}{u^2+v^2} \quad\Rightarrow\quad g_u = \dfrac{(u^2+v^2)(1)-(u+2v)(2u)}{(u^2+v^2)^2} = \dfrac{v^2-u^2-4uv}{(u^2+v^2)^2},$

$$g_v = \frac{(u^2+v^2)(2)-(u+2v)(2v)}{(u^2+v^2)^2} = \frac{2u^2-2v^2-2uv}{(u^2+v^2)^2}$$

15. $F(\alpha,\beta) = \alpha^2\ln(\alpha^2+\beta^2) \quad\Rightarrow\quad F_\alpha = \alpha^2\cdot\dfrac{1}{\alpha^2+\beta^2}\,(2\alpha) + \ln(\alpha^2+\beta^2)\cdot 2\alpha = \dfrac{2\alpha^3}{\alpha^2+\beta^2} + 2\alpha\ln(\alpha^2+\beta^2),$

$$F_\beta = \alpha^2\cdot\frac{1}{\alpha^2+\beta^2}\,(2\beta) = \frac{2\alpha^2\beta}{\alpha^2+\beta^2}$$

16. $G(x,y,z) = e^{xz}\sin(y/z) \quad\Rightarrow\quad G_x = ze^{xz}\sin(y/z),\ G_y = e^{xz}\cos(y/z)(1/z) = (e^{xz}/z)\cos(y/z),$

$$G_z = e^{xz}\cdot\cos(y/z)(-y/z^2) + \sin(y/z)\cdot xe^{xz} = e^{xz}\left[x\sin(y/z) - (y/z^2)\cos(y/z)\right]$$

17. $S(u,v,w) = u\arctan(v\sqrt{w}) \quad\Rightarrow\quad S_u = \arctan(v\sqrt{w}),\ S_v = u\cdot\dfrac{1}{1+(v\sqrt{w})^2}\,(\sqrt{w}) = \dfrac{u\sqrt{w}}{1+v^2w},$

$$S_w = u\cdot\frac{1}{1+(v\sqrt{w})^2}\left(v\cdot\tfrac{1}{2}w^{-1/2}\right) = \frac{uv}{2\sqrt{w}\,(1+v^2w)}$$

18. $C = 1449.2 + 4.6T - 0.055T^2 + 0.00029T^3 + (1.34 - 0.01T)(S-35) + 0.016D \quad\Rightarrow$
$\partial C/\partial T = 4.6 - 0.11T + 0.00087T^2 - 0.01(S-35)$, $\partial C/\partial S = 1.34 - 0.01T$, and $\partial C/\partial D = 0.016$. When $T = 10$, $S = 35$, and $D = 100$ we have $\partial C/\partial T = 4.6 - 0.11(10) + 0.00087(10)^2 - 0.01(35-35) \approx 3.587$, thus in 10°C water with salinity 35 parts per thousand and a depth of 100 m, the speed of sound increases by about 3.59 m/s for every degree Celsius that the water temperature rises. Similarly, $\partial C/\partial S = 1.34 - 0.01(10) = 1.24$, so the speed of sound increases by about 1.24 m/s for every part per thousand the salinity of the water increases. $\partial C/\partial D = 0.016$, so the speed of sound increases by about 0.016 m/s for every meter that the depth is increased.

19. $f(x,y) = 4x^3 - xy^2 \quad\Rightarrow\quad f_x = 12x^2 - y^2,\ f_y = -2xy,\ f_{xx} = 24x,\ f_{yy} = -2x,\ f_{xy} = f_{yx} = -2y$

20. $z = xe^{-2y} \quad\Rightarrow\quad z_x = e^{-2y},\ z_y = -2xe^{-2y},\ z_{xx} = 0,\ z_{yy} = 4xe^{-2y},\ z_{xy} = z_{yx} = -2e^{-2y}$

21. $f(x,y,z) = x^ky^lz^m \quad\Rightarrow\quad f_x = kx^{k-1}y^lz^m,\ f_y = lx^ky^{l-1}z^m,\ f_z = mx^ky^lz^{m-1},\ f_{xx} = k(k-1)x^{k-2}y^lz^m,$
$f_{yy} = l(l-1)x^ky^{l-2}z^m,\ f_{zz} = m(m-1)x^ky^lz^{m-2},\ f_{xy} = f_{yx} = klx^{k-1}y^{l-1}z^m, f_{xz} = f_{zx} = kmx^{k-1}y^lz^{m-1},$
$f_{yz} = f_{zy} = lmx^ky^{l-1}z^{m-1}$

22. $v = r\cos(s+2t) \quad\Rightarrow\quad v_r = \cos(s+2t),\ v_s = -r\sin(s+2t),\ v_t = -2r\sin(s+2t),\ v_{rr} = 0,\ v_{ss} = -r\cos(s+2t),$
$v_{tt} = -4r\cos(s+2t),\ v_{rs} = v_{sr} = -\sin(s+2t),\ v_{rt} = v_{tr} = -2\sin(s+2t),\ v_{st} = v_{ts} = -2r\cos(s+2t)$

23. $z = xy + xe^{y/x} \quad\Rightarrow\quad \dfrac{\partial z}{\partial x} = y - \dfrac{y}{x}e^{y/x} + e^{y/x},\ \dfrac{\partial z}{\partial y} = x + e^{y/x}$ and

$$x\frac{\partial z}{\partial x} + y\frac{\partial z}{\partial y} = x\Big(y - \frac{y}{x}e^{y/x} + e^{y/x}\Big) + y\Big(x + e^{y/x}\Big) = xy - ye^{y/x} + xe^{y/x} + xy + ye^{y/x} = xy + xy + xe^{y/x} = xy + z.$$

24. $z = \sin(x + \sin t) \;\Rightarrow\; \dfrac{\partial z}{\partial x} = \cos(x + \sin t),\; \dfrac{\partial z}{\partial t} = \cos(x + \sin t)\cos t,$

$\dfrac{\partial^2 z}{\partial x \partial t} = -\sin(x + \sin t)\cos t,\; \dfrac{\partial^2 z}{\partial x^2} = -\sin(x + \sin t)$ and

$$\frac{\partial z}{\partial x}\frac{\partial^2 z}{\partial x \partial t} = \cos(x + \sin t)\,[-\sin(x + \sin t)\cos t] = \cos(x + \sin t)\,(\cos t)\,[-\sin(x + \sin t)] = \frac{\partial z}{\partial t}\frac{\partial^2 z}{\partial x^2}.$$

25. (a) $z_x = 6x + 2 \;\Rightarrow\; z_x(1,-2) = 8$ and $z_y = -2y \;\Rightarrow\; z_y(1,-2) = 4$, so an equation of the tangent plane is $z - 1 = 8(x-1) + 4(y+2)$ or $z = 8x + 4y + 1$.

(b) A normal vector to the tangent plane (and the surface) at $(1,-2,1)$ is $\langle 8, 4, -1\rangle$. Then parametric equations for the normal line there are $x = 1 + 8t$, $y = -2 + 4t$, $z = 1 - t$, and symmetric equations are $\dfrac{x-1}{8} = \dfrac{y+2}{4} = \dfrac{z-1}{-1}$.

26. (a) $z_x = e^x \cos y \;\Rightarrow\; z_x(0,0) = 1$ and $z_y = -e^x \sin y \;\Rightarrow\; z_y(0,0) = 0$, so an equation of the tangent plane is $z - 1 = 1(x-0) + 0(y-0)$ or $z = x + 1$.

(b) A normal vector to the tangent plane (and the surface) at $(0,0,1)$ is $\langle 1, 0, -1\rangle$. Then parametric equations for the normal line there are $x = t$, $y = 0$, $z = 1 - t$, and symmetric equations are $x = 1 - z$, $y = 0$.

27. (a) Let $F(x,y,z) = x^2 + 2y^2 - 3z^2$. Then $F_x = 2x$, $F_y = 4y$, $F_z = -6z$, so $F_x(2,-1,1) = 4$, $F_y(2,-1,1) = -4$, $F_z(2,-1,1) = -6$. From Equation 14.6.19, an equation of the tangent plane is $4(x-2) - 4(y+1) - 6(z-1) = 0$ or, equivalently, $2x - 2y - 3z = 3$.

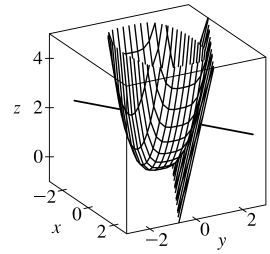
(b) From Equations 14.6.20, symmetric equations for the normal line are $\dfrac{x-2}{4} = \dfrac{y+1}{-4} = \dfrac{z-1}{-6}$.

28. (a) Let $F(x,y,z) = xy + yz + zx$. Then $F_x = y + z$, $F_y = x + z$, $F_z = x + y$, so $F_x(1,1,1) = F_y(1,1,1) = F_z(1,1,1) = 2$. From Equation 14.6.19, an equation of the tangent plane is $2(x-1) + 2(y-1) + 2(z-1) = 0$ or, equivalently, $x + y + z = 3$.

(b) From Equations 14.6.20, symmetric equations for the normal line are $\dfrac{x-1}{2} = \dfrac{y-1}{2} = \dfrac{z-1}{2}$ or, equivalently, $x = y = z$.

29. (a) Let $F(x,y,z) = x + 2y + 3z - \sin(xyz)$. Then $F_x = 1 - yz\cos(xyz)$, $F_y = 2 - xz\cos(xyz)$, $F_z = 3 - xy\cos(xyz)$, so $F_x(2,-1,0) = 1$, $F_y(2,-1,0) = 2$, $F_z(2,-1,0) = 5$. From Equation 14.6.19, an equation of the tangent plane is $1(x-2) + 2(y+1) + 5(z-0) = 0$ or $x + 2y + 5z = 0$.

(b) From Equations 14.6.20, symmetric equations for the normal line are $\dfrac{x-2}{1} = \dfrac{y+1}{2} = \dfrac{z}{5}$ or $x - 2 = \dfrac{y+1}{2} = \dfrac{z}{5}$. Parametric equations are $x = 2 + t$, $y = -1 + 2t$, $z = 5t$.



30. Let $f(x,y)=x^2+y^4$. Then $f_x(x,y)=2x$ and $f_y(x,y)=4y^3$, so $f_x(1,1)=2$, $f_y(1,1)=4$ and an equation of the tangent plane is $z-2=2(x-1)+4(y-1)$ or $2x+4y-z=4$. A normal vector to the tangent plane is $\langle 2,4,-1\rangle$ so the normal line is given by $\dfrac{x-1}{2}=\dfrac{y-1}{4}=\dfrac{z-2}{-1}$ or $x=1+2t,\ y=1+4t,$ $z=2-t$.

31. The hyperboloid is a level surface of the function $F(x,y,z)=x^2+4y^2-z^2$, so a normal vector to the surface at (x_0,y_0,z_0) is $\nabla F(x_0,y_0,z_0)=\langle 2x_0,8y_0,-2z_0\rangle$. A normal vector for the plane $2x+2y+z=5$ is $\langle 2,2,1\rangle$. For the planes to be parallel, we need the normal vectors to be parallel, so $\langle 2x_0,8y_0,-2z_0\rangle=k\langle 2,2,1\rangle$, or $x_0=k$, $y_0=\frac{1}{4}k$, and $z_0=-\frac{1}{2}k$. But $x_0^2+4y_0^2-z_0^2=4 \quad\Rightarrow\quad k^2+\frac{1}{4}k^2-\frac{1}{4}k^2=4 \quad\Rightarrow\quad k^2=4 \quad\Rightarrow\quad k=\pm 2$. So there are two such points: $\left(2,\frac{1}{2},-1\right)$ and $\left(-2,-\frac{1}{2},1\right)$.

32. $u=\ln(1+se^{2t}) \quad\Rightarrow\quad du=\dfrac{\partial u}{\partial s}\,ds+\dfrac{\partial u}{\partial t}\,dt=\dfrac{e^{2t}}{1+se^{2t}}\,ds+\dfrac{2se^{2t}}{1+se^{2t}}\,dt$

33. $f(x,y,z)=x^3\sqrt{y^2+z^2} \quad\Rightarrow\quad f_x(x,y,z)=3x^2\sqrt{y^2+z^2},\ f_y(x,y,z)=\dfrac{yx^3}{\sqrt{y^2+z^2}},\ f_z(x,y,z)=\dfrac{zx^3}{\sqrt{y^2+z^2}},$

so $f(2,3,4)=8(5)=40$, $f_x(2,3,4)=3(4)\sqrt{25}=60$, $f_y(2,3,4)=\frac{3(8)}{\sqrt{25}}=\frac{24}{5}$, and $f_z(2,3,4)=\frac{4(8)}{\sqrt{25}}=\frac{32}{5}$. Then the linear approximation of f at $(2,3,4)$ is

$$\begin{aligned}f(x,y,z)&\approx f(2,3,4)+f_x(2,3,4)(x-2)+f_y(2,3,4)(y-3)+f_z(2,3,4)(z-4)\\&=40+60(x-2)+\tfrac{24}{5}(y-3)+\tfrac{32}{5}(z-4)=60x+\tfrac{24}{5}y+\tfrac{32}{5}z-120\end{aligned}$$

Then $(1.98)^3\sqrt{(3.01)^2+(3.97)^2}=f(1.98,3.01,3.97)\approx 60(1.98)+\frac{24}{5}(3.01)+\frac{32}{5}(3.97)-120=38.656$.

34. (a) $dA=\dfrac{\partial A}{\partial x}\,dx+\dfrac{\partial A}{\partial y}\,dy=\frac{1}{2}y\,dx+\frac{1}{2}x\,dy$ and $|\Delta x|\leq 0.002$, $|\Delta y|\leq 0.002$. Thus the maximum error in the calculated area is about $dA=6(0.002)+\frac{5}{2}(0.002)=0.017\text{ m}^2$ or 170 cm^2.

(b) $z=\sqrt{x^2+y^2}$, $dz=\dfrac{x}{\sqrt{x^2+y^2}}\,dx+\dfrac{y}{\sqrt{x^2+y^2}}\,dy$ and $|\Delta x|\leq 0.002$, $|\Delta y|\leq 0.002$. Thus the maximum error in the calculated hypotenuse length is about $dz=\frac{5}{13}(0.002)+\frac{12}{13}(0.002)=\frac{0.17}{65}\approx 0.0026$ m or 0.26 cm.

35. $\dfrac{du}{dp}=\dfrac{\partial u}{\partial x}\dfrac{dx}{dp}+\dfrac{\partial u}{\partial y}\dfrac{dy}{dp}+\dfrac{\partial u}{\partial z}\dfrac{dz}{dp}=2xy^3(1+6p)+3x^2y^2(pe^p+e^p)+4z^3(p\cos p+\sin p)$

36. $\dfrac{\partial v}{\partial s}=\dfrac{\partial v}{\partial x}\dfrac{\partial x}{\partial s}+\dfrac{\partial v}{\partial y}\dfrac{\partial y}{\partial s}=\left(2x\sin y+y^2e^{xy}\right)(1)+\left(x^2\cos y+xye^{xy}+e^{xy}\right)(t).$

$s=0, t=1 \quad\Rightarrow\quad x=2, y=0$, so $\dfrac{\partial v}{\partial s}=0+(4+1)(1)=5$.

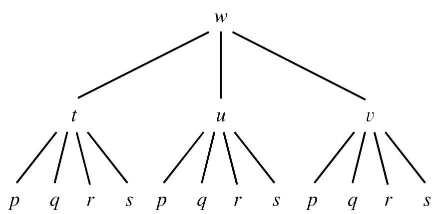
$\dfrac{\partial v}{\partial t}=\dfrac{\partial v}{\partial x}\dfrac{\partial x}{\partial t}+\dfrac{\partial v}{\partial y}\dfrac{\partial y}{\partial t}=\left(2x\sin y+y^2e^{xy}\right)(2)+\left(x^2\cos y+xye^{xy}+e^{xy}\right)(s)=0+0=0.$

37. By the Chain Rule, $\dfrac{\partial z}{\partial s} = \dfrac{\partial z}{\partial x}\dfrac{\partial x}{\partial s} + \dfrac{\partial z}{\partial y}\dfrac{\partial y}{\partial s}$. When $s = 1$ and $t = 2$, $x = g(1,2) = 3$ and $y = h(1,2) = 6$, so

$\dfrac{\partial z}{\partial s} = f_x(3,6)g_s(1,2) + f_y(3,6)\,h_s(1,2) = (7)(-1) + (8)(-5) = -47$. Similarly, $\dfrac{\partial z}{\partial t} = \dfrac{\partial z}{\partial x}\dfrac{\partial x}{\partial t} + \dfrac{\partial z}{\partial y}\dfrac{\partial y}{\partial t}$, so

$\dfrac{\partial z}{\partial t} = f_x(3,6)g_t(1,2) + f_y(3,6)\,h_t(1,2) = (7)(4) + (8)(10) = 108$.

38.



Using the tree diagram as a guide, we have

$$\frac{\partial w}{\partial p} = \frac{\partial w}{\partial t}\frac{\partial t}{\partial p} + \frac{\partial w}{\partial u}\frac{\partial u}{\partial p} + \frac{\partial w}{\partial v}\frac{\partial v}{\partial p} \qquad \frac{\partial w}{\partial q} = \frac{\partial w}{\partial t}\frac{\partial t}{\partial q} + \frac{\partial w}{\partial u}\frac{\partial u}{\partial q} + \frac{\partial w}{\partial v}\frac{\partial v}{\partial q}$$

$$\frac{\partial w}{\partial r} = \frac{\partial w}{\partial t}\frac{\partial t}{\partial r} + \frac{\partial w}{\partial u}\frac{\partial u}{\partial r} + \frac{\partial w}{\partial v}\frac{\partial v}{\partial r} \qquad \frac{\partial w}{\partial s} = \frac{\partial w}{\partial t}\frac{\partial t}{\partial s} + \frac{\partial w}{\partial u}\frac{\partial u}{\partial s} + \frac{\partial w}{\partial v}\frac{\partial v}{\partial s}$$

39. $\dfrac{\partial z}{\partial x} = 2xf'(x^2 - y^2)$, $\quad \dfrac{\partial z}{\partial y} = 1 - 2yf'(x^2 - y^2)$ $\quad \left[\text{where } f' = \dfrac{df}{d(x^2 - y^2)}\right]$. Then

$y\,\dfrac{\partial z}{\partial x} + x\,\dfrac{\partial z}{\partial y} = 2xyf'(x^2 - y^2) + x - 2xyf'(x^2 - y^2) = x$.

40. $A = \frac{1}{2}xy\sin\theta$, $dx/dt = 3$, $dy/dt = -2$, $d\theta/dt = 0.05$, and $\dfrac{dA}{dt} = \dfrac{1}{2}\left[(y\sin\theta)\,\dfrac{dx}{dt} + (x\sin\theta)\,\dfrac{dy}{dt} + (xy\cos\theta)\,\dfrac{d\theta}{dt}\right]$.

So when $x = 40$, $y = 50$ and $\theta = \frac{\pi}{6}$, $\dfrac{dA}{dt} = \dfrac{1}{2}\left[(25)(3) + (20)(-2) + \left(1000\sqrt{3}\right)(0.05)\right] = \dfrac{35 + 50\sqrt{3}}{2} \approx 60.8 \text{ in}^2\text{/s}$.

41. $\dfrac{\partial z}{\partial x} = \dfrac{\partial z}{\partial u}\,y + \dfrac{\partial z}{\partial v}\,\dfrac{-y}{x^2}$ and

$$\begin{aligned}\frac{\partial^2 z}{\partial x^2} &= y\,\frac{\partial}{\partial x}\left(\frac{\partial z}{\partial u}\right) + \frac{2y}{x^3}\frac{\partial z}{\partial v} + \frac{-y}{x^2}\,\frac{\partial}{\partial x}\left(\frac{\partial z}{\partial v}\right) = \frac{2y}{x^3}\frac{\partial z}{\partial v} + y\left(\frac{\partial^2 z}{\partial u^2}\,y + \frac{\partial^2 z}{\partial v\,\partial u}\,\frac{-y}{x^2}\right) + \frac{-y}{x^2}\left(\frac{\partial^2 z}{\partial v^2}\,\frac{-y}{x^2} + \frac{\partial^2 z}{\partial u\,\partial v}\,y\right)\\ &= \frac{2y}{x^3}\frac{\partial z}{\partial v} + y^2\,\frac{\partial^2 z}{\partial u^2} - \frac{2y^2}{x^2}\,\frac{\partial^2 z}{\partial u\,\partial v} + \frac{y^2}{x^4}\frac{\partial^2 z}{\partial v^2}\end{aligned}$$

Also $\dfrac{\partial z}{\partial y} = x\,\dfrac{\partial z}{\partial u} + \dfrac{1}{x}\dfrac{\partial z}{\partial v}$ and

$$\frac{\partial^2 z}{\partial y^2} = x\,\frac{\partial}{\partial y}\left(\frac{\partial z}{\partial u}\right) + \frac{1}{x}\frac{\partial}{\partial y}\left(\frac{\partial z}{\partial v}\right) = x\left(\frac{\partial^2 z}{\partial u^2}x + \frac{\partial^2 z}{\partial v\,\partial u}\frac{1}{x}\right) + \frac{1}{x}\left(\frac{\partial^2 z}{\partial v^2}\frac{1}{x} + \frac{\partial^2 z}{\partial u\,\partial v}\,x\right) = x^2\,\frac{\partial^2 z}{\partial u^2} + 2\,\frac{\partial^2 z}{\partial u\,\partial v} + \frac{1}{x^2}\frac{\partial^2 z}{\partial v^2}$$

Thus

$$\begin{aligned}x^2\,\frac{\partial^2 z}{\partial x^2} - y^2\,\frac{\partial^2 z}{\partial y^2} &= \frac{2y}{x}\frac{\partial z}{\partial v} + x^2y^2\,\frac{\partial^2 z}{\partial u^2} - 2y^2\,\frac{\partial^2 z}{\partial u\,\partial v} + \frac{y^2}{x^2}\frac{\partial^2 z}{\partial v^2} - x^2y^2\,\frac{\partial^2 z}{\partial u^2} - 2y^2\,\frac{\partial^2 z}{\partial u\,\partial v} - \frac{y^2}{x^2}\frac{\partial^2 z}{\partial v^2}\\ &= \frac{2y}{x}\frac{\partial z}{\partial v} - 4y^2\,\frac{\partial^2 z}{\partial u\,\partial v} = 2v\,\frac{\partial z}{\partial v} - 4uv\,\frac{\partial^2 z}{\partial u\,\partial v}\end{aligned}$$

since $y = xv = \dfrac{uv}{y}$ or $y^2 = uv$.

42. $\cos(xyz) = 1 + x^2y^2 + z^2$, so let $F(x, y, z) = 1 + x^2y^2 + z^2 - \cos(xyz) = 0$. Then by Equations 14.5.7 we have $\dfrac{\partial z}{\partial x} = -\dfrac{F_x}{F_z} = -\dfrac{2xy^2 + \sin(xyz) \cdot yz}{2z + \sin(xyz) \cdot xy} = -\dfrac{2xy^2 + yz\sin(xyz)}{2z + xy\sin(xyz)}$,

$$\frac{\partial z}{\partial y} = -\frac{F_y}{F_z} = -\frac{2x^2y + \sin(xyz) \cdot xz}{2z + \sin(xyz) \cdot xy} = -\frac{2x^2y + xz\sin(xyz)}{2z + xy\sin(xyz)}.$$

43. $f(x, y, z) = x^2e^{yz^2} \quad \Rightarrow \quad \nabla f = \langle f_x, f_y, f_z \rangle = \left\langle 2xe^{yz^2}, x^2e^{yz^2} \cdot z^2, x^2e^{yz^2} \cdot 2yz \right\rangle = \left\langle 2xe^{yz^2}, x^2z^2e^{yz^2}, 2x^2yze^{yz^2} \right\rangle$

44. (a) By Theorem 14.6.15, the maximum value of the directional derivative occurs when $\mathbf{u}$ has the same direction as the gradient vector.

(b) It is a minimum when $\mathbf{u}$ is in the direction opposite to that of the gradient vector (that is, $\mathbf{u}$ is in the direction of $-\nabla f$), since $D_{\mathbf{u}} f = |\nabla f| \cos\theta$ (see the proof of Theorem 14.6.15) has a minimum when $\theta = \pi$.

(c) The directional derivative is 0 when $\mathbf{u}$ is perpendicular to the gradient vector, since then $D_{\mathbf{u}} f = \nabla f \cdot \mathbf{u} = 0$.

(d) The directional derivative is half of its maximum value when $D_{\mathbf{u}} f = |\nabla f| \cos\theta = \frac{1}{2} |\nabla f| \quad \Leftrightarrow \quad \cos\theta = \frac{1}{2} \quad \Leftrightarrow$ $\theta = \frac{\pi}{3}$.

45. $f(x, y) = x^2e^{-y} \quad \Rightarrow \quad \nabla f = \langle 2xe^{-y}, -x^2e^{-y} \rangle$, $\nabla f(-2, 0) = \langle -4, -4 \rangle$. The direction is given by $\langle 4, -3 \rangle$, so $\mathbf{u} = \frac{1}{\sqrt{4^2 + (-3)^2}} \langle 4, -3 \rangle = \frac{1}{5} \langle 4, -3 \rangle$ and $D_{\mathbf{u}} f(-2, 0) = \nabla f(-2, 0) \cdot \mathbf{u} = \langle -4, -4 \rangle \cdot \frac{1}{5} \langle 4, -3 \rangle = \frac{1}{5}(-16 + 12) = -\frac{4}{5}$.

46. $\nabla f = \left\langle 2xy + \sqrt{1 + z}, x^2, x/\left(2\sqrt{1 + z}\right) \right\rangle$, $\nabla f(1, 2, 3) = \left\langle 6, 1, \frac{1}{4} \right\rangle$, $\mathbf{u} = \left\langle \frac{2}{3}, \frac{1}{3}, -\frac{2}{3} \right\rangle$. Then $D_{\mathbf{u}} f(1, 2, 3) = \frac{25}{6}$.

47. $\nabla f = \left\langle 2xy, x^2 + 1/\left(2\sqrt{y}\right) \right\rangle$, $|\nabla f(2, 1)| = \left|\left\langle 4, \frac{9}{2} \right\rangle\right|$. Thus the maximum rate of change of f at $(2, 1)$ is $\frac{\sqrt{145}}{2}$ in the direction $\left\langle 4, \frac{9}{2} \right\rangle$.

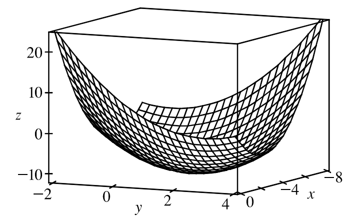
48. $\nabla f = \langle zye^{xy}, zxe^{xy}, e^{xy} \rangle$, $\nabla f(0, 1, 2) = \langle 2, 0, 1 \rangle$ is the direction of most rapid increase while the rate is $|\langle 2, 0, 1 \rangle| = \sqrt{5}$.

49. First we draw a line passing through Homestead and the eye of the hurricane. We can approximate the directional derivative at Homestead in the direction of the eye of the hurricane by the average rate of change of wind speed between the points where this line intersects the contour lines closest to Homestead. In the direction of the eye of the hurricane, the wind speed changes from 45 to 50 knots. We estimate the distance between these two points to be approximately 8 miles, so the rate of change of wind speed in the direction given is approximately $\frac{50 - 45}{8} = \frac{5}{8} = 0.625$ knot/mi.

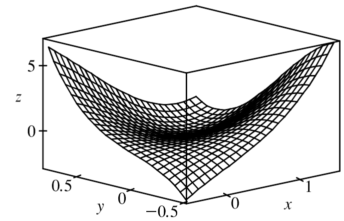
50. The surfaces are $f(x, y, z) = z - 2x^2 + y^2 = 0$ and $g(x, y, z) = z - 4 = 0$. The tangent line is perpendicular to both ∇f and ∇g at $(-2, 2, 4)$. The vector $\mathbf{v} = \nabla f \times \nabla g$ is therefore parallel to the line. $\nabla f(x, y, z) = \langle -4x, 2y, 1 \rangle \quad \Rightarrow$ $\nabla f(-2, 2, 4) = \langle 8, 4, 1 \rangle$, $\nabla g(x, y, z) = \langle 0, 0, 1 \rangle \quad \Rightarrow \quad \nabla g\langle -2, 2, 4 \rangle = \langle 0, 0, 1 \rangle$. Hence

$$\mathbf{v} = \nabla f \times \nabla g = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 8 & 4 & 1 \\ 0 & 0 & 1 \end{vmatrix} = 4\,\mathbf{i} - 8\,\mathbf{j}.$$ Thus, parametric equations are: $x = -2 + 4t,\ y = 2 - 8t,\ z = 4$.

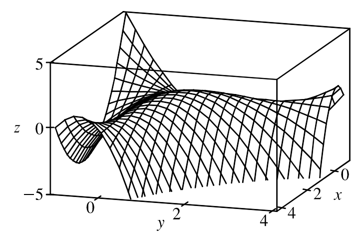
51. $f(x,y) = x^2 - xy + y^2 + 9x - 6y + 10 \quad \Rightarrow \quad f_x = 2x - y + 9$, $f_y = -x + 2y - 6$, $f_{xx} = 2 = f_{yy}$, $f_{xy} = -1$. Then $f_x = 0$ and $f_y = 0$ imply $y = 1$, $x = -4$. Thus the only critical point is $(-4, 1)$ and $f_{xx}(-4,1) > 0$, $D(-4,1) = 3 > 0$, so $f(-4,1) = -11$ is a local minimum.



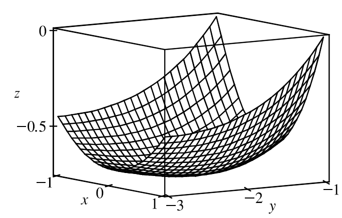
52. $f(x,y) = x^3 - 6xy + 8y^3 \quad \Rightarrow \quad f_x = 3x^2 - 6y$, $f_y = -6x + 24y^2$, $f_{xx} = 6x$, $f_{yy} = 48y$, $f_{xy} = -6$. Then $f_x = 0$ implies $y = x^2/2$, substituting into $f_y = 0$ implies $6x\left(x^3 - 1\right) = 0$, so the critical points are $(0,0)$, $\left(1, \frac{1}{2}\right)$. $D(0,0) = -36 < 0$ so $(0,0)$ is a saddle point while $f_{xx}\left(1, \frac{1}{2}\right) = 6 > 0$ and $D\left(1, \frac{1}{2}\right) = 108 > 0$ so $f\left(1, \frac{1}{2}\right) = -1$ is a local minimum.



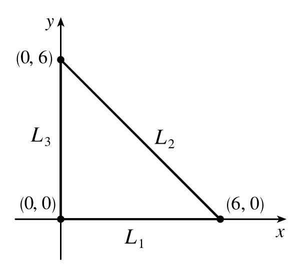
53. $f(x,y) = 3xy - x^2y - xy^2 \quad \Rightarrow \quad f_x = 3y - 2xy - y^2$, $f_y = 3x - x^2 - 2xy$, $f_{xx} = -2y$, $f_{yy} = -2x$, $f_{xy} = 3 - 2x - 2y$. Then $f_x = 0$ implies $y(3 - 2x - y) = 0$ so $y = 0$ or $y = 3 - 2x$. Substituting into $f_y = 0$ implies $x(3 - x) = 0$ or $3x(-1 + x) = 0$. Hence the critical points are $(0,0)$, $(3,0)$, $(0,3)$ and $(1,1)$. $D(0,0) = D(3,0) = D(0,3) = -9 < 0$ so $(0,0)$, $(3,0)$, and $(0,3)$ are saddle points. $D(1,1) = 3 > 0$ and $f_{xx}(1,1) = -2 < 0$, so $f(1,1) = 1$ is a local maximum.



54. $f(x,y) = (x^2 + y)e^{y/2} \quad \Rightarrow \quad f_x = 2xe^{y/2}$, $f_y = e^{y/2}(2 + x^2 + y)/2$, $f_{xx} = 2e^{y/2}$, $f_{yy} = e^{y/2}(4 + x^2 + y)/4$, $f_{xy} = xe^{y/2}$. Then $f_x = 0$ implies $x = 0$, so $f_y = 0$ implies $y = -2$. But $f_{xx}(0,-2) > 0$, $D(0,-2) = e^{-2} - 0 > 0$ so $f(0,-2) = -2/e$ is a local minimum.



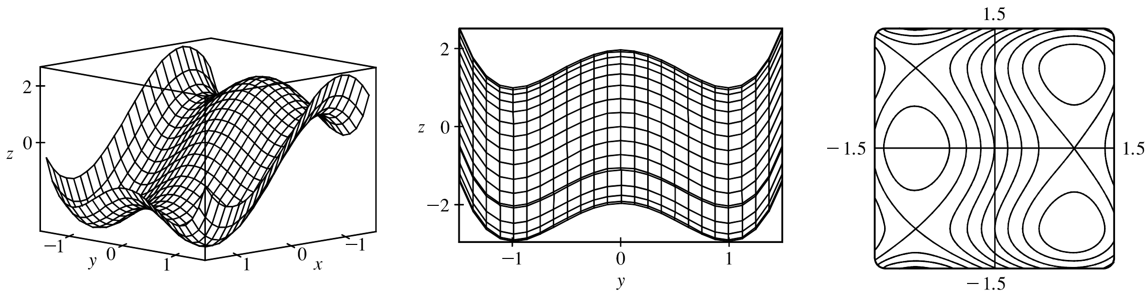
55. First solve inside D. Here $f_x = 4y^2 - 2xy^2 - y^3$, $f_y = 8xy - 2x^2y - 3xy^2$. Then $f_x = 0$ implies $y = 0$ or $y = 4 - 2x$, but $y = 0$ isn't inside D. Substituting $y = 4 - 2x$ into $f_y = 0$ implies $x = 0$, $x = 2$ or $x = 1$, but $x = 0$ isn't inside D, and when $x = 2$, $y = 0$ but $(2,0)$ isn't inside D. Thus the only critical point inside D is $(1,2)$ and $f(1,2) = 4$. Secondly we consider the boundary of D. On L_1: $f(x,0) = 0$ and so $f = 0$ on L_1. On L_2: $x = -y + 6$ and $f(-y + 6, y) = y^2(6 - y)(-2) = -2(6y^2 - y^3)$ which has critical points at $y = 0$ and $y = 4$. Then $f(6,0) = 0$ while $f(2,4) = -64$. On L_3: $f(0,y) = 0$, so $f = 0$ on L_3. Thus on D the absolute maximum of f is $f(1,2) = 4$ while the absolute minimum is $f(2,4) = -64$.



56. Inside D: $f_x = 2xe^{-x^2-y^2}(1 - x^2 - 2y^2) = 0$ implies $x = 0$ or $x^2 + 2y^2 = 1$. Then if $x = 0$, $f_y = 2ye^{-x^2-y^2}(2 - x^2 - 2y^2) = 0$ implies $y = 0$ or $2 - 2y^2 = 0$ giving the critical points $(0,0)$, $(0, \pm 1)$. If

$x^2 + 2y^2 = 1$, then $f_y = 0$ implies $y = 0$ giving the critical points $(\pm 1, 0)$. Now $f(0, 0) = 0$, $f(\pm 1, 0) = e^{-1}$ and $f(0, \pm 1) = 2e^{-1}$. On the boundary of D: $x^2 + y^2 = 4$, so $f(x, y) = e^{-4}(4 + y^2)$ and f is smallest when $y = 0$ and largest when $y^2 = 4$. But $f(\pm 2, 0) = 4e^{-4}$, $f(0, \pm 2) = 8e^{-4}$. Thus on D the absolute maximum of f is $f(0, \pm 1) = 2e^{-1}$ and the absolute minimum is $f(0, 0) = 0$.

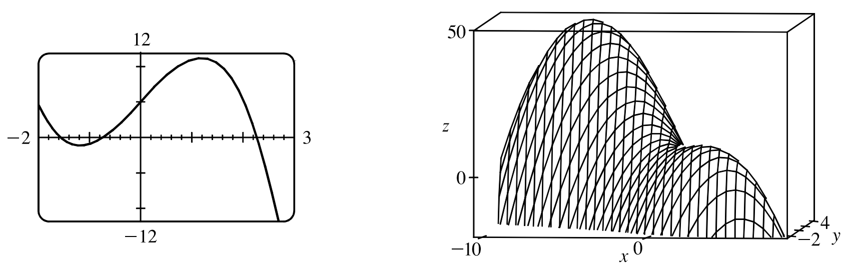
57. $f(x, y) = x^3 - 3x + y^4 - 2y^2$



From the graphs, it appears that f has a local maximum $f(-1, 0) \approx 2$, local minima $f(1, \pm 1) \approx -3$, and saddle points at $(-1, \pm 1)$ and $(1, 0)$.

To find the exact quantities, we calculate $f_x = 3x^2 - 3 = 0 \quad \Leftrightarrow \quad x = \pm 1$ and $f_y = 4y^3 - 4y = 0 \quad \Leftrightarrow$ $y = 0, \pm 1$, giving the critical points estimated above. Also $f_{xx} = 6x$, $f_{xy} = 0$, $f_{yy} = 12y^2 - 4$, so using the Second Derivatives Test, $D(-1, 0) = 24 > 0$ and $f_{xx}(-1, 0) = -6 < 0$ indicating a local maximum $f(-1, 0) = 2$; $D(1, \pm 1) = 48 > 0$ and $f_{xx}(1, \pm 1) = 6 > 0$ indicating local minima $f(1, \pm 1) = -3$; and $D(-1, \pm 1) = -48$ and $D(1, 0) = -24$, indicating saddle points.

58. $f(x, y) = 12 + 10y - 2x^2 - 8xy - y^4 \quad \Rightarrow \quad f_x(x, y) = -4x - 8y$, $f_y(x, y) = 10 - 8x - 4y^3$. Now $f_x(x, y) = 0 \quad \Rightarrow$ $x = -2x$, and substituting this into $f_y(x, y) = 0$ gives $10 + 16y - 4y^3 = 0 \quad \Leftrightarrow \quad 5 + 8y - 2y^3 = 0$.



From the first graph, we see that this is true when $y \approx -1.542, -0.717$, or 2.260. (Alternatively, we could have found the solutions to $f_x = f_y = 0$ using a CAS.) So to three decimal places, the critical points are $(3.085, -1.542)$, $(1.434, -0.717)$, and $(-4.519, 2.260)$. Now in order to use the Second Derivatives Test, we calculate $f_{xx} = -4$, $f_{xy} = -8$, $f_{yy} = -12y^2$, and $D = 48y^2 - 64$. So since $D(3.085, -1.542) > 0$, $D(1.434, -0.717) < 0$, and $D(-4.519, 2.260) > 0$, and f_{xx} is always negative, $f(x, y)$ has local maxima $f(-4.519, 2.260) \approx 49.373$ and $f(3.085, -1.542) \approx 9.948$, and a saddle point at approximately $(1.434, -0.717)$. The highest point on the graph is approximately $(-4.519, 2.260, 49.373)$.

59. $f(x,y)=x^2y,\ g(x,y)=x^2+y^2=1 \quad\Rightarrow\quad \nabla f=\langle 2xy,x^2\rangle=\lambda\nabla g=\langle 2\lambda x,2\lambda y\rangle$. Then $2xy=2\lambda x$ implies $x=0$ or $y=\lambda$. If $x=0$ then $x^2+y^2=1$ gives $y=\pm1$ and we have possible points $(0,\pm1)$ where $f(0,\pm1)=0$. If $y=\lambda$ then $x^2=2\lambda y$ implies $x^2=2y^2$ and substitution into $x^2+y^2=1$ gives $3y^2=1 \quad\Rightarrow\quad y=\pm\frac{1}{\sqrt3}$ and $x=\pm\sqrt{\frac23}$. The corresponding possible points are $\left(\pm\sqrt{\frac23},\pm\frac{1}{\sqrt3}\right)$. The absolute maximum is $f\left(\pm\sqrt{\frac23},\frac{1}{\sqrt3}\right)=\frac{2}{3\sqrt3}$ while the absolute minimum is $f\left(\pm\sqrt{\frac23},-\frac{1}{\sqrt3}\right)=-\frac{2}{3\sqrt3}$.

60. $f(x,y)=1/x+1/y,\ g(x,y)=1/x^2+1/y^2=1 \quad\Rightarrow\quad \nabla f=\langle -x^{-2},-y^{-2}\rangle=\lambda\nabla g=\langle -2\lambda x^{-3},-2\lambda y^{-3}\rangle$. Then $-x^{-2}=-2\lambda x^3$ or $x=2\lambda$ and $-y^{-2}=-2\lambda y^{-3}$ or $y=2\lambda$. Thus $x=y$, so $1/x^2+1/y^2=2/x^2=1$ implies $x=\pm\sqrt2$ and the possible points are $\left(\pm\sqrt2,\pm\sqrt2\right)$. The absolute maximum of f subject to $x^{-2}+y^{-2}=1$ is then $f\left(\sqrt2,\sqrt2\right)=\sqrt2$ and the absolute minimum is $f\left(-\sqrt2,-\sqrt2\right)=-\sqrt2$.

61. $f(x,y,z)=xyz,\ g(x,y,z)=x^2+y^2+z^2=3.\quad \nabla f=\lambda\nabla g \quad\Rightarrow\quad \langle yz,xz,xy\rangle=\lambda\langle 2x,2y,2z\rangle$. If any of x, y, or z is zero, then $x=y=z=0$ which contradicts $x^2+y^2+z^2=3$. Then $\lambda=\dfrac{yz}{2x}=\dfrac{xz}{2y}=\dfrac{xy}{2z} \quad\Rightarrow\quad 2y^2z=2x^2z \quad\Rightarrow$ $y^2=x^2$, and similarly $2yz^2=2x^2y \quad\Rightarrow\quad z^2=x^2$. Substituting into the constraint equation gives $x^2+x^2+x^2=3 \quad\Rightarrow$ $x^2=1=y^2=z^2$. Thus the possible points are $(1,1,\pm1)$, $(1,-1,\pm1)$, $(-1,1,\pm1)$, $(-1,-1,\pm1)$. The absolute maximum is $f(1,1,1)=f(1,-1,-1)=f(-1,1,-1)=f(-1,-1,1)=1$ and the absolute
minimum is $f(1,1,-1)=f(1,-1,1)=f(-1,1,1)=f(-1,-1,-1)=-1$.

62. $f(x,y,z)=x^2+2y^2+3z^2,\ g(x,y,z)=x+y+z=1,\ h(x,y,z)=x-y+2z=2 \quad\Rightarrow$ $\nabla f=\langle 2x,4y,6z\rangle=\lambda\nabla g+\mu\nabla h=\langle\lambda+\mu,\lambda-\mu,\lambda+2\mu\rangle$ and $2x=\lambda+\mu$ **(1)**, $\quad 4y=\lambda-\mu$ **(2)**, $\quad 6z=\lambda+2\mu$ **(3)**, $x+y+z=1$ **(4)**, $\quad x-y+2z=2$ **(5)**. Then six times **(1)** plus three times **(2)** plus two times **(3)** implies $12(x+y+z)=11\lambda+7\mu$, so **(4)** gives $11\lambda+7\mu=12$. Also six times **(1)** minus three times **(2)** plus four times **(3)** implies $12(x-y+2z)=7\lambda+17\mu$, so **(5)** gives $7\lambda+17\mu=24$. Solving $11\lambda+7\mu=12$, $7\lambda+17\mu=24$ simultaneously gives $\lambda=\frac{6}{23}$, $\mu=\frac{30}{23}$. Substituting into **(1)**, **(2)**, and **(3)** implies $x=\frac{18}{23}$, $y=-\frac{6}{23}$, $z=\frac{11}{23}$ giving only one point. Then $f\left(\frac{18}{23},-\frac{6}{23},\frac{11}{23}\right)=\frac{33}{23}$. Now since $(0,0,1)$ satisfies both constraints and $f(0,0,1)=3>\frac{33}{23}$, $f\left(\frac{18}{23},-\frac{6}{23},\frac{11}{23}\right)=\frac{33}{23}$ is an absolute minimum, and there is no absolute maximum.

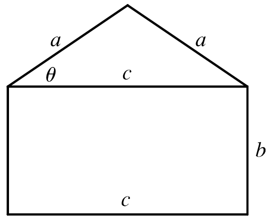
63. $f(x,y,z)=x^2+y^2+z^2,\ g(x,y,z)=xy^2z^3=2 \quad\Rightarrow\quad \nabla f=\langle 2x,2y,2z\rangle=\lambda\nabla g=\langle\lambda y^2z^3,2\lambda xyz^3,3\lambda xy^2z^2\rangle$. Since $xy^2z^3=2$, $x\neq0$, $y\neq0$ and $z\neq0$, so $2x=\lambda y^2z^3$ **(1)**, $\quad 1=\lambda xz^3$ **(2)**, $\quad 2=3\lambda xy^2z$ **(3)**. Then **(2)** and **(3)** imply $\dfrac{1}{xz^3}=\dfrac{2}{3xy^2z}$ or $y^2=\frac23z^2$ so $y=\pm z\sqrt{\frac23}$. Similarly **(1)** and **(3)** imply $\dfrac{2x}{y^2z^3}=\dfrac{2}{3xy^2z}$ or $3x^2=z^2$ so $x=\pm\frac{1}{\sqrt3}z$. But $xy^2z^3=2$ so x and z must have the same sign, that is, $x=\frac{1}{\sqrt3}z$. Thus $g(x,y,z)=2$ implies $\frac{1}{\sqrt3}z\left(\frac23z^2\right)z^3=2$ or

$z = \pm 3^{1/4}$ and the possible points are $(\pm 3^{-1/4}, 3^{-1/4}\sqrt{2}, \pm 3^{1/4})$, $(\pm 3^{-1/4}, -3^{-1/4}\sqrt{2}, \pm 3^{1/4})$. However at each of these points f takes on the same value, $2\sqrt{3}$. But $(2, 1, 1)$ also satisfies $g(x, y, z) = 2$ and $f(2, 1, 1) = 6 > 2\sqrt{3}$. Thus f has an absolute minimum value of $2\sqrt{3}$ and no absolute maximum subject to the constraint $xy^2z^3 = 2$.

Alternate solution: $g(x, y, z) = xy^2z^3 = 2$ implies $y^2 = \dfrac{2}{xz^3}$, so minimize $f(x, z) = x^2 + \dfrac{2}{xz^3} + z^2$. Then $f_x = 2x - \dfrac{2}{x^2z^3}$, $f_z = -\dfrac{6}{xz^4} + 2z$, $f_{xx} = 2 + \dfrac{4}{x^3z^3}$, $f_{zz} = \dfrac{24}{xz^5} + 2$ and $f_{xz} = \dfrac{6}{x^2z^4}$. Now $f_x = 0$ implies $2x^3z^3 - 2 = 0$ or $z = 1/x$. Substituting into $f_y = 0$ implies $-6x^3 + 2x^{-1} = 0$ or $x = \frac{1}{\sqrt[4]{3}}$, so the two critical points are $\left(\pm\frac{1}{\sqrt[4]{3}}, \pm\sqrt[4]{3}\right)$. Then $D\left(\pm\frac{1}{\sqrt[4]{3}}, \pm\sqrt[4]{3}\right) = (2+4)\left(2 + \frac{24}{3}\right) - \left(\frac{6}{\sqrt{3}}\right)^2 > 0$ and $f_{xx}\left(\pm\frac{1}{\sqrt[4]{3}}, \pm\sqrt[4]{3}\right) = 6 > 0$, so each point is a minimum. Finally, $y^2 = \dfrac{2}{xz^3}$, so the four points closest to the origin are $\left(\pm\frac{1}{\sqrt[4]{3}}, \frac{\sqrt{2}}{\sqrt[4]{3}}, \pm\sqrt[4]{3}\right)$, $\left(\pm\frac{1}{\sqrt[4]{3}}, -\frac{\sqrt{2}}{\sqrt[4]{3}}, \pm\sqrt[4]{3}\right)$.

64. $V = xyz$, say x is the length and $x + 2y + 2z \leq 108$, $x > 0$, $y > 0$, $z > 0$. First maximize V subject to $x + 2y + 2z = 108$ with x, y, z all positive. Then $\langle yz, xz, xy \rangle = \langle \lambda, 2\lambda, 2\lambda \rangle$ implies $2yz = xz$ or $x = 2y$ and $xz = xy$ or $z = y$. Thus $g(x, y, z) = 108$ implies $6y = 108$ or $y = 18 = z$, $x = 36$, so the volume is $V = 11{,}664$ cubic units. Since $(104, 1, 1)$ also satisfies $g(x, y, z) = 108$ and $V(104, 1, 1) = 104$ cubic units, $(36, 18, 18)$ gives an absolute maximum of V subject to $g(x, y, z) = 108$. But if $x + 2y + 2z < 108$, there exists $\alpha > 0$ such that $x + 2y + 2z = 108 - \alpha$ and as above $6y = 108 - \alpha$ implies $y = (108 - \alpha)/6 = z$, $x = (108 - \alpha)/3$ with $V = (108 - \alpha)^3/(6^2 \cdot 3) < (108)^3/(6^2 \cdot 3) = 11{,}664$. Hence we have shown that the maximum of V subject to $g(x, y, z) \leq 108$ is the maximum of V subject to $g(x, y, z) = 108$ (an intuitively obvious fact).

65.



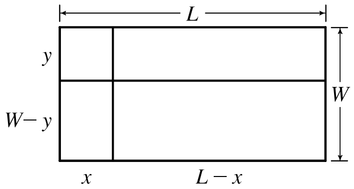
The area of the triangle is $\frac{1}{2}ca\sin\theta$ and the area of the rectangle is bc. Thus, the area of the whole object is $f(a, b, c) = \frac{1}{2}ca\sin\theta + bc$. The perimeter of the object is $g(a, b, c) = 2a + 2b + c = P$. To simplify $\sin\theta$ in terms of a, b, and c notice that $a^2\sin^2\theta + \left(\frac{1}{2}c\right)^2 = a^2 \quad\Rightarrow\quad \sin\theta = \dfrac{1}{2a}\sqrt{4a^2 - c^2}$. Thus $f(a, b, c) = \dfrac{c}{4}\sqrt{4a^2 - c^2} + bc$. (Instead of using θ, we could just have used the Pythagorean Theorem.) As a result, by Lagrange's method, we must find a, b, c, and λ by solving $\nabla f = \lambda\nabla g$ which gives the following equations: $ca(4a^2 - c^2)^{-1/2} = 2\lambda$ **(1)**, $c = 2\lambda$ **(2)**, $\frac{1}{4}(4a^2 - c^2)^{1/2} - \frac{1}{4}c^2(4a^2 - c^2)^{-1/2} + b = \lambda$ **(3)**, and $2a + 2b + c = P$ **(4)**. From **(2)**, $\lambda = \frac{1}{2}c$ and so **(1)** produces $ca(4a^2 - c^2)^{-1/2} = c \quad\Rightarrow\quad (4a^2 - c^2)^{1/2} = a \quad\Rightarrow\quad 4a^2 - c^2 = a^2 \quad\Rightarrow\quad c = \sqrt{3}\,a$ **(5)**. Similarly, since $\left(4a^2 - c^2\right)^{1/2} = a$ and $\lambda = \frac{1}{2}c$, **(3)** gives $\dfrac{a}{4} - \dfrac{c^2}{4a} + b = \dfrac{c}{2}$, so from **(5)**, $\dfrac{a}{4} - \dfrac{3a}{4} + b = \dfrac{\sqrt{3}\,a}{2} \quad\Rightarrow\quad -\dfrac{a}{2} - \dfrac{\sqrt{3}\,a}{2} = -b \quad\Rightarrow\quad b = \dfrac{a}{2}\left(1 + \sqrt{3}\right)$ **(6)**. Substituting **(5)** and **(6)** into **(4)** we get:

$2a + a\left(1+\sqrt{3}\right) + \sqrt{3}\,a = P \quad\Rightarrow\quad 3a + 2\sqrt{3}\,a = P \quad\Rightarrow\quad a = \dfrac{P}{3+2\sqrt{3}} = \dfrac{2\sqrt{3}-3}{3}P$ and thus

$b = \dfrac{\left(2\sqrt{3}-3\right)\left(1+\sqrt{3}\right)}{6}P = \dfrac{3-\sqrt{3}}{6}P$ and $c = \left(2-\sqrt{3}\right)P$.

PROBLEMS PLUS

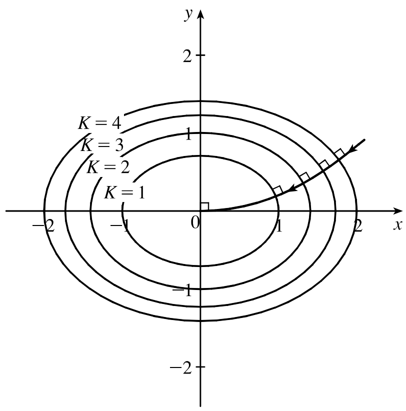
1. The areas of the smaller rectangles are $A_1 = xy$, $A_2 = (L-x)y$, $A_3 = (L-x)(W-y)$, $A_4 = x(W-y)$. For $0 \le x \le L$, $0 \le y \le W$, let



$$\begin{aligned} f(x,y) &= A_1^2 + A_2^2 + A_3^2 + A_4^2 \\ &= x^2y^2 + (L-x)^2y^2 + (L-x)^2(W-y)^2 + x^2(W-y)^2 \\ &= [x^2 + (L-x)^2][y^2 + (W-y)^2] \end{aligned}$$

Then we need to find the maximum and minimum values of $f(x,y)$. Here $f_x(x,y) = [2x - 2(L-x)][y^2 + (W-y)^2] = 0 \quad \Rightarrow \quad 4x - 2L = 0$ or $x = \frac{1}{2}L$, and $f_y(x,y) = [x^2 + (L-x)^2][2y - 2(W-y)] = 0 \quad \Rightarrow \quad 4y - 2W = 0$ or $y = W/2$. Also $f_{xx} = 4[y^2 + (W-y)^2]$, $f_{yy} = 4[x^2 + (L-x)^2]$, and $f_{xy} = (4x - 2L)(4y - 2W)$. Then $D = 16[y^2 + (W-y)^2][x^2 + (L-x)^2] - (4x-2L)^2(4y-2W)^2$. Thus when $x = \frac{1}{2}L$ and $y = \frac{1}{2}W$, $D > 0$ and $f_{xx} = 2W^2 > 0$. Thus a minimum of f occurs at $\left(\frac{1}{2}L, \frac{1}{2}W\right)$ and this minimum value is $f\left(\frac{1}{2}L, \frac{1}{2}W\right) = \frac{1}{4}L^2W^2$. There are no other critical points, so the maximum must occur on the boundary. Now along the width of the rectangle let $g(y) = f(0,y) = f(L,y) = L^2[y^2 + (W-y)^2]$, $0 \le y \le W$. Then $g'(y) = L^2[2y - 2(W-y)] = 0 \quad \Leftrightarrow \quad y = \frac{1}{2}W$. And $g\left(\frac{1}{2}\right) = \frac{1}{2}L^2W^2$. Checking the endpoints, we get $g(0) = g(W) = L^2W^2$. Along the length of the rectangle let $h(x) = f(x,0) = f(x,W) = W^2[x^2 + (L-x)^2]$, $0 \le x \le L$. By symmetry $h'(x) = 0 \quad \Leftrightarrow \quad x = \frac{1}{2}L$ and $h\left(\frac{1}{2}L\right) = \frac{1}{2}L^2W^2$. At the endpoints we have $h(0) = h(L) = L^2W^2$. Therefore L^2W^2 is the maximum value of f. This maximum value of f occurs when the "cutting" lines correspond to sides of the rectangle.

2. (a) The level curves of the function $C(x,y) = e^{-(x^2+2y^2)/10^4}$ are the curves $e^{-(x^2+2y^2)/10^4} = k$ (k is a positive constant). This equation is equivalent to $x^2 + 2y^2 = K \quad \Rightarrow \quad \dfrac{x^2}{\left(\sqrt{K}\right)^2} + \dfrac{y^2}{\left(\sqrt{K/2}\right)^2} = 1$, where $K = -10^4 \ln k$, a family of ellipses. We sketch level curves for $K = 1$, 2, 3, and 4. If the shark always swims in the direction of maximum increase of blood concentration, its direction at any point would coincide with the gradient vector. Then we know the shark's path is perpendicular to the level curves it intersects. We sketch one example of such a path.



(b) $\nabla C = -\frac{2}{10^4} e^{-(x^2+2y^2)/10^4}(x\,\mathbf{i} + 2y\,\mathbf{j})$. And ∇C points in the direction of most rapid increase in concentration; that is, ∇C is tangent to the most rapid increase curve. If $r(t) = x(t)\,\mathbf{i} + y(t)\,\mathbf{j}$ is a parametrization of the most rapid increase curve, then $\dfrac{d\mathbf{r}}{dt} = \dfrac{dx}{dt}\,\mathbf{i} + \dfrac{dy}{dt}\,\mathbf{j}$ is tangent to the curve, so $\dfrac{d\mathbf{r}}{dt} = \lambda \nabla C \;\Rightarrow\; \dfrac{dx}{dt} = \lambda\left[-\dfrac{2}{10^4}\, e^{-(x^2+2y^2)/10^4}\right] x$ and $\dfrac{dy}{dt} = \lambda\left[-\dfrac{2}{10^4} e^{-(x^2+2y^2)/10^4}\right](2y)$. Therefore $\dfrac{dy}{dx} = \dfrac{dy/dt}{dx/dt} = 2\,\dfrac{y}{x} \;\Rightarrow\; \dfrac{dy}{y} = 2\,\dfrac{dx}{x} \;\Rightarrow\; \ln|y| = 2\ln|x|$ so that $y = kx^2$ for some constant k. But $y(x_0) = y_0 \;\Rightarrow\; y_0 = kx_0^2 \;\Rightarrow\; k = y_0/x_0^2$ ($x_0 = 0 \;\Rightarrow\; y_0 = 0 \;\Rightarrow$ the shark is already at the origin, so we can assume $x_0 \neq 0$.) Therefore the path the shark will follow is along the parabola $y = y_0(x/x_0)^2$.

3. (a) The area of a trapezoid is $\frac{1}{2}h(b_1 + b_2)$, where h is the height (the distance between the two parallel sides) and b_1, b_2 are the lengths of the bases (the parallel sides). From the figure in the text, we see that $h = x\sin\theta$, $b_1 = w - 2x$, and $b_2 = w - 2x + 2x\cos\theta$. Therefore the cross-sectional area of the rain gutter is

$$\begin{aligned} A(x,\theta) &= \tfrac{1}{2}x\sin\theta\,[(w-2x) + (w - 2x + 2x\cos\theta)] = (x\sin\theta)(w - 2x + x\cos\theta) \\ &= wx\sin\theta - 2x^2\sin\theta + x^2\sin\theta\cos\theta,\;\; 0 < x \le \tfrac{1}{2}w, 0 < \theta \le \tfrac{\pi}{2} \end{aligned}$$

We look for the critical points of A: $\partial A/\partial x = w\sin\theta - 4x\sin\theta + 2x\sin\theta\cos\theta$ and $\partial A/\partial\theta = wx\cos\theta - 2x^2\cos\theta + x^2(\cos^2\theta - \sin^2\theta)$, so $\partial A/\partial x = 0 \;\Leftrightarrow\; \sin\theta\,(w - 4x + 2x\cos\theta) = 0 \;\Leftrightarrow\; \cos\theta = \dfrac{4x - w}{2x} = 2 - \dfrac{w}{2x}$ $\left(0 < \theta \le \frac{\pi}{2} \;\Rightarrow\; \sin\theta > 0\right)$. If, in addition, $\partial A/\partial\theta = 0$, then

$$\begin{aligned} 0 &= wx\cos\theta - 2x^2\cos\theta + x^2(2\cos^2\theta - 1) \\ &= wx\left(2 - \frac{w}{2x}\right) - 2x^2\left(2 - \frac{w}{2x}\right) + x^2\left[2\left(2 - \frac{w}{2x}\right)^2 - 1\right] \\ &= 2wx - \tfrac{1}{2}w^2 - 4x^2 + wx + x^2\left[8 - \frac{4w}{x} + \frac{w^2}{2x^2} - 1\right] = -wx + 3x^2 = x(3x - w) \end{aligned}$$

Since $x > 0$, we must have $x = \frac{1}{3}w$, in which case $\cos\theta = \frac{1}{2}$, so $\theta = \frac{\pi}{3}$, $\sin\theta = \frac{\sqrt{3}}{2}$, $k = \frac{\sqrt{3}}{6}w$, $b_1 = \frac{1}{3}w$, $b_2 = \frac{2}{3}w$, and $A = \frac{\sqrt{3}}{12}w^2$. As in Example 14.7.6, we can argue from the physical nature of this problem that we have found a local maximum of A. Now checking the boundary of A, let $g(\theta) = A(w/2,\theta) = \frac{1}{2}w^2\sin\theta - \frac{1}{2}w^2\sin\theta + \frac{1}{4}w^2\sin\theta\cos\theta = \frac{1}{8}w^2\sin 2\theta$, $0 < \theta \le \frac{\pi}{2}$. Clearly g is maximized when $\sin 2\theta = 1$ in which case $A = \frac{1}{8}w^2$. Also along the line $\theta = \frac{\pi}{2}$, let $h(x) = A\left(x, \frac{\pi}{2}\right) = wx - 2x^2$, $0 < x < \frac{1}{2}w \;\Rightarrow\; h'(x) = w - 4x = 0 \;\Leftrightarrow\; x = \frac{1}{4}w$, and $h\left(\frac{1}{4}w\right) = w\left(\frac{1}{4}w\right) - 2\left(\frac{1}{4}w\right)^2 = \frac{1}{8}w^2$. Since $\frac{1}{8}w^2 < \frac{\sqrt{3}}{12}w^2$, we conclude that the local maximum found earlier was an absolute maximum.

(b) If the metal were bent into a semi-circular gutter of radius r, we would have $w = \pi r$ and $A = \frac{1}{2}\pi r^2 = \frac{1}{2}\pi\left(\frac{w}{\pi}\right)^2 = \frac{w^2}{2\pi}$.

Since $\dfrac{w^2}{2\pi} > \dfrac{\sqrt{3}\,w^2}{12}$, it *would* be better to bend the metal into a gutter with a semicircular cross-section.

4. Since $(x+y+z)^r/(x^2+y^2+z^2)$ is a rational function with domain $\{(x,y,z) \mid (x,y,z) \neq (0,0,0)\}$, f is continuous on $\mathbb{R}^3$ if and only if $\lim\limits_{(x,y,z)\to(0,0,0)} f(x,y,z) = f(0,0,0) = 0$. Recall that $(a+b)^2 \le 2a^2 + 2b^2$ and a double application of this inequality to $(x+y+z)^2$ gives $(x+y+z)^2 \le 4x^2 + 4y^2 + 2z^2 \le 4(x^2+y^2+z^2)$. Now for each r,

$$|(x+y+z)^r| = \left(|x+y+z|^2\right)^{r/2} = \left[(x+y+z)^2\right]^{r/2} \le \left[4(x^2+y^2+z^2)\right]^{r/2} = 2^r(x^2+y^2+z^2)^{r/2}$$

for $(x,y,z) \neq (0,0,0)$. Thus

$$|f(x,y,z) - 0| = \left|\frac{(x+y+z)^r}{x^2+y^2+z^2}\right| = \frac{|(x+y+z)^r|}{x^2+y^2+z^2} \le 2^r\,\frac{(x^2+y^2+z^2)^{r/2}}{x^2+y^2+z^2} = 2^r(x^2+y^2+z^2)^{(r/2)-1}$$

for $(x,y,z) \neq (0,0,0)$. Thus if $(r/2) - 1 > 0$, that is $r > 2$, then $2^r(x^2+y^2+z^2)^{(r/2)-1} \to 0$ as $(x,y,z) \to (0,0,0)$ and so $\lim\limits_{(x,y,z)\to(0,0,0)} (x+y+z)^r/(x^2+y^2+z^2) = 0$. Hence for $r > 2$, f is continuous on $\mathbb{R}^3$. Now if $r \le 2$, then as $(x,y,z) \to (0,0,0)$ along the x-axis, $f(x,0,0) = x^r/x^2 = x^{r-2}$ for $x \neq 0$. So when $r = 2$, $f(x,y,z) \to 1 \neq 0$ as $(x,y,z) \to (0,0,0)$ along the x-axis and when $r < 2$ the limit of $f(x,y,z)$ as $(x,y,z) \to (0,0,0)$ along the x-axis doesn't exist and thus can't be zero. Hence for $r \le 2$ f isn't continuous at $(0,0,0)$ and thus is not continuous on $\mathbb{R}^3$.

5. Let $g(x,y) = xf\left(\frac{y}{x}\right)$. Then $g_x(x,y) = f\left(\frac{y}{x}\right) + xf'\left(\frac{y}{x}\right)\left(-\frac{y}{x^2}\right) = f\left(\frac{y}{x}\right) - \frac{y}{x}f'\left(\frac{y}{x}\right)$ and $g_y(x,y) = xf'\left(\frac{y}{x}\right)\left(\frac{1}{x}\right) = f'\left(\frac{y}{x}\right)$. Thus the tangent plane at (x_0, y_0, z_0) on the surface has equation

$$z - x_0 f\left(\frac{y_0}{x_0}\right) = \left[f\left(\frac{y_0}{x_0}\right) - y_0x_0^{-1}f'\left(\frac{y_0}{x_0}\right)\right](x-x_0) + f'\left(\frac{y_0}{x_0}\right)(y-y_0) \quad\Rightarrow$$

$\left[f\left(\frac{y_0}{x_0}\right) - y_0x_0^{-1}f'\left(\frac{y_0}{x_0}\right)\right]x + \left[f'\left(\frac{y_0}{x_0}\right)\right]y - z = 0$. But any plane whose equation is of the form $ax + by + cz = 0$ passes through the origin. Thus the origin is the common point of intersection.

6. (a) At $(x_1, y_1, 0)$ the equations of the tangent planes to $z = f(x,y)$ and $z = g(x,y)$ are

$$P_1:\ z - f(x_1,y_1) = f_x(x_1,y_1)(x-x_1) + f_y(x_1,y_1)(y-y_1)$$

and

$$P_2:\ z - g(x_1,y_1) = g_x(x_1,y_1)(x-x_1) + g_y(x_1,y_1)(y-y_1)$$

respectively. P_1 intersects the xy-plane in the line given by $f_x(x_1,y_1)(x-x_1) + f_y(x_1,y_1)(y-y_1) = -f(x_1,y_1)$, $z = 0$; and P_2 intersects the xy-plane in the line given by $g_x(x_1,y_1)(x-x_1) + g_y(x_1,y_1)(y-y_1) = -g(x_1,y_1)$, $z = 0$. The point $(x_2, y_2, 0)$ is the point of intersection of these two lines, since $(x_2, y_2, 0)$ is the point where the line of intersection of the two tangent planes intersects the xy-plane. Thus (x_2, y_2) is the solution of the simultaneous equations

$$f_x(x_1, y_1)(x_2 - x_1) + f_y(x_1, y_1)(y_2 - y_1) = -f(x_1, y_1)$$

and $$g_x(x_1, y_1)(x_2 - x_1) + g_y(x_1, y_1)(y_2 - y_1) = -g(x_1, y_1)$$

For simplicity, rewrite $f_x(x_1, y_1)$ as f_x and similarly for f_y, g_x, g_y, f and g and solve the equations $(f_x)(x_2 - x_1) + (f_y)(y_2 - y_1) = -f$ and $(g_x)(x_2 - x_1) + (g_y)(y_2 - y_1) = -g$ simultaneously for $(x_2 - x_1)$ and $(y_2 - y_1)$. Then $y_2 - y_1 = \dfrac{gf_x - fg_x}{g_x f_y - f_x g_y}$ or $y_2 = y_1 - \dfrac{gf_x - fg_x}{f_x g_y - g_x f_y}$ and $(f_x)(x_2 - x_1) + \dfrac{(f_y)(gf_x - fg_x)}{g_x f_y - f_x g_y} = -f$ so $x_2 - x_1 = \dfrac{-f - [(f_y)(gf_x - fg_x)/(g_x f_y - f_x g_y)]}{f_x} = \dfrac{fg_y - f_y g}{g_x f_y - f_x g_y}$. Hence $x_2 = x_1 - \dfrac{fg_y - f_y g}{f_x g_y - g_x f_y}$.

(b) Let $f(x, y) = x^x + y^y - 1000$ and $g(x, y) = x^y + y^x - 100$. Then we wish to solve the system of equations $f(x, y) = 0$, $g(x, y) = 0$. Recall $\dfrac{d}{dx}[x^x] = x^x(1 + \ln x)$ (differentiate logarithmically), so $f_x(x, y) = x^x(1 + \ln x)$, $f_y(x, y) = y^y(1 + \ln y)$, $g_x(x, y) = yx^{y-1} + y^x \ln y$, and $g_y(x, y) = x^y \ln x + xy^{x-1}$. Looking at the graph, we estimate the first point of intersection of the curves, and thus the solution to the system, to be approximately $(2.5, 4.5)$. Then following the method of part (a), $x_1 = 2.5$, $y_1 = 4.5$ and

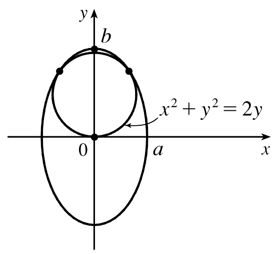
$$x_2 = 2.5 - \frac{f(2.5, 4.5)\, g_y(2.5, 4.5) - f_y(2.5, 4.5)\, g(2.5, 4.5)}{f_x(2.5, 4.5)\, g_y(2.5, 4.5) - f_y(2.5, 4.5)\, g_x(2.5, 4.5} \approx 2.447674117$$

$$y_2 = 4.5 - \frac{f_x(2.5, 4.5)\, g(2.5, 4.5) - f(2.5, 4.5)\, g_x(2.5, 4.5)}{f_x(2.5, 4.5)\, g_y(2.5, 4.5) - f_y(2.5, 4.5)\, g_x(2.5, 4.5)} \approx 4.555657467$$

Continuing this procedure, we arrive at the following values. (If you use a CAS, you may need to increase its computational precision.)

$x_1 = 2.5$	$y_1 = 4.5$
$x_2 = 2.447674117$	$y_2 = 4.555657467$
$x_3 = 2.449614877$	$y_3 = 4.551969333$
$x_4 = 2.449624628$	$y_4 = 4.551951420$
$x_5 = 2.449624628$	$y_5 = 4.551951420$

Thus, to six decimal places, the point of intersection is $(2.449625, 4.551951)$. The second point of intersection can be found similarly, or, by symmetry it is approximately $(4.551951, 2.449625)$.



7. Since we are minimizing the area of the ellipse, and the circle lies above the x-axis, the ellipse will intersect the circle for only one value of y. This y-value must satisfy both the equation of the circle and the equation of the ellipse. Now $\dfrac{x^2}{a^2}+\dfrac{y^2}{b^2}=1 \quad\Rightarrow\quad x^2=\dfrac{a^2}{b^2}\left(b^2-y^2\right)$. Substituting into the equation of the circle gives $\dfrac{a^2}{b^2}\left(b^2-y^2\right)+y^2-2y=0 \quad\Rightarrow\quad \left(\dfrac{b^2-a^2}{b^2}\right)y^2-2y+a^2=0$.

In order for there to be only one solution to this quadratic equation, the discriminant must be 0, so $4-4a^2\,\dfrac{b^2-a^2}{b^2}=0 \quad\Rightarrow$ $b^2-a^2b^2+a^4=0$. The area of the ellipse is $A(a,b)=\pi ab$, and we minimize this function subject to the constraint $g(a,b)=b^2-a^2b^2+a^4=0$.

Now $\nabla A=\lambda\nabla g \quad\Leftrightarrow\quad \pi b=\lambda(4a^3-2ab^2),\, \pi a=\lambda(2b-2ba^2) \quad\Rightarrow\quad \lambda=\dfrac{\pi b}{2a(2a^2-b^2)}$ **(1)**,

$\lambda=\dfrac{\pi a}{2b(1-a^2)}$ **(2)**, $b^2-a^2b^2+a^4=0$ **(3)**. Comparing **(1)** and **(2)** gives $\dfrac{\pi b}{2a(2a^2-b^2)}=\dfrac{\pi a}{2b(1-a^2)} \quad\Rightarrow$

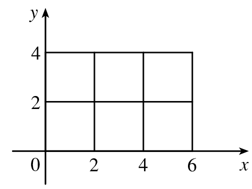
$2\pi b^2=4\pi a^4 \quad\Leftrightarrow\quad a^2=\frac{1}{\sqrt{2}}\,b$. Substitute this into **(3)** to get $b=\frac{3}{\sqrt{2}} \quad\Rightarrow\quad a=\sqrt{\frac{3}{2}}$.

8. Let $\mathbf{u}=\langle a,b,c\rangle$ and $\mathbf{v}=\langle x,y,1\rangle$, so $|\mathbf{u}|=\sqrt{a^2+b^2+c^2}$, $|\mathbf{v}|=\sqrt{x^2+y^2+1}$, and $\mathbf{u}\cdot\mathbf{v}=ax+by+c$. Then by the Cauchy-Schwarz Inequality, $|\mathbf{u}\cdot\mathbf{v}|\le|\mathbf{u}|\;|\mathbf{v}| \quad\Rightarrow\quad |ax+by+c|\le\sqrt{a^2+b^2+c^2}\,\sqrt{x^2+y^2+1}$. Squaring both sides, we have $(ax+by+c)^2\le\left(a^2+b^2+c^2\right)\left(x^2+y^2+1\right) \quad\Rightarrow\quad \dfrac{(ax+by+c)^2}{x^2+y^2+1}\le a^2+b^2+c^2$ (since $x^2+y^2+1>0$). Thus $f(x,y)=\dfrac{(ax+by+c)^2}{x^2+y^2+1}\le a^2+b^2+c^2$. We have equality if $(ax+by+c)^2=\left(a^2+b^2+c^2\right)\left(x^2+y^2+1\right)$ or equivalently $c^2\left[(a/c)x+(b/c)y+1\right]^2=c^2\left[(a/c)^2+(b/c)^2+1\right]\left(x^2+y^2+1\right)$ which is true when $x=a/c$ and $y=b/c$. Thus the maximum value of f is $f(a/c,b/c)=a^2+b^2+c^2$.

15 ☐ MULTIPLE INTEGRALS

15.1 Double Integrals over Rectangles

1. (a) The subrectangles are shown in the figure.



The surface is the graph of $f(x,y) = xy$ and $\Delta A = 4$, so we estimate

$$V \approx \sum_{i=1}^{3} \sum_{j=1}^{2} f(x_i, y_j)\,\Delta A$$

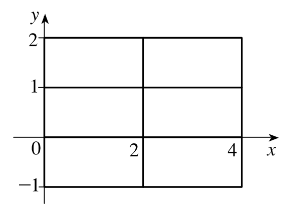
$$= f(2,2)\,\Delta A + f(2,4)\,\Delta A + f(4,2)\,\Delta A + f(4,4)\,\Delta A + f(6,2)\,\Delta A + f(6,4)\,\Delta A$$

$$= 4(4) + 8(4) + 8(4) + 16(4) + 12(4) + 24(4) = 288$$

(b) $V \approx \sum_{i=1}^{3} \sum_{j=1}^{2} f(\overline{x}_i, \overline{y}_j)\,\Delta A = f(1,1)\,\Delta A + f(1,3)\,\Delta A + f(3,1)\,\Delta A + f(3,3)\,\Delta A + f(5,1)\,\Delta A + f(5,3)\,\Delta A$

$$= 1(4) + 3(4) + 3(4) + 9(4) + 5(4) + 15(4) = 144$$

2. (a) The subrectangles are shown in the figure.



Here $\Delta A = 2$ and we estimate

$$\iint_R \left(1 - xy^2\right) dA \approx \sum_{i=1}^{2} \sum_{j=1}^{3} f\left(x_{ij}^*, y_{ij}^*\right)\Delta A$$

$$= f(2,-1)\,\Delta A + f(2,0)\,\Delta A + f(2,1)\,\Delta A + f(4,-1)\,\Delta A + f(4,0)\,\Delta A + f(4,1)\,\Delta A$$

$$= (-1)(2) + 1(2) + (-1)(2) + (-3)(2) + 1(2) + (-3)(2) = -12$$

(b) $\iint_R \left(1 - xy^2\right) dA \approx \sum_{i=1}^{2} \sum_{j=1}^{3} f\left(x_{ij}^*, y_{ij}^*\right)\Delta A$

$$= f(0,0)\,\Delta A + f(0,1)\,\Delta A + f(0,2)\,\Delta A + f(2,0)\,\Delta A + f(2,1)\,\Delta A + f(2,2)\,\Delta A$$

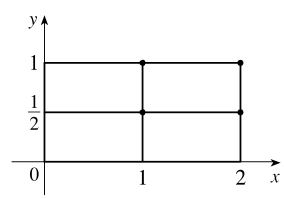
$$= 1(2) + 1(2) + 1(2) + 1(2) + (-1)(2) + (-7)(2) = -8$$

3. (a) The subrectangles are shown in the figure. Since $\Delta A = 1 \cdot \frac{1}{2} = \frac{1}{2}$, we estimate

$$\iint_R xe^{-xy}\,dA \approx \sum_{i=1}^{2} \sum_{j=1}^{2} f\left(x_{ij}^*, y_{ij}^*\right)\Delta A$$

$$= f\left(1, \tfrac{1}{2}\right)\,\Delta A + f(1,1)\,\Delta A + f\left(2, \tfrac{1}{2}\right)\Delta A + f(2,1)\,\Delta A$$

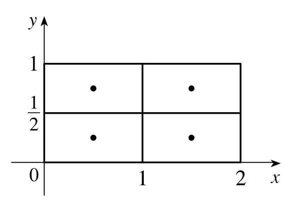
$$= e^{-1/2}\left(\tfrac{1}{2}\right) + e^{-1}\left(\tfrac{1}{2}\right) + 2e^{-1}\left(\tfrac{1}{2}\right) + 2e^{-2}\left(\tfrac{1}{2}\right) \approx 0.990$$



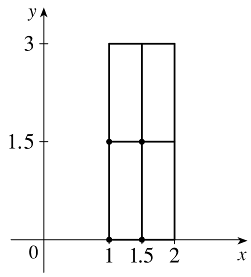
(b) $\iint_R xe^{-xy}\,dA \approx \sum_{i=1}^{2} \sum_{j=1}^{2} f(\overline{x}_i, \overline{y}_j)\,\Delta A$

$$= f\left(\tfrac{1}{2}, \tfrac{1}{4}\right)\,\Delta A + f\left(\tfrac{1}{2}, \tfrac{3}{4}\right)\Delta A + f\left(\tfrac{3}{2}, \tfrac{1}{4}\right)\Delta A + f\left(\tfrac{3}{2}, \tfrac{3}{4}\right)\Delta A$$

$$= \tfrac{1}{2}e^{-1/8}\left(\tfrac{1}{2}\right) + \tfrac{1}{2}e^{-3/8}\left(\tfrac{1}{2}\right) + \tfrac{3}{2}e^{-3/8}\left(\tfrac{1}{2}\right) + \tfrac{3}{2}e^{-9/8}\left(\tfrac{1}{2}\right) \approx 1.151$$



4. (a) The subrectangles are shown in the figure.



The surface is the graph of $f(x,y) = 1 + x^2 + 3y$ and $\Delta A = \frac{1}{2} \cdot \frac{3}{2} = \frac{3}{4}$, so we estimate

$$V = \iint_R (1 + x^2 + 3y)\,dA \approx \sum_{i=1}^{2} \sum_{j=1}^{2} f\left(x_{ij}^*, y_{ij}^*\right) \Delta A$$

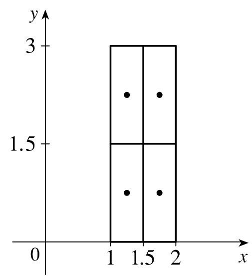
$$= f(1,0)\,\Delta A + f\left(1, \tfrac{3}{2}\right) \Delta A + f\left(\tfrac{3}{2}, 0\right) \Delta A + f\left(\tfrac{3}{2}, \tfrac{3}{2}\right) \Delta A$$

$$= 2\left(\tfrac{3}{4}\right) + \tfrac{13}{2}\left(\tfrac{3}{4}\right) + \tfrac{13}{4}\left(\tfrac{3}{4}\right) + \tfrac{31}{4}\left(\tfrac{3}{4}\right) = \tfrac{39}{2}\left(\tfrac{3}{4}\right) = \tfrac{117}{8} = 14.625$$

(b) $$V = \iint_R (1 + x^2 + 3y)\,dA \approx \sum_{i=1}^{2} \sum_{j=1}^{2} f\left(\overline{x}_i, \overline{y}_j\right) \Delta A$$

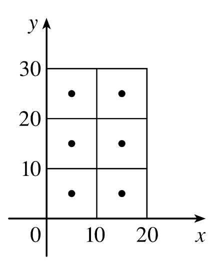
$$= f\left(\tfrac{5}{4}, \tfrac{3}{4}\right) \Delta A + f\left(\tfrac{5}{4}, \tfrac{9}{4}\right) \Delta A + f\left(\tfrac{7}{4}, \tfrac{3}{4}\right) \Delta A + f\left(\tfrac{7}{4}, \tfrac{9}{4}\right) \Delta A$$

$$= \tfrac{77}{16}\left(\tfrac{3}{4}\right) + \tfrac{149}{16}\left(\tfrac{3}{4}\right) + \tfrac{101}{16}\left(\tfrac{3}{4}\right) + \tfrac{173}{16}\left(\tfrac{3}{4}\right) = \tfrac{375}{16} = 23.4375$$



5. The values of $f(x,y) = \sqrt{52 - x^2 - y^2}$ get smaller as we move farther from the origin, so on any of the subrectangles in the problem, the function will have its largest value at the lower left corner of the subrectangle and its smallest value at the upper right corner, and any other value will lie between these two. So using these subrectangles we have $U < V < L$. (Note that this is true no matter how R is divided into subrectangles.)

6. To approximate the volume, let R be the planar region corresponding to the surface of the water in the pool, and place R on coordinate axes so that x and y correspond to the dimensions given. Then we define $f(x,y)$ to be the depth of the water at (x,y), so the volume of water in the pool is the volume of the solid that lies above the rectangle $R = [0, 20] \times [0, 30]$ and below the graph of $f(x,y)$. We can estimate this volume using the Midpoint Rule with $m = 2$ and $n = 3$, so $\Delta A = 100$. Each subrectangle with its midpoint is shown in the figure. Then



$$V \approx \sum_{i=1}^{2} \sum_{j=1}^{3} f\left(\overline{x}_i, \overline{y}_j\right) \Delta A = \Delta A[f(5,5) + f(5,15) + f(5,25) + f(15,5) + f(15,15) + f(15,25)]$$

$$= 100(3 + 7 + 10 + 3 + 5 + 8) = 3600$$

Thus, we estimate that the pool contains 3600 cubic feet of water.

Alternatively, we can approximate the volume with a Riemann sum where $m = 4$, $n = 6$ and the sample points are taken to be, for example, the upper right corner of each subrectangle. Then $\Delta A = 25$ and

$$V \approx \sum_{i=1}^{4} \sum_{j=1}^{6} f(x_i, y_j)\,\Delta A$$

$$= 25[3 + 4 + 7 + 8 + 10 + 8 + 4 + 6 + 8 + 10 + 12 + 10 + 3 + 4 + 5 + 6 + 8 + 7 + 2 + 2 + 2 + 3 + 4 + 4]$$

$$= 25(140) = 3500$$

So we estimate that the pool contains 3500 ft^3 of water.

7. (a) With $m = n = 2$, we have $\Delta A = 4$. Using the contour map to estimate the value of f at the center of each subrectangle, we have

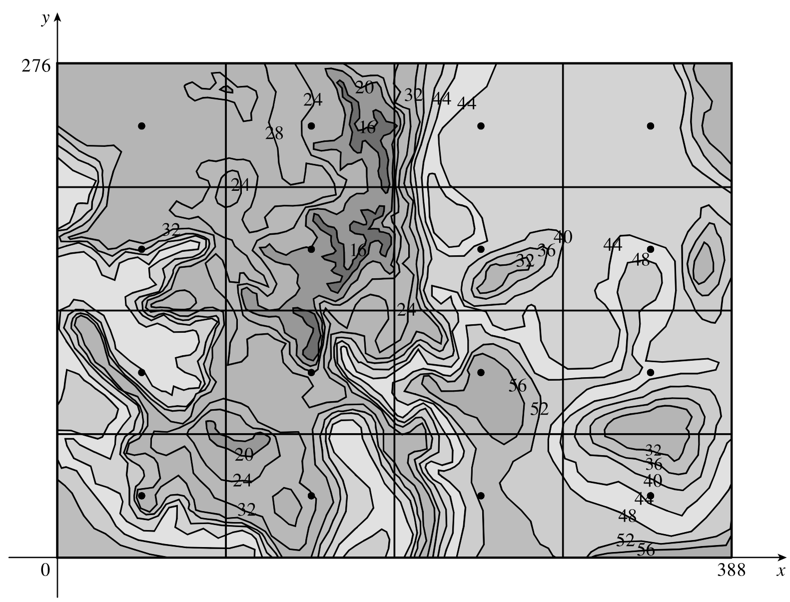
$$\iint_R f(x,y)\ dA \approx \sum_{i=1}^{2}\sum_{j=1}^{2} f\left(\overline{x}_i, \overline{y}_j\right) \Delta A = \Delta A[f(1,1) + f(1,3) + f(3,1) + f(3,3)] \approx 4(27 + 4 + 14 + 17) = 248$$

(b) $f_{\text{ave}} = \frac{1}{A(R)} \iint_R f(x,y)\, dA \approx \frac{1}{16}(248) = 15.5$

8. As in Example 9, we place the origin at the southwest corner of the state. Then $R = [0, 388] \times [0, 276]$ (in miles) is the rectangle corresponding to Colorado and we define $f(x,y)$ to be the temperature at the location (x,y). The average temperature is given by

$$f_{\text{ave}} = \frac{1}{A(R)} \iint_R f(x,y)\, dA = \frac{1}{388 \cdot 276} \iint_R f(x,y)\, dA$$

To use the Midpoint Rule with $m = n = 4$, we divide R into 16 regions of equal size, as shown in the figure, with the center of each subrectangle indicated.



The area of each subrectangle is $\Delta A = \frac{388}{4} \cdot \frac{276}{4} = 6693$, so using the contour map to estimate the function values at each midpoint, we have

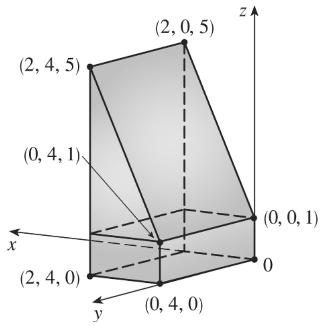
$$\begin{aligned} \iint_R f(x,y)\, dA &\approx \sum_{i=1}^{4}\sum_{j=1}^{4} f\left(\overline{x}_i, \overline{y}_j\right) \Delta A \\ &\approx \Delta A\, [31 + 28 + 52 + 43 + 43 + 25 + 57 + 46 + 36 + 20 + 42 + 45 + 30 + 23 + 43 + 41] \\ &= 6693(605) \end{aligned}$$

Therefore, $f_{\text{ave}} \approx \dfrac{6693 \cdot 605}{388 \cdot 276} \approx 37.8$, so the average temperature in Colorado at 4:00 PM on February 26, 2007, was approximately 37.8°F.

9. $z = \sqrt{2} > 0$, so we can interpret the double integral as the volume of the solid S that lies below the plane $z = \sqrt{2}$ and above the rectangle $[2, 6] \times [-1, 5]$. S is a rectangular solid, so $\iint_R \sqrt{2}\, dA = 4 \cdot 6 \cdot \sqrt{2} = 24\sqrt{2}$.

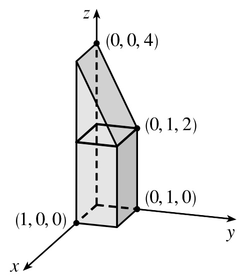
10. $z = 2x + 1 \geq 0$ for $0 \leq x \leq 2$, so we can interpret the integral as the volume of the solid S that lies below the plane $z = 2x + 1$ and above the rectangle $[0, 2] \times [0, 4]$. We can picture S as a rectangular solid (with height 1) surmounted by a triangular cylinder; thus

$$\iint_R (2x + 1)\, dA = (2)(4)(1) + \tfrac{1}{2}(2)(4)(4) = 24$$

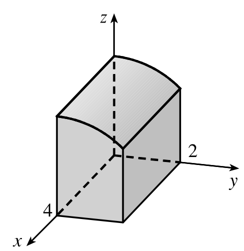


11. $z = 4 - 2y \geq 0$ for $0 \leq y \leq 1$, so we can interpret the integral as the volume of the solid S that lies below the plane $z = 4 - 2y$ and above the square $[0, 1] \times [0, 1]$. We can picture S as a rectangular solid (with height 2) surmounted by a triangular cylinder; thus

$$\iint_R (4 - 2y)\, dA = (1)(1)(2) + \tfrac{1}{2}(1)(1)(2) = 3$$



12. Here $z = \sqrt{9 - y^2}$, so $z^2 + y^2 = 9$, $z \geq 0$. Thus the integral represents the volume of the top half of the part of the circular cylinder $z^2 + y^2 = 9$ that lies above the rectangle $[0, 4] \times [0, 2]$.



13. $\int_0^2 (x + 3x^2y^2)\, dx = \left[\dfrac{x^2}{2} + 3\,\dfrac{x^3}{3}\,y^2\right]_{x=0}^{x=2} = \left[\tfrac{1}{2}x^2 + x^3y^2\right]_{x=0}^{x=2} = \left[\tfrac{1}{2}(2)^2 + (2)^3y^2\right] - \left[\tfrac{1}{2}(0)^2 + (0)^3y^2\right] = 2 + 8y^2$,

$\int_0^3 (x + 3x^2y^2)\, dy = \left[xy + 3x^2\,\dfrac{y^3}{3}\right]_{y=0}^{y=3} = \left[xy + x^2y^3\right]_{y=0}^{y=3} = \left[x(3) + x^2(3)^3\right] - \left[x(0) + x^2(0)^3\right] = 3x + 27x^2$

14. $\int_0^2 y\sqrt{x + 2}\, dx = \left[y \cdot \tfrac{2}{3}(x + 2)^{3/2}\right]_{x=0}^{x=2} = \tfrac{2}{3}y(4)^{3/2} - \tfrac{2}{3}y(2)^{3/2} = \tfrac{16}{3}y - \tfrac{4}{3}\sqrt{2}\,y = \tfrac{4}{3}(4 - \sqrt{2}\,)\,y$,

$\int_0^3 y\sqrt{x + 2}\, dy = \left[\dfrac{y^2}{2}\,\sqrt{x + 2}\right]_{y=0}^{y=3} = \tfrac{1}{2}(3)^2\sqrt{x + 2} - \tfrac{1}{2}(0)^2\sqrt{x + 2} = \tfrac{9}{2}\sqrt{x + 2}$

15. $\int_1^4 \int_0^2 (6x^2y - 2x)\, dy\, dx = \int_1^4 \left[3x^2y^2 - 2xy\right]_{y=0}^{y=2} dx = \int_1^4 \left[\left(12x^2 - 4x\right) - (0 - 0)\right] dx$

$$= \int_1^4 (12x^2 - 4x)\, dx = \left[4x^3 - 2x^2\right]_1^4 = (256 - 32) - (4 - 2) = 222$$

16. $\int_0^1 \int_0^1 (x + y)^2\, dx\, dy = \int_0^1 \int_0^1 (x^2 + 2xy + y^2)\, dx\, dy = \int_0^1 \left[\tfrac{1}{3}x^3 + x^2y + xy^2\right]_{x=0}^{x=1} dy$

$$= \int_0^1 (\tfrac{1}{3} + y + y^2)\, dy = \left[\tfrac{1}{3}y + \tfrac{1}{2}y^2 + \tfrac{1}{3}y^3\right]_0^1 = \tfrac{1}{3} + \tfrac{1}{2} + \tfrac{1}{3} - 0 = \tfrac{7}{6}$$

17. $\int_0^1 \int_1^2 (x + e^{-y})\, dx\, dy = \int_0^1 \left[\tfrac{1}{2}x^2 + xe^{-y}\right]_{x=1}^{x=2} dy = \int_0^1 \left[(2 + 2e^{-y}) - (\tfrac{1}{2} + e^{-y})\right] dy$

$$= \int_0^1 (\tfrac{3}{2} + e^{-y})\, dy = \left[\tfrac{3}{2}y - e^{-y}\right]_0^1 = \left(\tfrac{3}{2} - e^{-1}\right) - (0 - 1) = \tfrac{5}{2} - e^{-1}$$

18. $\int_0^{\pi/6}\int_0^{\pi/2}(\sin x+\sin y)\,dy\,dx = \int_0^{\pi/6}\left[y\sin x-\cos y\right]_{y=0}^{y=\pi/2}\,dx = \int_0^{\pi/6}\left[\left(\frac{\pi}{2}\sin x-0\right)-(0-1)\right]dx$

$= \int_0^{\pi/6}\left(\frac{\pi}{2}\sin x+1\right)dx = \left[-\frac{\pi}{2}\cos x+x\right]_0^{\pi/6}$

$= \left[\left(-\frac{\pi}{2}\cdot\frac{\sqrt{3}}{2}+\frac{\pi}{6}\right)-\left(-\frac{\pi}{2}+0\right)\right] = \left(\frac{2}{3}-\frac{\sqrt{3}}{4}\right)\pi$

19. $\int_{-3}^{3}\int_0^{\pi/2}(y+y^2\cos x)\,dx\,dy = \int_{-3}^{3}\left[xy+y^2\sin x\right]_{x=0}^{x=\pi/2}\,dy = \int_{-3}^{3}\left(\frac{\pi}{2}y+y^2\right)dy$

$= \left[\frac{\pi}{4}y^2+\frac{1}{3}y^3\right]_{-3}^{3} = \left[\left(\frac{9\pi}{4}+9\right)-\left(\frac{9\pi}{4}-9\right)\right] = 18$

20. $\displaystyle\int_1^3\int_1^5\frac{\ln y}{xy}\,dy\,dx = \int_1^3\frac{1}{x}\,dx\int_1^5\frac{\ln y}{y}\,dy$ [by Equation 11]

$= [\ln|x|]_1^3\left[\frac{1}{2}(\ln y)^2\right]_1^5$ [substitute $u=\ln y \Rightarrow du=(1/y)\,dy$]

$= (\ln 3-0)\cdot\frac{1}{2}[(\ln 5)^2-0] = \frac{1}{2}(\ln 3)(\ln 5)^2$

21. $\displaystyle\int_1^4\int_1^2\left(\frac{x}{y}+\frac{y}{x}\right)dy\,dx = \int_1^4\left[x\ln|y|+\frac{1}{x}\cdot\frac{1}{2}y^2\right]_{y=1}^{y=2}dx = \int_1^4\left(x\ln 2+\frac{3}{2x}\right)dx = \left[\frac{1}{2}x^2\ln 2+\frac{3}{2}\ln|x|\right]_1^4$

$= \left(8\ln 2+\frac{3}{2}\ln 4\right)-\left(\frac{1}{2}\ln 2+0\right) = \frac{15}{2}\ln 2+\frac{3}{2}\ln 4$ or $\frac{15}{2}\ln 2+3\ln(4^{1/2}) = \frac{21}{2}\ln 2$

22. $\int_0^1\int_0^2 ye^{x-y}\,dx\,dy = \int_0^1\int_0^2 ye^xe^{-y}\,dx\,dy = \int_0^2 e^x\,dx\int_0^1 ye^{-y}\,dy$ [by Equation 11]

$= [e^x]_0^2\left[(-y-1)e^{-y}\right]_0^1$ [by integrating by parts]

$= \left(e^2-e^0\right)\left[-2e^{-1}-\left(-e^0\right)\right] = (e^2-1)(1-2e^{-1})$ or $e^2-2e+2e^{-1}-1$

23. $\int_0^3\int_0^{\pi/2} t^2\sin^3\phi\,d\phi\,dt = \int_0^{\pi/2}\sin^3\phi\,d\phi\int_0^3 t^2\,dt$ [by Equation 11] $= \int_0^{\pi/2}(1-\cos^2\phi)\sin\phi\,d\phi\int_0^3 t^2\,dt$

$= \left[\frac{1}{3}\cos^3\phi-\cos\phi\right]_0^{\pi/2}\left[\frac{1}{3}t^3\right]_0^3 = \left[(0-0)-\left(\frac{1}{3}-1\right)\right]\cdot\frac{1}{3}(27-0) = \frac{2}{3}(9) = 6$

24. $\int_0^1\int_0^1 xy\sqrt{x^2+y^2}\,dy\,dx = \int_0^1 x\left[\frac{1}{3}(x^2+y^2)^{3/2}\right]_{y=0}^{y=1}dx = \frac{1}{3}\int_0^1 x[(x^2+1)^{3/2}-x^3]\,dx = \frac{1}{3}\int_0^1[x(x^2+1)^{3/2}-x^4]dx$

$= \frac{1}{3}\left[\frac{1}{5}(x^2+1)^{5/2}-\frac{1}{5}x^5\right]_0^1 = \frac{1}{15}\left[(2^{5/2}-1)-(1-0)\right] = \frac{2}{15}\left(2\sqrt{2}-1\right)$

25. $\int_0^1\int_0^1 v(u+v^2)^4\,du\,dv = \int_0^1\left[\frac{1}{5}v(u+v^2)^5\right]_{u=0}^{u=1}dv = \frac{1}{5}\int_0^1 v\left[(1+v^2)^5-(0+v^2)^5\right]dv$

$= \frac{1}{5}\int_0^1\left[v(1+v^2)^5-v^{11}\right]dv = \frac{1}{5}\left[\frac{1}{2}\cdot\frac{1}{6}(1+v^2)^6-\frac{1}{12}v^{12}\right]_0^1$

[substitute $t=1+v^2 \Rightarrow dt=2v\,dv$ in the first term]

$= \frac{1}{60}\left[(2^6-1)-(1-0)\right] = \frac{1}{60}(63-1) = \frac{31}{30}$

26. $\int_0^1\int_0^1\sqrt{s+t}\,ds\,dt = \int_0^1\left[\frac{2}{3}(s+t)^{3/2}\right]_{s=0}^{s=1}dt = \frac{2}{3}\int_0^1[(1+t)^{3/2}-t^{3/2}]\,dt = \frac{2}{3}\left[\frac{2}{5}(1+t)^{5/2}-\frac{2}{5}t^{5/2}\right]_0^1$

$= \frac{4}{15}[(2^{5/2}-1)-(1-0)] = \frac{4}{15}\left(2^{5/2}-2\right)$ or $\frac{8}{15}\left(2\sqrt{2}-1\right)$

27. $\iint_R x\sec^2 y\,dA = \int_0^2\int_0^{\pi/4}x\sec^2 y\,dy\,dx = \int_0^2 x\,dx\int_0^{\pi/4}\sec^2 y\,dy = \left[\frac{1}{2}x^2\right]_0^2\left[\tan y\right]_0^{\pi/4}$

$= (2-0)\left(\tan\frac{\pi}{4}-\tan 0\right) = 2(1-0) = 2$

28. $\iint_R (y + xy^{-2})\,dA = \int_1^2 \int_0^2 (y + xy^{-2})\,dx\,dy = \int_1^2 \left[xy + \frac{1}{2}x^2y^{-2}\right]_{x=0}^{x=2} dy = \int_1^2 \left(2y + 2y^{-2}\right) dy$

$= \left[y^2 - 2y^{-1}\right]_1^2 = (4-1) - (1-2) = 4$

29. $\displaystyle\iint_R \frac{xy^2}{x^2+1}\,dA = \int_0^1 \int_{-3}^3 \frac{xy^2}{x^2+1}\,dy\,dx = \int_0^1 \frac{x}{x^2+1}\,dx \int_{-3}^3 y^2\,dy = \left[\tfrac{1}{2}\ln(x^2+1)\right]_0^1 \left[\tfrac{1}{3}y^3\right]_{-3}^3$

$= \frac{1}{2}(\ln 2 - \ln 1) \cdot \frac{1}{3}(27 + 27) = 9\ln 2$

30. $\displaystyle\iint_R \frac{\tan\theta}{\sqrt{1-t^2}}\,dA = \int_0^{1/2}\int_0^{\pi/3} \frac{\tan\theta}{\sqrt{1-t^2}}\,d\theta\,dt = \int_0^{1/2} \frac{1}{\sqrt{1-t^2}}\,dt \int_0^{\pi/3} \tan\theta\,d\theta = \left[\sin^{-1} t\right]_0^{1/2} \left[\ln|\sec\theta|\right]_0^{\pi/3}$

$= \left(\sin^{-1}\frac{1}{2} - \sin^{-1} 0\right)\left(\ln\left|\sec\frac{\pi}{3}\right| - \ln|\sec 0|\right) = \left(\frac{\pi}{6} - 0\right)(\ln 2 - \ln 1) = \frac{\pi}{6}\ln 2$

31. $\int_0^{\pi/6}\int_0^{\pi/3} x\sin(x+y)\,dy\,dx$

$= \int_0^{\pi/6} \left[-x\cos(x+y)\right]_{y=0}^{y=\pi/3}\,dx = \int_0^{\pi/6} \left[x\cos x - x\cos\left(x + \frac{\pi}{3}\right)\right] dx$

$= x\left[\sin x - \sin\left(x + \frac{\pi}{3}\right)\right]_0^{\pi/6} - \int_0^{\pi/6}\left[\sin x - \sin\left(x + \frac{\pi}{3}\right)\right] dx$ [by integrating by parts separately for each term]

$= \frac{\pi}{6}\left[\frac{1}{2} - 1\right] - \left[-\cos x + \cos\left(x + \frac{\pi}{3}\right)\right]_0^{\pi/6} = -\frac{\pi}{12} - \left[-\frac{\sqrt{3}}{2} + 0 - \left(-1 + \frac{1}{2}\right)\right] = \frac{\sqrt{3}-1}{2} - \frac{\pi}{12}$

32. $\displaystyle\iint_R \frac{x}{1+xy}\,dA = \int_0^1\int_0^1 \frac{x}{1+xy}\,dy\,dx = \int_0^1 \left[\ln(1+xy)\right]_{y=0}^{y=1} dx = \int_0^1 \left[\ln(1+x) - \ln 1\right] dx$

$= \int_0^1 \ln(1+x)\,dx = \left[(1+x)\ln(1+x) - x\right]_0^1$ [by integrating by parts]

$= (2\ln 2 - 1) - (\ln 1 - 0) = 2\ln 2 - 1$

33. $\iint_R ye^{-xy}\,dA = \int_0^3\int_0^2 ye^{-xy}\,dx\,dy = \int_0^3 \left[-e^{-xy}\right]_{x=0}^{x=2} dy = \int_0^3 (-e^{-2y} + 1)\,dy = \left[\frac{1}{2}e^{-2y} + y\right]_0^3$

$= \frac{1}{2}e^{-6} + 3 - \left(\frac{1}{2} + 0\right) = \frac{1}{2}e^{-6} + \frac{5}{2}$

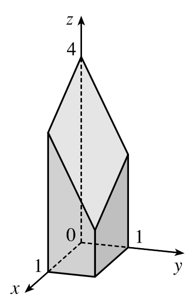
34. $\displaystyle\iint_R \frac{1}{1+x+y}\,dA = \int_1^3\int_1^2 \frac{1}{1+x+y}\,dy\,dx = \int_1^3 \left[\ln(1+x+y)\right]_{y=1}^{y=2} dx = \int_1^3 \left[\ln(x+3) - \ln(x+2)\right] dx$

$= \left[\left((x+3)\ln(x+3) - (x+3)\right) - \left((x+2)\ln(x+2) - (x+2)\right)\right]_1^3$

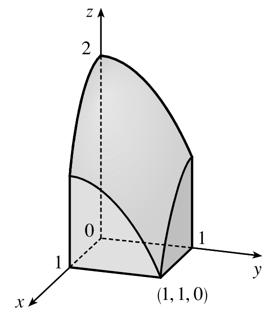
[by integrating by parts separately for each term]

$= (6\ln 6 - 6 - 5\ln 5 + 5) - (4\ln 4 - 4 - 3\ln 3 + 3) = 6\ln 6 - 5\ln 5 - 4\ln 4 + 3\ln 3$

35. $z = f(x,y) = 4 - x - 2y \geq 0$ for $0 \leq x \leq 1$ and $0 \leq y \leq 1$. So the solid is the region in the first octant which lies below the plane $z = 4 - x - 2y$ and above $[0,1] \times [0,1]$.



36. $z = 2 - x^2 - y^2 \geq 0$ for $0 \leq x \leq 1$ and $0 \leq y \leq 1$. So the solid is the region in the first octant which lies below the circular paraboloid $z = 2 - x^2 - y^2$ and above $[0, 1] \times [0, 1]$.



37. The solid lies under the plane $4x + 6y - 2z + 15 = 0$ or $z = 2x + 3y + \frac{15}{2}$ so

$$V = \iint_R (2x + 3y + \tfrac{15}{2})\, dA = \int_{-1}^{1} \int_{-1}^{2} (2x + 3y + \tfrac{15}{2})\, dx\, dy = \int_{-1}^{1} \left[x^2 + 3xy + \tfrac{15}{2}x\right]_{x=-1}^{x=2} dy$$
$$= \int_{-1}^{1} \left[(19 + 6y) - (-\tfrac{13}{2} - 3y)\right] dy = \int_{-1}^{1} (\tfrac{51}{2} + 9y)\, dy = \left[\tfrac{51}{2}y + \tfrac{9}{2}y^2\right]_{-1}^{1} = 30 - (-21) = 51$$

38. $V = \iint_R (3y^2 - x^2 + 2)\, dA = \int_{-1}^{1} \int_{1}^{2} (3y^2 - x^2 + 2)\, dy\, dx = \int_{-1}^{1} \left[y^3 - x^2 y + 2y\right]_{y=1}^{y=2} dx$

$$= \int_{-1}^{1} \left[(12 - 2x^2) - (3 - x^2)\right] dx = \int_{-1}^{1} \left(9 - x^2 dx\right) = \left[9x - \tfrac{1}{3}x^3\right]_{-1}^{1} = \tfrac{26}{3} + \tfrac{26}{3} = \tfrac{52}{3}$$

39. $V = \int_{-2}^{2} \int_{-1}^{1} \left(1 - \frac{1}{4}x^2 - \frac{1}{9}y^2\right) dx\, dy = 4 \int_0^2 \int_0^1 \left(1 - \frac{1}{4}x^2 - \frac{1}{9}y^2\right) dx\, dy$

$$= 4 \int_0^2 \left[x - \tfrac{1}{12}x^3 - \tfrac{1}{9}y^2 x\right]_{x=0}^{x=1} dy = 4 \int_0^2 \left(\tfrac{11}{12} - \tfrac{1}{9}y^2\right) dy = 4\left[\tfrac{11}{12}y - \tfrac{1}{27}y^3\right]_0^2 = 4 \cdot \tfrac{83}{54} = \tfrac{166}{27}$$

40. The solid lies under the surface $z = x^2 + xy^2$ and above the rectangle $R = [0, 5] \times [-2, 2]$, so its volume is

$$V = \iint_R (x^2 + xy^2)\, dA = \int_0^5 \int_{-2}^{2} (x^2 + xy^2)\, dy\, dx = \int_0^5 \left[x^2 y + \tfrac{1}{3}xy^3\right]_{y=-2}^{y=2} dx$$
$$= \int_0^5 \left[\left(2x^2 + \tfrac{8}{3}x\right) - \left(-2x^2 - \tfrac{8}{3}x\right)\right] dx = \int_0^5 (4x^2 + \tfrac{16}{3}x)\, dx$$
$$= \left[\tfrac{4}{3}x^3 + \tfrac{8}{3}x^2\right]_0^5 = \tfrac{500}{3} + \tfrac{200}{3} - 0 = \tfrac{700}{3}$$

41. The solid lies under the surface $z = 1 + x^2 y e^y$ and above the rectangle $R = [-1, 1] \times [0, 1]$, so its volume is

$$V = \iint_R (1 + x^2 y e^y)\, dA = \int_0^1 \int_{-1}^{1} (1 + x^2 y e^y)\, dx\, dy = \int_0^1 \left[x + \tfrac{1}{3}x^3 y e^y\right]_{x=-1}^{x=1} dy$$
$$= \int_0^1 (2 + \tfrac{2}{3}ye^y)\, dy = \left[2y + \tfrac{2}{3}(y - 1)\, e^y\right]_0^1 \quad \text{[by integrating by parts in the second term]}$$
$$= (2 + 0) - \left(0 - \tfrac{2}{3}e^0\right) = 2 + \tfrac{2}{3} = \tfrac{8}{3}$$

42. The cylinder intersects the xy-plane along the line $x = 4$, so in the first octant, the solid lies below the surface $z = 16 - x^2$ and above the rectangle $R = [0, 4] \times [0, 5]$ in the xy-plane.

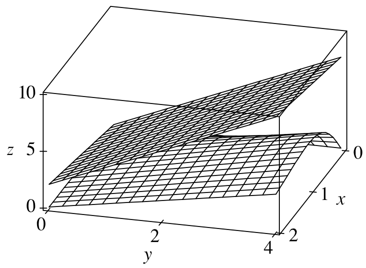
$$V = \int_0^5 \int_0^4 (16 - x^2)\, dx\, dy = \int_0^4 (16 - x^2)\, dx \int_0^5 dy$$
$$= \left[16x - \tfrac{1}{3}x^3\right]_0^4 \left[\, y\, \right]_0^5 = (64 - \tfrac{64}{3} - 0)(5 - 0) = \tfrac{640}{3}$$

43. The solid lies below the surface $z = 2 + x^2 + (y - 2)^2$ and above the plane $z = 1$ for $-1 \leq x \leq 1$, $0 \leq y \leq 4$. The volume of the solid is the difference in volumes between the solid that lies under $z = 2 + x^2 + (y - 2)^2$ over the rectangle

$R = [-1, 1] \times [0, 4]$ and the solid that lies under $z = 1$ over R.

$$\begin{aligned} V &= \textstyle\int_0^4 \int_{-1}^1 [2 + x^2 + (y-2)^2]\,dx\,dy - \int_0^4 \int_{-1}^1 (1)\,dx\,dy \\ &= \textstyle\int_0^4 \left[2x + \frac{1}{3}x^3 + x(y-2)^2\right]_{x=-1}^{x=1} dy - \int_{-1}^1 dx \int_0^4 dy \\ &= \textstyle\int_0^4 \left[(2 + \frac{1}{3} + (y-2)^2) - (-2 - \frac{1}{3} - (y-2)^2)\right] dy - [x]_{-1}^1 \, [y]_0^4 \\ &= \textstyle\int_0^4 \left[\frac{14}{3} + 2(y-2)^2\right] dy - [1 - (-1)][4 - 0] = \left[\frac{14}{3}y + \frac{2}{3}(y-2)^3\right]_0^4 - (2)(4) \\ &= \left[\left(\frac{56}{3} + \frac{16}{3}\right) - \left(0 - \frac{16}{3}\right)\right] - 8 = \frac{88}{3} - 8 = \frac{64}{3} \end{aligned}$$

44.



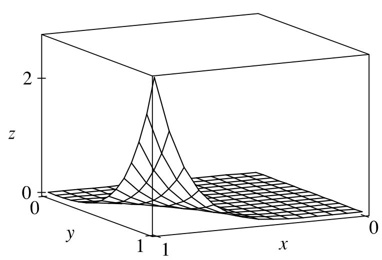
The solid lies below the plane $z = x + 2y$ and above the surface $z = \dfrac{2xy}{x^2+1}$ for $0 \le x \le 2$, $0 \le y \le 4$. The volume of the solid is the difference in volumes between the solid that lies under $z = x + 2y$ over the rectangle $R = [0, 2] \times [0, 4]$ and the solid that lies under $z = \dfrac{2xy}{x^2+1}$ over R.

$$\begin{aligned} V &= \int_0^2 \int_0^4 (x + 2y)dy\,dx - \int_0^2 \int_0^4 \frac{2xy}{x^2+1}\,dy\,dx = \int_0^2 \left[xy + y^2\right]_{y=0}^{y=4} dx - \int_0^2 \frac{2x}{x^2+1}\,dx \int_0^4 y\,dy \\ &= \textstyle\int_0^2 [(4x + 16) - (0 + 0)]\,dx - \left[\ln\left|x^2+1\right|\right]_0^2 \left[\frac{1}{2}y^2\right]_0^4 = \left[2x^2 + 16x\right]_0^2 - (\ln 5 - \ln 1)(8 - 0) \\ &= (8 + 32 - 0) - 8\ln 5 = 40 - 8\ln 5 \end{aligned}$$

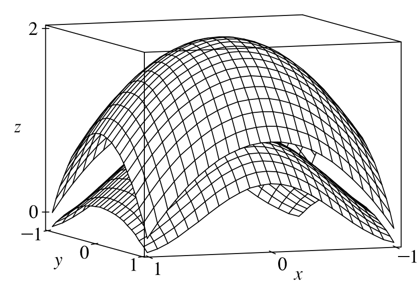
45. In Maple, we can calculate the integral by defining the integrand as `f` and then using the command `int(int(f,x=0..1),y=0..1);`. In Mathematica, we can use the command

```
Integrate[f,{x,0,1},{y,0,1}]
```

We find that $\iint_R x^5 y^3 e^{xy}\,dA = 21e - 57 \approx 0.0839$. We can use `plot3d` (in Maple) or `Plot3D` (in Mathematica) to graph the function.



46. In Maple, we can calculate the integral by defining `f:=exp(-x^2)*cos(x^2+y^2);` and `g:=2-x^2-y^2;` and then [since $2 - x^2 - y^2 > e^{-x^2}\cos(x^2 + y^2)$ for $-1 \le x \le 1$, $-1 \le y \le 1$] using the command `evalf(Int(Int(g-f,x=-1..1),y=-1..1));`. Using `Int` rather than `int` forces Maple to use purely numerical techniques in evaluating the integral.



In Mathematica, we can use the command `NIntegrate[g-f,{x,-1,1},{y,-1,1}]`. We find that $\iint_R \left[(2 - x^2 - y^2) - \left(e^{-x^2}\cos(x^2 + y^2)\right)\right] dA \approx 3.0271$. We can use the `plot3d` command (in Maple) or `Plot3D` (in Mathematica) to graph both functions on the same screen.

47. R is the rectangle $[-1,1]\times[0,5]$. Thus, $A(R)=2\cdot 5=10$ and

$$f_{\text{ave}}=\frac{1}{A(R)}\iint_R f(x,y)\,dA=\tfrac{1}{10}\int_0^5\int_{-1}^1 x^2y\,dx\,dy=\tfrac{1}{10}\int_0^5\left[\tfrac{1}{3}x^3y\right]_{x=-1}^{x=1}dy=\tfrac{1}{10}\int_0^5\tfrac{2}{3}y\,dy=\tfrac{1}{10}\left[\tfrac{1}{3}y^2\right]_0^5=\tfrac{5}{6}.$$

48. $A(R)=4\cdot 1=4$, so

$$f_{\text{ave}}=\frac{1}{A(R)}\iint_R f(x,y)\,dA=\tfrac{1}{4}\int_0^4\int_0^1 e^y\sqrt{x+e^y}\,dy\,dx=\tfrac{1}{4}\int_0^4\left[\tfrac{2}{3}(x+e^y)^{3/2}\right]_{y=0}^{y=1}dx$$
$$=\tfrac{1}{4}\cdot\tfrac{2}{3}\int_0^4[(x+e)^{3/2}-(x+1)^{3/2}]\,dx=\tfrac{1}{6}\left[\tfrac{2}{5}(x+e)^{5/2}-\tfrac{2}{5}(x+1)^{5/2}\right]_0^4$$
$$=\tfrac{1}{6}\cdot\tfrac{2}{5}[(4+e)^{5/2}-5^{5/2}-e^{5/2}+1]=\tfrac{1}{15}[(4+e)^{5/2}-e^{5/2}-5^{5/2}+1]\approx 3.327$$

49. $\displaystyle\iint_R\frac{xy}{1+x^4}\,dA=\int_{-1}^1\int_0^1\frac{xy}{1+x^4}\,dy\,dx=\int_{-1}^1\frac{x}{1+x^4}\,dx\int_0^1 y\,dy$ [by Equation 11] but $f(x)=\dfrac{x}{1+x^4}$ is an odd function so $\displaystyle\int_{-1}^1 f(x)\,dx=0$ (by Theorem 4.5.6 [ET 5.5.7]). Thus $\displaystyle\iint_R\frac{xy}{1+x^4}\,dA=0\cdot\int_0^1 y\,dy=0.$

50. $\iint_R(1+x^2\sin y+y^2\sin x)\,dA=\iint_R 1\,dA+\iint_R x^2\sin y\,dA+\iint_R y^2\sin x\,dA$

$$=A(R)+\int_{-\pi}^{\pi}\int_{-\pi}^{\pi}x^2\sin y\,dy\,dx+\int_{-\pi}^{\pi}\int_{-\pi}^{\pi}y^2\sin x\,dy\,dx$$
$$=(2\pi)(2\pi)+\int_{-\pi}^{\pi}x^2dx\int_{-\pi}^{\pi}\sin y\,dy+\int_{-\pi}^{\pi}\sin x\,dx\int_{-\pi}^{\pi}y^2\,dy$$

But $\sin x$ is an odd function, so $\int_{-\pi}^{\pi}\sin x\,dx=\int_{-\pi}^{\pi}\sin y\,dy=0$ (by Theorem 4.5.6 [ET 5.5.7]) and

$\iint_R(1+x^2\sin y+y^2\sin x)\,dA=4\pi^2+0+0=4\pi^2.$

51. Let $f(x,y)=\dfrac{x-y}{(x+y)^3}$. Then a CAS gives $\int_0^1\int_0^1 f(x,y)\,dy\,dx=\frac{1}{2}$ and $\int_0^1\int_0^1 f(x,y)\,dx\,dy=-\frac{1}{2}$.

To explain the seeming violation of Fubini's Theorem, note that f has an infinite discontinuity at $(0,0)$ and thus does not satisfy the conditions of Fubini's Theorem. In fact, both iterated integrals involve improper integrals which diverge at their lower limits of integration.

52. (a) Loosely speaking, Fubini's Theorem says that the order of integration of a function of two variables does not affect the value of the double integral, while Clairaut's Theorem says that the order of differentiation of such a function does not affect the value of the second-order derivative. Also, both theorems require continuity (though Fubini's allows a finite number of smooth curves to contain discontinuities).

(b) To find g_{xy}, we first hold y constant and use the single-variable Fundamental Theorem of Calculus, Part 1:

$g_x=\dfrac{d}{dx}\,g(x,y)=\dfrac{d}{dx}\displaystyle\int_a^x\left(\int_c^y f(s,t)\,dt\right)ds=\int_c^y f(x,t)\,dt$. Now we use the Fundamental Theorem again:

$g_{xy}=\dfrac{d}{dy}\displaystyle\int_c^y f(x,t)\,dt=f(x,y).$

To find g_{yx}, we first use Fubini's Theorem to find that $\int_a^x\int_c^y f(s,t)\,dt\,ds=\int_c^y\int_a^x f(s,t)\,dt\,ds$, and then use the Fundamental Theorem twice, as above, to get $g_{yx}=f(x,y)$. So $g_{xy}=g_{yx}=f(x,y)$.

15.2 Double Integrals over General Regions

1. $\int_1^5 \int_0^x (8x - 2y)\,dy\,dx = \int_1^5 \left[8xy - y^2\right]_{y=0}^{y=x} dx = \int_1^5 [8x(x) - (x)^2 - 8x(0) + (0)^2]dx$

$= \int_1^5 7x^2\,dx = \frac{7}{3}x^3\Big]_1^5 = \frac{7}{3}(125 - 1) = \frac{868}{3}$

2. $\int_0^2 \int_0^{y^2} x^2 y\,dx\,dy = \int_0^2 \left[\frac{1}{3}x^3 y\right]_{x=0}^{x=y^2} dy = \int_0^2 \frac{1}{3}y\left[(y^2)^3 - (0)^3\right] dy$

$= \int_0^2 \frac{1}{3}y^7\,dy = \frac{1}{3}\left[\frac{1}{8}y^8\right]_0^2 = \frac{1}{3}(32 - 0) = \frac{32}{3}$

3. $\int_0^1 \int_0^y xe^{y^3}\,dx\,dy = \int_0^1 \left[\frac{1}{2}x^2 e^{y^3}\right]_{x=0}^{x=y} dy = \int_0^1 \frac{1}{2}e^{y^3}\left[(y)^2 - (0)^2\right] dy$

$= \frac{1}{2}\int_0^1 y^2 e^{y^3}\,dy = \frac{1}{2}\left[\frac{1}{3}e^{y^3}\right]_0^1 = \frac{1}{2}\cdot\frac{1}{3}\left(e^1 - e^0\right) = \frac{1}{6}(e - 1)$

4. $\int_0^{\pi/2} \int_0^x x\sin y\,dy\,dx = \int_0^{\pi/2} [x(-\cos y)]_{y=0}^{y=x} dx = \int_0^{\pi/2} (-x\cos x + x)\,dx = \int_0^{\pi/2} (x - x\cos x)\,dx$

$= \left[\frac{1}{2}x^2 - (x\sin x + \cos x)\right]_0^{\pi/2}$ (by integrating by parts in the second term)

$= \left(\frac{1}{2}\cdot\frac{\pi^2}{4} - \frac{\pi}{2} - 0\right) - (0 - 0 - 1) = \frac{\pi^2}{8} - \frac{\pi}{2} + 1$

5. $\int_0^1 \int_0^{s^2} \cos(s^3)\,dt\,ds = \int_0^1 \left[t\cos(s^3)\right]_{t=0}^{t=s^2} ds = \int_0^1 s^2\cos(s^3)\,ds = \frac{1}{3}\sin(s^3)\Big]_0^1 = \frac{1}{3}(\sin 1 - \sin 0) = \frac{1}{3}\sin 1$

6. $\int_0^1 \int_0^{e^v} \sqrt{1 + e^v}\,dw\,dv = \int_0^1 \left[w\sqrt{1 + e^v}\right]_{w=0}^{w=e^v} dv = \int_0^1 e^v\sqrt{1 + e^v}\,dv = \frac{2}{3}(1 + e^v)^{3/2}\Big]_0^1$

$= \frac{2}{3}(1 + e)^{3/2} - \frac{2}{3}(1 + 1)^{3/2} = \frac{2}{3}(1 + e)^{3/2} - \frac{4}{3}\sqrt{2}$

7. $\displaystyle\iint_D \frac{y}{x^2 + 1}\,dA = \int_0^4 \int_0^{\sqrt{x}} \frac{y}{x^2 + 1}\,dy\,dx = \int_0^4 \left[\frac{1}{x^2 + 1}\cdot\frac{y^2}{2}\right]_{y=0}^{y=\sqrt{x}} dx = \frac{1}{2}\int_0^4 \frac{x}{x^2 + 1}\,dx$

$= \frac{1}{2}\left[\frac{1}{2}\ln\left|x^2 + 1\right|\right]_0^4 = \frac{1}{4}\left[\ln\left(x^2 + 1\right)\right]_0^4 = \frac{1}{4}(\ln 17 - \ln 1) = \frac{1}{4}\ln 17$

8. $\iint_D (2x + y)\,dA = \int_1^2 \int_{y-1}^1 (2x + y)\,dx\,dy = \int_1^2 \left[x^2 + xy\right]_{x=y-1}^{x=1} dy = \int_1^2 \left[1 + y - (y - 1)^2 - y(y - 1)\right] dy$

$= \int_1^2 (-2y^2 + 4y)\,dy = \left[-\frac{2}{3}y^3 + 2y^2\right]_1^2 = \left(-\frac{16}{3} + 8\right) - \left(-\frac{2}{3} + 2\right) = \frac{4}{3}$

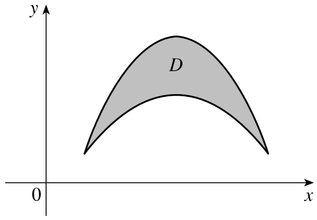
9. $\iint_D e^{-y^2}\,dA = \int_0^3 \int_0^y e^{-y^2}\,dx\,dy = \int_0^3 \left[xe^{-y^2}\right]_{x=0}^{x=y} dy = \int_0^3 \left(ye^{-y^2} - 0\right) dy = \int_0^3 ye^{-y^2}\,dy$

$= -\frac{1}{2}e^{-y^2}\Big]_0^3 = -\frac{1}{2}\left(e^{-9} - e^0\right) = \frac{1}{2}\left(1 - e^{-9}\right)$

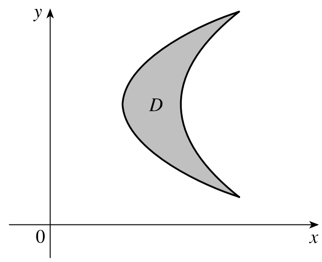
10. $\iint_D y\sqrt{x^2 - y^2}\,dA = \int_0^2 \int_0^x y\sqrt{x^2 - y^2}\,dy\,dx = \int_0^2 \left[-\frac{1}{3}(x^2 - y^2)^{3/2}\right]_{y=0}^{y=x} dx = \int_0^2 \left[0 + \frac{1}{3}(x^2)^{3/2}\right] dx$

$= \int_0^2 \frac{1}{3}x^3\,dx = \frac{1}{3}\cdot\frac{1}{4}x^4\Big]_0^2 = \frac{1}{12}(16 - 0) = \frac{4}{3}$

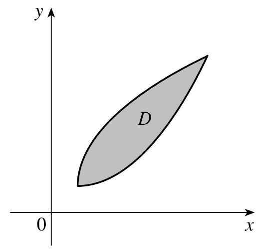
11. (a) At the right we sketch an example of a region D that can be described as lying between the graphs of two continuous functions of x (a type I region) but not as lying between graphs of two continuous functions of y (a type II region). The regions shown in Figures 6 and 8 in the text are additional examples.



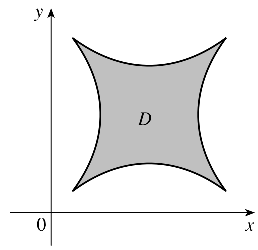
(b) Now we sketch an example of a region D that can be described as lying between the graphs of two continuous functions of y but not as lying between graphs of two continuous functions of x. The first region shown in Figure 7 is another example.



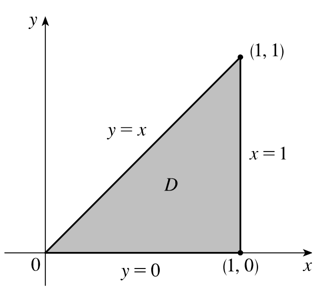
12. (a) At the right we sketch an example of a region D that can be described as lying between the graphs of two continuous functions of x (a type I region) and also as lying between graphs of two continuous functions of y (a type II region). For additional examples see Figures 9, 11, 12, and 14–16 in the text.



(b) Now we sketch an example of a region D that can't be described as lying between the graphs of two continuous functions of x or between graphs of two continuous functions of y. The region shown in Figure 18 is another example.



13.

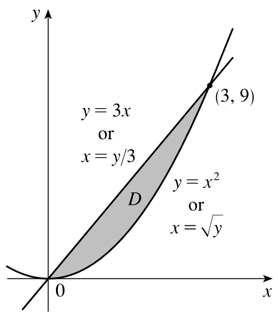


As a type I region, D lies between the lower boundary $y = 0$ and the upper boundary $y = x$ for $0 \le x \le 1$, so $D = \{(x, y) \mid 0 \le x \le 1, 0 \le y \le x\}$. If we describe D as a type II region, D lies between the left boundary $x = y$ and the right boundary $x = 1$ for $0 \le y \le 1$, so $D = \{(x, y) \mid 0 \le y \le 1, y \le x \le 1\}$.

Thus $\iint_D x\,dA = \int_0^1 \int_0^x x\,dy\,dx = \int_0^1 \left[xy\right]_{y=0}^{y=x} dx = \int_0^1 x^2\,dx = \frac{1}{3}x^3\Big]_0^1 = \frac{1}{3}(1-0) = \frac{1}{3}$ or

$\iint_D x\,dA = \int_0^1 \int_y^1 x\,dx\,dy = \int_0^1 \left[\frac{1}{2}x^2\right]_{x=y}^{x=1} dy = \frac{1}{2}\int_0^1 (1-y^2)\,dy = \frac{1}{2}\left[y - \frac{1}{3}y^3\right]_0^1 = \frac{1}{2}\left[\left(1-\frac{1}{3}\right) - 0\right] = \frac{1}{3}$.

14.

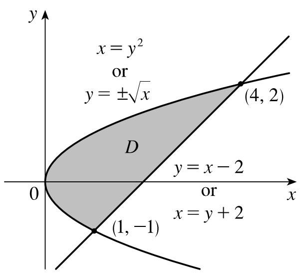


The curves $y = x^2$ and $y = 3x$ intersect at points $(0, 0)$, $(3, 9)$. As a type I region, D is enclosed by the lower boundary $y = x^2$ and the upper boundary $y = 3x$ for $0 \le x \le 3$, so $D = \{(x, y) \mid 0 \le x \le 3, x^2 \le y \le 3x\}$. If we describe D as a type II region, D is enclosed by the left boundary $x = y/3$ and the right boundary $x = \sqrt{y}$ for $0 \le y \le 9$, so $D = \{(x, y) \mid 0 \le y \le 9, y/3 \le x \le \sqrt{y}\}$. Thus

$$\iint_D xy\,dA = \int_0^3\int_{x^2}^{3x} xy\,dy\,dx = \int_0^3 \left[x\cdot\tfrac{1}{2}y^2\right]_{y=x^2}^{y=3x} dx = \tfrac{1}{2}\int_0^3 x(9x^2-x^4)\,dx = \tfrac{1}{2}\int_0^3 (9x^3-x^5)\,dx$$
$$= \tfrac{1}{2}\left[9\cdot\tfrac{1}{4}x^4 - \tfrac{1}{6}x^6\right]_0^3 = \tfrac{1}{2}\left[\left(\tfrac{9}{4}\cdot 81 - \tfrac{1}{6}\cdot 729\right) - 0\right] = \tfrac{243}{8}$$

or
$$\iint_D xy\,dA = \int_0^9\int_{y/3}^{\sqrt{y}} xy\,dx\,dy = \int_0^9 \left[\tfrac{1}{2}x^2y\right]_{x=y/3}^{x=\sqrt{y}} dy = \tfrac{1}{2}\int_0^9 \left(y-\tfrac{1}{9}y^2\right)y\,dy = \tfrac{1}{2}\int_0^9 \left(y^2-\tfrac{1}{9}y^3\right)dy$$
$$= \tfrac{1}{2}\left[\tfrac{1}{3}y^3 - \tfrac{1}{9}\cdot\tfrac{1}{4}y^4\right]_0^9 = \tfrac{1}{2}\left[\left(\tfrac{1}{3}\cdot 729 - \tfrac{1}{36}\cdot 6561\right) - 0\right] = \tfrac{243}{8}$$

15.

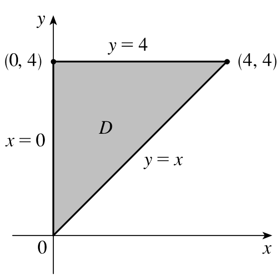


The curves $y = x - 2$ or $x = y + 2$ and $x = y^2$ intersect when $y + 2 = y^2 \iff y^2 - y - 2 = 0 \iff (y-2)(y+1) = 0 \iff y = -1, y = 2$, so the points of intersection are $(1,-1)$ and $(4,2)$. If we describe D as a type I region, the upper boundary curve is $y = \sqrt{x}$ but the lower boundary curve consists of two parts, $y = -\sqrt{x}$ for $0 \le x \le 1$ and $y = x - 2$ for $1 \le x \le 4$.

Thus $D = \{(x,y) \mid 0 \le x \le 1, -\sqrt{x} \le y \le \sqrt{x}\} \cup \{(x,y) \mid 1 \le x \le 4, x - 2 \le y \le \sqrt{x}\}$ and $\iint_D y\,dA = \int_0^1\int_{-\sqrt{x}}^{\sqrt{x}} y\,dy\,dx + \int_1^4\int_{x-2}^{\sqrt{x}} y\,dy\,dx$. If we describe D as a type II region, D is enclosed by the left boundary $x = y^2$ and the right boundary $x = y + 2$ for $-1 \le y \le 2$, so $D = \{(x,y) \mid -1 \le y \le 2, y^2 \le x \le y + 2\}$ and $\iint_D y\,dA = \int_{-1}^2\int_{y^2}^{y+2} y\,dx\,dy$. In either case, the resulting iterated integrals are not difficult to evaluate but the region D is more simply described as a type II region, giving one iterated integral rather than a sum of two, so we evaluate the latter integral:

$$\iint_D y\,dA = \int_{-1}^2\int_{y^2}^{y+2} y\,dx\,dy = \int_{-1}^2 \left[xy\right]_{x=y^2}^{x=y+2} dy = \int_{-1}^2 (y+2-y^2)y\,dy = \int_{-1}^2 (y^2+2y-y^3)\,dy$$
$$= \left[\tfrac{1}{3}y^3 + y^2 - \tfrac{1}{4}y^4\right]_{-1}^2 = \left(\tfrac{8}{3}+4-4\right) - \left(-\tfrac{1}{3}+1-\tfrac{1}{4}\right) = \tfrac{9}{4}$$

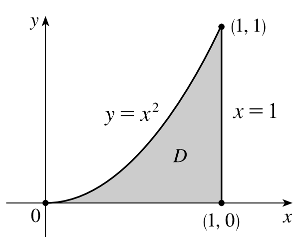
16.



As a type I region, $D = \{(x,y) \mid 0 \le x \le 4, x \le y \le 4\}$ and $\iint_D y^2 e^{xy}\,dA = \int_0^4\int_x^4 y^2e^{xy}\,dy\,dx$. As a type II region, $D = \{(x,y) \mid 0 \le y \le 4, 0 \le x \le y\}$ and $\iint_D y^2e^{xy}\,dA = \int_0^4\int_0^y y^2e^{xy}\,dx\,dy$. Evaluating $\int y^2e^{xy}\,dy$ requires integration by parts whereas $\int y^2e^{xy}\,dx$ does not, so the iterated integral corresponding to D as a type II region appears easier to evaluate.

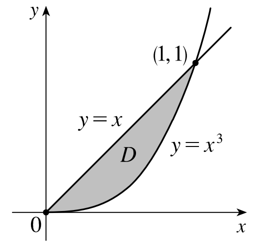
$$\iint_D y^2e^{xy}\,dA = \int_0^4\int_0^y y^2e^{xy}\,dx\,dy = \int_0^4 \left[ye^{xy}\right]_{x=0}^{x=y} dy = \int_0^4 \left(ye^{y^2} - y\right)dy$$
$$= \left[\tfrac{1}{2}e^{y^2} - \tfrac{1}{2}y^2\right]_0^4 = \left(\tfrac{1}{2}e^{16} - 8\right) - \left(\tfrac{1}{2} - 0\right) = \tfrac{1}{2}e^{16} - \tfrac{17}{2}$$

17.



$$\int_0^1\int_0^{x^2} x\cos y\,dy\,dx = \int_0^1 \left[x\sin y\right]_{y=0}^{y=x^2} dx = \int_0^1 x\sin x^2\,dx$$
$$= -\tfrac{1}{2}\cos x^2\Big]_0^1 = -\tfrac{1}{2}(\cos 1 - \cos 0) = \tfrac{1}{2}(1-\cos 1)$$

18.

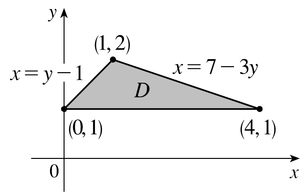


$$\iint_D (x^2 + 2y)\,dA = \int_0^1 \int_{x^3}^{x} (x^2 + 2y)\,dy\,dx = \int_0^1 \left[x^2 y + y^2\right]_{y=x^3}^{y=x}\,dx$$

$$= \int_0^1 (x^3 + x^2 - x^5 - x^6)\,dx = \left[\tfrac{1}{4}x^4 + \tfrac{1}{3}x^3 - \tfrac{1}{6}x^6 - \tfrac{1}{7}x^7\right]_0^1$$

$$= \tfrac{1}{4} + \tfrac{1}{3} - \tfrac{1}{6} - \tfrac{1}{7} = \tfrac{23}{84}$$

19.

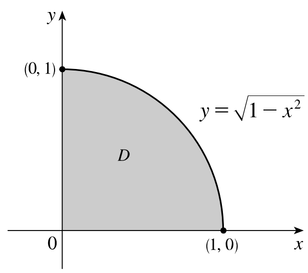


$$\iint_D y^2\,dA = \int_1^2 \int_{y-1}^{7-3y} y^2\,dx\,dy = \int_1^2 \left[xy^2\right]_{x=y-1}^{x=7-3y}\,dy$$

$$= \int_1^2 \left[(7-3y) - (y-1)\right] y^2\,dy = \int_1^2 (8y^2 - 4y^3)\,dy$$

$$= \left[\tfrac{8}{3}y^3 - y^4\right]_1^2 = \tfrac{64}{3} - 16 - \tfrac{8}{3} + 1 = \tfrac{11}{3}$$

20.



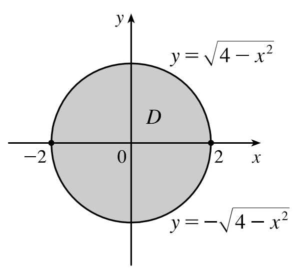
$$\iint_D xy\,dA = \int_0^1 \int_0^{\sqrt{1-x^2}} xy\,dy\,dx$$

$$= \int_0^1 \left[\tfrac{1}{2}xy^2\right]_{y=0}^{y=\sqrt{1-x^2}}\,dx = \int_0^1 \tfrac{1}{2}x(1-x^2)\,dx$$

$$= \tfrac{1}{2}\int_0^1 (x - x^3)\,dx = \tfrac{1}{2}\left[\tfrac{1}{2}x^2 - \tfrac{1}{4}x^4\right]_0^1$$

$$= \tfrac{1}{2}\left(\tfrac{1}{2} - \tfrac{1}{4} - 0\right) = \tfrac{1}{8}$$

21.



$$\int_{-2}^{2} \int_{-\sqrt{4-x^2}}^{\sqrt{4-x^2}} (2x - y)\,dy\,dx$$

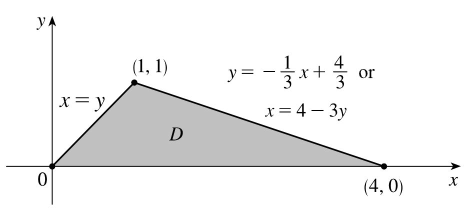
$$= \int_{-2}^{2} \left[2xy - \tfrac{1}{2}y^2\right]_{y=-\sqrt{4-x^2}}^{y=\sqrt{4-x^2}}\,dx$$

$$= \int_{-2}^{2} \left[2x\sqrt{4-x^2} - \tfrac{1}{2}\left(4-x^2\right) + 2x\sqrt{4-x^2} + \tfrac{1}{2}\left(4-x^2\right)\right]dx$$

$$= \int_{-2}^{2} 4x\sqrt{4-x^2}\,dx = -\tfrac{4}{3}\left(4-x^2\right)^{3/2}\Big]_{-2}^{2} = 0$$

[Or, note that $4x\sqrt{4-x^2}$ is an odd function, so $\int_{-2}^{2} 4x\sqrt{4-x^2}\,dx = 0$.]

22.

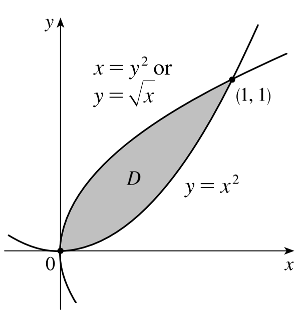


$$\iint_D y\,dA = \int_0^1 \int_y^{4-3y} y\,dx\,dy$$

$$= \int_0^1 \left[xy\right]_{x=y}^{x=4-3y}\,dy = \int_0^1 (4y - 3y^2 - y^2)\,dy$$

$$= \int_0^1 (4y - 4y^2)\,dy = \left[2y^2 - \tfrac{4}{3}y^3\right]_0^1 = 2 - \tfrac{4}{3} - 0 = \tfrac{2}{3}$$

23.

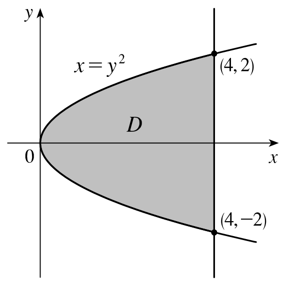


$$V = \int_0^1 \int_{x^2}^{\sqrt{x}} (3x + 2y)\,dy\,dx = \int_0^1 \left[3xy + y^2\right]_{y=x^2}^{y=\sqrt{x}}\,dx$$

$$= \int_0^1 \left[(3x\sqrt{x} + x) - (3x^3 + x^4)\right]dx = \int_0^1 (3x^{3/2} + x - 3x^3 - x^4)\,dx$$

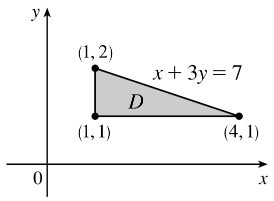
$$= \left[3 \cdot \tfrac{2}{5}x^{5/2} + \tfrac{1}{2}x^2 - \tfrac{3}{4}x^4 - \tfrac{1}{5}x^5\right]_0^1 = \tfrac{6}{5} + \tfrac{1}{2} - \tfrac{3}{4} - \tfrac{1}{5} - 0 = \tfrac{3}{4}$$

24.



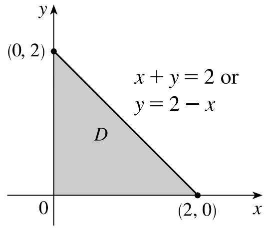
$$V = \int_{-2}^{2}\int_{y^2}^{4}(1 + x^2y^2)\,dx\,dy$$
$$= \int_{-2}^{2}\left[x + \tfrac{1}{3}x^3y^2\right]_{x=y^2}^{x=4}\,dy = \int_{-2}^{2}(4 + \tfrac{61}{3}y^2 - \tfrac{1}{3}y^8)\,dy$$
$$= \left[4y + \tfrac{61}{9}y^3 - \tfrac{1}{27}y^9\right]_{-2}^{2} = 8 + \tfrac{488}{9} - \tfrac{512}{27} + 8 + \tfrac{488}{9} - \tfrac{512}{27} = \tfrac{2336}{27}$$

25.



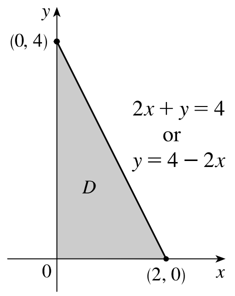
$$V = \int_{1}^{2}\int_{1}^{7-3y}xy\,dx\,dy = \int_{1}^{2}\left[\tfrac{1}{2}x^2y\right]_{x=1}^{x=7-3y}\,dy$$
$$= \tfrac{1}{2}\int_{1}^{2}y\left[(7-3y)^2 - 1\right]dy = \tfrac{1}{2}\int_{1}^{2}(48y - 42y^2 + 9y^3)\,dy$$
$$= \tfrac{1}{2}\left[24y^2 - 14y^3 + \tfrac{9}{4}y^4\right]_{1}^{2} = \tfrac{31}{8}$$

26.



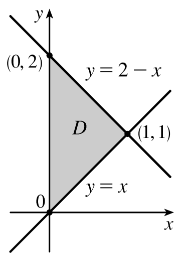
$$V = \int_{0}^{2}\int_{0}^{2-x}(x^2 + y^2 + 1)\,dy\,dx = \int_{0}^{2}\left[x^2y + \tfrac{1}{3}y^3 + y\right]_{y=0}^{y=2-x}\,dx$$
$$= \int_{0}^{2}\left[x^2(2-x) + \tfrac{1}{3}(2-x)^3 + (2-x) - 0\right]dx$$
$$= \int_{0}^{2}\left(-\tfrac{4}{3}x^3 + 4x^2 - 5x + \tfrac{14}{3}\right)dx = \left[-\tfrac{1}{3}x^4 + \tfrac{4}{3}x^3 - \tfrac{5}{2}x^2 + \tfrac{14}{3}x\right]_{0}^{2}$$
$$= -\tfrac{16}{3} + \tfrac{32}{3} - 10 + \tfrac{28}{3} - 0 = \tfrac{14}{3}$$

27.



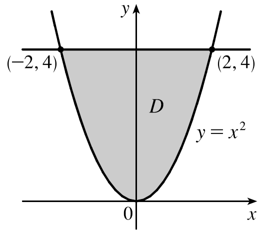
$$V = \int_{0}^{2}\int_{0}^{4-2x}(4 - 2x - y)\,dy\,dx = \int_{0}^{2}\left[4y - 2xy - \tfrac{1}{2}y^2\right]_{y=0}^{y=4-2x}\,dx$$
$$= \int_{0}^{2}\left[4(4-2x) - 2x(4-2x) - \tfrac{1}{2}(4-2x)^2 - 0\right]dx$$
$$= \int_{0}^{2}\left(2x^2 - 8x + 8\right)dx = \left[\tfrac{2}{3}x^3 - 4x^2 + 8x\right]_{0}^{2} = \tfrac{16}{3} - 16 + 16 - 0 = \tfrac{16}{3}$$

28.



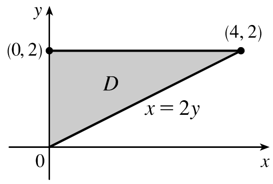
$$V = \int_{0}^{1}\int_{x}^{2-x}x\,dy\,dx$$
$$= \int_{0}^{1}\left[xy\right]_{y=x}^{y=2-x}\,dx = \int_{0}^{1}(2x - 2x^2)\,dx$$
$$= \left[x^2 - \tfrac{2}{3}x^3\right]_{0}^{1} = \tfrac{1}{3}$$

29.



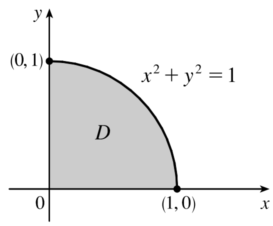
$$V = \int_{-2}^{2}\int_{x^2}^{4}x^2\,dy\,dx$$
$$= \int_{-2}^{2}\left[x^2y\right]_{y=x^2}^{y=4}\,dx = \int_{-2}^{2}(4x^2 - x^4)\,dx$$
$$= \left[\tfrac{4}{3}x^3 - \tfrac{1}{5}x^5\right]_{-2}^{2} = \tfrac{32}{3} - \tfrac{32}{5} + \tfrac{32}{3} - \tfrac{32}{5} = \tfrac{128}{15}$$

30.



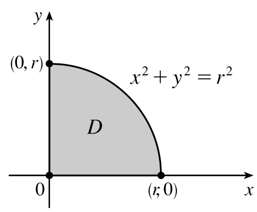
$$V=\int_0^2\int_0^{2y}\sqrt{4-y^2}\,dx\,dy=\int_0^2\left[x\sqrt{4-y^2}\right]_{x=0}^{x=2y}dy$$
$$=\int_0^2 2y\sqrt{4-y^2}\,dy=\left[-\tfrac{2}{3}\left(4-y^2\right)^{3/2}\right]_0^2=0+\tfrac{16}{3}=\tfrac{16}{3}$$

31.



$$V=\int_0^1\int_0^{\sqrt{1-x^2}}y\,dy\,dx=\int_0^1\left[\frac{y^2}{2}\right]_{y=0}^{y=\sqrt{1-x^2}}dx$$
$$=\int_0^1\frac{1-x^2}{2}\,dx=\tfrac{1}{2}\left[x-\tfrac{1}{3}x^3\right]_0^1=\tfrac{1}{3}$$

32.

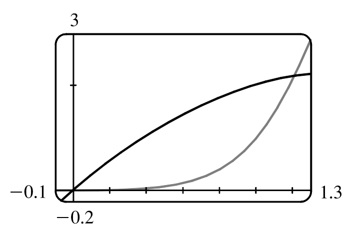


By symmetry, the desired volume V is 8 times the volume V_1 in the first octant. Now

$$V_1=\int_0^r\int_0^{\sqrt{r^2-y^2}}\sqrt{r^2-y^2}\,dx\,dy=\int_0^r\left[x\sqrt{r^2-y^2}\right]_{x=0}^{x=\sqrt{r^2-y^2}}dy$$
$$=\int_0^r(r^2-y^2)\,dy=\left[r^2y-\tfrac{1}{3}y^3\right]_0^r=\tfrac{2}{3}r^3$$

Thus $V=\frac{16}{3}r^3$.

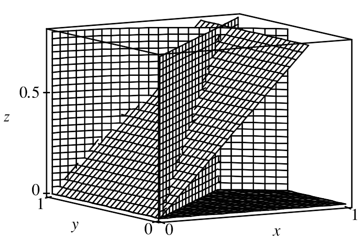
33.

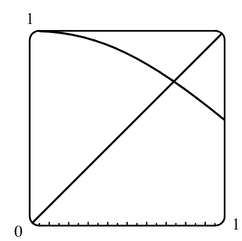


From the graph, it appears that the two curves intersect at $x=0$ and at $x\approx 1.213$. Thus the desired integral is

$$\iint_D x\,dA\approx\int_0^{1.213}\int_{x^4}^{3x-x^2}x\,dy\,dx=\int_0^{1.213}\left[xy\right]_{y=x^4}^{y=3x-x^2}dx$$
$$=\int_0^{1.213}(3x^2-x^3-x^5)\,dx=\left[x^3-\tfrac{1}{4}x^4-\tfrac{1}{6}x^6\right]_0^{1.213}$$
$$\approx 0.713$$

34.





The desired solid is shown in the first graph. From the second graph, we estimate that $y=\cos x$ intersects $y=x$ at $x\approx 0.7391$. Therefore the volume of the solid is

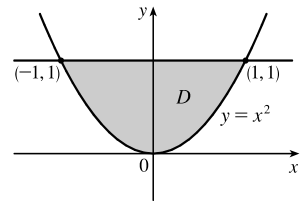
$$V\approx\int_0^{0.7391}\int_x^{\cos x}x\,dy\,dx=\int_0^{0.7391}\left[xy\right]_{y=x}^{y=\cos x}dx$$
$$=\int_0^{0.7391}(x\cos x-x^2)\,dx=\left[\cos x+x\sin x-\tfrac{1}{3}x^3\right]_0^{0.7391}\approx 0.1024$$

Note: There is a different solid which can also be construed to satisfy the conditions stated in the exercise. This is the solid bounded by all of the given surfaces, as well as the plane $y=0$. In case you calculated the volume of this solid and want to check your work, its volume is $V\approx\int_0^{0.7391}\int_0^x x\,dy\,dx+\int_{0.7391}^{\pi/2}\int_0^{\cos x}x\,dy\,dx\approx 0.4684$.

35. The region of integration is bounded by the curves $y = 1 - x^2$ and $y = x^2 - 1$ which intersect at $(\pm 1, 0)$ with $1 - x^2 \geq x^2 - 1$ on $[-1, 1]$. Within this region, the plane $z = 2x + 2y + 10$ is above the plane $z = 2 - x - y$, so

$$\begin{aligned} V &= \int_{-1}^{1}\int_{x^2-1}^{1-x^2}(2x + 2y + 10)\,dy\,dx - \int_{-1}^{1}\int_{x^2-1}^{1-x^2}(2 - x - y)\,dy\,dx \\ &= \int_{-1}^{1}\int_{x^2-1}^{1-x^2}(2x + 2y + 10 - (2 - x - y))\,dy\,dx \\ &= \int_{-1}^{1}\int_{x^2-1}^{1-x^2}(3x + 3y + 8)\,dy\,dx = \int_{-1}^{1}\left[3xy + \tfrac{3}{2}y^2 + 8y\right]_{y=x^2-1}^{y=1-x^2}dx \\ &= \int_{-1}^{1}\left[3x(1 - x^2) + \tfrac{3}{2}(1 - x^2)^2 + 8(1 - x^2) - 3x(x^2 - 1) - \tfrac{3}{2}(x^2 - 1)^2 - 8(x^2 - 1)\right]dx \\ &= \int_{-1}^{1}(-6x^3 - 16x^2 + 6x + 16)\,dx = \left[-\tfrac{3}{2}x^4 - \tfrac{16}{3}x^3 + 3x^2 + 16x\right]_{-1}^{1} \\ &= -\tfrac{3}{2} - \tfrac{16}{3} + 3 + 16 + \tfrac{3}{2} - \tfrac{16}{3} - 3 + 16 = \tfrac{64}{3} \end{aligned}$$

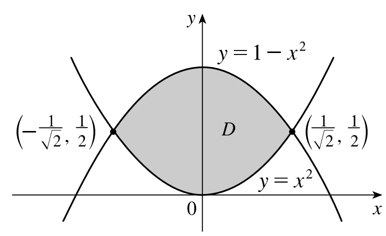
36. The two planes intersect in the line $y = 1$, $z = 3$, so the region of integration is the plane region enclosed by the parabola $y = x^2$ and the line $y = 1$. We have $2 + y \geq 3y$ for $0 \leq y \leq 1$, so the solid region is bounded above by $z = 2 + y$ and bounded below by $z = 3y$.



$$\begin{aligned} V &= \int_{-1}^{1}\int_{x^2}^{1}(2 + y)\,dy\,dx - \int_{-1}^{1}\int_{x^2}^{1}(3y)\,dy\,dx = \int_{-1}^{1}\int_{x^2}^{1}(2 + y - 3y)\,dy\,dx \\ &= \int_{-1}^{1}\int_{x^2}^{1}(2 - 2y)\,dy\,dx = \int_{-1}^{1}\left[2y - y^2\right]_{y=x^2}^{y=1}dx \\ &= \int_{-1}^{1}(1 - 2x^2 + x^4)\,dx = x - \tfrac{2}{3}x^3 + \tfrac{1}{5}x^5\Big]_{-1}^{1} = \tfrac{16}{15} \end{aligned}$$

37. The region of integration is bounded by the curves $y = x^2$ and $y = 1 - x^2$ which intersect at $\left(\pm\frac{1}{\sqrt{2}}, \frac{1}{2}\right)$.

The solid lies under the graph of $z = 3$ and above the graph of $z = y$, so its volume is



$$\begin{aligned} V &= \int_{-1/\sqrt{2}}^{1/\sqrt{2}}\int_{x^2}^{1-x^2}3\,dy\,dx - \int_{-1/\sqrt{2}}^{1/\sqrt{2}}\int_{x^2}^{1-x^2}y\,dy\,dx = \int_{-1/\sqrt{2}}^{1/\sqrt{2}}\int_{x^2}^{1-x^2}(3 - y)\,dy\,dx \\ &= \int_{-1/\sqrt{2}}^{1/\sqrt{2}}\left[3y - \tfrac{1}{2}y^2\right]_{y=x^2}^{y=1-x^2}dx = \int_{-1/\sqrt{2}}^{1/\sqrt{2}}\left[\left(3(1 - x^2) - \tfrac{1}{2}(1 - x^2)^2\right) - \left(3x^2 - \tfrac{1}{2}(x^2)^2\right)\right]dx \\ &= \int_{-1/\sqrt{2}}^{1/\sqrt{2}}\left(\tfrac{5}{2} - 5x^2\right)dx = \left[\tfrac{5}{2}x - \tfrac{5}{3}x^3\right]_{-1/\sqrt{2}}^{1/\sqrt{2}} = \left(\tfrac{5}{2\sqrt{2}} - \tfrac{5}{6\sqrt{2}}\right) - \left(-\tfrac{5}{2\sqrt{2}} + \tfrac{5}{6\sqrt{2}}\right) \\ &= \tfrac{10}{3\sqrt{2}} \text{ or } \tfrac{5\sqrt{2}}{3} \end{aligned}$$

38. The region of integration is the portion of the first quadrant bounded by the axes and the curve $y = \sqrt{4 - x^2}$. The solid lies under the graph of $z = x + y$ and above the graph of $z = xy$, so its volume is

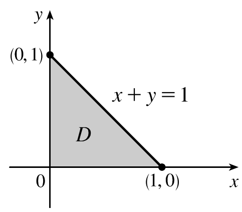
$$V = \int_0^2 \int_0^{\sqrt{4-x^2}} (x + y)\,dy\,dx - \int_0^2 \int_0^{\sqrt{4-x^2}} xy\,dy\,dx = \int_0^2 \int_0^{\sqrt{4-x^2}} (x + y - xy)\,dy\,dx$$

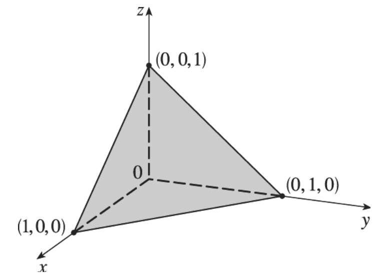
$$= \int_0^2 \left[xy + \tfrac{1}{2}y^2 - \tfrac{1}{2}xy^2\right]_{y=0}^{y=\sqrt{4-x^2}} dx = \int_0^2 \left[x\sqrt{4-x^2} + \tfrac{1}{2}(4 - x^2) - \tfrac{1}{2}x(4 - x^2) - 0\right] dx$$

$$= \int_0^2 \left(x\sqrt{4-x^2} + 2 - \tfrac{1}{2}x^2 - 2x + \tfrac{1}{2}x^3\right) dx = \left[-\tfrac{1}{3}(4 - x^2)^{3/2} + 2x - \tfrac{1}{6}x^3 - x^2 + \tfrac{1}{8}x^4\right]_0^2$$

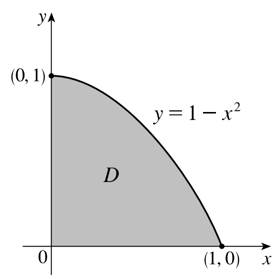
$$= \left(4 - \tfrac{4}{3} - 4 + 2\right) - \left(-\tfrac{1}{3} \cdot 4^{3/2}\right) = \tfrac{2}{3} + \tfrac{8}{3} = \tfrac{10}{3}$$

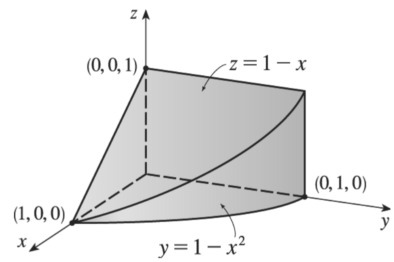
39. The solid lies below the plane $z = 1 - x - y$ or $x + y + z = 1$ and above the region $D = \{(x, y) \mid 0 \le x \le 1, 0 \le y \le 1 - x\}$ in the xy-plane. The solid is a tetrahedron.





40. The solid lies below the plane $z = 1 - x$ and above the region $D = \left\{(x, y) \mid 0 \le x \le 1, 0 \le y \le 1 - x^2\right\}$ in the xy-plane.





41. The two bounding curves $y = x^3 - x$ and $y = x^2 + x$ intersect at the origin and at $x = 2$, with $x^2 + x > x^3 - x$ on $(0, 2)$. Using a CAS, we find that the volume of the solid is

$$V = \int_0^2 \int_{x^3 - x}^{x^2 + x} (x^3y^4 + xy^2)\,dy\,dx = \frac{13{,}984{,}735{,}616}{14{,}549{,}535}$$

42. For $|x| \le 1$ and $|y| \le 1$, $2x^2 + y^2 < 8 - x^2 - 2y^2$. Also, the cylinder is described by the inequalities $-1 \le x \le 1$, $-\sqrt{1 - x^2} \le y \le \sqrt{1 - x^2}$. So the volume is given by

$$V = \int_{-1}^1 \int_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}} \left[(8 - x^2 - 2y^2) - (2x^2 + y^2)\right] dy\,dx = \frac{13\pi}{2} \qquad \text{[using a CAS]}$$

43. The two surfaces intersect in the circle $x^2 + y^2 = 1$, $z = 0$ and the region of integration is the disk D: $x^2 + y^2 \le 1$.

Using a CAS, the volume is $\iint_D (1 - x^2 - y^2)\,dA = \int_{-1}^1 \int_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}} (1 - x^2 - y^2)\,dy\,dx = \dfrac{\pi}{2}$.

44. The projection onto the xy-plane of the intersection of the two surfaces is the circle $x^2 + y^2 = 2y \Rightarrow$ $x^2 + y^2 - 2y = 0 \Rightarrow x^2 + (y-1)^2 = 1$, so the region of integration is given by $-1 \le x \le 1$, $1 - \sqrt{1-x^2} \le y \le 1 + \sqrt{1-x^2}$. In this region, $2y \ge x^2 + y^2$ so, using a CAS, the volume is

$$V = \int_{-1}^{1} \int_{1-\sqrt{1-x^2}}^{1+\sqrt{1-x^2}} [2y - (x^2 + y^2)]\, dy\, dx = \frac{\pi}{2}$$

45. 
Because the region of integration is

$D = \{(x,y) \mid 0 \le x \le y, 0 \le y \le 1\} = \{(x,y) \mid x \le y \le 1, 0 \le x \le 1\}$

we have $\int_0^1 \int_0^y f(x,y)\, dx\, dy = \iint_D f(x,y)\, dA = \int_0^1 \int_x^1 f(x,y)\, dy\, dx$.

46. 
Because the region of integration is

$$\begin{aligned} D &= \left\{(x,y) \mid x^2 \le y \le 4, 0 \le x \le 2\right\} \\ &= \left\{(x,y) \mid 0 \le x \le \sqrt{y}, 0 \le y \le 4\right\} \end{aligned}$$

we have $\int_0^2 \int_{x^2}^4 f(x,y)\, dy\, dx = \iint_D f(x,y)\, dA = \int_0^4 \int_0^{\sqrt{y}} f(x,y)\, dx\, dy$.

47. 
Because the region of integration is

$$\begin{aligned} D &= \{(x,y) \mid 0 \le y \le \cos x, 0 \le x \le \pi/2\} \\ &= \left\{(x,y) \mid 0 \le x \le \cos^{-1} y, 0 \le y \le 1\right\} \end{aligned}$$

we have

$\int_0^{\pi/2} \int_0^{\cos x} f(x,y)\, dy\, dx = \iint_D f(x,y)\, dA = \int_0^1 \int_0^{\cos^{-1} y} f(x,y)\, dx\, dy$.

48. 
Because the region of integration is

$$\begin{aligned} D &= \left\{(x,y) \mid 0 \le x \le \sqrt{4-y^2}, -2 \le y \le 2\right\} \\ &= \left\{(x,y) \mid -\sqrt{4-x^2} \le y \le \sqrt{4-x^2}, 0 \le x \le 2\right\} \end{aligned}$$

we have

$\int_{-2}^2 \int_0^{\sqrt{4-y^2}} f(x,y)\, dx\, dy = \iint_D f(x,y)\, dA = \int_0^2 \int_{-\sqrt{4-x^2}}^{\sqrt{4-x^2}} f(x,y)\, dy\, dx$.

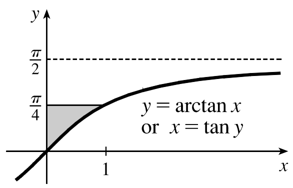
49. 
Because the region of integration is

$D = \{(x,y) \mid 0 \le y \le \ln x, 1 \le x \le 2\} = \{(x,y) \mid e^y \le x \le 2, 0 \le y \le \ln 2\}$

we have

$$\int_1^2 \int_0^{\ln x} f(x,y)\, dy\, dx = \iint_D f(x,y)\, dA = \int_0^{\ln 2} \int_{e^y}^2 f(x,y)\, dx\, dy$$

50.



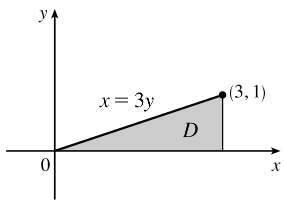
Because the region of integration is

$$D = \left\{(x, y) \mid \arctan x \le y \le \tfrac{\pi}{4}, 0 \le x \le 1\right\}$$
$$= \left\{(x, y) \mid 0 \le x \le \tan y, 0 \le y \le \tfrac{\pi}{4}\right\}$$

we have

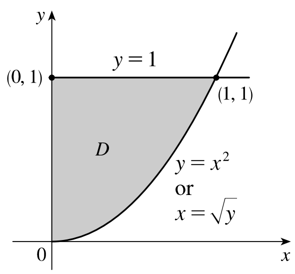
$$\int_0^1 \int_{\arctan x}^{\pi/4} f(x,y)\,dy\,dx = \iint_D f(x,y)\,dA = \int_0^{\pi/4} \int_0^{\tan y} f(x,y)\,dx\,dy$$

51.



$$\int_0^1 \int_{3y}^3 e^{x^2}\,dx\,dy = \int_0^3 \int_0^{x/3} e^{x^2}\,dy\,dx = \int_0^3 \left[e^{x^2} y\right]_{y=0}^{y=x/3} dx$$
$$= \int_0^3 \left(\frac{x}{3}\right) e^{x^2}\,dx = \tfrac{1}{6}\, e^{x^2}\Big]_0^3 = \frac{e^9 - 1}{6}$$

52.

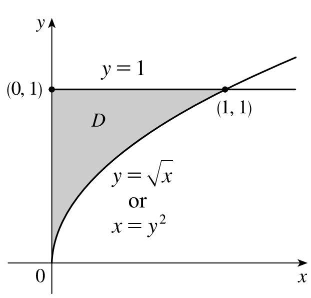


$$\int_0^1 \int_{x^2}^1 \sqrt{y}\,\sin y\,dy\,dx = \int_0^1 \int_0^{\sqrt{y}} \sqrt{y}\,\sin y\,dx\,dy = \int_0^1 \sqrt{y}\,\sin y\,[x]_{x=0}^{x=\sqrt{y}}\,dy$$
$$= \int_0^1 (\sqrt{y}\,\sin y)\,(\sqrt{y} - 0)\,dy = \int_0^1 y\,\sin y\,dy$$
$$= -y\cos y\Big]_0^1 + \textstyle\int_0^1 \cos y\,dy$$

[by integrating by parts with $u = y$, $dv = \sin y\,dy$]

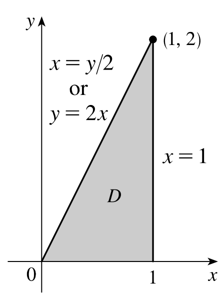
$$= \left[-y\cos y + \sin y\right]_0^1 = -\cos 1 + \sin 1 - 0 = \sin 1 - \cos 1$$

53.



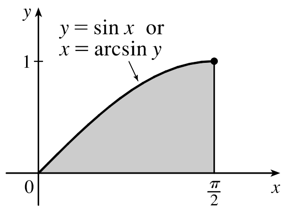
$$\int_0^1 \int_{\sqrt{x}}^1 \sqrt{y^3+1}\,dy\,dx = \int_0^1 \int_0^{y^2} \sqrt{y^3+1}\,dx\,dy = \int_0^1 \sqrt{y^3+1}\,[x]_{x=0}^{x=y^2}\,dy$$
$$= \int_0^1 y^2\sqrt{y^3+1}\,dy = \tfrac{2}{9}\left(y^3+1\right)^{3/2}\Big]_0^1$$
$$= \tfrac{2}{9}\left(2^{3/2} - 1^{3/2}\right) = \tfrac{2}{9}\left(2\sqrt{2} - 1\right)$$

54.



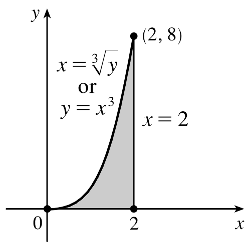
$$\int_0^2 \int_{y/2}^1 y\cos(x^3 - 1)\,dx\,dy = \int_0^1 \int_0^{2x} y\cos(x^3 - 1)\,dy\,dx$$
$$= \int_0^1 \cos(x^3 - 1)\,\left[\tfrac{1}{2}y^2\right]_{y=0}^{y=2x}\,dx$$
$$= \int_0^1 2x^2\cos(x^3 - 1)\,dx = \tfrac{2}{3}\sin(x^3 - 1)\Big]_0^1$$
$$= \tfrac{2}{3}\left[0 - \sin(-1)\right] = -\tfrac{2}{3}\sin(-1) = \tfrac{2}{3}\sin 1$$

55.



$$\int_0^1 \int_{\arcsin y}^{\pi/2} \cos x\,\sqrt{1+\cos^2 x}\,dx\,dy$$
$$= \int_0^{\pi/2} \int_0^{\sin x} \cos x\,\sqrt{1+\cos^2 x}\,dy\,dx$$
$$= \int_0^{\pi/2} \cos x\,\sqrt{1+\cos^2 x}\,\big[\,y\,\big]_{y=0}^{y=\sin x}\,dx$$
$$= \int_0^{\pi/2} \cos x\,\sqrt{1+\cos^2 x}\,\sin x\,dx \qquad \begin{bmatrix}\text{Let } u = \cos x,\ du = -\sin x\,dx, \\ dx = du/(-\sin x)\end{bmatrix}$$
$$= \int_1^0 -u\,\sqrt{1+u^2}\,du = -\tfrac{1}{3}\left(1+u^2\right)^{3/2}\Big]_1^0$$
$$= \tfrac{1}{3}\left(\sqrt{8}-1\right) = \tfrac{1}{3}\left(2\sqrt{2}-1\right)$$

56.



$$\int_0^8 \int_{\sqrt[3]{y}}^2 e^{x^4}\,dx\,dy = \int_0^2 \int_0^{x^3} e^{x^4}\,dy\,dx$$
$$= \int_0^2 e^{x^4}\Big[\,y\,\Big]_{y=0}^{y=x^3}\,dx = \int_0^2 x^3 e^{x^4}\,dx$$
$$= \tfrac{1}{4}e^{x^4}\Big]_0^2 = \tfrac{1}{4}(e^{16}-1)$$

57. $D = \{(x,y) \mid 0 \le x \le 1,\ -x+1 \le y \le 1\} \cup \{(x,y) \mid -1 \le x \le 0,\ x+1 \le y \le 1\}$
$\cup \{(x,y) \mid 0 \le x \le 1,\ -1 \le y \le x-1\} \cup \{(x,y) \mid -1 \le x \le 0,\ -1 \le y \le -x-1\}$, all type I.

$$\iint_D x^2\,dA = \int_0^1 \int_{1-x}^1 x^2\,dy\,dx + \int_{-1}^0 \int_{x+1}^1 x^2\,dy\,dx + \int_0^1 \int_{-1}^{x-1} x^2\,dy\,dx + \int_{-1}^0 \int_{-1}^{-x-1} x^2\,dy\,dx$$
$$= 4\int_0^1 \int_{1-x}^1 x^2\,dy\,dx \qquad \text{[by symmetry of the regions and because } f(x,y) = x^2 \ge 0\text{]}$$
$$= 4\int_0^1 x^3\,dx = 4\left[\tfrac{1}{4}x^4\right]_0^1 = 1$$

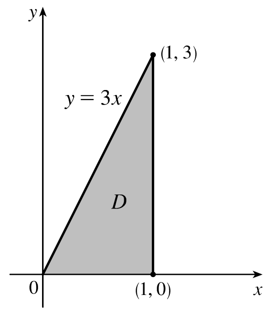
58. $D = \left\{(x,y) \mid -1 \le y \le 0,\ -1 \le x \le y - y^3\right\} \cup \left\{(x,y) \mid 0 \le y \le 1,\ \sqrt{y} - 1 \le x \le y - y^3\right\}$, both type II.

$$\iint_D y\,dA = \int_{-1}^0 \int_{-1}^{y-y^3} y\,dx\,dy + \int_0^1 \int_{\sqrt{y}-1}^{y-y^3} y\,dx\,dy = \int_{-1}^0 \left[xy\right]_{x=-1}^{x=y-y^3}\,dy + \int_0^1 \left[xy\right]_{x=\sqrt{y}-1}^{x=y-y^3}\,dy$$
$$= \int_{-1}^0 (y^2 - y^4 + y)\,dy + \int_0^1 (y^2 - y^4 - y^{3/2} + y)\,dy$$
$$= \left[\tfrac{1}{3}y^3 - \tfrac{1}{5}y^5 + \tfrac{1}{2}y^2\right]_{-1}^0 + \left[\tfrac{1}{3}y^3 - \tfrac{1}{5}y^5 - \tfrac{2}{5}y^{5/2} + \tfrac{1}{2}y^2\right]_0^1$$
$$= \left(0 - \tfrac{11}{30}\right) + \left(\tfrac{7}{30} - 0\right) = -\tfrac{2}{15}$$

59. Since $x^2 + y^2 \le 1$ on S, we must have $0 \le x^2 \le 1$ and $0 \le y^2 \le 1$, so $0 \le x^2y^2 \le 1 \quad \Rightarrow \quad 3 \le 4 - x^2y^2 \le 4 \quad \Rightarrow$
$\sqrt{3} \le \sqrt{4 - x^2y^2} \le 2$. Here we have $A(S) = \frac{1}{2}\pi(1)^2 = \frac{\pi}{2}$, so by Property 11,
$\sqrt{3}A(S) \le \iint_S \sqrt{4 - x^2y^2}\,dA \le 2A(S) \quad \Rightarrow \quad \frac{\sqrt{3}}{2}\pi \le \iint_S \sqrt{4 - x^2y^2}\,dA \le \pi$ or we can say
$2.720 < \iint_S \sqrt{4 - x^2y^2}\,dA < 3.142$. (We have rounded the lower bound down and the upper bound up to preserve the inequalities.)

60. T is the triangle with vertices $(0,0)$, $(1,0)$, and $(1,2)$ so $A(T)=\frac{1}{2}(1)(2)=1$. We have $0\le\sin^4(x+y)\le 1$ for all x, y, and Property 11 gives $0\cdot A(T)\le\iint_T\sin^4(x+y)dA\le 1\cdot A(T)\quad\Rightarrow\quad 0\le\iint_T\sin^4(x+y)dA\le 1$.

61. The average value of a function f of two variables defined on a rectangle R was defined in Section 15.1 as $f_{\text{ave}}=\frac{1}{A(R)}\iint_R f(x,y)dA$. Extending this definition to general regions D, we have $f_{\text{ave}}=\frac{1}{A(D)}\iint_D f(x,y)dA$.

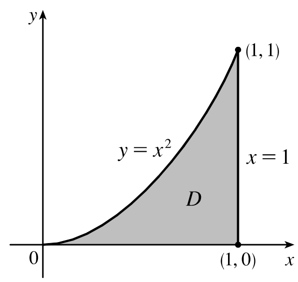


Here $D=\{(x,y)\mid 0\le x\le 1, 0\le y\le 3x\}$, so $A(D)=\frac{1}{2}(1)(3)=\frac{3}{2}$ and

$$f_{\text{ave}}=\frac{1}{A(D)}\iint_D f(x,y)dA=\frac{1}{3/2}\int_0^1\int_0^{3x}xy\,dy\,dx$$
$$=\frac{2}{3}\int_0^1\left[\tfrac{1}{2}xy^2\right]_{y=0}^{y=3x}dx=\frac{1}{3}\int_0^1 9x^3\,dx=\tfrac{3}{4}x^4\Big]_0^1=\frac{3}{4}$$

62. Here $D=\left\{(x,y)\mid 0\le x\le 1, 0\le y\le x^2\right\}$, so

$A(D)=\int_0^1 x^2\,dx=\frac{1}{3}x^3\Big]_0^1=\frac{1}{3}$ and

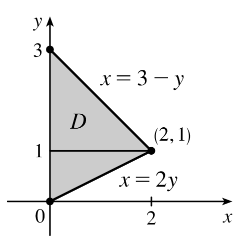


$$f_{\text{ave}}=\frac{1}{A(D)}\iint_D f(x,y)dA=\frac{1}{1/3}\int_0^1\int_0^{x^2}x\sin y\,dy\,dx$$
$$=3\int_0^1\left[-x\cos y\right]_{y=0}^{y=x^2}\,dx$$
$$=3\int_0^1\left[x-x\cos(x^2)\right]dx=3\left[\tfrac{1}{2}x^2-\tfrac{1}{2}\sin(x^2)\right]_0^1$$
$$=3\left(\tfrac{1}{2}-\tfrac{1}{2}\sin 1-0\right)=\tfrac{3}{2}(1-\sin 1)$$

63. Since $m\le f(x,y)\le M$, $\iint_D m\,dA\le\iint_D f(x,y)\,dA\le\iint_D M\,dA$ by (8) $\Rightarrow$

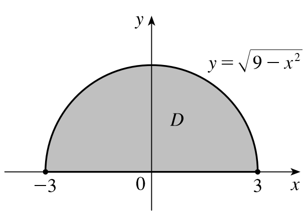
$m\iint_D 1\,dA\le\iint_D f(x,y)\,dA\le M\iint_D 1\,dA$ by (7) $\Rightarrow$ $mA(D)\le\iint_D f(x,y)\,dA\le MA(D)$ by (10).

64.



$$\iint_D f(x,y)\,dA=\int_0^1\int_0^{2y}f(x,y)\,dx\,dy+\int_1^3\int_0^{3-y}f(x,y)\,dx\,dy$$
$$=\int_0^2\int_{x/2}^{3-x}f(x,y)\,dy\,dx$$

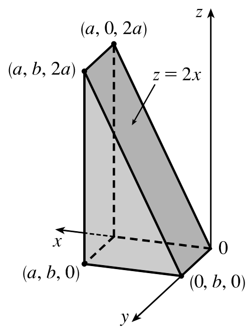
65.

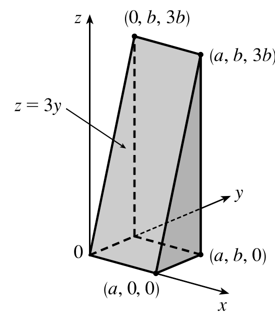


First we can write $\iint_D(x+2)\,dA=\iint_D x\,dA+\iint_D 2\,dA$. But $f(x,y)=x$ is an odd function with respect to x [that is, $f(-x,y)=-f(x,y)$] and D is symmetric with respect to x. Consequently, the volume above D and below the graph of f is the same as the volume below D and above the graph of f, so $\iint_D x\,dA=0$. Also, $\iint_D 2\,dA=2\cdot A(D)=2\cdot\frac{1}{2}\pi(3)^2=9\pi$ since D is a half disk of radius 3. Thus $\iint_D(x+2)\,dA=0+9\pi=9\pi$.

66. The graph of $f(x,y)=\sqrt{R^2-x^2-y^2}$ is the top half of the sphere $x^2+y^2+z^2=R^2$, centered at the origin with radius R, and D is the disk in the xy-plane also centered at the origin with radius R. Thus $\iint_D\sqrt{R^2-x^2-y^2}\,dA$ represents the volume of a half ball of radius R which is $\frac{1}{2}\cdot\frac{4}{3}\pi R^3=\frac{2}{3}\pi R^3$.

67. We can write $\iint_D (2x + 3y)\,dA = \iint_D 2x\,dA + \iint_D 3y\,dA$. $\iint_D 2x\,dA$ represents the volume of the solid lying under the plane $z = 2x$ and above the rectangle D. This solid region is a triangular cylinder with length b and whose cross-section is a triangle with width a and height $2a$. (See the first figure.)

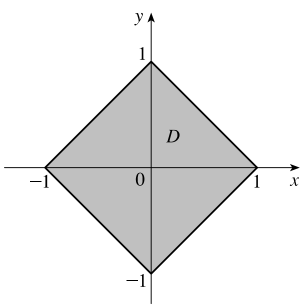




Thus its volume is $\frac{1}{2} \cdot a \cdot 2a \cdot b = a^2 b$. Similarly, $\iint_D 3y\,dA$ represents the volume of a triangular cylinder with length a, triangular cross-section with width b and height $3b$, and volume $\frac{1}{2} \cdot b \cdot 3b \cdot a = \frac{3}{2}ab^2$. (See the second figure.) Thus

$$\iint_D (2x + 3y)\,dA = a^2 b + \tfrac{3}{2}ab^2$$

68.

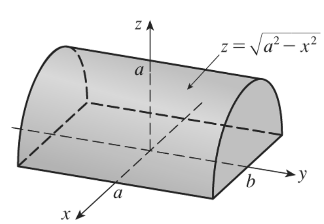


In the first quadrant, x and y are positive and the boundary of D is $x + y = 1$. But D is symmetric with respect to both axes because of the absolute values, so the region of integration is the square shown at the left. To evaluate the double integral, we first write $\iint_D (2 + x^2 y^3 - y^2 \sin x)\,dA = \iint_D 2\,dA + \iint_D x^2 y^3\,dA - \iint_D y^2 \sin x\,dA$. Now $f(x, y) = x^2 y^3$ is odd with respect to y [that is, $f(x, -y) = -f(x, y)$] and D is symmetric with respect to y, so $\iint_D x^2 y^3\,dA = 0$.

Similarly, $g(x, y) = y^2 \sin x$ is odd with respect to x [since $g(-x, y) = -g(x, y)$] and D is symmetric with respect to x, so $\iint_D y^2 \sin x\,dA = 0$. D is a square with side length $\sqrt{2}$, so $\iint_D 2\,dA = 2 \cdot A(D) = 2\left(\sqrt{2}\right)^2 = 4$, and $\iint_D (2 + x^2 y^3 - y^2 \sin x)\,dA = 4 + 0 + 0 = 4$.

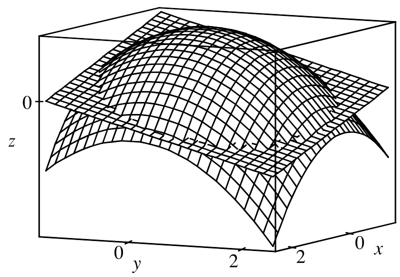
69. $\iint_D \left(ax^3 + by^3 + \sqrt{a^2 - x^2}\,\right) dA = \iint_D ax^3\,dA + \iint_D by^3\,dA + \iint_D \sqrt{a^2 - x^2}\,dA$. Now ax^3 is odd with respect to x and by^3 is odd with respect to y, and the region of integration is symmetric with respect to both x and y, so $\iint_D ax^3\,dA = \iint_D by^3\,dA = 0$.

$\iint_D \sqrt{a^2 - x^2}\,dA$ represents the volume of the solid region under the graph of $z = \sqrt{a^2 - x^2}$ and above the rectangle D, namely a half circular cylinder with radius a and length $2b$ (see the figure) whose volume is $\frac{1}{2} \cdot \pi r^2 h = \frac{1}{2}\pi a^2 (2b) = \pi a^2 b$. Thus



$\iint_D \left(ax^3 + by^3 + \sqrt{a^2 - x^2}\,\right) dA = 0 + 0 + \pi a^2 b = \pi a^2 b$.

70. To find the equations of the boundary curves, we require that the z-values of the two surfaces be the same. In Maple, we use the command `solve(4-x^2-y^2=1-x-y,y);` and in Mathematica, we use `Solve[4-x^2-y^2==1-x-y,y]`. We find that the curves have equations $y = \dfrac{1 \pm \sqrt{13+4x-4x^2}}{2}$. To find the two points of intersection of these curves, we use the CAS to solve $13 + 4x - 4x^2 = 0$, finding that $x = \frac{1\pm\sqrt{14}}{2}$. So, using the CAS to evaluate the integral, the volume of intersection is



$$V = \int_{(1-\sqrt{14})/2}^{(1+\sqrt{14})/2} \int_{(1-\sqrt{13+4x-4x^2})/2}^{(1+\sqrt{13+4x-4x^2})/2} [(4-x^2-y^2)-(1-x-y)]\,dy\,dx = \frac{49\pi}{8}$$

15.3 Double Integrals in Polar Coordinates

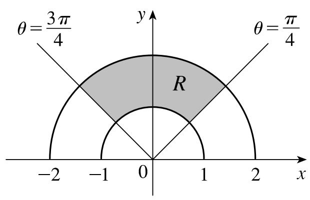
1. The region R is more easily described by polar coordinates: $R = \{(r,\theta) \mid 2 \le r \le 5, 0 \le \theta \le 2\pi\}$. Thus $\iint_R f(x,y)\,dA = \int_0^{2\pi}\int_2^5 f(r\cos\theta, r\sin\theta)\,r\,dr\,d\theta$.

2. The region R is more easily described by rectangular coordinates: $R = \{(x,y) \mid -1 \le x \le 1,\ -x \le y \le 1\}$. Thus $\iint_R f(x,y)\,dA = \int_{-1}^1\int_{-x}^1 f(x,y)\,dy\,dx$.

3. The region R is more easily described by polar coordinates: $R = \{(r,\theta) \mid 0 \le r \le 1, \pi \le \theta \le 2\pi\}$. Thus $\iint_R f(x,y)\,dA = \int_\pi^{2\pi}\int_0^1 f(r\cos\theta, r\sin\theta)\,r\,dr\,d\theta$.

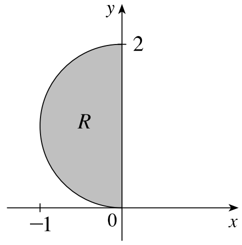
4. The region R is more easily described by polar coordinates: $R = \left\{(r,\theta) \mid 0 \le r \le 3,\ -\frac{\pi}{4} \le \theta \le \frac{3\pi}{4}\right\}$. Thus $\iint_R f(x,y)\,dA = \int_{-\pi/4}^{3\pi/4}\int_0^3 f(r\cos\theta, r\sin\theta)\,r\,dr\,d\theta$.

5. The integral $\int_{\pi/4}^{3\pi/4}\int_1^2 r\,dr\,d\theta$ represents the area of the region $R = \{(r,\theta) \mid 1 \le r \le 2, \pi/4 \le \theta \le 3\pi/4\}$, the top quarter portion of a ring (annulus).



$$\int_{\pi/4}^{3\pi/4}\int_1^2 r\,dr\,d\theta = \left(\int_{\pi/4}^{3\pi/4} d\theta\right)\left(\int_1^2 r\,dr\right)$$
$$= \left[\theta\right]_{\pi/4}^{3\pi/4}\left[\tfrac{1}{2}r^2\right]_1^2 = \left(\tfrac{3\pi}{4} - \tfrac{\pi}{4}\right)\cdot\tfrac{1}{2}(4-1) = \tfrac{\pi}{2}\cdot\tfrac{3}{2} = \tfrac{3\pi}{4}$$

6. The integral $\int_{\pi/2}^{\pi}\int_0^{2\sin\theta} r\,dr\,d\theta$ represents the area of the region $R = \{(r,\theta) \mid 0 \le r \le 2\sin\theta, \pi/2 \le \theta \le \pi\}$. Since $r = 2\sin\theta \;\Rightarrow\; r^2 = 2r\sin\theta \;\Leftrightarrow\; x^2+y^2 = 2y \;\Leftrightarrow\; x^2 + (y-1)^2 = 1$, R is the portion in the second quadrant of a disk of radius 1 with center $(0,1)$.



$$\int_{\pi/2}^{\pi}\int_0^{2\sin\theta} r\,dr\,d\theta = \int_{\pi/2}^{\pi}\left[\tfrac{1}{2}r^2\right]_{r=0}^{r=2\sin\theta} d\theta = \int_{\pi/2}^{\pi} 2\sin^2\theta\,d\theta$$
$$= \int_{\pi/2}^{\pi} 2\cdot\tfrac{1}{2}(1-\cos 2\theta)\,d\theta = \left[\theta - \tfrac{1}{2}\sin 2\theta\right]_{\pi/2}^{\pi}$$
$$= \pi - 0 - \tfrac{\pi}{2} + 0 = \tfrac{\pi}{2}$$

7. The half disk D can be described in polar coordinates as $D = \{(r,\theta) \mid 0 \le r \le 5, 0 \le \theta \le \pi\}$. Then

$$\iint_D x^2 y\, dA = \int_0^\pi \int_0^5 (r\cos\theta)^2 (r\sin\theta)\, r\, dr\, d\theta = \left(\int_0^\pi \cos^2\theta \sin\theta\, d\theta\right)\left(\int_0^5 r^4\, dr\right)$$

$$= \left[-\tfrac{1}{3}\cos^3\theta\right]_0^\pi \left[\tfrac{1}{5}r^5\right]_0^5 = -\tfrac{1}{3}(-1-1)\cdot 625 = \tfrac{1250}{3}$$

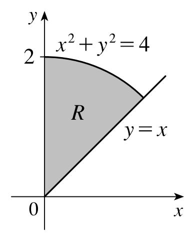
8. The region R is $\frac{1}{8}$ of a disk, as shown in the figure, and can be described by $R = \{(r,\theta) \mid 0 \le r \le 2, \pi/4 \le \theta \le \pi/2\}$. Thus

$$\iint_R (2x-y)\, dA = \int_{\pi/4}^{\pi/2} \int_0^2 (2r\cos\theta - r\sin\theta)\, r\, dr\, d\theta$$

$$= \int_{\pi/4}^{\pi/2} (2\cos\theta - \sin\theta)\, d\theta \int_0^2 r^2\, dr$$

$$= \left[2\sin\theta + \cos\theta\right]_{\pi/4}^{\pi/2} \left[\tfrac{1}{3}r^3\right]_0^2$$

$$= \left(2 + 0 - \sqrt{2} - \tfrac{\sqrt{2}}{2}\right)\left(\tfrac{8}{3}\right) = \tfrac{16}{3} - 4\sqrt{2}$$



9. $\iint_R \sin(x^2+y^2)\, dA = \int_0^{\pi/2} \int_1^3 \sin(r^2)\, r\, dr\, d\theta = \int_0^{\pi/2} d\theta \int_1^3 r\sin(r^2)\, dr = \left[\theta\right]_0^{\pi/2} \left[-\tfrac{1}{2}\cos(r^2)\right]_1^3$

$$= \left(\tfrac{\pi}{2}\right)\left[-\tfrac{1}{2}(\cos 9 - \cos 1)\right] = \tfrac{\pi}{4}(\cos 1 - \cos 9)$$

10. $\displaystyle \iint_R \frac{y^2}{x^2+y^2}\, dA = \int_0^{2\pi} \int_a^b \frac{(r\sin\theta)^2}{r^2}\, r\, dr\, d\theta = \int_0^{2\pi} \sin^2\theta\, d\theta \int_a^b r\, dr = \int_0^{2\pi} \frac{1}{2}(1-\cos 2\theta)\, d\theta \int_a^b r\, dr$

$$= \tfrac{1}{2}\left[\theta - \tfrac{1}{2}\sin 2\theta\right]_0^{2\pi} \left[\tfrac{1}{2}r^2\right]_a^b = \tfrac{1}{2}(2\pi - 0 - 0)\cdot \tfrac{1}{2}\left(b^2 - a^2\right) = \tfrac{\pi}{2}(b^2 - a^2)$$

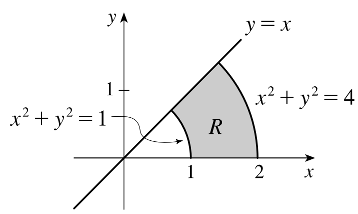
11. $\iint_D e^{-x^2-y^2}\, dA = \int_{-\pi/2}^{\pi/2} \int_0^2 e^{-r^2}\, r\, dr\, d\theta = \int_{-\pi/2}^{\pi/2} d\theta \int_0^2 re^{-r^2}\, dr$

$$= \left[\theta\right]_{-\pi/2}^{\pi/2} \left[-\tfrac{1}{2}e^{-r^2}\right]_0^2 = \pi\left(-\tfrac{1}{2}\right)(e^{-4} - e^0) = \tfrac{\pi}{2}(1 - e^{-4})$$

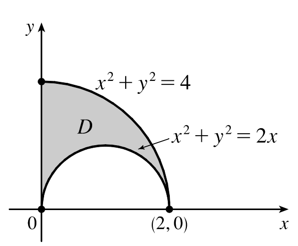
12. $\iint_D \cos\sqrt{x^2+y^2}\, dA = \int_0^{2\pi} \int_0^2 \cos\sqrt{r^2}\; r\, dr\, d\theta = \int_0^{2\pi} d\theta \int_0^2 r\cos r\, dr$. For the second integral, integrate by parts with $u = r$, $dv = \cos r\, dr$. Then $\iint_D \cos\sqrt{x^2+y^2}\, dA = \left[\theta\right]_0^{2\pi} \left[r\sin r + \cos r\right]_0^2 = 2\pi(2\sin 2 + \cos 2 - 1)$.

13. R is the region shown in the figure, and can be described by $R = \{(r,\theta) \mid 0 \le \theta \le \pi/4, 1 \le r \le 2\}$. Thus $\iint_R \arctan(y/x)\, dA = \int_0^{\pi/4} \int_1^2 \arctan(\tan\theta)\, r\, dr\, d\theta$ since $y/x = \tan\theta$. Also, $\arctan(\tan\theta) = \theta$ for $0 \le \theta \le \pi/4$, so the integral becomes

$$\int_0^{\pi/4} \int_1^2 \theta\, r\, dr\, d\theta = \int_0^{\pi/4} \theta\, d\theta \int_1^2 r\, dr = \left[\tfrac{1}{2}\theta^2\right]_0^{\pi/4} \left[\tfrac{1}{2}r^2\right]_1^2 = \tfrac{\pi^2}{32}\cdot\tfrac{3}{2} = \tfrac{3}{64}\pi^2.$$



14.



$$\iint\limits_D x\, dA = \iint\limits_{\substack{x^2+y^2 \le 4 \\ x \ge 0,\, y \ge 0}} x\, dA - \iint\limits_{\substack{(x-1)^2+y^2 \le 1 \\ y \ge 0}} x\, dA$$

$$= \int_0^{\pi/2} \int_0^2 r^2 \cos\theta\, dr\, d\theta - \int_0^{\pi/2} \int_0^{2\cos\theta} r^2 \cos\theta\, dr\, d\theta$$

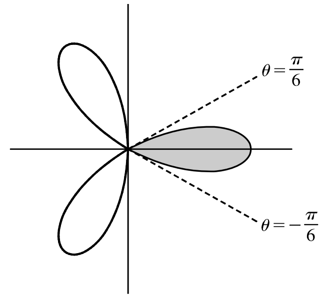
$$= \int_0^{\pi/2} \tfrac{1}{3}(8\cos\theta)\, d\theta - \int_0^{\pi/2} \tfrac{1}{3}(8\cos^4\theta)\, d\theta$$

$$= \tfrac{8}{3} - \tfrac{8}{12}\left[\cos^3\theta\sin\theta + \tfrac{3}{2}(\theta + \sin\theta\cos\theta)\right]_0^{\pi/2}$$

$$= \tfrac{8}{3} - \tfrac{2}{3}\left[0 + \tfrac{3}{2}\left(\tfrac{\pi}{2}\right)\right] = \tfrac{16 - 3\pi}{6}$$

15. One loop is given by the region

$D = \{(r, \theta) \mid -\pi/6 \le \theta \le \pi/6, 0 \le r \le \cos 3\theta\}$, so the area is

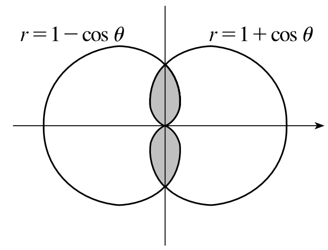


$$\iint_D dA = \int_{-\pi/6}^{\pi/6} \int_0^{\cos 3\theta} r\,dr\,d\theta = \int_{-\pi/6}^{\pi/6} \left[\frac{1}{2}r^2\right]_{r=0}^{r=\cos 3\theta} d\theta$$

$$= \int_{-\pi/6}^{\pi/6} \frac{1}{2}\cos^2 3\theta\,d\theta = 2\int_0^{\pi/6} \frac{1}{2}\left(\frac{1+\cos 6\theta}{2}\right) d\theta$$

$$= \frac{1}{2}\left[\theta + \frac{1}{6}\sin 6\theta\right]_0^{\pi/6} = \frac{\pi}{12}$$

16. By symmetry, the area of the region is 4 times the area of the region D in the first quadrant enclosed by the cardiod $r = 1 - \cos\theta$ (see the figure). Here $D = \{(r, \theta) \mid 0 \le r \le 1 - \cos\theta, 0 \le \theta \le \pi/2\}$, so the total area is



$$4A(D) = 4\iint_D dA = 4\int_0^{\pi/2}\int_0^{1-\cos\theta} r\,dr\,d\theta = 4\int_0^{\pi/2}\left[\tfrac{1}{2}r^2\right]_{r=0}^{r=1-\cos\theta} d\theta$$

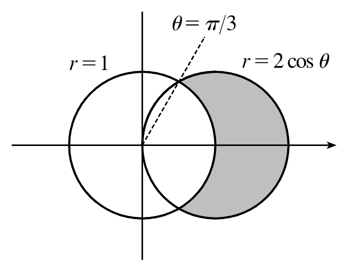
$$= 2\int_0^{\pi/2}(1-\cos\theta)^2 d\theta = 2\int_0^{\pi/2}(1 - 2\cos\theta + \cos^2\theta)\,d\theta$$

$$= 2\int_0^{\pi/2}\left[1 - 2\cos\theta + \tfrac{1}{2}(1+\cos 2\theta)\right] d\theta$$

$$= 2\left[\theta - 2\sin\theta + \tfrac{1}{2}\theta + \tfrac{1}{4}\sin 2\theta\right]_0^{\pi/2}$$

$$= 2\left(\tfrac{\pi}{2} - 2 + \tfrac{\pi}{4}\right) = \tfrac{3\pi}{2} - 4$$

17. In polar coordinates the circle $(x-1)^2 + y^2 = 1 \quad\Leftrightarrow\quad x^2 + y^2 = 2x$ is $r^2 = 2r\cos\theta \quad\Rightarrow\quad r = 2\cos\theta$, and the circle $x^2 + y^2 = 1$ is $r = 1$. The curves intersect in the first quadrant when $2\cos\theta = 1 \quad\Rightarrow\quad \cos\theta = \frac{1}{2} \quad\Rightarrow\quad \theta = \pi/3$, so the portion of the region in the first quadrant is given by $D = \{(r, \theta) \mid 1 \le r \le 2\cos\theta, 0 \le \theta \le \pi/3\}$. By symmetry, the total area is twice the area of D:

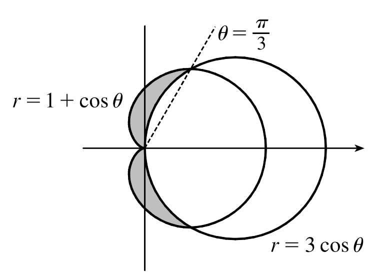


$$2A(D) = 2\iint_D dA = 2\int_0^{\pi/3}\int_1^{2\cos\theta} r\,dr\,d\theta = 2\int_0^{\pi/3}\left[\tfrac{1}{2}r^2\right]_{r=1}^{r=2\cos\theta} d\theta$$

$$= \int_0^{\pi/3}\left(4\cos^2\theta - 1\right) d\theta = \int_0^{\pi/3}\left[4\cdot\tfrac{1}{2}(1+\cos 2\theta) - 1\right] d\theta$$

$$= \int_0^{\pi/3}(1 + 2\cos 2\theta)\,d\theta = \left[\theta + \sin 2\theta\right]_0^{\pi/3} = \tfrac{\pi}{3} + \tfrac{\sqrt{3}}{2}$$

18. The region lies between the two polar curves in quadrants I and IV, but in quadrants II and III the region is enclosed by the cardioid. In the first quadrant, $1 + \cos\theta = 3\cos\theta$ when $\cos\theta = \frac{1}{2} \quad\Rightarrow\quad \theta = \frac{\pi}{3}$, so the area of the region inside the cardioid and outside the circle is



$$A_1 = \int_{\pi/3}^{\pi/2}\int_{3\cos\theta}^{1+\cos\theta} r\,dr\,d\theta = \int_{\pi/3}^{\pi/2}\left[\tfrac{1}{2}r^2\right]_{r=3\cos\theta}^{r=1+\cos\theta} d\theta$$

$$= \tfrac{1}{2}\int_{\pi/3}^{\pi/2}(1 + 2\cos\theta - 8\cos^2\theta)d\theta = \tfrac{1}{2}\left[\theta + 2\sin\theta - 8\left(\tfrac{1}{2}\theta + \tfrac{1}{4}\sin 2\theta\right)\right]_{\pi/3}^{\pi/2}$$

$$= \left[-\tfrac{3}{2}\theta + \sin\theta - \sin 2\theta\right]_{\pi/3}^{\pi/2} = \left(-\tfrac{3\pi}{4} + 1 - 0\right) - \left(-\tfrac{\pi}{2} + \tfrac{\sqrt{3}}{2} - \tfrac{\sqrt{3}}{2}\right) = 1 - \tfrac{\pi}{4}.$$

[continued]

The area of the region in the second quadrant is

$$\begin{aligned} A_2 &= \int_{\pi/2}^{\pi}\int_0^{1+\cos\theta} r\,dr\,d\theta = \int_{\pi/2}^{\pi}\left[\tfrac{1}{2}r^2\right]_{r=0}^{r=1+\cos\theta} d\theta = \tfrac{1}{2}\int_{\pi/2}^{\pi}(1+2\cos\theta+\cos^2\theta)d\theta \\ &= \tfrac{1}{2}\left[\theta+2\sin\theta+\tfrac{1}{2}\theta+\tfrac{1}{4}\sin 2\theta\right]_{\pi/2}^{\pi} = \tfrac{1}{2}\left(\tfrac{3\pi}{4}-2\right) = \tfrac{3\pi}{8}-1. \end{aligned}$$

By symmetry, the total area is $A = 2(A_1 + A_2) = 2\left(1-\frac{\pi}{4}+\frac{3\pi}{8}-1\right) = \frac{\pi}{4}$.

19. $V = \iint_{x^2+y^2\le 25}\left(x^2+y^2\right)dA = \int_0^{2\pi}\int_0^5 r^2\cdot r\,dr\,d\theta = \int_0^{2\pi}d\theta\int_0^5 r^3\,dr = \left[\theta\right]_0^{2\pi}\left[\frac{1}{4}r^4\right]_0^5 = 2\pi\left(\frac{625}{4}\right) = \frac{625}{2}\pi$

20. $V = \iint_{1\le x^2+y^2\le 4}\sqrt{x^2+y^2}\,dA = \int_0^{2\pi}\int_1^2\sqrt{r^2}\,r\,dr\,d\theta = \int_0^{2\pi}d\theta\int_1^2 r^2\,dr = \left[\theta\right]_0^{2\pi}\left[\frac{1}{3}r^3\right]_1^2 = 2\pi\left(\frac{8}{3}-\frac{1}{3}\right) = \frac{14}{3}\pi$

21. $2x+y+z=4 \quad\Leftrightarrow\quad z = 4-2x-y$, so the volume of the solid is

$$\begin{aligned} V &= \iint_{x^2+y^2\le 1}(4-2x-y)\,dA = \int_0^{2\pi}\int_0^1(4-2r\cos\theta-r\sin\theta)\,r\,dr\,d\theta \\ &= \int_0^{2\pi}\int_0^1\left[4r-r^2\left(2\cos\theta+\sin\theta\right)\right]dr\,d\theta = \int_0^{2\pi}\left[2r^2-\tfrac{1}{3}r^3\left(2\cos\theta+\sin\theta\right)\right]_{r=0}^{r=1}d\theta \\ &= \int_0^{2\pi}\left[2-\tfrac{1}{3}\left(2\cos\theta+\sin\theta\right)\right]d\theta = \left[2\theta-\tfrac{1}{3}\left(2\sin\theta-\cos\theta\right)\right]_0^{2\pi} = 4\pi+\tfrac{1}{3}-0-\tfrac{1}{3} = 4\pi \end{aligned}$$

22. The sphere $x^2+y^2+z^2=16$ intersects the xy-plane in the circle $x^2+y^2=16$, so

$$\begin{aligned} V &= 2\iint\limits_{4\le x^2+y^2\le 16}\sqrt{16-x^2-y^2}\,dA \quad \text{[by symmetry]} \quad = 2\int_0^{2\pi}\int_2^4\sqrt{16-r^2}\,r\,dr\,d\theta = 2\int_0^{2\pi}d\theta\int_2^4 r(16-r^2)^{1/2}dr \\ &= 2\left[\theta\right]_0^{2\pi}\left[-\tfrac{1}{3}(16-r^2)^{3/2}\right]_2^4 = -\tfrac{2}{3}(2\pi)(0-12^{3/2}) = \tfrac{4\pi}{3}\left(12\sqrt{12}\right) = 32\sqrt{3}\,\pi \end{aligned}$$

23. By symmetry,

$$\begin{aligned} V &= 2\iint\limits_{x^2+y^2\le a^2}\sqrt{a^2-x^2-y^2}\,dA = 2\int_0^{2\pi}\int_0^a\sqrt{a^2-r^2}\,r\,dr\,d\theta = 2\int_0^{2\pi}d\theta\int_0^a r\sqrt{a^2-r^2}\,dr \\ &= 2\left[\theta\right]_0^{2\pi}\left[-\tfrac{1}{3}(a^2-r^2)^{3/2}\right]_0^a = 2(2\pi)\left(0+\tfrac{1}{3}a^3\right) = \tfrac{4}{3}\pi a^3 \end{aligned}$$

24. The paraboloid $z = 1+2x^2+2y^2$ intersects the plane $z=7$ when $7 = 1+2x^2+2y^2$ or $x^2+y^2=3$ and we are restricted to the first octant, so

$$\begin{aligned} V &= \iint\limits_{\substack{x^2+y^2\le 3,\\ x\ge 0,y\ge 0}}\left[7-\left(1+2x^2+2y^2\right)\right]dA = \int_0^{\pi/2}\int_0^{\sqrt{3}}\left[7-\left(1+2r^2\right)\right]r\,dr\,d\theta \\ &= \int_0^{\pi/2}d\theta\int_0^{\sqrt{3}}\left(6r-2r^3\right)dr = \left[\theta\right]_0^{\pi/2}\left[3r^2-\tfrac{1}{2}r^4\right]_0^{\sqrt{3}} = \tfrac{\pi}{2}\cdot\tfrac{9}{2} = \tfrac{9}{4}\pi \end{aligned}$$

25. The cone $z=\sqrt{x^2+y^2}$ intersects the sphere $x^2+y^2+z^2=1$ when $x^2+y^2+\left(\sqrt{x^2+y^2}\right)^2 = 1$ or $x^2+y^2=\frac{1}{2}$. So

$$\begin{aligned} V &= \iint\limits_{x^2+y^2\le 1/2}\left(\sqrt{1-x^2-y^2}-\sqrt{x^2+y^2}\right)dA = \int_0^{2\pi}\int_0^{1/\sqrt{2}}\left(\sqrt{1-r^2}-r\right)r\,dr\,d\theta \\ &= \int_0^{2\pi}d\theta\int_0^{1/\sqrt{2}}\left(r\sqrt{1-r^2}-r^2\right)dr = \left[\theta\right]_0^{2\pi}\left[-\tfrac{1}{3}(1-r^2)^{3/2}-\tfrac{1}{3}r^3\right]_0^{1/\sqrt{2}} = 2\pi\left(-\tfrac{1}{3}\right)\left(\tfrac{1}{\sqrt{2}}-1\right) = \tfrac{\pi}{3}\left(2-\sqrt{2}\right) \end{aligned}$$

26. The two paraboloids intersect when $6 - x^2 - y^2 = 2x^2 + 2y^2$ or $x^2 + y^2 = 2$. For $x^2 + y^2 \le 2$, the paraboloid $z = 6 - x^2 - y^2$ is above $z = 2x^2 + 2y^2$ so

$$V = \iint_{x^2+y^2\le 2} \left[(6 - x^2 - y^2) - (2x^2 + 2y^2)\right] dA = \iint_{x^2+y^2\le 2} \left[6 - 3(x^2 + y^2)\right] dA = \int_0^{2\pi}\int_0^{\sqrt{2}} (6 - 3r^2)\, r\, dr\, d\theta$$

$$= \int_0^{2\pi} d\theta \int_0^{\sqrt{2}} (6r - 3r^3)\, dr = \left[\,\theta\,\right]_0^{2\pi} \left[3r^2 - \tfrac{3}{4}r^4\right]_0^{\sqrt{2}} = 2\pi\,(6 - 3) = 6\pi$$

27. The given solid is the region inside the cylinder $x^2 + y^2 = 4$ between the surfaces $z = \sqrt{64 - 4x^2 - 4y^2}$ and $z = -\sqrt{64 - 4x^2 - 4y^2}$. So

$$V = \iint_{x^2+y^2\le 4} \left[\sqrt{64 - 4x^2 - 4y^2} - \left(-\sqrt{64 - 4x^2 - 4y^2}\right)\right] dA = \iint_{x^2+y^2\le 4} 2\cdot 2\sqrt{16 - x^2 - y^2}\, dA$$

$$= 4\int_0^{2\pi}\int_0^2 \sqrt{16 - r^2}\; r\, dr\, d\theta = 4\int_0^{2\pi} d\theta \int_0^2 r\sqrt{16 - r^2}\, dr = 4\left[\,\theta\,\right]_0^{2\pi} \left[-\tfrac{1}{3}(16 - r^2)^{3/2}\right]_0^2$$

$$= 8\pi\left(-\tfrac{1}{3}\right)\left(12^{3/2} - 16^{2/3}\right) = \tfrac{8\pi}{3}\left(64 - 24\sqrt{3}\right)$$

28. (a) Here the region in the xy-plane is the annular region $r_1^2 \le x^2 + y^2 \le r_2^2$ and the desired volume is twice that above the xy-plane. Hence

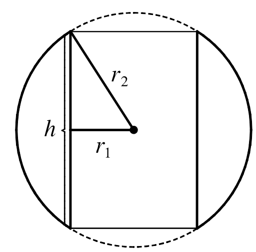
$$V = 2\iint_{r_1^2 \le x^2+y^2 \le r_2^2} \sqrt{r_2^2 - x^2 - y^2}\, dA = 2\int_0^{2\pi}\int_{r_1}^{r_2} \sqrt{r_2^2 - r^2}\; r\, dr\, d\theta = 2\int_0^{2\pi} d\theta \int_{r_1}^{r_2} \sqrt{r_2^2 - r^2}\; r\, dr$$

$$= 2\,(2\pi)\left[-\tfrac{1}{3}(r_2^2 - r^2)^{3/2}\right]_{r_1}^{r_2} = \tfrac{4\pi}{3}(r_2^2 - r_1^2)^{3/2}$$

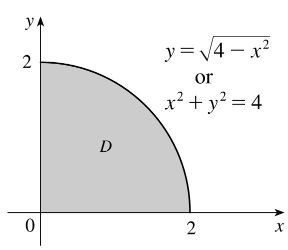
(b) A cross-sectional cut is shown in the figure. So $r_2^2 = \left(\tfrac{1}{2}h\right)^2 + r_1^2$ or

$\tfrac{1}{4}h^2 = r_2^2 - r_1^2$.

Thus the volume in terms of h is $V = \tfrac{4\pi}{3}\left(\tfrac{1}{4}h^2\right)^{3/2} = \tfrac{\pi}{6}h^3$.



29.

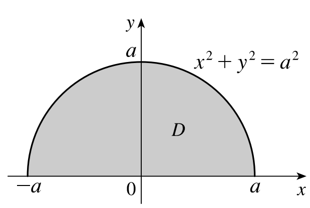


$$\int_0^2\int_0^{\sqrt{4-x^2}} e^{-x^2-y^2}\, dy\, dx = \int_0^{\pi/2}\int_0^2 e^{-r^2}\, r\, dr\, d\theta$$

$$= \int_0^{\pi/2} d\theta \int_0^2 re^{-r^2} dr = \left[\,\theta\,\right]_0^{\pi/2} \left[-\tfrac{1}{2}e^{-r^2}\right]_0^2$$

$$= \tfrac{\pi}{2}\left[-\tfrac{1}{2}\left(e^{-4} - 1\right)\right] = \tfrac{\pi}{4}\left(1 - e^{-4}\right)$$

30.



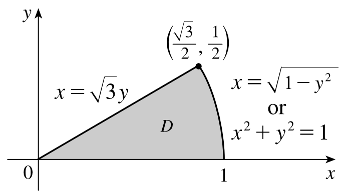
$$\int_0^a\int_{-\sqrt{a^2-y^2}}^{\sqrt{a^2-y^2}} (2x + y)\, dx\, dy = \int_0^{\pi}\int_0^a (2r\cos\theta + r\sin\theta)\, r\, dr\, d\theta$$

$$= \int_0^{\pi} (2\cos\theta + \sin\theta)\, d\theta \int_0^a r^2\, dr$$

$$= \left[2\sin\theta - \cos\theta\right]_0^{\pi} \left[\tfrac{1}{3}r^3\right]_0^a$$

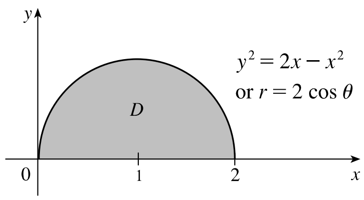
$$= \left[(0 + 1) - (0 - 1)\right]\cdot \tfrac{1}{3}(a^3 - 0) = \tfrac{2}{3}a^3$$

31. The region D of integration is shown in the figure. In polar coordinates the line $x = \sqrt{3}\,y$ is $\theta = \pi/6$, so



$$\int_0^{1/2}\int_{\sqrt{3}\,y}^{\sqrt{1-y^2}} xy^2\,dx\,dy = \int_0^{\pi/6}\int_0^1 (r\cos\theta)(r\sin\theta)^2\,r\,dr\,d\theta$$
$$= \int_0^{\pi/6}\sin^2\theta\cos\theta\,d\theta\,\int_0^1 r^4\,dr$$
$$= \left[\tfrac{1}{3}\sin^3\theta\right]_0^{\pi/6}\left[\tfrac{1}{5}r^5\right]_0^1$$
$$= \left[\tfrac{1}{3}\left(\tfrac{1}{2}\right)^3 - 0\right]\left[\tfrac{1}{5} - 0\right] = \tfrac{1}{120}$$

32.



$$\int_0^{\pi/2}\int_0^{2\cos\theta} r^2\,dr\,d\theta = \int_0^{\pi/2}\left[\tfrac{1}{3}r^3\right]_{r=0}^{r=2\cos\theta}d\theta = \int_0^{\pi/2}\left(\tfrac{8}{3}\cos^3\theta\right)d\theta$$
$$= \tfrac{8}{3}\int_0^{\pi/2}(1 - \sin^2\theta)\cos\theta\,d\theta$$
$$= \tfrac{8}{3}\left[\sin\theta - \tfrac{1}{3}\sin^3\theta\right]_0^{\pi/2} = \tfrac{16}{9}$$

33. $D = \{(r,\theta) \mid 0 \le r \le 1, 0 \le \theta \le 2\pi\}$, so

$\iint_D e^{(x^2+y^2)^2}\,dA = \int_0^{2\pi}\int_0^1 e^{(r^2)^2}\,r\,dr\,d\theta = \int_0^{2\pi}d\theta\int_0^1 re^{r^4}\,dr = 2\pi\int_0^1 re^{r^4}\,dr$. Using a calculator, we estimate $2\pi\int_0^1 re^{r^4}\,dr \approx 4.5951$.

34. $D = \{(r,\theta) \mid 0 \le r \le 1, 0 \le \theta \le \pi/2\}$, so

$$\iint_D xy\sqrt{1 + x^2 + y^2}\,dA = \int_0^{\pi/2}\int_0^1 (r\cos\theta)(r\sin\theta)\sqrt{1 + r^2}\;r\,dr\,d\theta$$
$$= \int_0^{\pi/2}\sin\theta\cos\theta\,d\theta\,\int_0^1 r^3\sqrt{1 + r^2}\,dr = \left[\tfrac{1}{2}\sin^2\theta\right]_0^{\pi/2}\int_0^1 r^3\sqrt{1 + r^2}\,dr$$
$$= \tfrac{1}{2}\int_0^1 r^3\sqrt{1 + r^2}\,dr \approx 0.1609$$

35. The surface of the water in the pool is a circular disk D with radius 20 ft. If we place D on coordinate axes with the origin at the center of D and define $f(x,y)$ to be the depth of the water at (x,y), then the volume of water in the pool is the volume of the solid that lies above $D = \left\{(x,y) \mid x^2 + y^2 \le 400\right\}$ and below the graph of $f(x,y)$. We can associate north with the positive y-direction, so we are given that the depth is constant in the x-direction and the depth increases linearly in the y-direction from $f(0,-20) = 2$ to $f(0,20) = 7$. The trace in the yz-plane is a line segment from $(0,-20,2)$ to $(0,20,7)$. The slope of this line is $\frac{7-2}{20-(-20)} = \frac{1}{8}$, so an equation of the line is $z - 7 = \frac{1}{8}(y - 20) \quad\Rightarrow\quad z = \frac{1}{8}y + \frac{9}{2}$. Since $f(x,y)$ is independent of x, $f(x,y) = \frac{1}{8}y + \frac{9}{2}$. Thus the volume is given by $\iint_D f(x,y)\,dA$, which is most conveniently evaluated using polar coordinates. Then $D = \{(r,\theta) \mid 0 \le r \le 20, 0 \le \theta \le 2\pi\}$ and substituting $x = r\cos\theta$, $y = r\sin\theta$ the integral becomes

$$\int_0^{2\pi}\int_0^{20}\left(\tfrac{1}{8}r\sin\theta + \tfrac{9}{2}\right)r\,dr\,d\theta = \int_0^{2\pi}\left[\tfrac{1}{24}r^3\sin\theta + \tfrac{9}{4}r^2\right]_{r=0}^{r=20}d\theta = \int_0^{2\pi}\left(\tfrac{1000}{3}\sin\theta + 900\right)d\theta$$
$$= \left[-\tfrac{1000}{3}\cos\theta + 900\theta\right]_0^{2\pi} = 1800\pi$$

Thus the pool contains $1800\pi \approx 5655\text{ ft}^3$ of water.

36. (a) If $R \leq 100$, the total amount of water supplied each hour to the region within R feet of the sprinkler is

$$V = \int_0^{2\pi}\int_0^R e^{-r} r\,dr\,d\theta = \int_0^{2\pi} d\theta \int_0^R re^{-r}\,dr = \left[\,\theta\,\right]_0^{2\pi} \left[-re^{-r} - e^{-r}\right]_0^R$$
$$= 2\pi[-Re^{-R} - e^{-R} + 0 + 1] = 2\pi(1 - Re^{-R} - e^{-R})\text{ ft}^3$$

(b) The average amount of water per hour per square foot supplied to the region within R feet of the sprinkler is

$\dfrac{V}{\text{area of region}} = \dfrac{V}{\pi R^2} = \dfrac{2\left(1 - Re^{-R} - e^{-R}\right)}{R^2}$ ft^3 (per hour per square foot). See the definition of the average value of a function on page 1037 [ET 997].

37. As in Exercise 15.2.61, $f_{\text{ave}} = \frac{1}{A(D)}\iint_D f(x,y)dA$. Here $D = \{(r,\theta) \mid a \leq r \leq b, 0 \leq \theta \leq 2\pi\}$,

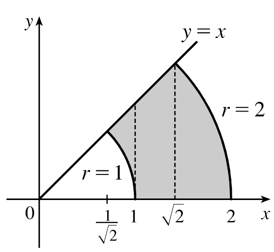
so $A(D) = \pi b^2 - \pi a^2 = \pi(b^2 - a^2)$ and

$$f_{\text{ave}} = \frac{1}{A(D)}\iint_D \frac{1}{\sqrt{x^2+y^2}}\,dA = \frac{1}{\pi(b^2-a^2)}\int_0^{2\pi}\int_a^b \frac{1}{\sqrt{r^2}}\,r\,dr\,d\theta = \frac{1}{\pi(b^2-a^2)}\int_0^{2\pi} d\theta \int_a^b dr$$
$$= \frac{1}{\pi(b^2-a^2)}\,\left[\theta\right]_0^{2\pi}\,\left[r\right]_a^b = \frac{1}{\pi(b^2-a^2)}\,(2\pi)(b-a) = \frac{2(b-a)}{(b+a)(b-a)} = \frac{2}{a+b}$$

38. The distance from a point (x, y) to the origin is $f(x,y) = \sqrt{x^2+y^2}$, so the average distance from points in D to the origin is

$$f_{\text{ave}} = \tfrac{1}{A(D)}\iint_D \sqrt{x^2+y^2}\,dA = \tfrac{1}{\pi a^2}\int_0^{2\pi}\int_0^a \sqrt{r^2}\;r\,dr\,d\theta$$
$$= \tfrac{1}{\pi a^2}\int_0^{2\pi} d\theta \int_0^a r^2\,dr = \tfrac{1}{\pi a^2}\,\left[\theta\right]_0^{2\pi}\,\left[\tfrac{1}{3}r^3\right]_0^a = \tfrac{1}{\pi a^2}\cdot 2\pi \cdot \tfrac{1}{3}a^3 = \tfrac{2}{3}a$$

39. $$\int_{1/\sqrt{2}}^1 \int_{\sqrt{1-x^2}}^x xy\,dy\,dx + \int_1^{\sqrt{2}}\int_0^x xy\,dy\,dx + \int_{\sqrt{2}}^2 \int_0^{\sqrt{4-x^2}} xy\,dy\,dx$$
$$= \int_0^{\pi/4}\int_1^2 r^3\cos\theta\sin\theta\,dr\,d\theta = \int_0^{\pi/4}\left[\frac{r^4}{4}\cos\theta\sin\theta\right]_{r=1}^{r=2} d\theta$$
$$= \frac{15}{4}\int_0^{\pi/4}\sin\theta\cos\theta\,d\theta = \frac{15}{4}\left[\frac{\sin^2\theta}{2}\right]_0^{\pi/4} = \frac{15}{16}$$



40. (a) $\iint_{D_a} e^{-(x^2+y^2)}dA = \int_0^{2\pi}\int_0^a re^{-r^2}\,dr\,d\theta = 2\pi\left[-\frac{1}{2}e^{-r^2}\right]_0^a = \pi\left(1 - e^{-a^2}\right)$ for each a. Then $\lim\limits_{a\to\infty}\pi\left(1 - e^{-a^2}\right) = \pi$ since $e^{-a^2} \to 0$ as $a \to \infty$. Hence $\int_{-\infty}^{\infty}\int_{-\infty}^{\infty} e^{-(x^2+y^2)}\,dA = \pi$.

(b) $\iint_{S_a} e^{-(x^2+y^2)}\,dA = \int_{-a}^a\int_{-a}^a e^{-x^2}e^{-y^2}\,dx\,dy = \left(\int_{-a}^a e^{-x^2}\,dx\right)\left(\int_{-a}^a e^{-y^2}\,dy\right)$ for each a.

Then, from (a), $\pi = \iint_{\mathbb{R}^2} -(x^2+y^2)\,dA$, so

$\pi = \lim\limits_{a\to\infty}\iint_{S_a} e^{-(x^2+y^2)}\,dA = \lim\limits_{a\to\infty}\left(\int_{-a}^a e^{-x^2}\,dx\right)\left(\int_{-a}^a e^{-y^2}\,dy\right) = \left(\int_{-\infty}^{\infty} e^{-x^2}\,dx\right)\left(\int_{-\infty}^{\infty} e^{-y^2}\,dy\right)$.

To evaluate $\lim\limits_{a\to\infty}\left(\int_{-a}^a e^{-x^2}\,dx\right)\left(\int_{-a}^a e^{-y^2}\,dy\right)$, we are using the fact that these integrals are bounded. This is true since on $[-1,1]$, $0 < e^{-x^2} \leq 1$ while on $(-\infty,-1)$, $0 < e^{-x^2} \leq e^x$ and on $(1,\infty)$, $0 < e^{-x^2} < e^{-x}$. Hence $0 \leq \int_{-\infty}^{\infty} e^{-x^2}\,dx \leq \int_{-\infty}^{-1} e^x\,dx + \int_{-1}^1\,dx + \int_1^{\infty} e^{-x}\,dx = 2(e^{-1}+1)$.

(c) Since $\left(\int_{-\infty}^{\infty} e^{-x^2}\,dx\right)\left(\int_{-\infty}^{\infty} e^{-y^2}\,dy\right) = \pi$ and y can be replaced by x, $\left(\int_{-\infty}^{\infty} e^{-x^2}\,dx\right)^2 = \pi$ implies that

$\int_{-\infty}^{\infty} e^{-x^2}\,dx = \pm\sqrt{\pi}$. But $e^{-x^2} \geq 0$ for all x, so $\int_{-\infty}^{\infty} e^{-x^2}\,dx = \sqrt{\pi}$.

(d) Letting $t = \sqrt{2}\,x$, $\int_{-\infty}^{\infty} e^{-x^2}\,dx = \int_{-\infty}^{\infty} \frac{1}{\sqrt{2}}\left(e^{-t^2/2}\right)dt$, so that $\sqrt{\pi} = \frac{1}{\sqrt{2}}\int_{-\infty}^{\infty} e^{-t^2/2}\,dt$ or $\int_{-\infty}^{\infty} e^{-t^2/2}\,dt = \sqrt{2\pi}$.

41. (a) We integrate by parts with $u = x$ and $dv = xe^{-x^2}\,dx$. Then $du = dx$ and $v = -\frac{1}{2}e^{-x^2}$, so

$$\begin{aligned}\int_0^{\infty} x^2 e^{-x^2}\,dx &= \lim_{t\to\infty}\int_0^t x^2 e^{-x^2}\,dx = \lim_{t\to\infty}\left(\left[-\tfrac{1}{2}xe^{-x^2}\right]_0^t + \int_0^t \tfrac{1}{2}e^{-x^2}\,dx\right)\\ &= \lim_{t\to\infty}\left(-\tfrac{1}{2}te^{-t^2}\right) + \tfrac{1}{2}\int_0^{\infty} e^{-x^2}\,dx = 0 + \tfrac{1}{2}\int_0^{\infty} e^{-x^2}\,dx \qquad \text{[by l'Hospital's Rule]}\\ &= \tfrac{1}{4}\int_{-\infty}^{\infty} e^{-x^2}\,dx \qquad \text{[since } e^{-x^2} \text{ is an even function]}\\ &= \tfrac{1}{4}\sqrt{\pi} \qquad \text{[by Exercise 40(c)]}\end{aligned}$$

(b) Let $u = \sqrt{x}$. Then $u^2 = x \quad\Rightarrow\quad dx = 2u\,du \quad\Rightarrow$

$\int_0^{\infty}\sqrt{x}\,e^{-x}\,dx = \lim_{t\to\infty}\int_0^t \sqrt{x}\,e^{-x}\,dx = \lim_{t\to\infty}\int_0^{\sqrt{t}} ue^{-u^2}2u\,du = 2\int_0^{\infty} u^2 e^{-u^2}\,du = 2\left(\frac{1}{4}\sqrt{\pi}\right)$ [by part(a)] $= \frac{1}{2}\sqrt{\pi}$.

15.4 Applications of Double Integrals

1. $Q = \iint_D \sigma(x,y)\,dA = \int_0^5\int_2^5 (2x+4y)\,dy\,dx = \int_0^5 \left[2xy + 2y^2\right]_{y=2}^{y=5}\,dx$

$= \int_0^5 (10x + 50 - 4x - 8)\,dx = \int_0^5 (6x+42)\,dx = \left[3x^2 + 42x\right]_0^5 = 75 + 210 = 285$ C

2. $Q = \iint_D \sigma(x,y)\,dA = \iint_D \sqrt{x^2+y^2}\,dA = \int_0^{2\pi}\int_0^1 \sqrt{r^2}\;r\,dr\,d\theta$

$= \int_0^{2\pi} d\theta\;\int_0^1 r^2\,dr = [\theta]_0^{2\pi}\;\left[\frac{1}{3}r^3\right]_0^1 = 2\pi\cdot\frac{1}{3} = \frac{2\pi}{3}$ C

3. $m = \iint_D \rho(x,y)\,dA = \int_1^3\int_1^4 ky^2\,dy\,dx = k\int_1^3 dx\;\int_1^4 y^2\,dy = k\,[x]_1^3\;\left[\frac{1}{3}y^3\right]_1^4 = k(2)(21) = 42k$,

$\overline{x} = \frac{1}{m}\iint_D x\rho(x,y)\,dA = \frac{1}{42k}\int_1^3\int_1^4 kxy^2\,dy\,dx = \frac{1}{42}\int_1^3 x\,dx\;\int_1^4 y^2\,dy = \frac{1}{42}\left[\frac{1}{2}x^2\right]_1^3\;\left[\frac{1}{3}y^3\right]_1^4 = \frac{1}{42}(4)(21) = 2$,

$\overline{y} = \frac{1}{m}\iint_D y\rho(x,y)\,dA = \frac{1}{42k}\int_1^3\int_1^4 ky^3\,dy\,dx = \frac{1}{42}\int_1^3 dx\;\int_1^4 y^3\,dy = \frac{1}{42}\,[x]_1^3\;\left[\frac{1}{4}y^4\right]_1^4 = \frac{1}{42}(2)\left(\frac{255}{4}\right) = \frac{85}{28}$

Hence $m = 42k$, $(\overline{x},\overline{y}) = \left(2, \frac{85}{28}\right)$.

4. $m = \iint_D \rho(x,y)\,dA = \int_0^a\int_0^b (1+x^2+y^2)\,dy\,dx = \int_0^a \left[y + x^2y + \frac{1}{3}y^3\right]_{y=0}^{y=b}\,dx = \int_0^a \left(b + bx^2 + \frac{1}{3}b^3\right)dx$

$= \left[bx + \frac{1}{3}bx^3 + \frac{1}{3}b^3x\right]_0^a = ab + \frac{1}{3}a^3b + \frac{1}{3}ab^3 = \frac{1}{3}ab(3 + a^2 + b^2)$,

$M_y = \iint_D x\rho(x,y)\,dA = \int_0^a\int_0^b (x + x^3 + xy^2)\,dy\,dx = \int_0^a \left[xy + x^3y + \frac{1}{3}xy^3\right]_{y=0}^{y=b}\,dx = \int_0^a \left(bx + bx^3 + \frac{1}{3}b^3x\right)dx$

$= \left[\frac{1}{2}bx^2 + \frac{1}{4}bx^4 + \frac{1}{6}b^3x^2\right]_0^a = \frac{1}{2}a^2b + \frac{1}{4}a^4b + \frac{1}{6}a^2b^3 = \frac{1}{12}a^2b(6 + 3a^2 + 2b^2)$, and

$M_x = \iint_D y\rho(x,y)\,dA = \int_0^a\int_0^b (y + x^2y + y^3)\,dy\,dx = \int_0^a \left[\frac{1}{2}y^2 + \frac{1}{2}x^2y^2 + \frac{1}{4}y^4\right]_{y=0}^{y=b}\,dx = \int_0^a \left(\frac{1}{2}b^2 + \frac{1}{2}b^2x^2 + \frac{1}{4}b^4\right)dx$

$= \left[\frac{1}{2}b^2x + \frac{1}{6}b^2x^3 + \frac{1}{4}b^4x\right]_0^a = \frac{1}{2}ab^2 + \frac{1}{6}a^3b^2 + \frac{1}{4}ab^4 = \frac{1}{12}ab^2(6 + 2a^2 + 3b^2)$.

Hence, $(\overline{x},\overline{y}) = \left(\dfrac{M_y}{m},\dfrac{M_x}{m}\right) = \left(\dfrac{\frac{1}{12}a^2b(6+3a^2+2b^2)}{\frac{1}{3}ab(3+a^2+b^2)},\dfrac{\frac{1}{12}ab^2(6+2a^2+3b^2)}{\frac{1}{3}ab(3+a^2+b^2)}\right)$

$= \left(\dfrac{a(6+3a^2+2b^2)}{4(3+a^2+b^2)},\dfrac{b(6+2a^2+3b^2)}{4(3+a^2+b^2)}\right).$

5. $m = \int_0^2\int_{x/2}^{3-x}(x+y)\,dy\,dx = \int_0^2\left[xy+\frac{1}{2}y^2\right]_{y=x/2}^{y=3-x}dx = \int_0^2\left[x(3-x)+\frac{1}{2}(3-x)^2-\frac{1}{2}x^2-\frac{1}{8}x^2\right]dx$

$= \int_0^2\left(-\frac{9}{8}x^2+\frac{9}{2}\right)dx = \left[-\frac{9}{8}\left(\frac{1}{3}x^3\right)+\frac{9}{2}x\right]_0^2 = 6,$

$M_y = \int_0^2\int_{x/2}^{3-x}(x^2+xy)\,dy\,dx = \int_0^2\left[x^2y+\frac{1}{2}xy^2\right]_{y=x/2}^{y=3-x}dx = \int_0^2\left(\frac{9}{2}x-\frac{9}{8}x^3\right)dx = \frac{9}{2},$

$M_x = \int_0^2\int_{x/2}^{3-y}(xy+y^2)\,dy\,dx = \int_0^2\left[\frac{1}{2}xy^2+\frac{1}{3}y^3\right]_{y=x/2}^{y=3-x}dx = \int_0^2\left(9-\frac{9}{2}x\right)dx = 9.$

Hence $m = 6$, $(\overline{x},\overline{y}) = \left(\dfrac{M_y}{m},\dfrac{M_x}{m}\right) = \left(\dfrac{3}{4},\dfrac{3}{2}\right).$

6. Here $D = \left\{(x,y)\mid 0\le y\le\frac{2}{5},\ y/2\le x\le 1-2y\right\}.$

$m = \int_0^{2/5}\int_{y/2}^{1-2y}x\,dx\,dy = \int_0^{2/5}\left[\frac{1}{2}x^2\right]_{x=y/2}^{x=1-2y}dy = \frac{1}{2}\int_0^{2/5}\left[(1-2y)^2-\left(\frac{1}{2}y\right)^2\right]dy$

$= \frac{1}{2}\int_0^{2/5}\left(\frac{15}{4}y^2-4y+1\right)dy = \frac{1}{2}\left[\frac{5}{4}y^3-2y^2+y\right]_0^{2/5} = \frac{1}{2}\left[\frac{2}{25}-\frac{8}{25}+\frac{2}{5}\right] = \frac{2}{25},$

$M_y = \int_0^{2/5}\int_{y/2}^{1-2y}x\cdot x\,dx\,dy = \int_0^{2/5}\left[\frac{1}{3}x^3\right]_{x=y/2}^{x=1-2y}dy = \frac{1}{3}\int_0^{2/5}\left[(1-2y)^3-\left(\frac{1}{2}y\right)^3\right]dy$

$= \frac{1}{3}\int_0^{2/5}\left(-\frac{65}{8}y^3+12y^2-6y+1\right)dy = \frac{1}{3}\left[-\frac{65}{32}y^4+4y^3-3y^2+y\right]_0^{2/5} = \frac{1}{3}\left[-\frac{13}{250}+\frac{32}{125}-\frac{12}{25}+\frac{2}{5}\right] = \frac{31}{750},$

$M_x = \int_0^{2/5}\int_{y/2}^{1-2y}y\cdot x\,dx\,dy = \int_0^{2/5}y\left[\frac{1}{2}x^2\right]_{x=y/2}^{x=1-2y}dy = \frac{1}{2}\int_0^{2/5}y\left(\frac{15}{4}y^2-4y+1\right)dy$

$= \frac{1}{2}\int_0^{2/5}\left(\frac{15}{4}y^3-4y^2+y\right)dy = \frac{1}{2}\left[\frac{15}{16}y^4-\frac{4}{3}y^3+\frac{1}{2}y^2\right]_0^{2/5} = \frac{1}{2}\left[\frac{3}{125}-\frac{32}{375}+\frac{2}{25}\right] = \frac{7}{750}.$

Hence $m = \frac{2}{25}$, $(\overline{x},\overline{y}) = \left(\frac{31/750}{2/25},\frac{7/750}{2/25}\right) = \left(\frac{31}{60},\frac{7}{60}\right).$

7. $m = \int_{-1}^1\int_0^{1-x^2}ky\,dy\,dx = k\int_{-1}^1\left[\frac{1}{2}y^2\right]_{y=0}^{y=1-x^2}dx = \frac{1}{2}k\int_{-1}^1(1-x^2)^2\,dx = \frac{1}{2}k\int_{-1}^1(1-2x^2+x^4)\,dx$

$= \frac{1}{2}k\left[x-\frac{2}{3}x^3+\frac{1}{5}x^5\right]_{-1}^1 = \frac{1}{2}k\left(1-\frac{2}{3}+\frac{1}{5}+1-\frac{2}{3}+\frac{1}{5}\right) = \frac{8}{15}k,$

$M_y = \int_{-1}^1\int_0^{1-x^2}kxy\,dy\,dx = k\int_{-1}^1\left[\frac{1}{2}xy^2\right]_{y=0}^{y=1-x^2}dx = \frac{1}{2}k\int_{-1}^1x\,(1-x^2)^2\,dx = \frac{1}{2}k\int_{-1}^1(x-2x^3+x^5)\,dx$

$= \frac{1}{2}k\left[\frac{1}{2}x^2-\frac{1}{2}x^4+\frac{1}{6}x^6\right]_{-1}^1 = \frac{1}{2}k\left(\frac{1}{2}-\frac{1}{2}+\frac{1}{6}-\frac{1}{2}+\frac{1}{2}-\frac{1}{6}\right) = 0,$

$M_x = \int_{-1}^1\int_0^{1-x^2}ky^2\,dy\,dx = k\int_{-1}^1\left[\frac{1}{3}y^3\right]_{y=0}^{y=1-x^2}dx = \frac{1}{3}k\int_{-1}^1(1-x^2)^3\,dx = \frac{1}{3}k\int_{-1}^1(1-3x^2+3x^4-x^6)\,dx$

$= \frac{1}{3}k\left[x-x^3+\frac{3}{5}x^5-\frac{1}{7}x^7\right]_{-1}^1 = \frac{1}{3}k\left(1-1+\frac{3}{5}-\frac{1}{7}+1-1+\frac{3}{5}-\frac{1}{7}\right) = \frac{32}{105}k.$

Hence $m = \frac{8}{15}k$, $(\overline{x},\overline{y}) = \left(0,\frac{32k/105}{8k/15}\right) = \left(0,\frac{4}{7}\right).$

8. The boundary curves intersect when $x+2 = x^2 \quad\Leftrightarrow\quad x^2-x-2=0 \quad\Leftrightarrow\quad x=-1, x=2$. Thus here $D = \left\{(x,y)\mid -1\le x\le 2,\ x^2\le y\le x+2\right\}.$

$m = \int_{-1}^2\int_{x^2}^{x+2}kx^2\,dy\,dx = k\int_{-1}^2x^2\left[y\right]_{y=x^2}^{y=x+2}dx = k\int_{-1}^2(x^3+2x^2-x^4)\,dx$

$= k\left[\frac{1}{4}x^4+\frac{2}{3}x^3-\frac{1}{5}x^5\right]_{-1}^2 = k\left(\frac{44}{15}+\frac{13}{60}\right) = \frac{63}{20}k,$

$$M_y = \int_{-1}^{2}\int_{x^2}^{x+2} kx^3\,dy\,dx = k\int_{-1}^{2} x^3\left[y\right]_{y=x^2}^{y=x+2}\,dx = k\int_{-1}^{2}(x^4+2x^3-x^5)\,dx$$
$$= k\left[\tfrac{1}{5}x^5+\tfrac{1}{2}x^4-\tfrac{1}{6}x^6\right]_{-1}^{2} = k\left(\tfrac{56}{15}-\tfrac{2}{15}\right) = \tfrac{18}{5}k,$$

$$M_x = \int_{-1}^{2}\int_{x^2}^{x+2} kx^2y\,dy\,dx = k\int_{-1}^{2} x^2\left[\tfrac{1}{2}y^2\right]_{y=x^2}^{y=x+2}dx = \tfrac{1}{2}k\int_{-1}^{2}x^2\left(x^2+4x+4-x^4\right)dx$$
$$= \tfrac{1}{2}k\int_{-1}^{2}(x^4+4x^3+4x^2-x^6)\,dx = \tfrac{1}{2}k\left[\tfrac{1}{5}x^5+x^4+\tfrac{4}{3}x^3-\tfrac{1}{7}x^7\right]_{-1}^{2} = \tfrac{1}{2}k\left(\tfrac{1552}{105}+\tfrac{41}{105}\right) = \tfrac{531}{70}k.$$

Hence $m=\frac{63}{20}k$, $(\overline{x},\overline{y}) = \left(\frac{18k/5}{63k/20},\frac{531k/70}{63k/20}\right) = \left(\frac{8}{7},\frac{118}{49}\right)$.

9. $m = \int_0^1\int_0^{e^{-x}} xy\,dy\,dx = \int_0^1 x\left[\frac{1}{2}y^2\right]_{y=0}^{y=e^{-x}}dx = \frac{1}{2}\int_0^1 x\left(e^{-x}\right)^2dx = \frac{1}{2}\int_0^1 xe^{-2x}\,dx$ $\left[\begin{array}{c}\text{integrate by parts with}\\ u=x,\,dv=e^{-2x}\,dx\end{array}\right]$

$$= \tfrac{1}{2}\left[-\tfrac{1}{4}(2x+1)e^{-2x}\right]_0^1 = -\tfrac{1}{8}\left(3e^{-2}-1\right) = \tfrac{1}{8}-\tfrac{3}{8}e^{-2},$$

$M_y = \int_0^1\int_0^{e^{-x}} x^2y\,dy\,dx = \int_0^1 x^2\left[\frac{1}{2}y^2\right]_{y=0}^{y=e^{-x}}dx = \frac{1}{2}\int_0^1 x^2e^{-2x}\,dx$ [integrate by parts twice]

$$= \tfrac{1}{2}\left[-\tfrac{1}{4}\left(2x^2+2x+1\right)e^{-2x}\right]_0^1 = -\tfrac{1}{8}\left(5e^{-2}-1\right) = \tfrac{1}{8}-\tfrac{5}{8}e^{-2},$$

$$M_x = \int_0^1\int_0^{e^{-x}} xy^2\,dy\,dx = \int_0^1 x\left[\tfrac{1}{3}y^3\right]_{y=0}^{y=e^{-x}}dx = \tfrac{1}{3}\int_0^1 xe^{-3x}\,dx$$
$$= \tfrac{1}{3}\left[-\tfrac{1}{9}(3x+1)e^{-3x}\right]_0^1 = -\tfrac{1}{27}\left(4e^{-3}-1\right) = \tfrac{1}{27}-\tfrac{4}{27}e^{-3}.$$

Hence $m=\frac{1}{8}(1-3e^{-2})$, $(\overline{x},\overline{y}) = \left(\dfrac{\frac{1}{8}\left(1-5e^{-2}\right)}{\frac{1}{8}\left(1-3e^{-2}\right)},\dfrac{\frac{1}{27}\left(1-4e^{-3}\right)}{\frac{1}{8}\left(1-3e^{-2}\right)}\right) = \left(\dfrac{e^2-5}{e^2-3},\dfrac{8\left(e^3-4\right)}{27\left(e^3-3e\right)}\right)$.

10. Note that $\cos x \geq 0$ for $-\pi/2 \leq x \leq \pi/2$.

$$m = \int_{-\pi/2}^{\pi/2}\int_0^{\cos x} y\,dy\,dx = \int_{-\pi/2}^{\pi/2}\left[\tfrac{1}{2}y^2\right]_{y=0}^{y=\cos x}dx = \tfrac{1}{2}\int_{-\pi/2}^{\pi/2}\cos^2x\,dx = \tfrac{1}{2}\left[\tfrac{1}{2}x+\tfrac{1}{4}\sin 2x\right]_{-\pi/2}^{\pi/2} = \tfrac{\pi}{4},$$

$M_y = \int_{-\pi/2}^{\pi/2}\int_0^{\cos x} xy\,dy\,dx = \int_{-\pi/2}^{\pi/2} x\left[\frac{1}{2}y^2\right]_{y=0}^{y=\cos x}dx = \frac{1}{2}\int_{-\pi/2}^{\pi/2} x\cos^2x\,dx$ $\left[\begin{array}{c}\text{integrate by parts with}\\ u=x,\,dv=\cos^2x\,dx\end{array}\right]$

$$= \tfrac{1}{2}\left[x\left(\tfrac{1}{2}x+\tfrac{1}{4}\sin 2x\right)\Big|_{-\pi/2}^{\pi/2} - \int_{-\pi/2}^{\pi/2}\left(\tfrac{1}{2}x+\tfrac{1}{4}\sin 2x\right)dx\right]$$
$$= \tfrac{1}{2}\left(\tfrac{1}{8}\pi^2-\tfrac{1}{8}\pi^2-\left[\tfrac{1}{4}x^2-\tfrac{1}{8}\cos 2x\right]_{-\pi/2}^{\pi/2}\right) = \tfrac{1}{2}\left(0-\left[\tfrac{1}{16}\pi^2+\tfrac{1}{8}-\tfrac{1}{16}\pi^2-\tfrac{1}{8}\right]\right) = 0,$$

$$M_x = \int_{-\pi/2}^{\pi/2}\int_0^{\cos x} y^2\,dy\,dx = \int_{-\pi/2}^{\pi/2}\left[\tfrac{1}{3}y^3\right]_{y=0}^{y=\cos x}dx = \tfrac{1}{3}\int_{-\pi/2}^{\pi/2}\cos^3x\,dx = \tfrac{1}{3}\int_{-\pi/2}^{\pi/2}(1-\sin^2x)\cos x\,dx$$

[substitute $u=\sin x \quad\Rightarrow\quad du=\cos x\,dx$]

$$= \tfrac{1}{3}\left[\sin x-\tfrac{1}{3}\sin^3x\right]_{-\pi/2}^{\pi/2} = \tfrac{1}{3}\left(1-\tfrac{1}{3}+1-\tfrac{1}{3}\right) = \tfrac{4}{9}.$$

Hence $m=\frac{\pi}{4}$, $(\overline{x},\overline{y}) = \left(0,\frac{4/9}{\pi/4}\right) = \left(0,\frac{16}{9\pi}\right)$.

11. $\rho(x,y)=ky$, $\quad m = \iint_D ky\,dA = \int_0^{\pi/2}\int_0^1 k(r\sin\theta)\,r\,dr\,d\theta = k\int_0^{\pi/2}\sin\theta\,d\theta\int_0^1 r^2\,dr$

$$= k\left[-\cos\theta\right]_0^{\pi/2}\left[\tfrac{1}{3}r^3\right]_0^1 = k(1)\left(\tfrac{1}{3}\right) = \tfrac{1}{3}k,$$

$$M_y = \iint_D x\cdot ky\,dA = \int_0^{\pi/2}\int_0^1 k(r\cos\theta)(r\sin\theta)\,r\,dr\,d\theta = k\int_0^{\pi/2}\sin\theta\cos\theta\,d\theta\int_0^1 r^3\,dr$$
$$= k\left[\tfrac{1}{2}\sin^2\theta\right]_0^{\pi/2}\left[\tfrac{1}{4}r^4\right]_0^1 = k\left(\tfrac{1}{2}\right)\left(\tfrac{1}{4}\right) = \tfrac{1}{8}k,$$

$$M_x = \iint_D y \cdot ky\, dA = \int_0^{\pi/2}\int_0^1 k(r\sin\theta)^2\, r\, dr\, d\theta = k\int_0^{\pi/2} \sin^2\theta\, d\theta \int_0^1 r^3\, dr$$
$$= k\left[\tfrac{1}{2}\theta - \tfrac{1}{4}\sin 2\theta\right]_0^{\pi/2}\left[\tfrac{1}{4}r^4\right]_0^1 = k\left(\tfrac{\pi}{4}\right)\left(\tfrac{1}{4}\right) = \tfrac{\pi}{16}k.$$

Hence $(\overline{x}, \overline{y}) = \left(\frac{k/8}{k/3}, \frac{k\pi/16}{k/3}\right) = \left(\frac{3}{8}, \frac{3\pi}{16}\right)$.

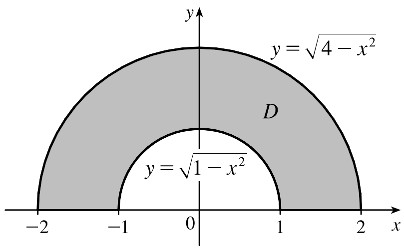
12. $\rho(x,y) = k(x^2+y^2) = kr^2$, $m = \int_0^{\pi/2}\int_0^1 kr^3\, dr\, d\theta = \frac{\pi}{8}k$,

$M_y = \int_0^{\pi/2}\int_0^1 kr^4 \cos\theta\, dr\, d\theta = \frac{1}{5}k\int_0^{\pi/2}\cos\theta\, d\theta = \frac{1}{5}k\big[\sin\theta\big]_0^{\pi/2} = \frac{1}{5}k$,

$M_x = \int_0^{\pi/2}\int_0^1 kr^4 \sin\theta\, dr\, d\theta = \frac{1}{5}k\int_0^{\pi/2}\sin\theta\, d\theta = \frac{1}{5}k\big[-\cos\theta\big]_0^{\pi/2} = \frac{1}{5}k$.

Hence $(\overline{x}, \overline{y}) = \left(\frac{8}{5\pi}, \frac{8}{5\pi}\right)$.

13.



$\rho(x,y) = k\sqrt{x^2+y^2} = kr$,

$$m = \iint_D \rho(x,y)dA = \int_0^{\pi}\int_1^2 kr \cdot r\, dr\, d\theta$$
$$= k\int_0^{\pi} d\theta \int_1^2 r^2\, dr = k(\pi)\left[\tfrac{1}{3}r^3\right]_1^2 = \tfrac{7}{3}\pi k,$$

$$M_y = \iint_D x\rho(x,y)dA = \int_0^{\pi}\int_1^2 (r\cos\theta)(kr)\, r\, dr\, d\theta = k\int_0^{\pi}\cos\theta\, d\theta \int_1^2 r^3\, dr$$
$$= k\left[\sin\theta\right]_0^{\pi}\left[\tfrac{1}{4}r^4\right]_1^2 = k(0)\left(\tfrac{15}{4}\right) = 0$$

[this is to be expected as the region and density function are symmetric about the y-axis]

$$M_x = \iint_D y\rho(x,y)dA = \int_0^{\pi}\int_1^2 (r\sin\theta)(kr)\, r\, dr\, d\theta = k\int_0^{\pi}\sin\theta\, d\theta \int_1^2 r^3\, dr$$
$$= k\left[-\cos\theta\right]_0^{\pi}\left[\tfrac{1}{4}r^4\right]_1^2 = k(1+1)\left(\tfrac{15}{4}\right) = \tfrac{15}{2}k.$$

Hence $(\overline{x}, \overline{y}) = \left(0, \frac{15k/2}{7\pi k/3}\right) = \left(0, \frac{45}{14\pi}\right)$.

14. Now $\rho(x,y) = k/\sqrt{x^2+y^2} = k/r$, so

$$m = \iint_D \rho(x,y)dA = \int_0^{\pi}\int_1^2 (k/r)\, r\, dr\, d\theta = k\int_0^{\pi} d\theta \int_1^2 dr = k(\pi)(1) = \pi k,$$

$$M_y = \iint_D x\rho(x,y)dA = \int_0^{\pi}\int_1^2 (r\cos\theta)(k/r)\, r\, dr\, d\theta = k\int_0^{\pi}\cos\theta\, d\theta \int_1^2 r\, dr$$
$$= k\left[\sin\theta\right]_0^{\pi}\left[\tfrac{1}{2}r^2\right]_1^2 = k(0)\left(\tfrac{3}{2}\right) = 0,$$

$$M_x = \iint_D y\rho(x,y)dA = \int_0^{\pi}\int_1^2 (r\sin\theta)(k/r)\, r\, dr\, d\theta = k\int_0^{\pi}\sin\theta\, d\theta \int_1^2 r\, dr$$
$$= k\left[-\cos\theta\right]_0^{\pi}\left[\tfrac{1}{2}r^2\right]_1^2 = k(1+1)\left(\tfrac{3}{2}\right) = 3k.$$

Hence $(\overline{x}, \overline{y}) = \left(0, \frac{3k}{\pi k}\right) = \left(0, \frac{3}{\pi}\right)$.

15. Placing the vertex opposite the hypotenuse at $(0,0)$, $\rho(x,y) = k(x^2+y^2)$. Then

$$m = \int_0^a\int_0^{a-x} k\left(x^2+y^2\right) dy\, dx = k\int_0^a \left[ax^2 - x^3 + \tfrac{1}{3}(a-x)^3\right] dx = k\left[\tfrac{1}{3}ax^3 - \tfrac{1}{4}x^4 - \tfrac{1}{12}(a-x)^4\right]_0^a = \tfrac{1}{6}ka^4.$$

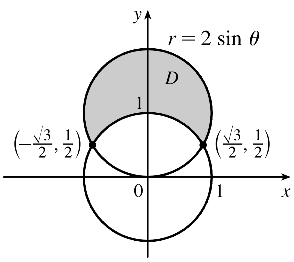
[continued]

By symmetry, $M_y = M_x = \int_0^a \int_0^{a-x} ky(x^2+y^2)\,dy\,dx = k\int_0^a \left[\frac{1}{2}(a-x)^2x^2 + \frac{1}{4}(a-x)^4\right]dx$

$$= k\left[\tfrac{1}{6}a^2x^3 - \tfrac{1}{4}ax^4 + \tfrac{1}{10}x^5 - \tfrac{1}{20}(a-x)^5\right]_0^a = \tfrac{1}{15}ka^5$$

Hence $(\overline{x},\overline{y}) = \left(\frac{2}{5}a, \frac{2}{5}a\right)$.

16. $\rho(x,y) = k/\sqrt{x^2+y^2} = k/r$.



$$m = \int_{\pi/6}^{5\pi/6}\int_1^{2\sin\theta} \frac{k}{r}\,r\,dr\,d\theta = k\int_{\pi/6}^{5\pi/6}\left[(2\sin\theta) - 1\right]d\theta$$

$$= k\left[-2\cos\theta - \theta\right]_{\pi/6}^{5\pi/6} = 2k\left(\sqrt{3} - \tfrac{\pi}{3}\right)$$

By symmetry of D and $f(x) = x$, $M_y = 0$, and

$$M_x = \int_{\pi/6}^{5\pi/6}\int_1^{2\sin\theta} kr\sin\theta\,dr\,d\theta = \tfrac{1}{2}k\int_{\pi/6}^{5\pi/6}(4\sin^3\theta - \sin\theta)\,d\theta$$

$$= \tfrac{1}{2}k\left[-3\cos\theta + \tfrac{4}{3}\cos^3\theta\right]_{\pi/6}^{5\pi/6} = \sqrt{3}\,k$$

Hence $(\overline{x},\overline{y}) = \left(0, \frac{3\sqrt{3}}{2\left(3\sqrt{3}-\pi\right)}\right)$.

17. $I_x = \iint_D y^2\rho(x,y)dA = \int_1^3\int_1^4 y^2\cdot ky^2\,dy\,dx = k\int_1^3 dx\,\int_1^4 y^4\,dy = k\,[x]_1^3\,\left[\frac{1}{5}y^5\right]_1^4 = k(2)\left(\frac{1023}{5}\right) = 409.2k$,

$I_y = \iint_D x^2\rho(x,y)\,dA = \int_1^3\int_1^4 x^2\cdot ky^2\,dy\,dx = k\int_1^3 x^2\,dx\,\int_1^4 y^2\,dy = k\left[\frac{1}{3}x^3\right]_1^3\left[\frac{1}{3}y^3\right]_1^4 = k\left(\frac{26}{3}\right)(21) = 182k$,

and $I_0 = I_x + I_y = 409.2k + 182k = 591.2k$.

18. $I_x = \iint_D y^2\rho(x,y)dA = \int_0^{2/5}\int_{y/2}^{1-2y} y^2\cdot x\,dx\,dy = \int_0^{2/5} y^2\left[\frac{1}{2}x^2\right]_{x=y/2}^{x=1-2y}dy = \frac{1}{2}\int_0^{2/5} y^2\left(\frac{15}{4}y^2 - 4y + 1\right)dy$

$= \frac{1}{2}\int_0^{2/5}\left(\frac{15}{4}y^4 - 4y^3 + y^2\right)dy = \frac{1}{2}\left[\frac{3}{4}y^5 - y^4 + \frac{1}{3}y^3\right]_0^{2/5} = \frac{16}{9375}$,

$I_y = \iint_D x^2\rho(x,y)\,dA = \int_0^{2/5}\int_{y/2}^{1-2y} x^2\cdot x\,dx\,dy = \int_0^{2/5}\left[\frac{1}{4}x^4\right]_{x=y/2}^{x=1-2y}dy = \frac{1}{4}\int_0^{2/5}\left[(1-2y)^4 - \frac{1}{16}y^4\right]dy$

$= \frac{1}{4}\int_0^{2/5}\left(\frac{255}{16}y^4 - 32y^3 + 24y^2 - 8y + 1\right)dy = \frac{1}{4}\left[\frac{51}{16}y^5 - 8y^4 + 8y^3 - 4y^2 + y\right]_0^{2/5} = \frac{78}{3125}$,

and $I_0 = I_x + I_y = \frac{16}{9375} + \frac{78}{3125} = \frac{2}{75}$.

19. As in Exercise 15, we place the vertex opposite the hypotenuse at $(0,0)$ and the equal sides along the positive axes.

$I_x = \int_0^a\int_0^{a-x} y^2k(x^2+y^2)\,dy\,dx = k\int_0^a\int_0^{a-x}(x^2y^2 + y^4)\,dy\,dx = k\int_0^a\left[\frac{1}{3}x^2y^3 + \frac{1}{5}y^5\right]_{y=0}^{y=a-x}\,dx$

$= k\int_0^a\left[\frac{1}{3}x^2(a-x)^3 + \frac{1}{5}(a-x)^5\right]dx = k\left[\frac{1}{3}\left(\frac{1}{3}a^3x^3 - \frac{3}{4}a^2x^4 + \frac{3}{5}ax^5 - \frac{1}{6}x^6\right) - \frac{1}{30}(a-x)^6\right]_0^a = \frac{7}{180}ka^6$,

$I_y = \int_0^a\int_0^{a-x} x^2k(x^2+y^2)\,dy\,dx = k\int_0^a\int_0^{a-x}(x^4 + x^2y^2)\,dy\,dx = k\int_0^a\left[x^4y + \frac{1}{3}x^2y^3\right]_{y=0}^{y=a-x}\,dx$

$= k\int_0^a\left[x^4(a-x) + \frac{1}{3}x^2(a-x)^3\right]dx = k\left[\frac{1}{5}ax^5 - \frac{1}{6}x^6 + \frac{1}{3}\left(\frac{1}{3}a^3x^3 - \frac{3}{4}a^2x^4 + \frac{3}{5}ax^5 - \frac{1}{6}x^6\right)\right]_0^a = \frac{7}{180}ka^6$,

and $I_0 = I_x + I_y = \frac{7}{90}ka^6$.

20. If we find the moments of inertia about the x- and y-axes, we can determine in which direction rotation will be more difficult. (See the explanation following Example 4.) The moment of inertia about the x-axis is given by

$$I_x = \iint_D y^2 \rho(x,y)\,dA = \int_0^2\int_0^2 y^2(1+0.1x)\,dy\,dx = \int_0^2 (1+0.1x)\left[\tfrac{1}{3}y^3\right]_{y=0}^{y=2}\,dx$$
$$= \tfrac{8}{3}\int_0^2 (1+0.1x)\,dx = \tfrac{8}{3}\left[x+0.1\cdot\tfrac{1}{2}x^2\right]_0^2 = \tfrac{8}{3}(2.2) \approx 5.87$$

Similarly, the moment of inertia about the y-axis is given by

$$I_y = \iint_D x^2 \rho(x,y)\,dA = \int_0^2\int_0^2 x^2(1+0.1x)\,dy\,dx = \int_0^2 x^2(1+0.1x)\left[\,y\,\right]_{y=0}^{y=2}\,dx$$
$$= 2\int_0^2 (x^2+0.1x^3)\,dx = 2\left[\tfrac{1}{3}x^3+0.1\cdot\tfrac{1}{4}x^4\right]_0^2 = 2\left(\tfrac{8}{3}+0.4\right) \approx 6.13$$

Since $I_y > I_x$, more force is required to rotate the fan blade about the y-axis.

21. $I_x = \iint_D y^2\rho(x,y)dA = \int_0^h\int_0^b \rho y^2\,dx\,dy = \rho\int_0^b dx\,\int_0^h y^2\,dy = \rho\left[\,x\,\right]_0^b\,\left[\tfrac{1}{3}y^3\right]_0^h = \rho b\left(\tfrac{1}{3}h^3\right) = \tfrac{1}{3}\rho b h^3$,

$I_y = \iint_D x^2\rho(x,y)dA = \int_0^h\int_0^b \rho x^2\,dx\,dy = \rho\int_0^b x^2\,dx\,\int_0^h dy = \rho\left[\,\tfrac{1}{3}x^3\,\right]_0^b\,[y]_0^h = \tfrac{1}{3}\rho b^3 h$,

and $m = \rho\,(\text{area of rectangle}) = \rho b h$ since the lamina is homogeneous. Hence $\overline{\overline{x}}^2 = \dfrac{I_y}{m} = \dfrac{\frac{1}{3}\rho b^3 h}{\rho b h} = \dfrac{b^2}{3} \;\;\Rightarrow\;\; \overline{\overline{x}} = \dfrac{b}{\sqrt{3}}$

and $\overline{\overline{y}}^2 = \dfrac{I_x}{m} = \dfrac{\frac{1}{3}\rho b h^3}{\rho b h} = \dfrac{h^2}{3} \;\;\Rightarrow\;\; \overline{\overline{y}} = \dfrac{h}{\sqrt{3}}$.

22. Here we assume $b > 0$, $h > 0$ but note that we arrive at the same results if $b < 0$ or $h < 0$. We have

$D = \left\{(x,y) \mid 0 \le x \le b, 0 \le y \le h - \tfrac{h}{b}x\right\}$, so

$$I_x = \int_0^b\int_0^{h-hx/b} y^2\rho\,dy\,dx = \rho\int_0^b\left[\tfrac{1}{3}y^3\right]_{y=0}^{y=h-hx/b}dx = \tfrac{1}{3}\rho\int_0^b\left(h-\tfrac{h}{b}x\right)^3 dx$$
$$= \tfrac{1}{3}\rho\left[-\tfrac{b}{h}\left(\tfrac{1}{4}\right)\left(h-\tfrac{h}{b}x\right)^4\right]_0^b = -\tfrac{b}{12h}\rho(0-h^4) = \tfrac{1}{12}\rho b h^3,$$

$$I_y = \int_0^b\int_0^{h-hx/b} x^2\rho\,dy\,dx = \rho\int_0^b x^2\left(h-\tfrac{h}{b}x\right)dx = \rho\int_0^b\left(hx^2-\tfrac{h}{b}x^3\right)dx$$
$$= \rho\left[\tfrac{h}{3}x^3-\tfrac{h}{4b}x^4\right]_0^b = \rho\left(\tfrac{hb^3}{3}-\tfrac{hb^3}{4}\right) = \tfrac{1}{12}\rho b^3 h,$$

and $m = \int_0^b\int_0^{h-hx/b}\rho\,dy\,dx = \rho\int_0^b\left(h-\tfrac{h}{b}x\right)dx = \rho\left[hx-\tfrac{h}{2b}x^2\right]_0^b = \tfrac{1}{2}\rho b h$. Hence $\overline{\overline{x}}^2 = \dfrac{I_y}{m} = \dfrac{\frac{1}{12}\rho b^3 h}{\frac{1}{2}\rho b h} = \dfrac{b^2}{6} \;\;\Rightarrow$

$\overline{\overline{x}} = \dfrac{b}{\sqrt{6}}$ and $\overline{\overline{y}}^2 = \dfrac{I_x}{m} = \dfrac{\frac{1}{12}\rho b h^3}{\frac{1}{2}\rho b h} = \dfrac{h^2}{6} \;\;\Rightarrow\;\; \overline{\overline{y}} = \dfrac{h}{\sqrt{6}}$.

23. In polar coordinates, the region is $D = \left\{(r,\theta) \mid 0 \le r \le a, 0 \le \theta \le \tfrac{\pi}{2}\right\}$, so

$$I_x = \iint_D y^2\rho\,dA = \int_0^{\pi/2}\int_0^a \rho(r\sin\theta)^2\,r\,dr\,d\theta = \rho\int_0^{\pi/2}\sin^2 d\theta\,\int_0^a r^3\,dr$$
$$= \rho\left[\tfrac{1}{2}\theta-\tfrac{1}{4}\sin 2\theta\right]_0^{\pi/2}\,\left[\tfrac{1}{4}r^4\right]_0^a = \rho\left(\tfrac{\pi}{4}\right)\left(\tfrac{1}{4}a^4\right) = \tfrac{1}{16}\rho a^4\pi,$$

$$I_y = \iint_D x^2\rho\,dA = \int_0^{\pi/2}\int_0^a \rho(r\cos\theta)^2\,r\,dr\,d\theta = \rho\int_0^{\pi/2}\cos^2 d\theta\,\int_0^a r^3\,dr$$
$$= \rho\left[\tfrac{1}{2}\theta+\tfrac{1}{4}\sin 2\theta\right]_0^{\pi/2}\,\left[\tfrac{1}{4}r^4\right]_0^a = \rho\left(\tfrac{\pi}{4}\right)\left(\tfrac{1}{4}a^4\right) = \tfrac{1}{16}\rho a^4\pi,$$

and $m = \rho\cdot A(D) = \rho\cdot\tfrac{1}{4}\pi a^2$ since the lamina is homogeneous. Hence $\overline{\overline{x}}^2 = \overline{\overline{y}}^2 = \dfrac{\frac{1}{16}\rho a^4\pi}{\frac{1}{4}\rho a^2\pi} = \dfrac{a^2}{4} \;\;\Rightarrow\;\; \overline{\overline{x}} = \overline{\overline{y}} = \dfrac{a}{2}$.

24. $m = \int_0^\pi \int_0^{\sin x} \rho\, dy\, dx = \rho \int_0^\pi \sin x\, dx = \rho\big[-\cos x\big]_0^\pi = 2\rho$,

$I_x = \int_0^\pi \int_0^{\sin x} \rho y^2\, dy\, dx = \frac{1}{3}\rho \int_0^\pi \sin^3 x\, dx = \frac{1}{3}\rho \int_0^\pi (1-\cos^2 x)\sin x\, dx = \frac{1}{3}\rho\big[-\cos x + \frac{1}{3}\cos^3 x\big]_0^\pi = \frac{4}{9}\rho$,

$I_y = \int_0^\pi \int_0^{\sin x} \rho x^2\, dy\, dx = \rho \int_0^\pi x^2 \sin x\, dx = \rho\big[-x^2\cos x + 2x\sin x + 2\cos x\big]_0^\pi$ [by integrating by parts twice]

$= \rho(\pi^2 - 4)$.

Then $\overline{\overline{y}}^{\,2} = \dfrac{I_x}{m} = \dfrac{2}{9}$, so $\overline{\overline{y}} = \dfrac{\sqrt{2}}{3}$ and $\overline{\overline{x}}^{\,2} = \dfrac{I_y}{m} = \dfrac{\pi^2-4}{2}$, so $\overline{\overline{x}} = \sqrt{\dfrac{\pi^2-4}{2}}$.

25. The right loop of the curve is given by $D = \{(r,\theta) \mid 0 \le r \le \cos 2\theta,\ -\pi/4 \le \theta \le \pi/4\}$. Using a CAS, we find $m = \iint_D \rho(x,y)\, dA = \iint_D (x^2+y^2)\, dA = \int_{-\pi/4}^{\pi/4} \int_0^{\cos 2\theta} r^2\, r\, dr\, d\theta = \dfrac{3\pi}{64}$. Then

$$\overline{x} = \frac{1}{m}\iint_D x\rho(x,y)\, dA = \frac{64}{3\pi}\int_{-\pi/4}^{\pi/4}\int_0^{\cos 2\theta} (r\cos\theta)\, r^2\, r\, dr\, d\theta = \frac{64}{3\pi}\int_{-\pi/4}^{\pi/4}\int_0^{\cos 2\theta} r^4 \cos\theta\, dr\, d\theta = \frac{16384\sqrt{2}}{10395\pi} \text{ and}$$

$$\overline{y} = \frac{1}{m}\iint_D y\rho(x,y)\, dA = \frac{64}{3\pi}\int_{-\pi/4}^{\pi/4}\int_0^{\cos 2\theta} (r\sin\theta)\, r^2\, r\, dr\, d\theta = \frac{64}{3\pi}\int_{-\pi/4}^{\pi/4}\int_0^{\cos 2\theta} r^4 \sin\theta\, dr\, d\theta = 0, \text{ so}$$

$$(\overline{x},\overline{y}) = \left(\frac{16384\sqrt{2}}{10395\pi}, 0\right).$$

The moments of inertia are

$$I_x = \iint_D y^2\rho(x,y)\, dA = \int_{-\pi/4}^{\pi/4}\int_0^{\cos 2\theta} (r\sin\theta)^2\, r^2\, r\, dr\, d\theta = \int_{-\pi/4}^{\pi/4}\int_0^{\cos 2\theta} r^5 \sin^2\theta\, dr\, d\theta = \frac{5\pi}{384} - \frac{4}{105},$$

$$I_y = \iint_D x^2\rho(x,y)\, dA = \int_{-\pi/4}^{\pi/4}\int_0^{\cos 2\theta} (r\cos\theta)^2\, r^2\, r\, dr\, d\theta = \int_{-\pi/4}^{\pi/4}\int_0^{\cos 2\theta} r^5 \cos^2\theta\, dr\, d\theta = \frac{5\pi}{384} + \frac{4}{105}, \text{ and}$$

$$I_0 = I_x + I_y = \frac{5\pi}{192}.$$

26. Using a CAS, we find $m = \iint_D \rho(x,y)\, dA = \int_0^2 \int_0^{xe^{-x}} x^2 y^2\, dy\, dx = \frac{8}{729}(5 - 899e^{-6})$. Then

$$\overline{x} = \frac{1}{m}\iint_D x\rho(x,y)\, dA = \frac{729}{8(5-899e^{-6})}\int_0^2\int_0^{xe^{-x}} x^3y^2\, dy\, dx = \frac{2(5e^6-1223)}{5e^6-899} \text{ and}$$

$$\overline{y} = \frac{1}{m}\iint_D y\rho(x,y)\, dA = \frac{729}{8(5-899e^{-6})}\int_0^2\int_0^{xe^{-x}} x^2y^3\, dy\, dx = \frac{729(45e^6-42037e^{-2})}{32768(5e^6-899)}, \text{ so}$$

$$(\overline{x},\overline{y}) = \left(\frac{2(5e^6-1223)}{5e^6-899}, \frac{729(45e^6-42037e^{-2})}{32768(5e^6-899)}\right).$$

The moments of inertia are $I_x = \iint_D y^2\rho(x,y)\, dA = \int_0^2 \int_0^{xe^{-x}} x^2y^4\, dy\, dx = \frac{16}{390625}(63 - 305593e^{-10})$,

$I_y = \iint_D x^2\rho(x,y)\, dA = \int_0^2 \int_0^{xe^{-x}} x^4y^2\, dy\, dx = \frac{80}{2187}(7 - 2101e^{-6})$, and

$I_0 = I_x + I_y = \frac{16}{854296875}(13809656 - 4103515625e^{-6} - 668331891e^{-10})$.

27. (a) $f(x,y)$ is a joint density function, so we know $\iint_{\mathbb{R}^2} f(x,y)\, dA = 1$. Since $f(x,y) = 0$ outside the rectangle $[0,1]\times[0,2]$, we can say

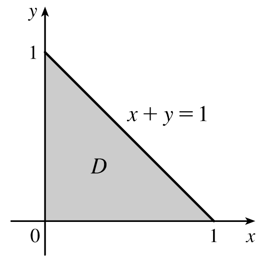
$$\begin{aligned}\iint_{\mathbb{R}^2} f(x,y)\, dA &= \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} f(x,y)\, dy\, dx = \int_0^1\int_0^2 Cx(1+y)\, dy\, dx \\ &= C\int_0^1 x\big[y + \tfrac{1}{2}y^2\big]_{y=0}^{y=2}\, dx = C\int_0^1 4x\, dx = C\big[2x^2\big]_0^1 = 2C\end{aligned}$$

Then $2C = 1 \;\Rightarrow\; C = \frac{1}{2}$.

(b) $P(X \le 1, Y \le 1) = \int_{-\infty}^{1}\int_{-\infty}^{1} f(x,y)\,dy\,dx = \int_0^1\int_0^1 \frac{1}{2}x(1+y)\,dy\,dx$

$$= \int_0^1 \tfrac{1}{2}x\left[y+\tfrac{1}{2}y^2\right]_{y=0}^{y=1} dx = \int_0^1 \tfrac{1}{2}x\left(\tfrac{3}{2}\right) dx = \tfrac{3}{4}\left[\tfrac{1}{2}x^2\right]_0^1 = \tfrac{3}{8} \text{ or } 0.375$$

(c) $P(X+Y \le 1) = P((X,Y) \in D)$ where D is the triangular region shown in the figure. Thus



$$P(X+Y \le 1) = \iint_D f(x,y)\,dA = \int_0^1\int_0^{1-x} \tfrac{1}{2}x(1+y)\,dy\,dx$$

$$= \int_0^1 \tfrac{1}{2}x\left[y+\tfrac{1}{2}y^2\right]_{y=0}^{y=1-x} dx = \int_0^1 \tfrac{1}{2}x\left(\tfrac{1}{2}x^2 - 2x + \tfrac{3}{2}\right) dx$$

$$= \tfrac{1}{4}\int_0^1 \left(x^3 - 4x^2 + 3x\right) dx = \tfrac{1}{4}\left[\tfrac{x^4}{4} - 4\tfrac{x^3}{3} + 3\tfrac{x^2}{2}\right]_0^1$$

$$= \tfrac{5}{48} \approx 0.1042$$

28. (a) $f(x,y) \ge 0$, so f is a joint density function if $\iint_{\mathbb{R}^2} f(x,y)\,dA = 1$. Here, $f(x,y) = 0$ outside the square $[0,1]\times[0,1]$, so $\iint_{\mathbb{R}^2} f(x,y)\,dA = \int_0^1\int_0^1 4xy\,dy\,dx = \int_0^1 \left[2xy^2\right]_{y=0}^{y=1} dx = \int_0^1 2x\,dx = \left.x^2\right]_0^1 = 1.$

Thus, $f(x,y)$ is a joint density function.

(b) (i) No restriction is placed on Y, so

$$P\left(X \ge \tfrac{1}{2}\right) = \int_{1/2}^{\infty}\int_{-\infty}^{\infty} f(x,y)\,dy\,dx = \int_{1/2}^{1}\int_0^1 4xy\,dy\,dx = \int_{1/2}^{1}\left[2xy^2\right]_{y=0}^{y=1} dx = \int_{1/2}^{1} 2x\,dx = \left.x^2\right]_{1/2}^{1} = \tfrac{3}{4}.$$

(ii) $P\left(X \ge \tfrac{1}{2}, Y \le \tfrac{1}{2}\right) = \int_{1/2}^{\infty}\int_{-\infty}^{1/2} f(x,y)\,dy\,dx = \int_{1/2}^{1}\int_0^{1/2} 4xy\,dy\,dx$

$$= \int_{1/2}^{1}\left[2xy^2\right]_{y=0}^{y=1/2} dx = \int_{1/2}^{1} \tfrac{1}{2}x\,dx = \left.\tfrac{1}{2}\cdot\tfrac{1}{2}x^2\right]_{1/2}^{1} = \tfrac{3}{16}$$

(c) The expected value of X is given by

$$\mu_1 = \iint_{\mathbb{R}^2} x\,f(x,y)\,dA = \int_0^1\int_0^1 x(4xy)\,dy\,dx = \int_0^1 2x^2\left[y^2\right]_{y=0}^{y=1} dx = 2\int_0^1 x^2\,dx = 2\left[\tfrac{1}{3}x^3\right]_0^1 = \tfrac{2}{3}$$

The expected value of Y is

$$\mu_2 = \iint_{\mathbb{R}^2} y\,f(x,y)\,dA = \int_0^1\int_0^1 y(4xy)\,dy\,dx = \int_0^1 4x\left[\tfrac{1}{3}y^3\right]_{y=0}^{y=1} dx = \tfrac{4}{3}\int_0^1 x\,dx = \tfrac{4}{3}\left[\tfrac{1}{2}x^2\right]_0^1 = \tfrac{2}{3}$$

29. (a) $f(x,y) \ge 0$, so f is a joint density function if $\iint_{\mathbb{R}^2} f(x,y)\,dA = 1$. Here, $f(x,y) = 0$ outside the first quadrant, so

$$\iint_{\mathbb{R}^2} f(x,y)\,dA = \int_0^{\infty}\int_0^{\infty} 0.1e^{-(0.5x+0.2y)}\,dy\,dx = 0.1\int_0^{\infty}\int_0^{\infty} e^{-0.5x}e^{-0.2y}\,dy\,dx = 0.1\int_0^{\infty} e^{-0.5x}\,dx \int_0^{\infty} e^{-0.2y}\,dy$$

$$= 0.1 \lim_{t\to\infty}\int_0^t e^{-0.5x}\,dx \lim_{t\to\infty}\int_0^t e^{-0.2y}\,dy = 0.1\lim_{t\to\infty}\left[-2e^{-0.5x}\right]_0^t \lim_{t\to\infty}\left[-5e^{-0.2y}\right]_0^t$$

$$= 0.1\lim_{t\to\infty}\left[-2(e^{-0.5t}-1)\right]\lim_{t\to\infty}\left[-5(e^{-0.2t}-1)\right] = (0.1)\cdot(-2)(0-1)\cdot(-5)(0-1) = 1$$

Thus $f(x,y)$ is a joint density function.

(b) (i) No restriction is placed on X, so

$$P(Y \ge 1) = \int_{-\infty}^{\infty}\int_1^{\infty} f(x,y)\,dy\,dx = \int_0^{\infty}\int_1^{\infty} 0.1e^{-(0.5x+0.2y)}\,dy\,dx$$

$$= 0.1\int_0^{\infty} e^{-0.5x}\,dx\int_1^{\infty} e^{-0.2y}\,dy = 0.1\lim_{t\to\infty}\int_0^t e^{-0.5x}\,dx \lim_{t\to\infty}\int_1^t e^{-0.2y}\,dy$$

$$= 0.1\lim_{t\to\infty}\left[-2e^{-0.5x}\right]_0^t \lim_{t\to\infty}\left[-5e^{-0.2y}\right]_1^t = 0.1\lim_{t\to\infty}\left[-2(e^{-0.5t}-1)\right]\lim_{t\to\infty}\left[-5(e^{-0.2t}-e^{-0.2})\right]$$

$$(0.1)\cdot(-2)(0-1)\cdot(-5)(0-e^{-0.2}) = e^{-0.2} \approx 0.8187$$

(ii) $P(X \le 2, Y \le 4) = \int_{-\infty}^{2} \int_{-\infty}^{4} f(x,y)\,dy\,dx = \int_0^2 \int_0^4 0.1e^{-(0.5x+0.2y)}\,dy\,dx$

$$= 0.1 \int_0^2 e^{-0.5x}\,dx \int_0^4 e^{-0.2y}\,dy = 0.1\left[-2e^{-0.5x}\right]_0^2 \left[-5e^{-0.2y}\right]_0^4$$
$$= (0.1)\cdot(-2)(e^{-1}-1)\cdot(-5)(e^{-0.8}-1)$$
$$= (e^{-1}-1)(e^{-0.8}-1) = 1 + e^{-1.8} - e^{-0.8} - e^{-1} \approx 0.3481$$

(c) The expected value of X is given by

$$\mu_1 = \iint_{\mathbb{R}^2} x\,f(x,y)\,dA = \int_0^\infty \int_0^\infty x\left[0.1e^{-(0.5x+0.2y)}\right] dy\,dx$$
$$= 0.1 \int_0^\infty xe^{-0.5x}\,dx \int_0^\infty e^{-0.2y}\,dy = 0.1 \lim_{t\to\infty} \int_0^t xe^{-0.5x}\,dx \lim_{t\to\infty} \int_0^t e^{-0.2y}\,dy$$

To evaluate the first integral, we integrate by parts with $u = x$ and $dv = e^{-0.5x}\,dx$ (or we can use Formula 96 in the Table of Integrals): $\int xe^{-0.5x}\,dx = -2xe^{-0.5x} - \int -2e^{-0.5x}\,dx = -2xe^{-0.5x} - 4e^{-0.5x} = -2(x+2)e^{-0.5x}$. Thus

$$\mu_1 = 0.1 \lim_{t\to\infty} \left[-2(x+2)e^{-0.5x}\right]_0^t \lim_{t\to\infty} \left[-5e^{-0.2y}\right]_0^t$$
$$= 0.1 \lim_{t\to\infty} (-2)\left[(t+2)e^{-0.5t} - 2\right] \lim_{t\to\infty} (-5)\left[e^{-0.2t} - 1\right]$$
$$= 0.1(-2)\left(\lim_{t\to\infty} \frac{t+2}{e^{0.5t}} - 2\right)(-5)(-1) = 2 \qquad \text{[by l'Hospital's Rule]}$$

The expected value of Y is given by

$$\mu_2 = \iint_{\mathbb{R}^2} y\,f(x,y)\,dA = \int_0^\infty \int_0^\infty y\left[0.1e^{-(0.5\,+0.2y)}\right] dy\,dx$$
$$= 0.1 \int_0^\infty e^{-0.5x}\,dx \int_0^\infty ye^{-0.2y}\,dy = 0.1 \lim_{t\to\infty} \int_0^t e^{-0.5x}\,dx \lim_{t\to\infty} \int_0^t ye^{-0.2y}\,dy$$

To evaluate the second integral, we integrate by parts with $u = y$ and $dv = e^{-0.2y}\,dy$ (or again we can use Formula 96 in the Table of Integrals) which gives $\int ye^{-0.2y}\,dy = -5ye^{-0.2y} + \int 5e^{-0.2y}\,dy = -5(y+5)e^{-0.2y}$. Then

$$\mu_2 = 0.1 \lim_{t\to\infty} \left[-2e^{-0.5x}\right]_0^t \lim_{t\to\infty} \left[-5(y+5)e^{-0.2y}\right]_0^t$$
$$= 0.1 \lim_{t\to\infty} \left[-2(e^{-0.5t}-1)\right] \lim_{t\to\infty} \left(-5\left[(t+5)e^{-0.2t} - 5\right]\right)$$
$$= 0.1(-2)(-1)\cdot(-5)\left(\lim_{t\to\infty} \frac{t+5}{e^{0.2t}} - 5\right) = 5 \qquad \text{[by l'Hospital's Rule]}$$

30. (a) The lifetime of each bulb has exponential density function

$$f(t) = \begin{cases} 0 & \text{if } t < 0 \\ \frac{1}{1000} e^{-t/1000} & \text{if } t \ge 0 \end{cases}$$

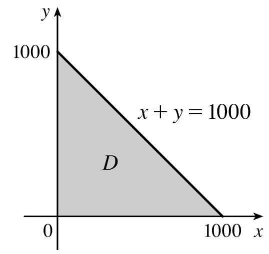
If X and Y are the lifetimes of the individual bulbs, then X and Y are independent, so the joint density function is the product of the individual density functions:

$$f(x,y) = \begin{cases} 10^{-6} e^{-(x+y)/1000} & \text{if } x \ge 0, y \ge 0 \\ 0 & \text{otherwise} \end{cases}$$

The probability that both of the bulbs fail within 1000 hours is

$$\begin{aligned} P(X \le 1000, Y \le 1000) &= \int_{-\infty}^{1000} \int_{-\infty}^{1000} f(x,y)\,dy\,dx = \int_0^{1000} \int_0^{1000} 10^{-6} e^{-(x+y)/1000}\,dy\,dx \\ &= 10^{-6} \int_0^{1000} e^{-x/1000}\,dx \int_0^{1000} e^{-y/1000}\,dy \\ &= 10^{-6} \left[-1000e^{-x/1000}\right]_0^{1000} \left[-1000e^{-y/1000}\right]_0^{1000} \\ &= \left(e^{-1} - 1\right)^2 \approx 0.3996 \end{aligned}$$

(b) Now we are asked for the probability that the combined lifetimes of both bulbs is 1000 hours or less. Thus we want to find $P(X + Y \le 1000)$, or equivalently $P((X,Y) \in D)$ where D is the triangular region shown in the figure. Then



$$\begin{aligned} P(X + Y \le 1000) &= \iint_D f(x,y)\;dA \\ &= \int_0^{1000} \int_0^{1000-x} 10^{-6} e^{-(x+y)/1000}\,dy\,dx \\ &= 10^{-6} \int_0^{1000} \left[-1000e^{-(x+y)/1000}\right]_{y=0}^{y=1000-x} dx = -10^{-3} \int_0^{1000} \left(e^{-1} - e^{-x/1000}\right) dx \\ &= -10^{-3} \left[e^{-1}x + 1000e^{-x/1000}\right]_0^{1000} = 1 - 2e^{-1} \approx 0.2642 \end{aligned}$$

31. (a) The random variables X and Y are normally distributed with $\mu_1 = 45$, $\mu_2 = 20$, $\sigma_1 = 0.5$, and $\sigma_2 = 0.1$. The individual density functions for X and Y, then, are $f_1(x) = \dfrac{1}{0.5\sqrt{2\pi}}\, e^{-(x-45)^2/0.5}$ and $f_2(y) = \dfrac{1}{0.1\sqrt{2\pi}}\, e^{-(y-20)^2/0.02}$. Since X and Y are independent, the joint density function is the product

$f(x,y) = f_1(x) f_2(y) = \dfrac{1}{0.5\sqrt{2\pi}}\, e^{-(x-45)^2/0.5} \dfrac{1}{0.1\sqrt{2\pi}}\, e^{-(y-20)^2/0.02} = \frac{10}{\pi} e^{-2(x-45)^2 - 50(y-20)^2}$.

Then $P(40 \le X \le 50, 20 \le Y \le 25) = \int_{40}^{50}\int_{20}^{25} f(x,y)\,dy\,dx = \frac{10}{\pi} \int_{40}^{50}\int_{20}^{25} e^{-2(x-45)^2 - 50(y-20)^2}\,dy\,dx$.

Using a CAS or calculator to evaluate the integral, we get $P(40 \le X \le 50, 20 \le Y \le 25) \approx 0.500$.

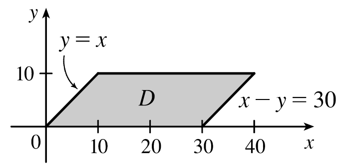
(b) $P(4(X-45)^2 + 100(Y-20)^2 \le 2) = \iint_D \frac{10}{\pi} e^{-2(x-45)^2 - 50(y-20)^2}\,dA$, where D is the region enclosed by the ellipse $4(x-45)^2 + 100(y-20)^2 = 2$. Solving for y gives $y = 20 \pm \frac{1}{10}\sqrt{2 - 4(x-45)^2}$, the upper and lower halves of the ellipse, and these two halves meet where $y = 20$ [since the ellipse is centered at $(45, 20)$] $\Rightarrow$ $4(x-45)^2 = 2$ $\Rightarrow$ $x = 45 \pm \frac{1}{\sqrt{2}}$. Thus

$$\iint_D \tfrac{10}{\pi} e^{-2(x-45)^2 - 50(y-20)^2}\,dA = \tfrac{10}{\pi} \int_{45-1/\sqrt{2}}^{45+1/\sqrt{2}} \int_{20-\frac{1}{10}\sqrt{2-4(x-45)^2}}^{20+\frac{1}{10}\sqrt{2-4(x-45)^2}} e^{-2(x-45)^2 - 50(y-20)^2}\,dy\,dx.$$

Using a CAS or calculator to evaluate the integral, we get $P(4(X-45)^2 + 100(Y-20)^2 \le 2) \approx 0.632$.

32. Because X and Y are independent, the joint density function for Xavier's and Yolanda's arrival times is the product of the individual density functions:

$$f(x,y) = f_1(x)f_2(y) = \begin{cases} \frac{1}{50}e^{-x}y & \text{if } x \geq 0, 0 \leq y \leq 10 \\ 0 & \text{otherwise} \end{cases}$$



Since Xavier won't wait for Yolanda, they won't meet unless $X \geq Y$. Additionally, Yolanda will wait up to half an hour but no longer, so they won't meet unless $X - Y \leq 30$. Thus the probability that they meet is $P((X,Y) \in D)$ where D is the parallelogram shown in the figure. The integral is simpler to evaluate if we consider D as a type II region, so

$$\begin{aligned} P((X,Y) \in D) &= \iint_D f(x,y)\,dx\,dy = \int_0^{10}\int_y^{y+30} \tfrac{1}{50}e^{-x}y\,dx\,dy \\ &= \tfrac{1}{50}\int_0^{10} y\left[-e^{-x}\right]_{x=y}^{x=y+30}\,dy = \tfrac{1}{50}\int_0^{10} y(-e^{-(y+30)} + e^{-y})\,dy \\ &= \tfrac{1}{50}(1 - e^{-30})\int_0^{10} ye^{-y}\,dy \end{aligned}$$

By integration by parts (or Formula 96 in the Table of Integrals), this is

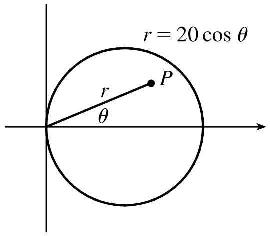
$\frac{1}{50}(1 - e^{-30})\left[-(y+1)e^{-y}\right]_0^{10} = \frac{1}{50}(1 - e^{-30})(1 - 11e^{-10}) \approx 0.020$. Thus there is only about a 2% chance they will meet. Such is student life!

33. (a) If $f(P, A)$ is the probability that an individual at A will be infected by an individual at P, and $k\,dA$ is the number of infected individuals in an element of area dA, then $f(P, A)k\,dA$ is the number of infections that should result from exposure of the individual at A to infected people in the element of area dA. Integration over D gives the number of infections of the person at A due to all the infected people in D. In rectangular coordinates (with the origin at the city's center), the exposure of a person at A is

$$E = \iint_D kf(P,A)\,dA = k\iint_D \tfrac{1}{20}\left[20 - d(P,A)\right]\,dA = k\iint_D \left[1 - \tfrac{1}{20}\sqrt{(x-x_0)^2 + (y-y_0)^2}\right]dA$$

(b) If $A = (0, 0)$, then

$$\begin{aligned} E &= k\iint_D \left[1 - \tfrac{1}{20}\sqrt{x^2+y^2}\right]dA \\ &= k\int_0^{2\pi}\int_0^{10} \left(1 - \tfrac{1}{20}r\right)r\,dr\,d\theta = 2\pi k\left[\tfrac{1}{2}r^2 - \tfrac{1}{60}r^3\right]_0^{10} \\ &= 2\pi k\left(50 - \tfrac{50}{3}\right) = \tfrac{200}{3}\pi k \approx 209k \end{aligned}$$



For A at the edge of the city, it is convenient to use a polar coordinate system centered at A. Then the polar equation for the circular boundary of the city becomes $r = 20\cos\theta$ instead of $r = 10$, and the distance from A to a point P in the city is again r (see the figure). So

$$E = k\int_{-\pi/2}^{\pi/2}\int_0^{20\cos\theta}\left(1-\tfrac{1}{20}r\right)r\,dr\,d\theta = k\int_{-\pi/2}^{\pi/2}\left[\tfrac{1}{2}r^2-\tfrac{1}{60}r^3\right]_{r=0}^{r=20\cos\theta}d\theta$$
$$= k\int_{-\pi/2}^{\pi/2}\left(200\cos^2\theta-\tfrac{400}{3}\cos^3\theta\right)d\theta = 200k\int_{-\pi/2}^{\pi/2}\left[\tfrac{1}{2}+\tfrac{1}{2}\cos 2\theta-\tfrac{2}{3}\left(1-\sin^2\theta\right)\cos\theta\right]d\theta$$
$$= 200k\left[\tfrac{1}{2}\theta+\tfrac{1}{4}\sin 2\theta-\tfrac{2}{3}\sin\theta+\tfrac{2}{3}\cdot\tfrac{1}{3}\sin^3\theta\right]_{-\pi/2}^{\pi/2} = 200k\left[\tfrac{\pi}{4}+0-\tfrac{2}{3}+\tfrac{2}{9}+\tfrac{\pi}{4}+0-\tfrac{2}{3}+\tfrac{2}{9}\right]$$
$$= 200k\left(\tfrac{\pi}{2}-\tfrac{8}{9}\right)\approx 136k$$

Therefore the risk of infection is much lower at the edge of the city than in the middle, so it is better to live at the edge.

15.5 Surface Area

1. Here $z = f(x,y) = 5x + 3y + 6$ and D is the rectangle $[1,4]\times[2,6]$, so by Formula 2 the area of the surface is

$$A(S) = \iint_D \sqrt{[f_x(x,y)]^2+[f_y(x,y)]^2+1}\,dA = \iint_D \sqrt{5^2+3^2+1}\,dA = \sqrt{35}\iint_D dA$$
$$= \sqrt{35}\,A(D) = \sqrt{35}\,(3)(4) = 12\sqrt{35}$$

2. $z = f(x,y) = \frac{1}{2} - 3x - 2y$ and D is the disk $x^2+y^2\le 25$, so by Formula 2

$$A(S) = \iint_D \sqrt{(-3)^2+(-2)^2+1}\,dA = \sqrt{14}\iint_D dA = \sqrt{14}\,A(D) = \sqrt{14}\,(\pi\cdot 5^2) = 25\sqrt{14}\,\pi$$

3. The surface S is given by $z = f(x,y) = 6-3x-2y$ which intersects the xy-plane in the line $3x+2y=6$, so D is the triangular region given by $\left\{(x,y)\;\middle|\;0\le x\le 2,\,0\le y\le 3-\frac{3}{2}x\right\}$. By Formula 2, the surface area of S is

$$A(S) = \iint_D \sqrt{(-3)^2+(-2)^2+1}\,dA = \sqrt{14}\iint_D dA = \sqrt{14}\,A(D) = \sqrt{14}\left(\tfrac{1}{2}\cdot 2\cdot 3\right) = 3\sqrt{14}$$

4. $z = f(x,y) = \frac{1}{4}x^2 - \frac{1}{2}y + \frac{5}{4}$, and D is the triangular region given by $\{(x,y)\mid 0\le x\le 2,\ 0\le y\le 2x\}$. By Formula 2,

$$A(S) = \iint_D \sqrt{\left(\tfrac{1}{2}x\right)^2+\left(-\tfrac{1}{2}\right)^2+1}\,dA = \int_0^2\int_0^{2x}\sqrt{\tfrac{1}{4}x^2+\tfrac{5}{4}}\,dy\,dx = \int_0^2 \tfrac{1}{2}\sqrt{x^2+5}\,\left[\,y\,\right]_{y=0}^{y=2x}dx$$
$$= \tfrac{1}{2}\int_0^2 2x\sqrt{x^2+5}\,dx = \tfrac{1}{2}\cdot\tfrac{2}{3}(x^2+5)^{3/2}\Big]_0^2 = \tfrac{1}{3}(9^{3/2}-5^{3/2}) = 9-\tfrac{5}{3}\sqrt{5}$$

5. The paraboloid intersects the plane $z=-2$ when $1-x^2-y^2=-2 \quad\Leftrightarrow\quad x^2+y^2=3$, so $D = \left\{(x,y)\mid x^2+y^2\le 3\right\}$. Here $z = f(x,y) = 1-x^2-y^2 \quad\Rightarrow\quad f_x=-2x,\ f_y=-2y$ and

$$A(S) = \iint_D \sqrt{(-2x)^2+(-2y)^2+1}\,dA = \iint_D \sqrt{4(x^2+y^2)+1}\,dA = \int_0^{2\pi}\int_0^{\sqrt{3}}\sqrt{4r^2+1}\,r\,dr\,d\theta$$
$$= \int_0^{2\pi}d\theta\int_0^{\sqrt{3}} r\sqrt{4r^2+1}\,dr = \left[\,\theta\,\right]_0^{2\pi}\left[\tfrac{1}{12}(4r^2+1)^{3/2}\right]_0^{\sqrt{3}} = 2\pi\cdot\tfrac{1}{12}\left(13^{3/2}-1\right) = \tfrac{\pi}{6}\left(13\sqrt{13}-1\right)$$

6. $x^2+z^2=4 \quad\Rightarrow\quad z=\sqrt{4-x^2}$ (since $z\ge 0$), so $f_x = -x(4-x^2)^{-1/2}$, $f_y=0$ and

$$A(S) = \int_0^1\int_0^1\sqrt{[-x(4-x^2)^{-1/2}]^2+0^2+1}\;dy\,dx = \int_0^1\int_0^1\sqrt{\frac{x^2}{4-x^2}+1}\;dy\,dx$$
$$= \int_0^1\frac{2}{\sqrt{4-x^2}}\,dx\int_0^1 dy = \left[2\sin^{-1}\frac{x}{2}\right]_0^1\left[\,y\,\right]_0^1 = \left(2\cdot\tfrac{\pi}{6}-0\right)(1) = \tfrac{\pi}{3}$$

7. $z = f(x,y) = y^2 - x^2$ with $1 \le x^2 + y^2 \le 4$. Then

$$A(S) = \iint_D \sqrt{4x^2 + 4y^2 + 1}\, dA = \int_0^{2\pi} \int_1^2 \sqrt{4r^2+1}\, r\, dr\, d\theta = \int_0^{2\pi} d\theta \int_1^2 r\sqrt{4r^2+1}\, dr$$

$$= \big[\,\theta\,\big]_0^{2\pi} \left[\tfrac{1}{12}(4r^2+1)^{3/2}\right]_1^2 = \tfrac{\pi}{6}\big(17\sqrt{17} - 5\sqrt{5}\big)$$

8. $z = f(x,y) = \frac{2}{3}(x^{3/2} + y^{3/2})$ and $D = \{(x,y) \mid 0 \le x \le 1, 0 \le y \le 1\}$. Then $f_x = x^{1/2}$, $f_y = y^{1/2}$ and

$$A(S) = \iint_D \sqrt{\left(\sqrt{x}\right)^2 + \left(\sqrt{y}\right)^2 + 1}\, dA = \int_0^1 \int_0^1 \sqrt{x+y+1}\, dy\, dx = \int_0^1 \left[\tfrac{2}{3}(x+y+1)^{3/2}\right]_{y=0}^{y=1} dx$$

$$= \tfrac{2}{3}\int_0^1 \left[(x+2)^{3/2} - (x+1)^{3/2}\right] dx = \tfrac{2}{3}\left[\tfrac{2}{5}(x+2)^{5/2} - \tfrac{2}{5}(x+1)^{5/2}\right]_0^1$$

$$= \tfrac{4}{15}(3^{5/2} - 2^{5/2} - 2^{5/2} + 1) = \tfrac{4}{15}(3^{5/2} - 2^{7/2} + 1)$$

9. $z = f(x,y) = xy$ with $x^2 + y^2 \le 1$, so $f_x = y$, $f_y = x \quad \Rightarrow$

$$A(S) = \iint_D \sqrt{y^2 + x^2 + 1}\, dA = \int_0^{2\pi}\int_0^1 \sqrt{r^2+1}\, r\, dr\, d\theta = \int_0^{2\pi} \left[\tfrac{1}{3}(r^2+1)^{3/2}\right]_{r=0}^{r=1} d\theta$$

$$= \int_0^{2\pi} \tfrac{1}{3}\big(2\sqrt{2} - 1\big)\, d\theta = \tfrac{2\pi}{3}\big(2\sqrt{2} - 1\big)$$

10. Given the sphere $x^2 + y^2 + z^2 = 4$, when $z = 1$, we get $x^2 + y^2 = 3$ so $D = \left\{(x,y) \mid x^2 + y^2 \le 3\right\}$ and $z = f(x,y) = \sqrt{4 - x^2 - y^2}$. Thus

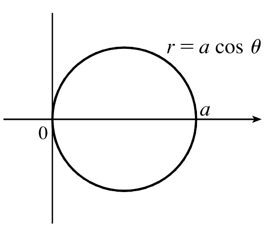
$$A(S) = \iint_D \sqrt{[(-x)(4-x^2-y^2)^{-1/2}]^2 + [(-y)(4-x^2-y^2)^{-1/2}]^2 + 1}\, dA$$

$$= \int_0^{2\pi}\int_0^{\sqrt{3}} \sqrt{\frac{r^2}{4-r^2} + 1}\, r\, dr\, d\theta = \int_0^{2\pi}\int_0^{\sqrt{3}} \sqrt{\frac{r^2 + 4 - r^2}{4-r^2}}\, r\, dr\, d\theta$$

$$= \int_0^{2\pi}\int_0^{\sqrt{3}} \frac{2r}{\sqrt{4-r^2}}\, dr\, d\theta$$

$$= \int_0^{2\pi} \left[-2(4-r^2)^{1/2}\right]_{r=0}^{r=\sqrt{3}} d\theta = \int_0^{2\pi} (-2+4)\, d\theta = 2\theta\big]_0^{2\pi} = 4\pi$$

11. $z = \sqrt{a^2 - x^2 - y^2}$, $z_x = -x(a^2 - x^2 - y^2)^{-1/2}$, $z_y = -y(a^2 - x^2 - y^2)^{-1/2}$,



$$A(S) = \iint_D \sqrt{\frac{x^2 + y^2}{a^2 - x^2 - y^2} + 1}\, dA$$

$$= \int_{-\pi/2}^{\pi/2}\int_0^{a\cos\theta} \sqrt{\frac{r^2}{a^2 - r^2} + 1}\, r\, dr\, d\theta$$

$$= \int_{-\pi/2}^{\pi/2}\int_0^{a\cos\theta} \frac{ar}{\sqrt{a^2 - r^2}}\, dr\, d\theta$$

$$= \int_{-\pi/2}^{\pi/2} \left[-a\sqrt{a^2 - r^2}\right]_{r=0}^{r=a\cos\theta} d\theta$$

$$= \int_{-\pi/2}^{\pi/2} -a\left(\sqrt{a^2 - a^2\cos^2\theta} - a\right) d\theta = 2a^2 \int_0^{\pi/2} \left(1 - \sqrt{1 - \cos^2\theta}\right) d\theta$$

$$= 2a^2 \int_0^{\pi/2} d\theta - 2a^2 \int_0^{\pi/2} \sqrt{\sin^2\theta}\, d\theta = a^2\pi - 2a^2 \int_0^{\pi/2} \sin\theta\, d\theta = a^2(\pi - 2)$$

12. To find the region D: $z = x^2 + y^2$ implies $z + z^2 = 4z$ or $z^2 - 3z = 0$. Thus $z = 0$ or $z = 3$ are the planes where the surfaces intersect. But $x^2 + y^2 + z^2 = 4z$ implies $x^2 + y^2 + (z-2)^2 = 4$, so $z = 3$ intersects the upper hemisphere. Thus $(z-2)^2 = 4 - x^2 - y^2$ or $z = 2 + \sqrt{4 - x^2 - y^2}$. Therefore D is the region inside the circle $x^2 + y^2 + (3-2)^2 = 4$, that is, $D = \{(x, y) \mid x^2 + y^2 \le 3\}$.

$$\begin{aligned} A(S) &= \iint_D \sqrt{[(-x)(4 - x^2 - y^2)^{-1/2}]^2 + [(-y)(4 - x^2 - y^2)^{-1/2}]^2 + 1}\, dA \\ &= \int_0^{2\pi} \int_0^{\sqrt{3}} \sqrt{\frac{r^2}{4 - r^2} + 1}\, r\, dr\, d\theta = \int_0^{2\pi} \int_0^{\sqrt{3}} \frac{2r\, dr}{\sqrt{4 - r^2}}\, d\theta = \int_0^{2\pi} \Big[-2(4 - r^2)^{1/2}\Big]_{r=0}^{r=\sqrt{3}} d\theta \\ &= \textstyle\int_0^{2\pi} (-2 + 4)\, d\theta = 2\theta\Big]_0^{2\pi} = 4\pi \end{aligned}$$

13. $z = f(x, y) = (1 + x^2 + y^2)^{-1}$, $f_x = -2x(1 + x^2 + y^2)^{-2}$, $f_y = -2y(1 + x^2 + y^2)^{-2}$. Then

$$\begin{aligned} A(S) &= \iint\limits_{x^2+y^2 \le 1} \sqrt{\left[-2x(1 + x^2 + y^2)^{-2}\right]^2 + \left[-2y(1 + x^2 + y^2)^{-2}\right]^2 + 1}\; dA \\ &= \iint\limits_{x^2+y^2 \le 1} \sqrt{4(x^2 + y^2)(1 + x^2 + y^2)^{-4} + 1}\; dA \end{aligned}$$

Converting to polar coordinates we have

$$\begin{aligned} A(S) &= \textstyle\int_0^{2\pi} \int_0^1 \sqrt{4r^2(1 + r^2)^{-4} + 1}\; r\, dr\, d\theta = \int_0^{2\pi} d\theta \int_0^1 r \sqrt{4r^2(1 + r^2)^{-4} + 1}\, dr \\ &= 2\pi \textstyle\int_0^1 r \sqrt{4r^2(1 + r^2)^{-4} + 1}\, dr \approx 3.6258 \text{ using a calculator.} \end{aligned}$$

14. $z = f(x, y) = \cos(x^2 + y^2)$, $f_x = -2x \sin(x^2 + y^2)$, $f_y = -2y \sin(x^2 + y^2)$.

$$A(S) = \iint\limits_{x^2+y^2 \le 1} \sqrt{4x^2 \sin^2(x^2 + y^2) + 4y^2 \sin^2(x^2 + y^2) + 1}\, dA = \iint\limits_{x^2+y^2 \le 1} \sqrt{4(x^2 + y^2) \sin^2(x^2 + y^2) + 1}\, dA.$$

Converting to polar coordinates gives

$$\begin{aligned} A(S) &= \textstyle\int_0^{2\pi} \int_0^1 \sqrt{4r^2 \sin^2(r^2) + 1}\, r\, dr\, d\theta = \int_0^{2\pi} d\theta \int_0^1 r \sqrt{4r^2 \sin^2(r^2) + 1}\, dr \\ &= 2\pi \textstyle\int_0^1 r \sqrt{4r^2 \sin^2(r^2) + 1}\, dr \approx 4.1073 \quad \text{using a calculator.} \end{aligned}$$

15. (a) The midpoints of the four squares are $\left(\frac{1}{4}, \frac{1}{4}\right)$, $\left(\frac{1}{4}, \frac{3}{4}\right)$, $\left(\frac{3}{4}, \frac{1}{4}\right)$, and $\left(\frac{3}{4}, \frac{3}{4}\right)$. Here $f(x, y) = x^2 + y^2$, so the Midpoint Rule gives

$$\begin{aligned} A(S) &= \textstyle\iint_D \sqrt{[f_x(x, y)]^2 + [f_y(x, y)]^2 + 1}\, dA = \iint_D \sqrt{(2x)^2 + (2y)^2 + 1}\, dA \\ &\approx \tfrac{1}{4}\Bigg(\sqrt{\left[2\left(\tfrac{1}{4}\right)\right]^2 + \left[2\left(\tfrac{1}{4}\right)\right]^2 + 1} + \sqrt{\left[2\left(\tfrac{1}{4}\right)\right]^2 + \left[2\left(\tfrac{3}{4}\right)\right]^2 + 1} \\ &\qquad + \sqrt{\left[2\left(\tfrac{3}{4}\right)\right]^2 + \left[2\left(\tfrac{1}{4}\right)\right]^2 + 1} + \sqrt{\left[2\left(\tfrac{3}{4}\right)\right]^2 + \left[2\left(\tfrac{3}{4}\right)\right]^2 + 1}\Bigg) \\ &= \tfrac{1}{4}\left(\sqrt{\tfrac{3}{2}} + 2\sqrt{\tfrac{7}{2}} + \sqrt{\tfrac{11}{2}}\right) \approx 1.8279 \end{aligned}$$

(b) A CAS estimates the integral to be $A(S) = \iint_D \sqrt{1 + (2x)^2 + (2y)^2}\, dA = \int_0^1 \int_0^1 \sqrt{1 + 4x^2 + 4y^2}\, dy\, dx \approx 1.8616$.

This agrees with the Midpoint estimate only in the first decimal place.

16. (a) With $m = n = 2$ we have four squares with midpoints $\left(\frac{1}{2}, \frac{1}{2}\right)$, $\left(\frac{1}{2}, \frac{3}{2}\right)$, $\left(\frac{3}{2}, \frac{1}{2}\right)$, and $\left(\frac{3}{2}, \frac{3}{2}\right)$. Since $z = xy + x^2 + y^2$, the Midpoint Rule gives

$$\begin{aligned} A(S) &= \iint_D \sqrt{1 + \left(\frac{\partial z}{\partial x}\right)^2 + \left(\frac{\partial z}{\partial y}\right)^2}\, dA = \iint_D \sqrt{1 + (y + 2x)^2 + (x + 2y)^2}\, dA \\ &\approx 1\left(\sqrt{1 + \left(\tfrac{3}{2}\right)^2 + \left(\tfrac{3}{2}\right)^2} + \sqrt{1 + \left(\tfrac{5}{2}\right)^2 + \left(\tfrac{7}{2}\right)^2} + \sqrt{1 + \left(\tfrac{7}{2}\right)^2 + \left(\tfrac{5}{2}\right)^2} + \sqrt{1 + \left(\tfrac{9}{2}\right)^2 + \left(\tfrac{9}{2}\right)^2}\right) \\ &= \tfrac{\sqrt{22}}{2} + \tfrac{\sqrt{78}}{2} + \tfrac{\sqrt{78}}{2} + \tfrac{\sqrt{166}}{2} \approx 17.619 \end{aligned}$$

(b) Using a CAS, we have

$A(S) = \iint_D \sqrt{1 + (y + 2x)^2 + (x + 2y)^2}\, dA = \int_0^2 \int_0^2 \sqrt{1 + (y + 2x)^2 + (x + 2y)^2}\, dy\, dx \approx 17.7165$. This is within about 0.1 of the Midpoint Rule estimate.

17. $z = 1 + 2x + 3y + 4y^2$, so

$$A(S) = \iint_D \sqrt{1 + \left(\frac{\partial z}{\partial x}\right)^2 + \left(\frac{\partial z}{\partial y}\right)^2}\, dA = \int_1^4 \int_0^1 \sqrt{1 + 4 + (3 + 8y)^2}\, dy\, dx = \int_1^4 \int_0^1 \sqrt{14 + 48y + 64y^2}\, dy\, dx.$$

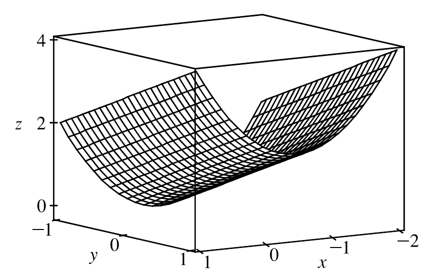
Using a CAS, we have $\int_1^4 \int_0^1 \sqrt{14 + 48y + 64y^2}\, dy\, dx = \frac{45}{8}\sqrt{14} + \frac{15}{16}\ln\left(11\sqrt{5} + 3\sqrt{14}\sqrt{5}\right) - \frac{15}{16}\ln\left(3\sqrt{5} + \sqrt{14}\sqrt{5}\right)$ or $\frac{45}{8}\sqrt{14} + \frac{15}{16}\ln\dfrac{11\sqrt{5} + 3\sqrt{70}}{3\sqrt{5} + \sqrt{70}}$.

18. $f(x, y) = 1 + x + y + x^2 \quad\Rightarrow\quad f_x = 1 + 2x$, $f_y = 1$. We use a CAS to calculate the integral

$$\begin{aligned} A(S) &= \int_{-2}^1 \int_{-1}^1 \sqrt{f_x^2 + f_y^2 + 1}\, dy\, dx \\ &= \int_{-2}^1 \int_{-1}^1 \sqrt{(1 + 2x)^2 + 2}\, dy\, dx = 2\int_{-2}^1 \sqrt{4x^2 + 4x + 3}\, dx \end{aligned}$$

and find that $A(S) = 3\sqrt{11} + 2\sinh^{-1}\left(\frac{3\sqrt{2}}{2}\right)$ or

$A(S) = 3\sqrt{11} + \ln\left(10 + 3\sqrt{11}\right)$.

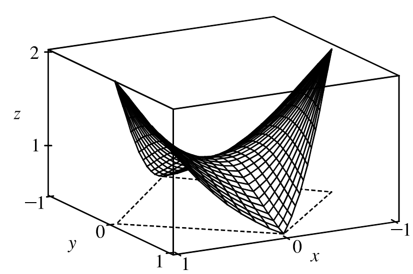


19. $f(x, y) = 1 + x^2y^2 \quad\Rightarrow\quad f_x = 2xy^2$, $f_y = 2x^2y$. We use a CAS (with precision reduced to five significant digits, to speed up the calculation) to estimate the integral

$$A(S) = \int_{-1}^1 \int_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}} \sqrt{f_x^2 + f_y^2 + 1}\, dy\, dx = \int_{-1}^1 \int_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}} \sqrt{4x^2y^4 + 4x^4y^2 + 1}\, dy\, dx,$$ and find that $A(S) \approx 3.3213$.

20. Let $f(x, y) = \dfrac{1 + x^2}{1 + y^2}$. Then $f_x = \dfrac{2x}{1 + y^2}$,

$f_y = \left(1 + x^2\right)\left[-\dfrac{2y}{\left(1 + y^2\right)^2}\right] = -\dfrac{2y\left(1 + x^2\right)}{\left(1 + y^2\right)^2}$. We use a CAS to estimate $\int_{-1}^1 \int_{-(1-|x|)}^{1-|x|} \sqrt{f_x^2 + f_y^2 + 1}\, dy\, dx \approx 2.6959$. In order to graph only the part of the surface above the square, we use $-\left(1 - |x|\right) \le y \le 1 - |x|$ as the y-range in our plot command.



21. Here $z = f(x,y) = ax + by + c$, $f_x(x,y) = a$, $f_y(x,y) = b$, so

$A(S) = \iint_D \sqrt{a^2 + b^2 + 1}\, dA = \sqrt{a^2 + b^2 + 1} \iint_D dA = \sqrt{a^2 + b^2 + 1}\, A(D)$.

22. Let S be the upper hemisphere. Then $z = f(x,y) = \sqrt{a^2 - x^2 - y^2}$, so

$$\begin{aligned} A(S) &= \iint_D \sqrt{[-x(a^2 - x^2 - y^2)^{-1/2}]^2 + [-y(a^2 - x^2 - y^2)^{-1/2}]^2 + 1}\, dA \\ &= \iint_D \sqrt{\frac{x^2 + y^2}{a^2 - x^2 - y^2} + 1}\, dA = \lim_{t \to a^-} \int_0^{2\pi} \int_0^t \sqrt{\frac{r^2}{a^2 - r^2} + 1}\, r\, dr\, d\theta \\ &= \lim_{t \to a^-} \int_0^{2\pi} \int_0^t \frac{ar}{\sqrt{a^2 - r^2}}\, dr\, d\theta = 2\pi \lim_{t \to a^-} \Big[-a\sqrt{a^2 - r^2}\,\Big]_0^t = 2\pi \lim_{t \to a^-} -a\Big[\sqrt{a^2 - t^2} - a\Big] \\ &= 2\pi(-a)(-a) = 2\pi a^2. \text{ Thus the surface area of the entire sphere is } 4\pi a^2. \end{aligned}$$

23. If we project the surface onto the xz-plane, then the surface lies "above" the disk $x^2 + z^2 \leq 25$ in the xz-plane.

We have $y = f(x,z) = x^2 + z^2$ and, adapting Formula 2, the area of the surface is

$$A(S) = \iint_{x^2 + z^2 \leq 25} \sqrt{[f_x(x,z)]^2 + [f_z(x,z)]^2 + 1}\, dA = \iint_{x^2 + z^2 \leq 25} \sqrt{4x^2 + 4z^2 + 1}\, dA$$

Converting to polar coordinates $x = r\cos\theta$, $z = r\sin\theta$ we have

$$A(S) = \int_0^{2\pi} \int_0^5 \sqrt{4r^2 + 1}\, r\, dr\, d\theta = \int_0^{2\pi} d\theta \int_0^5 r(4r^2 + 1)^{1/2}\, dr = \big[\,\theta\,\big]_0^{2\pi} \left[\tfrac{1}{12}(4r^2 + 1)^{3/2}\right]_0^5 = \tfrac{\pi}{6}\big(101\sqrt{101} - 1\big)$$

24. First we find the area of the face of the surface that intersects the positive y-axis. As in Exercise 23, we can project the face onto the xz-plane, so the surface lies "above" the disk $x^2 + z^2 \leq 1$. Then $y = f(x,z) = \sqrt{1 - z^2}$ and the area is

$$\begin{aligned} A\,(S) &= \iint_{x^2 + z^2 \leq 1} \sqrt{[f_x(x,z)]^2 + [f_z(x,z)]^2 + 1}\, dA = \iint_{x^2 + z^2 \leq 1} \sqrt{0 + \left(\frac{-z}{\sqrt{1 - z^2}}\right)^2 + 1}\, dA \\ &= \iint_{x^2 + z^2 \leq 1} \sqrt{\frac{z^2}{1 - z^2} + 1}\, dA = \int_{-1}^1 \int_{-\sqrt{1-z^2}}^{\sqrt{1-z^2}} \frac{1}{\sqrt{1 - z^2}}\, dx\, dz \\ &= 4\int_0^1 \int_0^{\sqrt{1-z^2}} \frac{1}{\sqrt{1 - z^2}}\, dx\, dz \qquad \text{[by the symmetry of the surface]} \end{aligned}$$

This integral is improper (when $z = 1$), so

$$A\,(S) = \lim_{t \to 1^-} 4\int_0^t \int_0^{\sqrt{1-z^2}} \frac{1}{\sqrt{1 - z^2}}\, dx\, dz = \lim_{t \to 1^-} 4\int_0^t \frac{\sqrt{1 - z^2}}{\sqrt{1 - z^2}}\, dz = \lim_{t \to 1^-} 4\int_0^t dz = \lim_{t \to 1^-} 4t = 4.$$

Since the complete surface consists of four congruent faces, the total surface area is $4(4) = 16$.

15.6 Triple Integrals

1. $$\begin{aligned} \iiint_B xyz^2\, dV &= \int_0^1 \int_0^3 \int_{-1}^2 xyz^2\, dy\, dz\, dx = \int_0^1 \int_0^3 \left[\tfrac{1}{2}xy^2z^2\right]_{y=-1}^{y=2} dz\, dx = \int_0^1 \int_0^3 \tfrac{3}{2}xz^2\, dz\, dx \\ &= \int_0^1 \left[\tfrac{1}{2}xz^3\right]_{z=0}^{z=3} dx = \int_0^1 \tfrac{27}{2}\, x\, dx = \tfrac{27}{4}x^2\Big]_0^1 = \tfrac{27}{4} \end{aligned}$$

2. There are six different possible orders of integration.

$$\iiint_E (xy+z^2)\,dV = \int_0^2\int_0^1\int_0^3 (xy+z^2)\,dz\,dy\,dx = \int_0^2\int_0^1 \left[xyz+\tfrac{1}{3}z^3\right]_{z=0}^{z=3} dy\,dx = \int_0^2\int_0^1 (3xy+9)\,dy\,dx$$
$$= \int_0^2 \left[\tfrac{3}{2}xy^2+9y\right]_{y=0}^{y=1} dx = \int_0^2 \left(\tfrac{3}{2}x+9\right) dx = \left[\tfrac{3}{4}x^2+9x\right]_0^2 = 21$$

$$\iiint_E (xy+z^2)\,dV = \int_0^1\int_0^2\int_0^3 (xy+z^2)\,dz\,dx\,dy = \int_0^1\int_0^2 \left[xyz+\tfrac{1}{3}z^3\right]_{z=0}^{z=3} dx\,dy = \int_0^1\int_0^2 (3xy+9)\,dx\,dy$$
$$= \int_0^1 \left[\tfrac{3}{2}x^2y+9x\right]_{x=0}^{x=2} dy = \int_0^1 (6y+18)\,dy = \left[3y^2+18y\right]_0^1 = 21$$

$$\iiint_E (xy+z^2)\,dV = \int_0^2\int_0^3\int_0^1 (xy+z^2)\,dy\,dz\,dx = \int_0^2\int_0^3 \left[\tfrac{1}{2}xy^2+yz^2\right]_{y=0}^{y=1} dz\,dx = \int_0^2\int_0^3 \left(\tfrac{1}{2}x+z^2\right) dz\,dx$$
$$= \int_0^2 \left[\tfrac{1}{2}xz+\tfrac{1}{3}z^3\right]_{z=0}^{z=3} dx = \int_0^2 \left(\tfrac{3}{2}x+9\right) dx = \left[\tfrac{3}{4}x^2+9x\right]_0^2 = 21$$

$$\iiint_E (xy+z^2)\,dV = \int_0^3\int_0^2\int_0^1 (xy+z^2)\,dy\,dx\,dz = \int_0^3\int_0^2 \left[\tfrac{1}{2}xy^2+yz^2\right]_{y=0}^{y=1} dx\,dz = \int_0^3\int_0^2 \left(\tfrac{1}{2}x+z^2\right) dx\,dz$$
$$= \int_0^3 \left[\tfrac{1}{4}x^2+xz^2\right]_{x=0}^{x=2} dz = \int_0^3 \left(1+2z^2\right) dz = \left[z+\tfrac{2}{3}z^3\right]_0^3 = 21$$

$$\iiint_E (xy+z^2)\,dV = \int_0^1\int_0^3\int_0^2 (xy+z^2)\,dx\,dz\,dy = \int_0^1\int_0^3 \left[\tfrac{1}{2}x^2y+xz^2\right]_{x=0}^{x=2} dz\,dy = \int_0^1\int_0^3 \left(2y+2z^2\right) dz\,dy$$
$$= \int_0^1 \left[2yz+\tfrac{2}{3}z^3\right]_{z=0}^{z=3} dy = \int_0^1 (6y+18)\,dy = \left[3y^2+18y\right]_0^1 = 21$$

$$\iiint_E (xy+z^2)\,dV = \int_0^3\int_0^1\int_0^2 (xy+z^2)\,dx\,dy\,dz = \int_0^3\int_0^1 \left[\tfrac{1}{2}x^2y+xz^2\right]_{x=0}^{x=2} dy\,dz = \int_0^3\int_0^1 \left(2y+2z^2\right) dy\,dz$$
$$= \int_0^3 \left[y^2+2yz^2\right]_{y=0}^{y=1} dz = \int_0^3 \left(1+2z^2\right) dz = \left[z+\tfrac{2}{3}z^3\right]_0^3 = 21$$

3. $$\int_0^2\int_0^{z^2}\int_0^{y-z}(2x-y)\,dx\,dy\,dz = \int_0^2\int_0^{z^2} \left[x^2-xy\right]_{x=0}^{x=y-z} dy\,dz = \int_0^2\int_0^{z^2} \left[(y-z)^2-(y-z)y\right] dy\,dz$$
$$= \int_0^2\int_0^{z^2} \left(z^2-yz\right) dy\,dz = \int_0^2 \left[yz^2-\tfrac{1}{2}y^2z\right]_{y=0}^{y=z^2} dz = \int_0^2 \left(z^4-\tfrac{1}{2}z^5\right) dz$$
$$= \left[\tfrac{1}{5}z^5-\tfrac{1}{12}z^6\right]_0^2 = \tfrac{32}{5}-\tfrac{64}{12} = \tfrac{16}{15}$$

4. $$\int_0^1\int_y^{2y}\int_0^{x+y} 6xy\,dz\,dx\,dy = \int_0^1\int_y^{2y} \left[6xyz\right]_{z=0}^{z=x+y} dx\,dy = \int_0^1\int_y^{2y} 6xy(x+y)\,dx\,dy = \int_0^1\int_y^{2y} (6x^2y+6xy^2)\,dx\,dy$$
$$= \int_0^1 \left[2x^3y+3x^2y^2\right]_{x=y}^{x=2y} dy = \int_0^1 23y^4\,dy = \left.\tfrac{23}{5}y^5\right]_0^1 = \tfrac{23}{5}$$

5. $$\int_1^2\int_0^{2z}\int_0^{\ln x} xe^{-y}\,dy\,dx\,dz = \int_1^2\int_0^{2z} \left[-xe^{-y}\right]_{y=0}^{y=\ln x} dx\,dz = \int_1^2\int_0^{2z} \left(-xe^{-\ln x}+xe^0\right) dx\,dz$$
$$= \int_1^2\int_0^{2z} (-1+x)\,dx\,dz = \int_1^2 \left[-x+\tfrac{1}{2}x^2\right]_{x=0}^{x=2z} dz$$
$$= \int_1^2 \left(-2z+2z^2\right) dz = \left[-z^2+\tfrac{2}{3}z^3\right]_1^2 = -4+\tfrac{16}{3}+1-\tfrac{2}{3} = \tfrac{5}{3}$$

6. $$\int_0^1\int_0^1\int_0^{\sqrt{1-z^2}} \frac{z}{y+1}\,dx\,dz\,dy = \int_0^1\int_0^1 \left[\frac{z}{y+1}\cdot x\right]_{x=0}^{x=\sqrt{1-z^2}} dz\,dy = \int_0^1\int_0^1 \frac{z\sqrt{1-z^2}}{y+1}\,dz\,dy$$
$$= \int_0^1 \left[\frac{-\frac{1}{3}(1-z^2)^{3/2}}{y+1}\right]_{z=0}^{z=1} dy = \frac{1}{3}\int_0^1 \frac{1}{y+1}\,dy = \left.\frac{1}{3}\ln(y+1)\right]_0^1$$
$$= \tfrac{1}{3}(\ln 2-\ln 1) = \tfrac{1}{3}\ln 2$$

7. $\int_0^\pi \int_0^1 \int_0^{\sqrt{1-z^2}} z\sin x\,dy\,dz\,dx = \int_0^\pi \int_0^1 \left[yz\sin x\right]_{y=0}^{y=\sqrt{1-z^2}} dz\,dx = \int_0^\pi \int_0^1 z\sqrt{1-z^2}\,\sin x\,dz\,dx$

$= \int_0^\pi \sin x\left[-\frac{1}{3}(1-z^2)^{3/2}\right]_{z=0}^{z=1} dx = \int_0^\pi \frac{1}{3}\sin x\,dx = -\frac{1}{3}\cos x\Big]_0^\pi = -\frac{1}{3}(-1-1) = \frac{2}{3}$

8. $\int_0^1 \int_0^1 \int_0^{2-x^2-y^2} xye^z\,dz\,dy\,dx = \int_0^1 \int_0^1 \left[xye^z\right]_{z=0}^{z=2-x^2-y^2} dy\,dx = \int_0^1 \int_0^1 (xye^{2-x^2-y^2} - xy)\,dy\,dx$

$= \int_0^1 \left[-\frac{1}{2}xe^{2-x^2-y^2} - \frac{1}{2}xy^2\right]_{y=0}^{y=1} dx = \int_0^1 \left(-\frac{1}{2}xe^{1-x^2} - \frac{1}{2}x + \frac{1}{2}xe^{2-x^2}\right) dx$

$= \left[\frac{1}{4}e^{1-x^2} - \frac{1}{4}x^2 - \frac{1}{4}e^{2-x^2}\right]_0^1 = \frac{1}{4} - \frac{1}{4} - \frac{1}{4}e - \frac{1}{4}e + 0 + \frac{1}{4}e^2 = \frac{1}{4}e^2 - \frac{1}{2}e$

9. $\iiint_E y\,dV = \int_0^3 \int_0^x \int_{x-y}^{x+y} y\,dz\,dy\,dx = \int_0^3 \int_0^x \left[yz\right]_{z=x-y}^{z=x+y} dy\,dx = \int_0^3 \int_0^x 2y^2\,dy\,dx$

$= \int_0^3 \left[\frac{2}{3}y^3\right]_{y=0}^{y=x} dx = \int_0^3 \frac{2}{3}x^3\,dx = \frac{1}{6}x^4\Big]_0^3 = \frac{81}{6} = \frac{27}{2}$

10. $\iiint_E e^{z/y}\,dV = \int_0^1 \int_y^1 \int_0^{xy} e^{z/y}\,dz\,dx\,dy = \int_0^1 \int_y^1 \left[ye^{z/y}\right]_{z=0}^{z=xy} dx\,dy$

$= \int_0^1 \int_y^1 (ye^x - y)\,dx\,dy = \int_0^1 \left[ye^x - xy\right]_{x=y}^{x=1} dy = \int_0^1 \left(ey - y - ye^y + y^2\right) dy$

$= \left[\frac{1}{2}ey^2 - \frac{1}{2}y^2 - (y-1)e^y + \frac{1}{3}y^3\right]_0^1$ [integrate by parts]

$= \frac{1}{2}e - \frac{1}{2} + \frac{1}{3} - 1 = \frac{1}{2}e - \frac{7}{6}$

11. $\displaystyle\iiint_E \frac{z}{x^2+z^2}\,dV = \int_1^4 \int_y^4 \int_0^z \frac{z}{x^2+z^2}\,dx\,dz\,dy = \int_1^4 \int_y^4 \left[z \cdot \frac{1}{z}\tan^{-1}\frac{x}{z}\right]_{x=0}^{x=z} dz\,dy$

$= \int_1^4 \int_y^4 \left[\tan^{-1}(1) - \tan^{-1}(0)\right] dz\,dy = \int_1^4 \int_y^4 \left(\frac{\pi}{4} - 0\right) dz\,dy = \frac{\pi}{4}\int_1^4 \left[z\right]_{z=y}^{z=4} dy$

$= \frac{\pi}{4}\int_1^4 (4-y)\,dy = \frac{\pi}{4}\left[4y - \frac{1}{2}y^2\right]_1^4 = \frac{\pi}{4}\left(16 - 8 - 4 + \frac{1}{2}\right) = \frac{9\pi}{8}$

12. Here $E = \{(x,y,z) \mid 0 \le x \le \pi, 0 \le y \le \pi - x, 0 \le z \le x\}$, so

$\iiint_E \sin y\,dV = \int_0^\pi \int_0^{\pi-x} \int_0^x \sin y\,dz\,dy\,dx = \int_0^\pi \int_0^{\pi-x} \left[z\sin y\right]_{z=0}^{z=x} dy\,dx = \int_0^\pi \int_0^{\pi-x} x\sin y\,dy\,dx$

$= \int_0^\pi \left[-x\cos y\right]_{y=0}^{y=\pi-x} dx = \int_0^\pi \left[-x\cos(\pi-x) + x\right] dx$

$= \left[x\sin(\pi-x) - \cos(\pi-x) + \frac{1}{2}x^2\right]_0^\pi$ [integrate by parts]

$= 0 - 1 + \frac{1}{2}\pi^2 - 0 - 1 - 0 = \frac{1}{2}\pi^2 - 2$

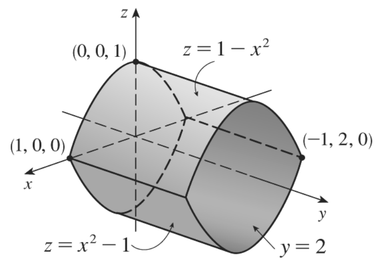
13. Here $E = \{(x,y,z) \mid 0 \le x \le 1, 0 \le y \le \sqrt{x}, 0 \le z \le 1 + x + y\}$, so

$\iiint_E 6xy\,dV = \int_0^1 \int_0^{\sqrt{x}} \int_0^{1+x+y} 6xy\,dz\,dy\,dx = \int_0^1 \int_0^{\sqrt{x}} \left[6xyz\right]_{z=0}^{z=1+x+y} dy\,dx$

$= \int_0^1 \int_0^{\sqrt{x}} 6xy(1+x+y)\,dy\,dx = \int_0^1 \left[3xy^2 + 3x^2y^2 + 2xy^3\right]_{y=0}^{y=\sqrt{x}} dx$

$= \int_0^1 (3x^2 + 3x^3 + 2x^{5/2})\,dx = \left[x^3 + \frac{3}{4}x^4 + \frac{4}{7}x^{7/2}\right]_0^1 = \frac{65}{28}$

14.

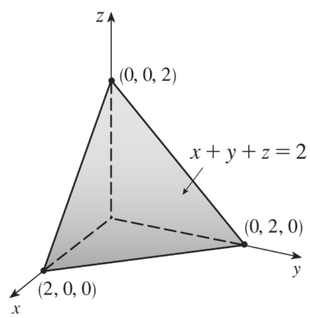


Here $E = \{(x, y, z) \mid -1 \le x \le 1,\ 0 \le y \le 2,\ x^2 - 1 \le z \le 1 - x^2\}$.

Thus,

$$\begin{aligned}\iiint_E (x-y)\,dV &= \int_{-1}^1\int_0^2\int_{x^2-1}^{1-x^2}(x-y)\,dz\,dy\,dx\\ &= \int_{-1}^1\int_0^2 (x-y)(1-x^2-(x^2-1))\,dy\,dx\\ &= \int_{-1}^1\int_0^2 (2x-2x^3-2y+2x^2y)\,dy\,dx\\ &= \int_{-1}^1 \left[2xy-2x^3y-y^2+x^2y^2\right]_{y=0}^{y=2}\,dx\\ &= \int_{-1}^1 (4x-4x^3-4+4x^2)\,dx\\ &= \left[2x^2-x^4-4x+\tfrac{4}{3}x^3\right]_{-1}^1 = -\tfrac{5}{3}-\tfrac{11}{3} = -\tfrac{16}{3}\end{aligned}$$

15.

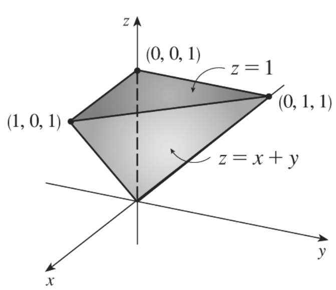


Here $T = \{(x, y, z) \mid 0 \le x \le 2,\ 0 \le y \le 2 - x,\ 0 \le z \le 2 - x - y\}$.

Thus,

$$\begin{aligned}\iiint_T y^2\,dV &= \int_0^2\int_0^{2-x}\int_0^{2-x-y} y^2\,dz\,dy\,dx\\ &= \int_0^2\int_0^{2-x} y^2(2-x-y)\,dy\,dx\\ &= \int_0^2\int_0^{2-x} [(2-x)y^2-y^3]\,dy\,dx\\ &= \int_0^2 \left[(2-x)\left(\tfrac{1}{3}y^3\right)-\tfrac{1}{4}y^4\right]_{y=0}^{y=2-x}\,dx\\ &= \int_0^2 \left[\tfrac{1}{3}(2-x)^4-\tfrac{1}{4}(2-x)^4\right]dx = \int_0^2 \tfrac{1}{12}(2-x)^4\,dx\\ &= \left[\tfrac{1}{12}\left(-\tfrac{1}{5}\right)(2-x)^5\right]_0^2 = -\tfrac{1}{60}(0-32) = \tfrac{8}{15}\end{aligned}$$

16.

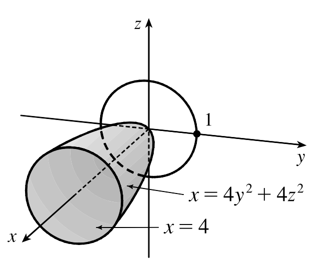


The projection of T onto the xz-plane is the triangle bounded by the lines $z = x$, $x = 0$, and $z = 1$. Then

$T = \{(x, y, z) \mid 0 \le x \le 1,\ x \le z \le 1,\ 0 \le y \le z - x\}$, and

$$\begin{aligned}\iiint_T xz\,dV &= \int_0^1\int_x^1\int_0^{z-x} xz\,dy\,dz\,dx = \int_0^1\int_x^1 xz(z-x)\,dz\,dx\\ &= \int_0^1\int_x^1 (xz^2-x^2z)\,dz\,dx = \int_0^1 \left[\tfrac{1}{3}xz^3-\tfrac{1}{2}x^2z^2\right]_{z=x}^{z=1}\,dx\\ &= \int_0^1 \left(\tfrac{1}{3}x-\tfrac{1}{2}x^2-\tfrac{1}{3}x^4+\tfrac{1}{2}x^4\right)dx\\ &= \left[\tfrac{1}{6}x^2-\tfrac{1}{6}x^3+\tfrac{1}{30}x^5\right]_0^1 = \tfrac{1}{6}-\tfrac{1}{6}+\tfrac{1}{30} = \tfrac{1}{30}\end{aligned}$$

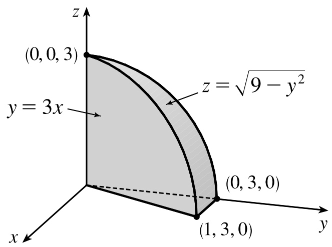
17.



The projection of E onto the yz-plane is the disk $y^2 + z^2 \le 1$. Using polar coordinates $y = r\cos\theta$ and $z = r\sin\theta$, we get

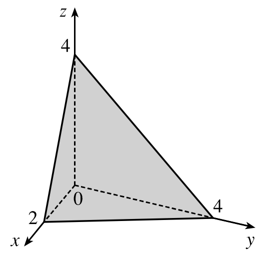
$$\begin{aligned}\iiint_E x\,dV &= \iint_D \left[\int_{4y^2+4z^2}^4 x\,dx\right] dA = \tfrac{1}{2}\iint_D \left[4^2-(4y^2+4z^2)^2\right] dA\\ &= 8\int_0^{2\pi}\int_0^1 (1-r^4)\,r\,dr\,d\theta = 8\int_0^{2\pi} d\theta \int_0^1 (r-r^5)\,dr\\ &= 8(2\pi)\left[\tfrac{1}{2}r^2-\tfrac{1}{6}r^6\right]_0^1 = \tfrac{16\pi}{3}\end{aligned}$$

18.



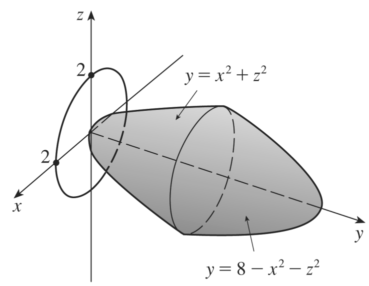
$$\int_0^1\int_{3x}^3\int_0^{\sqrt{9-y^2}} z\,dz\,dy\,dx = \int_0^1\int_{3x}^3 \tfrac{1}{2}(9-y^2)\,dy\,dx$$
$$= \int_0^1 \left[\tfrac{9}{2}y - \tfrac{1}{6}y^3\right]_{y=3x}^{y=3} dx$$
$$= \int_0^1 \left[9 - \tfrac{27}{2}x + \tfrac{9}{2}x^3\right] dx$$
$$= \left[9x - \tfrac{27}{4}x^2 + \tfrac{9}{8}x^4\right]_0^1 = \tfrac{27}{8}$$

19. The plane $2x+y+z=4$ intersects the xy-plane when $2x+y+0=4 \quad\Rightarrow\quad y=4-2x$, so $E=\{(x,y,z)\mid 0\le x\le 2, 0\le y\le 4-2x, 0\le z\le 4-2x-y\}$ and



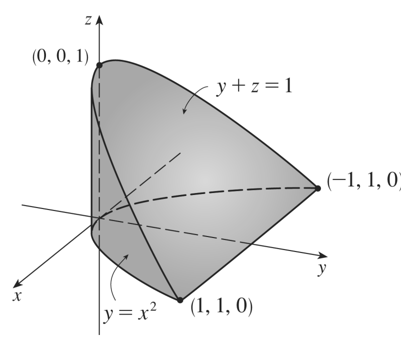
$$V=\int_0^2\int_0^{4-2x}\int_0^{4-2x-y} dz\,dy\,dx = \int_0^2\int_0^{4-2x}(4-2x-y)\,dy\,dx$$
$$= \int_0^2 \left[4y-2xy-\tfrac{1}{2}y^2\right]_{y=0}^{y=4-2x} dx$$
$$= \int_0^2 \left[4(4-2x)-2x(4-2x)-\tfrac{1}{2}(4-2x)^2\right] dx$$
$$= \int_0^2 (2x^2-8x+8)\,dx = \left[\tfrac{2}{3}x^3-4x^2+8x\right]_0^2 = \tfrac{16}{3}$$

20. The paraboloids intersect when $x^2+z^2=8-x^2-z^2 \quad\Leftrightarrow\quad x^2+z^2=4$, thus the intersection is the circle $x^2+z^2=4$, $y=4$. The projection of E onto the xz-plane is the disk $x^2+z^2\le 4$, so $E=\{(x,y,z)\mid x^2+z^2\le y\le 8-x^2-z^2, x^2+z^2\le 4\}$. Let $D=\{(x,z)\mid x^2+z^2\le 4\}$. Then using polar coordinates $x=r\cos\theta$ and $z=r\sin\theta$, we have



$$V=\iiint_E dV = \iint_D\left(\int_{x^2+z^2}^{8-x^2-z^2} dy\right) dA = \iint_D (8-2x^2-2z^2)\,dA$$
$$= \int_0^{2\pi}\int_0^2 (8-2r^2)\,r\,dr\,d\theta = \int_0^{2\pi} d\theta\int_0^2 (8r-2r^3)\,dr$$
$$= \left[\,\theta\,\right]_0^{2\pi}\left[4r^2-\tfrac{1}{2}r^4\right]_0^2 = 2\pi(16-8) = 16\pi$$

21. The plane $y+z=1$ intersects the xy-plane in the line $y=1$, so $E=\{(x,y,z)\mid -1\le x\le 1, x^2\le y\le 1, 0\le z\le 1-y\}$ and



$$V=\iiint_E dV = \int_{-1}^1\int_{x^2}^1\int_0^{1-y} dz\,dy\,dx = \int_{-1}^1\int_{x^2}^1 (1-y)\,dy\,dx$$
$$= \int_{-1}^1 \left[y-\tfrac{1}{2}y^2\right]_{y=x^2}^{y=1} dx = \int_{-1}^1 \left(\tfrac{1}{2}-x^2+\tfrac{1}{2}x^4\right) dx$$
$$= \left[\tfrac{1}{2}x-\tfrac{1}{3}x^3+\tfrac{1}{10}x^5\right]_{-1}^1 = \tfrac{1}{2}-\tfrac{1}{3}+\tfrac{1}{10}+\tfrac{1}{2}-\tfrac{1}{3}+\tfrac{1}{10} = \tfrac{8}{15}$$

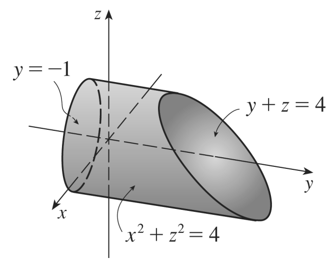
22. Here $E = \left\{(x,y,z) \mid -1 \le y \le 4 - z, x^2 + z^2 \le 4\right\}$, so

$$V = \int_{-2}^{2} \int_{-\sqrt{4-x^2}}^{\sqrt{4-x^2}} \int_{-1}^{4-z} dy\,dz\,dx = \int_{-2}^{2} \int_{-\sqrt{4-x^2}}^{\sqrt{4-x^2}} (4 - z + 1)\,dz\,dx$$

$$= \int_{-2}^{2} \left[5z - \tfrac{1}{2}z^2\right]_{z=-\sqrt{4-x^2}}^{z=\sqrt{4-x^2}} dx = \int_{-2}^{2} 10\sqrt{4-x^2}\,dx$$

$$= 10\left[\tfrac{x}{2}\sqrt{4-x^2} + 2\sin^{-1}\left(\tfrac{x}{2}\right)\right]_{-2}^{2} \quad \left[\begin{array}{l}\text{using trigonometric substitution or}\\ \text{Formula 30 in the Table of Integrals}\end{array}\right]$$

$$= 10\left[2\sin^{-1}(1) - 2\sin^{-1}(-1)\right] = 20\left(\tfrac{\pi}{2} - \left(-\tfrac{\pi}{2}\right)\right) = 20\pi$$



Alternatively, use polar coordinates to evaluate the double integral:

$$\int_{-2}^{2} \int_{-\sqrt{4-x^2}}^{\sqrt{4-x^2}} (5 - z)\,dz\,dx = \int_{0}^{2\pi} \int_{0}^{2} (5 - r\sin\theta)\,r\,dr\,d\theta$$

$$= \int_0^{2\pi} \left[\tfrac{5}{2}r^2 - \tfrac{1}{3}r^3\sin\theta\right]_{r=0}^{r=2} d\theta$$

$$= \int_0^{2\pi} \left(10 - \tfrac{8}{3}\sin\theta\right) d\theta$$

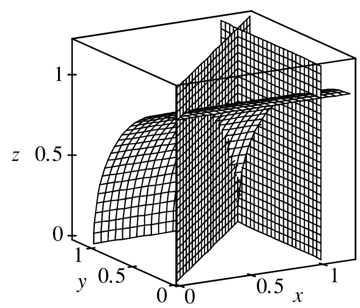
$$= 10\theta + \tfrac{8}{3}\cos\theta\Big]_0^{2\pi} = 20\pi$$

23. (a) The wedge can be described as the region

$$D = \left\{(x,y,z) \mid y^2 + z^2 \le 1, 0 \le x \le 1, 0 \le y \le x\right\}$$
$$= \left\{(x,y,z) \mid 0 \le x \le 1, 0 \le y \le x, 0 \le z \le \sqrt{1-y^2}\right\}$$

So the integral expressing the volume of the wedge is

$\iiint_D dV = \int_0^1 \int_0^x \int_0^{\sqrt{1-y^2}} dz\,dy\,dx.$



(b) A CAS gives $\int_0^1 \int_0^x \int_0^{\sqrt{1-y^2}} dz\,dy\,dx = \frac{\pi}{4} - \frac{1}{3}$.

(Or use Formulas 30 and 87 from the Table of Integrals.)

24. (a) Divide B into 8 cubes of size $\Delta V = 8$. With $f(x,y,z) = \sqrt{x^2+y^2+z^2}$, the Midpoint Rule gives

$$\iiint_B \sqrt{x^2+y^2+z^2}\,dV \approx \sum_{i=1}^{2}\sum_{j=1}^{2}\sum_{k=1}^{2} f\left(\overline{x}_i, \overline{y}_j, \overline{z}_k\right)\Delta V$$

$$= 8[f(1,1,1) + f(1,1,3) + f(1,3,1) + f(1,3,3) + f(3,1,1) + f(3,1,3) + f(3,3,1) + f(3,3,3)]$$

$$\approx 239.64$$

(b) Using a CAS we have $\iiint_B \sqrt{x^2+y^2+z^2}\,dV = \int_0^4 \int_0^4 \int_0^4 \sqrt{x^2+y^2+z^2}\,dz\,dy\,dx \approx 245.91$. This differs from the estimate in part (a) by about 2.5%.

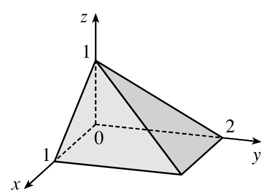
25. Here $f(x,y,z)=\cos(xyz)$ and $\Delta V=\frac{1}{2}\cdot\frac{1}{2}\cdot\frac{1}{2}=\frac{1}{8}$, so the Midpoint Rule gives

$$\begin{aligned}\iiint_B f(x,y,z)\,dV &\approx \sum_{i=1}^{l}\sum_{j=1}^{m}\sum_{k=1}^{n} f\big(\overline{x}_i,\overline{y}_j,\overline{z}_k\big)\,\Delta V\\ &=\tfrac{1}{8}\big[f\big(\tfrac14,\tfrac14,\tfrac14\big)+f\big(\tfrac14,\tfrac14,\tfrac34\big)+f\big(\tfrac14,\tfrac34,\tfrac14\big)+f\big(\tfrac14,\tfrac34,\tfrac34\big)\\ &\qquad +f\big(\tfrac34,\tfrac14,\tfrac14\big)+f\big(\tfrac34,\tfrac14,\tfrac34\big)+f\big(\tfrac34,\tfrac34,\tfrac14\big)+f\big(\tfrac34,\tfrac34,\tfrac34\big)\big]\\ &=\tfrac18\big[\cos\tfrac{1}{64}+\cos\tfrac{3}{64}+\cos\tfrac{3}{64}+\cos\tfrac{9}{64}+\cos\tfrac{3}{64}+\cos\tfrac{9}{64}+\cos\tfrac{9}{64}+\cos\tfrac{27}{64}\big]\approx 0.985\end{aligned}$$

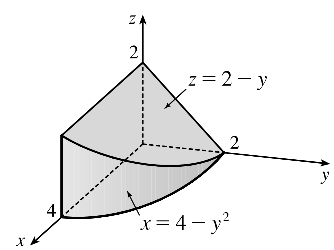
26. Here $f(x,y,z)=\sqrt{x}\,e^{xyz}$ and $\Delta V=2\cdot\frac12\cdot 1=1$, so the Midpoint Rule gives

$$\begin{aligned}\iiint_B f(x,y,z)\,dV &\approx \sum_{i=1}^{l}\sum_{j=1}^{m}\sum_{k=1}^{n} f\big(\overline{x}_i,\overline{y}_j,\overline{z}_k\big)\,\Delta V\\ &=1\big[f\big(1,\tfrac14,\tfrac12\big)+f\big(1,\tfrac14,\tfrac32\big)+f\big(1,\tfrac34,\tfrac12\big)+f\big(1,\tfrac34,\tfrac32\big)\\ &\qquad +f\big(3,\tfrac14,\tfrac12\big)+f\big(3,\tfrac14,\tfrac32\big)+f\big(3,\tfrac34,\tfrac12\big)+f\big(3,\tfrac34,\tfrac32\big)\big]\\ &=e^{1/8}+e^{3/8}+e^{3/8}+e^{9/8}+\sqrt{3}e^{3/8}+\sqrt{3}e^{9/8}+\sqrt{3}e^{9/8}+\sqrt{3}e^{27/8}\approx 70.932\end{aligned}$$

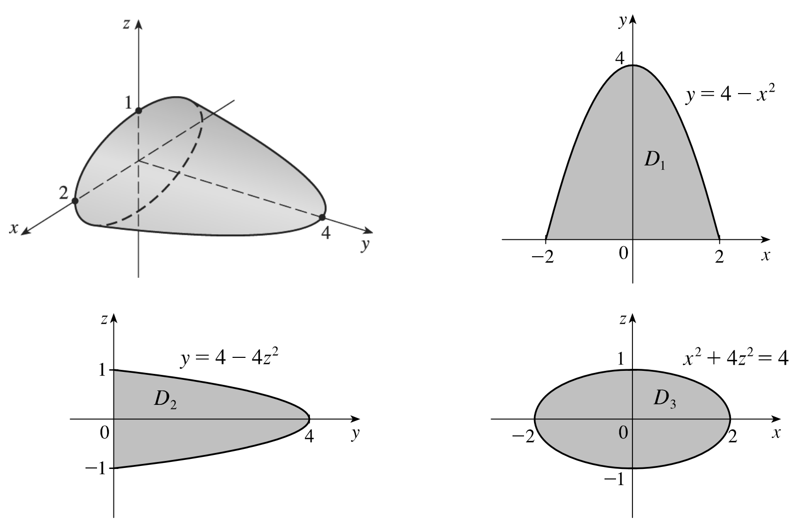
27. $E=\{(x,y,z)\mid 0\le x\le 1, 0\le z\le 1-x, 0\le y\le 2-2z\}$, the solid bounded by the three coordinate planes and the planes $z=1-x$, $y=2-2z$.



28. $E=\left\{(x,y,z)\mid 0\le y\le 2, 0\le z\le 2-y, 0\le x\le 4-y^2\right\}$, the solid bounded by the three coordinate planes, the plane $z=2-y$, and the cylindrical surface $x=4-y^2$.



29.



[continued]

If D_1, D_2, D_3 are the projections of E on the xy-, yz-, and xz-planes, then

$$D_1 = \left\{(x,y) \mid -2 \le x \le 2, 0 \le y \le 4 - x^2\right\} = \left\{(x,y) \mid 0 \le y \le 4,\ -\sqrt{4-y} \le x \le \sqrt{4-y}\right\}$$

$$D_2 = \left\{(y,z) \mid 0 \le y \le 4,\ -\tfrac{1}{2}\sqrt{4-y} \le z \le \tfrac{1}{2}\sqrt{4-y}\right\} = \left\{(y,z) \mid -1 \le z \le 1, 0 \le y \le 4 - 4z^2\right\}$$

$$D_3 = \left\{(x,z) \mid x^2 + 4z^2 \le 4\right\}$$

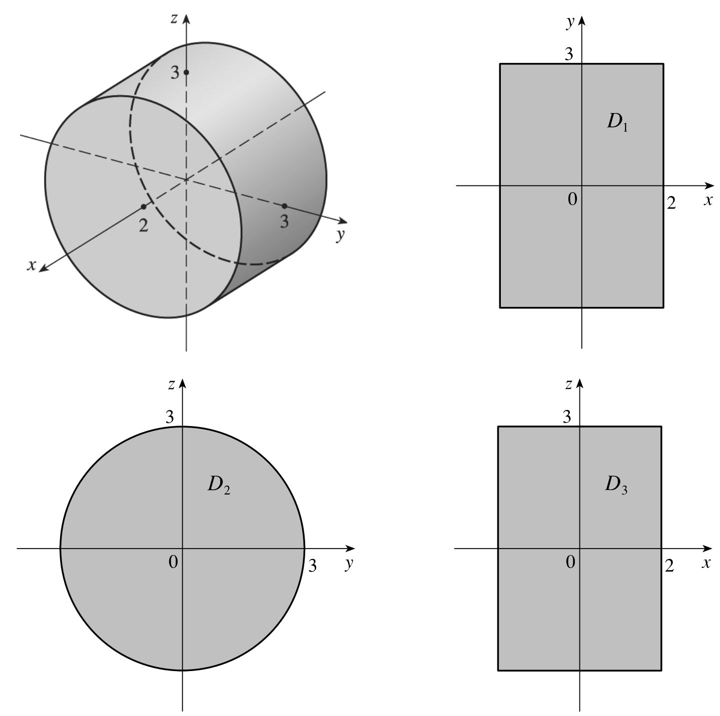
Therefore

$$\begin{aligned} E &= \left\{(x,y,z) \mid -2 \le x \le 2, 0 \le y \le 4 - x^2,\ -\tfrac{1}{2}\sqrt{4-x^2-y} \le z \le \tfrac{1}{2}\sqrt{4-x^2-y}\right\} \\ &= \left\{(x,y,z) \mid 0 \le y \le 4,\ -\sqrt{4-y} \le x \le \sqrt{4-y},\ -\tfrac{1}{2}\sqrt{4-x^2-y} \le z \le \tfrac{1}{2}\sqrt{4-x^2-y}\right\} \\ &= \left\{(x,y,z) \mid -1 \le z \le 1, 0 \le y \le 4 - 4z^2,\ -\sqrt{4-y-4z^2} \le x \le \sqrt{4-y-4z^2}\right\} \\ &= \left\{(x,y,z) \mid 0 \le y \le 4,\ -\tfrac{1}{2}\sqrt{4-y} \le z \le \tfrac{1}{2}\sqrt{4-y},\ -\sqrt{4-y-4z^2} \le x \le \sqrt{4-y-4z^2}\right\} \\ &= \left\{(x,y,z) \mid -2 \le x \le 2,\ -\tfrac{1}{2}\sqrt{4-x^2} \le z \le \tfrac{1}{2}\sqrt{4-x^2}, 0 \le y \le 4 - x^2 - 4z^2\right\} \\ &= \left\{(x,y,z) \mid -1 \le z \le 1,\ -\sqrt{4-4z^2} \le x \le \sqrt{4-4z^2}, 0 \le y \le 4 - x^2 - 4z^2\right\} \end{aligned}$$

Then

$$\begin{aligned} \iiint_E f(x,y,z)\,dV &= \int_{-2}^{2}\int_0^{4-x^2}\int_{-\sqrt{4-x^2-y}/2}^{\sqrt{4-x^2-y}/2} f(x,y,z)\,dz\,dy\,dx = \int_0^4\int_{-\sqrt{4-y}}^{\sqrt{4-y}}\int_{-\sqrt{4-x^2-y}/2}^{\sqrt{4-x^2-y}/2} f(x,y,z)\,dz\,dx\,dy \\ &= \int_{-1}^{1}\int_0^{4-4z^2}\int_{-\sqrt{4-y-4z^2}}^{\sqrt{4-y-4z^2}} f(x,y,z)\,dx\,dy\,dz = \int_0^4\int_{-\sqrt{4-y}/2}^{\sqrt{4-y}/2}\int_{-\sqrt{4-y-4z^2}}^{\sqrt{4-y-4z^2}} f(x,y,z)\,dx\,dz\,dy \\ &= \int_{-2}^{2}\int_{-\sqrt{4-x^2}/2}^{\sqrt{4-x^2}/2}\int_0^{4-x^2-4z^2} f(x,y,z)\,dy\,dz\,dx = \int_{-1}^{1}\int_{-\sqrt{4-4z^2}}^{\sqrt{4-4z^2}}\int_0^{4-x^2-4z^2} f(x,y,z)\,dy\,dx\,dz \end{aligned}$$

30.



If D_1, D_2, D_3 are the projections of E on the xy-, yz-, and xz-planes, then

$$D_1 = \{(x,y) \mid -2 \le x \le 2,\ -3 \le y \le 3\}$$
$$D_2 = \left\{(y,z) \mid y^2 + z^2 \le 9\right\}$$
$$D_3 = \{(x,z) \mid -2 \le x \le 2,\ -3 \le z \le 3\}$$

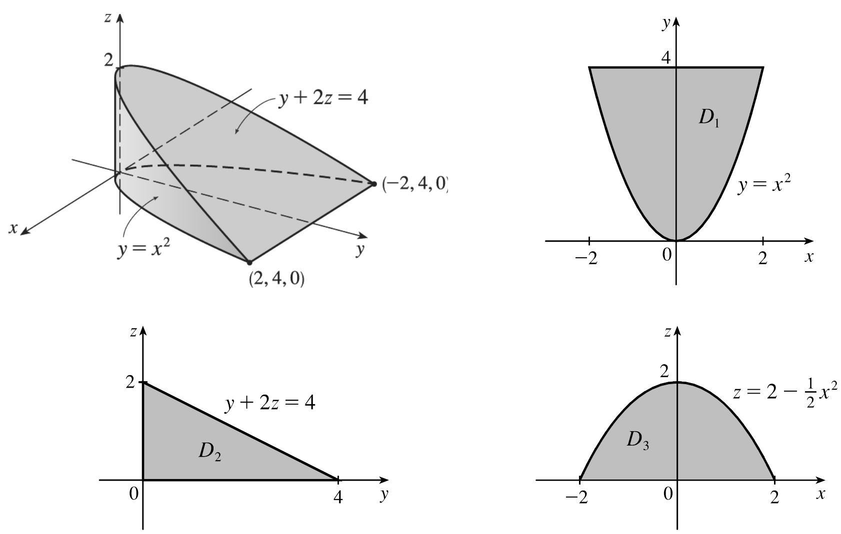
Therefore

$$\begin{aligned} E &= \left\{(x,y,z) \mid -2 \le x \le 2,\ -3 \le y \le 3,\ -\sqrt{9-y^2} \le z \le \sqrt{9-y^2}\right\} \\ &= \left\{(x,y,z) \mid -3 \le y \le 3,\ -\sqrt{9-y^2} \le z \le \sqrt{9-y^2},\ -2 \le x \le 2\right\} \\ &= \left\{(x,y,z) \mid -3 \le z \le 3,\ -\sqrt{9-z^2} \le y \le \sqrt{9-z^2},\ -2 \le x \le 2\right\} \\ &= \left\{(x,y,z) \mid -2 \le x \le 2,\ -3 \le z \le 3,\ -\sqrt{9-z^2} \le y \le \sqrt{9-z^2}\right\} \end{aligned}$$

and

$$\begin{aligned} \iiint_E f(x,y,z)\,dV &= \int_{-2}^{2}\int_{-3}^{3}\int_{-\sqrt{9-y^2}}^{\sqrt{9-y^2}} f(x,y,z)\,dz\,dy\,dx = \int_{-3}^{3}\int_{-2}^{2}\int_{-\sqrt{9-y^2}}^{\sqrt{9-y^2}} f(x,y,z)\,dz\,dx\,dy \\ &= \int_{-3}^{3}\int_{-\sqrt{9-y^2}}^{\sqrt{9-y^2}}\int_{-2}^{2} f(x,y,z)\,dx\,dz\,dy = \int_{-3}^{3}\int_{-\sqrt{9-z^2}}^{\sqrt{9-z^2}}\int_{-2}^{2} f(x,y,z)\,dx\,dy\,dz \\ &= \int_{-2}^{2}\int_{-3}^{3}\int_{-\sqrt{9-z^2}}^{\sqrt{9-z^2}} f(x,y,z)\,dy\,dz\,dx = \int_{-3}^{3}\int_{-2}^{2}\int_{-\sqrt{9-z^2}}^{\sqrt{9-z^2}} f(x,y,z)\,dy\,dx\,dz \end{aligned}$$

31.



If D_1, D_2, and D_3 are the projections of E on the xy-, yz-, and xz-planes, then

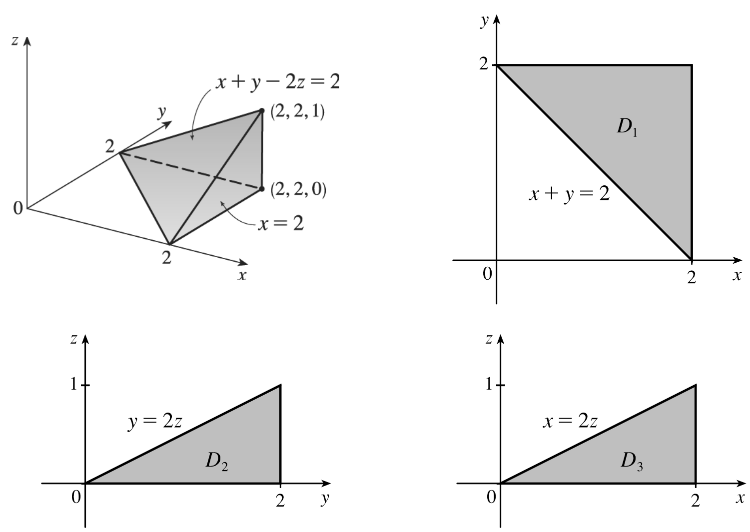
$$D_1 = \left\{(x,y) \mid -2 \le x \le 2, x^2 \le y \le 4\right\} = \left\{(x,y) \mid 0 \le y \le 4, -\sqrt{y} \le x \le \sqrt{y}\right\},$$
$$D_2 = \left\{(y,z) \mid 0 \le y \le 4, 0 \le z \le 2 - \tfrac{1}{2}y\right\} = \left\{(y,z) \mid 0 \le z \le 2, 0 \le y \le 4 - 2z\right\}, \text{ and}$$
$$D_3 = \left\{(x,z) \mid -2 \le x \le 2, 0 \le z \le 2 - \tfrac{1}{2}x^2\right\} = \left\{(x,z) \mid 0 \le z \le 2, -\sqrt{4-2z} \le x \le \sqrt{4-2z}\right\}$$

[continued]

Therefore
$$\begin{aligned} E &= \left\{(x,y,z) \mid -2 \le x \le 2, x^2 \le y \le 4, 0 \le z \le 2 - \tfrac{1}{2}y\right\} \\ &= \left\{(x,y,z) \mid 0 \le y \le 4, -\sqrt{y} \le x \le \sqrt{y}, 0 \le z \le 2 - \tfrac{1}{2}y\right\} \\ &= \left\{(x,y,z) \mid 0 \le y \le 4, 0 \le z \le 2 - \tfrac{1}{2}y, -\sqrt{y} \le x \le \sqrt{y}\right\} \\ &= \left\{(x,y,z) \mid 0 \le z \le 2, 0 \le y \le 4 - 2z, -\sqrt{y} \le x \le \sqrt{y}\right\} \\ &= \left\{(x,y,z) \mid -2 \le x \le 2, 0 \le z \le 2 - \tfrac{1}{2}x^2, x^2 \le y \le 4 - 2z\right\} \\ &= \left\{(x,y,z) \mid 0 \le z \le 2, -\sqrt{4-2z} \le x \le \sqrt{4-2z}, x^2 \le y \le 4 - 2z\right\} \end{aligned}$$

Then
$$\begin{aligned} \iiint_E f(x,y,z)\,dV &= \int_{-2}^{2}\int_{x^2}^{4}\int_{0}^{2-y/2} f(x,y,z)\,dz\,dy\,dx = \int_0^4\int_{-\sqrt{y}}^{\sqrt{y}}\int_0^{2-y/2} f(x,y,z)\,dz\,dx\,dy \\ &= \int_0^4\int_0^{2-y/2}\int_{-\sqrt{y}}^{\sqrt{y}} f(x,y,z)\,dx\,dz\,dy = \int_0^2\int_0^{4-2z}\int_{-\sqrt{y}}^{\sqrt{y}} f(x,y,z)\,dx\,dy\,dz \\ &= \int_{-2}^{2}\int_0^{2-x^2/2}\int_{x^2}^{4-2z} f(x,y,z)\,dy\,dz\,dx = \int_0^2\int_{-\sqrt{4-2z}}^{\sqrt{4-2z}}\int_{x^2}^{4-2z} f(x,y,z)\,dy\,dx\,dz \end{aligned}$$

32.



If D_1, D_2, and D_3 are the projections of E on the xy-, yz-, and xz-planes, then

$$D_1 = \{(x,y) \mid 0 \le x \le 2, 2 - x \le y \le 2\} = \{(x,y) \mid 0 \le y \le 2, 2 - y \le x \le 2\},$$

$$D_2 = \left\{(y,z) \mid 0 \le y \le 2, 0 \le z \le \tfrac{1}{2}y\right\} = \{(y,z) \mid 0 \le z \le 1, 2z \le y \le 2\}, \text{ and}$$

$$D_3 = \left\{(x,z) \mid 0 \le x \le 2, 0 \le z \le \tfrac{1}{2}x\right\} = \{(x,z) \mid 0 \le z \le 1, 2z \le x \le 2\}$$

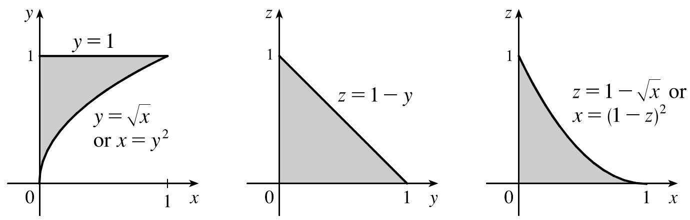
Therefore
$$\begin{aligned} E &= \left\{(x,y,z) \mid 0 \le x \le 2, 2 - x \le y \le 2, 0 \le z \le \tfrac{1}{2}(x+y-2)\right\} \\ &= \left\{(x,y,z) \mid 0 \le y \le 2, 2 - y \le x \le 2, 0 \le z \le \tfrac{1}{2}(x+y-2)\right\} \\ &= \left\{(x,y,z) \mid 0 \le y \le 2, 0 \le z \le \tfrac{1}{2}y, 2 - y + 2z \le x \le 2\right\} \\ &= \{(x,y,z) \mid 0 \le z \le 1, 2z \le y \le 2, 2 - y + 2z \le x \le 2\} \\ &= \left\{(x,y,z) \mid 0 \le x \le 2, 0 \le z \le \tfrac{1}{2}x, 2 - x + 2z \le y \le 2\right\} \\ &= \{(x,y,z) \mid 0 \le z \le 1, 2z \le x \le 2, 2 - x + 2z \le y \le 2\} \end{aligned}$$

Then $\iiint_E f(x,y,z)\,dV = \int_0^2 \int_{2-x}^2 \int_0^{(x+y-2)/2} f(x,y,z)\,dz\,dy\,dx = \int_0^2 \int_{2-y}^2 \int_0^{(x+y-2)/2} f(x,y,z)\,dz\,dx\,dy$

$$= \int_0^2 \int_0^{y/2} \int_{2-y+2z}^2 f(x,y,z)\,dx\,dz\,dy = \int_0^1 \int_{2z}^2 \int_{2-y+2z}^2 f(x,y,z)\,dx\,dy\,dz$$

$$= \int_0^2 \int_0^{x/2} \int_{2-x+2z}^2 f(x,y,z)\,dy\,dz\,dx = \int_0^1 \int_{2z}^2 \int_{2-x+2z}^2 f(x,y,z)\,dy\,dx\,dz$$

33.



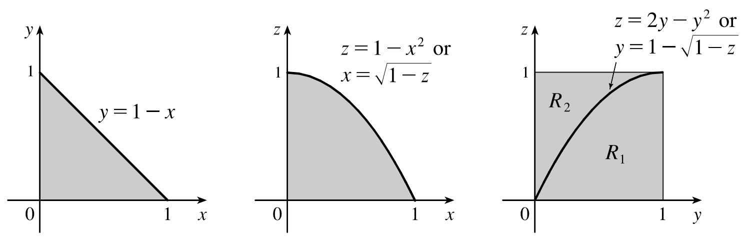
The diagrams show the projections of E onto the xy-, yz-, and xz-planes. Therefore

$$\int_0^1 \int_{\sqrt{x}}^1 \int_0^{1-y} f(x,y,z)\,dz\,dy\,dx = \int_0^1 \int_0^{y^2} \int_0^{1-y} f(x,y,z)\,dz\,dx\,dy = \int_0^1 \int_0^{1-z} \int_0^{y^2} f(x,y,z)\,dx\,dy\,dz$$

$$= \int_0^1 \int_0^{1-y} \int_0^{y^2} f(x,y,z)\,dx\,dz\,dy = \int_0^1 \int_0^{1-\sqrt{x}} \int_{\sqrt{x}}^{1-z} f(x,y,z)\,dy\,dz\,dx$$

$$= \int_0^1 \int_0^{(1-z)^2} \int_{\sqrt{x}}^{1-z} f(x,y,z)\,dy\,dx\,dz$$

34.



The projections of E onto the xy- and xz-planes are as in the first two diagrams and so

$$\int_0^1 \int_0^{1-x^2} \int_0^{1-x} f(x,y,z)\,dy\,dz\,dx = \int_0^1 \int_0^{\sqrt{1-z}} \int_0^{1-x} f(x,y,z)\,dy\,dx\,dz$$

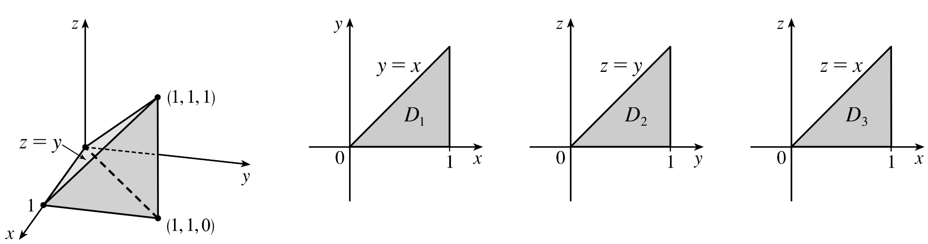
$$= \int_0^1 \int_0^{1-y} \int_0^{1-x^2} f(x,y,z)\,dz\,dx\,dy = \int_0^1 \int_0^{1-x} \int_0^{1-x^2} f(x,y,z)\,dz\,dy\,dx$$

Now the surface $z = 1 - x^2$ intersects the plane $y = 1 - x$ in a curve whose projection in the yz-plane is $z = 1 - (1-y)^2$ or $z = 2y - y^2$. So we must split up the projection of E on the yz-plane into two regions as in the third diagram. For (y,z) in R_1, $0 \le x \le 1 - y$ and for (y,z) in R_2, $0 \le x \le \sqrt{1-z}$, and so the given integral is also equal to

$$\int_0^1 \int_0^{1-\sqrt{1-z}} \int_0^{\sqrt{1-z}} f(x,y,z)\,dx\,dy\,dz + \int_0^1 \int_{1-\sqrt{1-z}}^1 \int_0^{1-y} f(x,y,z)\,dx\,dy\,dz$$

$$= \int_0^1 \int_0^{2y-y^2} \int_0^{1-y} f(x,y,z)\,dx\,dz\,dy + \int_0^1 \int_{2y-y^2}^1 \int_0^{\sqrt{1-z}} f(x,y,z)\,dx\,dz\,dy.$$

35.



$\int_0^1 \int_y^1 \int_0^y f(x,y,z)\,dz\,dx\,dy = \iiint_E f(x,y,z)\,dV$ where $E = \{(x,y,z) \mid 0 \le z \le y, y \le x \le 1, 0 \le y \le 1\}$.

[continued]

If D_1, D_2, and D_3 are the projections of E onto the xy-, yz- and xz-planes then

$$D_1 = \{(x,y) \mid 0 \le y \le 1, y \le x \le 1\} = \{(x,y) \mid 0 \le x \le 1, 0 \le y \le x\},$$

$$D_2 = \{(y,z) \mid 0 \le y \le 1, 0 \le z \le y\} = \{(y,z) \mid 0 \le z \le 1, z \le y \le 1\}, \text{ and}$$

$$D_3 = \{(x,z) \mid 0 \le x \le 1, 0 \le z \le x\} = \{(x,z) \mid 0 \le z \le 1, z \le x \le 1\}.$$

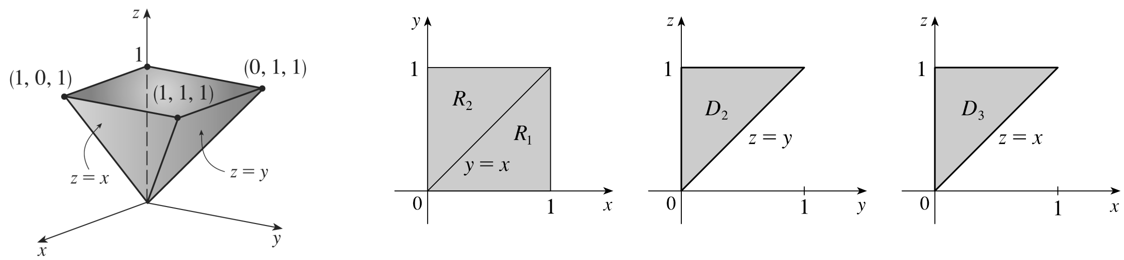
Thus we also have

$$\begin{aligned} E &= \{(x,y,z) \mid 0 \le x \le 1, 0 \le y \le x, 0 \le z \le y\} = \{(x,y,z) \mid 0 \le y \le 1, 0 \le z \le y, y \le x \le 1\} \\ &= \{(x,y,z) \mid 0 \le z \le 1, z \le y \le 1, y \le x \le 1\} = \{(x,y,z) \mid 0 \le x \le 1, 0 \le z \le x, z \le y \le x\} \\ &= \{(x,y,z) \mid 0 \le z \le 1, z \le x \le 1, z \le y \le x\}. \end{aligned}$$

Then

$$\begin{aligned} \int_0^1\int_y^1\int_0^y f(x,y,z)\,dz\,dx\,dy &= \int_0^1\int_0^x\int_0^y f(x,y,z)\,dz\,dy\,dx = \int_0^1\int_0^y\int_y^1 f(x,y,z)\,dx\,dz\,dy \\ &= \int_0^1\int_z^1\int_y^1 f(x,y,z)\,dx\,dy\,dz = \int_0^1\int_0^x\int_z^x f(x,y,z)\,dy\,dz\,dx \\ &= \int_0^1\int_z^1\int_z^x f(x,y,z)\,dy\,dx\,dz \end{aligned}$$

36.



$\int_0^1\int_y^1\int_0^z f(x,y,z)\,dx\,dz\,dy = \iiint_E f(x,y,z)\,dV$ where $E = \{(x,y,z) \mid 0 \le x \le z, y \le z \le 1, 0 \le y \le 1\}$.

Notice that E is bounded below by two different surfaces, so we must split the projection of E onto the xy-plane into two regions as in the second diagram. If D_1, D_2, and D_3 are the projections of E on the xy-, yz- and xz-planes then

$$\begin{aligned} D_1 = R_1 \cup R_2 &= \{(x,y) \mid 0 \le x \le 1, 0 \le y \le x\} \cup \{(x,y) \mid 0 \le x \le 1, x \le y \le 1\} \\ &= \{(x,y) \mid 0 \le y \le 1, y \le x \le 1\} \cup \{(x,y) \mid 0 \le y \le 1, 0 \le x \le y\}, \end{aligned}$$

$$D_2 = \{(y,z) \mid 0 \le y \le 1, y \le z \le 1\} = \{(y,z) \mid 0 \le z \le 1, 0 \le y \le z\}, \text{ and}$$

$$D_3 = \{(x,z) \mid 0 \le x \le 1, x \le z \le 1\} = \{(x,z) \mid 0 \le z \le 1, 0 \le x \le z\}.$$

Thus we also have

$$\begin{aligned} E &= \{(x,y,z) \mid 0 \le x \le 1, 0 \le y \le x, x \le z \le 1\} \cup \{(x,y,z) \mid 0 \le x \le 1, x \le y \le 1, y \le z \le 1\} \\ &= \{(x,y,z) \mid 0 \le y \le 1, y \le x \le 1, x \le z \le 1\} \cup \{(x,y,z) \mid 0 \le y \le 1, 0 \le x \le y, y \le z \le 1\} \\ &= \{(x,y,z) \mid 0 \le z \le 1, 0 \le y \le z, 0 \le x \le z\} = \{(x,y,z) \mid 0 \le x \le 1, x \le z \le 1, 0 \le y \le z\} \\ &= \{(x,y,z) \mid 0 \le z \le 1, 0 \le x \le z, 0 \le y \le z\}. \end{aligned}$$

Then

$$\begin{aligned} \int_0^1\int_y^1\int_0^z f(x,y,z)\,dx\,dz\,dy &= \int_0^1\int_0^x\int_x^1 f(x,y,z)\,dz\,dy\,dx + \int_0^1\int_x^1\int_y^1 f(x,y,z)\,dz\,dy\,dx \\ &= \int_0^1\int_y^1\int_x^1 f(x,y,z)\,dz\,dx\,dy + \int_0^1\int_0^y\int_y^1 f(x,y,z)\,dz\,dx\,dy \\ &= \int_0^1\int_0^z\int_0^z f(x,y,z)\,dx\,dy\,dz = \int_0^1\int_x^1\int_0^z f(x,y,z)\,dy\,dz\,dx \\ &= \int_0^1\int_0^z\int_0^z f(x,y,z)\,dy\,dx\,dz \end{aligned}$$

37. The region C is the solid bounded by a circular cylinder of radius 2 with axis the z-axis for $-2 \le z \le 2$. We can write $\iiint_C (4 + 5x^2yz^2)\,dV = \iiint_C 4\,dV + \iiint_C 5x^2yz^2\,dV$, but $f(x,y,z) = 5x^2yz^2$ is an odd function with respect to y. Since C is symmetrical about the xz-plane, we have $\iiint_C 5x^2yz^2\,dV = 0$. Thus $\iiint_C (4 + 5x^2yz^2)\,dV = \iiint_C 4\,dV = 4 \cdot V(E) = 4 \cdot \pi(2)^2(4) = 64\pi$.

38. We can write $\iiint_B (z^3 + \sin y + 3)\,dV = \iiint_B z^3\,dV + \iiint_B \sin y\,dV + \iiint_B 3\,dV$. But z^3 is an odd function with respect to z and the region B is symmetric about the xy-plane, so $\iiint_B z^3\,dV = 0$. Similarly, $\sin y$ is an odd function with respect to y and B is symmetric about the xz-plane, so $\iiint_B \sin y\,dV = 0$. Thus $\iiint_B (z^3 + \sin y + 3)\,dV = \iiint_B 3\,dV = 3 \cdot V(B) = 3 \cdot \frac{4}{3}\pi(1)^3 = 4\pi$.

39. The projection of E onto the xy-plane is the disk $D = \{(x,y) \mid x^2 + y^2 \le 1\}$.

$$m = \iiint_E \rho(x,y,z)\,dV = \iint_D \left[\int_0^{1-x^2-y^2} 3\,dz\right] dA = \iint_D 3(1 - x^2 - y^2)\,dA$$
$$= 3\int_0^1 \int_0^{2\pi} (1 - r^2)\,r\,dr\,d\theta = 3\int_0^{2\pi} d\theta \int_0^1 (r - r^3)\,dr$$
$$= 3\left[\,\theta\,\right]_0^{2\pi} \left[\tfrac{1}{2}r^2 - \tfrac{1}{4}r^4\right]_0^1 = 3\,(2\pi)\left(\tfrac{1}{2} - \tfrac{1}{4}\right) = \tfrac{3}{2}\pi$$

$$M_{yz} = \iiint_E x\rho(x,y,z)\,dV = \iint_D \left[\int_0^{1-x^2-y^2} 3x\,dz\right] dA = \iint_D 3x(1 - x^2 - y^2)\,dA$$
$$= 3\int_0^1 \int_0^{2\pi} (r\cos\theta)(1 - r^2)\,r\,dr\,d\theta = 3\int_0^{2\pi} \cos\theta\,d\theta \int_0^1 (r^2 - r^4)\,dr$$
$$= 3\left[\,\sin\theta\,\right]_0^{2\pi} \left[\tfrac{1}{3}r^3 - \tfrac{1}{5}r^5\right]_0^1 = 3\,(0)\left(\tfrac{1}{3} - \tfrac{1}{5}\right) = 0$$

$$M_{xz} = \iiint_E y\rho(x,y,z)\,dV = \iint_D \left[\int_0^{1-x^2-y^2} 3y\,dz\right] dA = \iint_D 3y(1 - x^2 - y^2)\,dA$$
$$= 3\int_0^1 \int_0^{2\pi} (r\sin\theta)(1 - r^2)\,r\,dr\,d\theta = 3\int_0^{2\pi} \sin\theta\,d\theta \int_0^1 (r^2 - r^4)\,dr$$
$$= 3\left[\,-\cos\theta\,\right]_0^{2\pi} \left[\tfrac{1}{3}r^3 - \tfrac{1}{5}r^5\right]_0^1 = 3\,(0)\left(\tfrac{1}{3} - \tfrac{1}{5}\right) = 0$$

$$M_{xy} = \iiint_E z\rho(x,y,z)\,dV = \iint_D \left[\int_0^{1-x^2-y^2} 3z\,dz\right] dA = \iint_D \left[\tfrac{3}{2}z^2\right]_{z=0}^{z=1-x^2-y^2} dA$$
$$= \tfrac{3}{2}\iint_D (1 - x^2 - y^2)^2\,dA = \tfrac{3}{2}\int_0^1 \int_0^{2\pi} (1 - r^2)^2\,r\,dr\,d\theta$$
$$= \tfrac{3}{2}\int_0^{2\pi} d\theta \int_0^1 (r - 2r^3 + r^5)\,dr = \tfrac{3}{2}\left[\,\theta\,\right]_0^{2\pi} \left[\tfrac{1}{2}r^2 - \tfrac{1}{2}r^4 + \tfrac{1}{6}r^6\right]_0^1$$
$$= \tfrac{3}{2}\,(2\pi)\left(\tfrac{1}{2} - \tfrac{1}{2} + \tfrac{1}{6}\right) = \tfrac{1}{2}\pi$$

Thus the mass is $\frac{3}{2}\pi$ and the center of mass is $(\overline{x}, \overline{y}, \overline{z}) = \left(\dfrac{M_{yz}}{m}, \dfrac{M_{xz}}{m}, \dfrac{M_{xy}}{m}\right) = \left(0, 0, \dfrac{1}{3}\right)$.

40. $m = \int_{-1}^1 \int_0^{1-y^2} \int_0^{1-z} 4\,dx\,dz\,dy = 4\int_{-1}^1 \int_0^{1-y^2} (1 - z)\,dz\,dy = 4\int_{-1}^1 \left[z - \tfrac{1}{2}z^2\right]_{z=0}^{z=1-y^2} dy = 2\int_{-1}^1 (1 - y^4)\,dy = \frac{16}{5}$,

$$M_{yz} = \int_{-1}^1 \int_0^{1-y^2} \int_0^{1-z} 4x\,dx\,dz\,dy = 2\int_{-1}^1 \int_0^{1-y^2} (1 - z)^2\,dz\,dy = 2\int_{-1}^1 \left[-\tfrac{1}{3}(1 - z)^3\right]_{z=0}^{z=1-y^2} dy$$
$$= \tfrac{2}{3}\int_{-1}^1 (1 - y^6)\,dy = \left(\tfrac{4}{3}\right)\left(\tfrac{6}{7}\right) = \tfrac{24}{21}$$

[continued]

$$M_{xz} = \int_{-1}^{1}\int_0^{1-y^2}\int_0^{1-z} 4y\,dx\,dz\,dy = \int_{-1}^{1}\int_0^{1-y^2} 4y(1-z)\,dz\,dy$$

$$= \int_{-1}^{1}\left[4y(1-y^2) - 2y(1-y^2)^2\right]dy = \int_{-1}^{1}(2y - 2y^5)\,dy = 0 \quad \text{[the integrand is odd]}$$

$$M_{xy} = \int_{-1}^{1}\int_0^{1-y^2}\int_0^{1-z} 4z\,dx\,dz\,dy = \int_{-1}^{1}\int_0^{1-y^2}(4z - 4z^2)\,dz\,dy = 2\int_{-1}^{1}\left[(1-y^2)^2 - \tfrac{2}{3}(1-y^2)^3\right]dy$$

$$= 2\int_{-1}^{1}\left[\tfrac{1}{3} - y^4 + \tfrac{2}{3}y^6\right]dy = \left[\tfrac{4}{3}y - \tfrac{4}{5}y^5 + \tfrac{8}{21}y^7\right]_0^1 = \tfrac{96}{105} = \tfrac{32}{35}$$

Thus, $(\overline{x}, \overline{y}, \overline{z}) = \left(\frac{5}{14}, 0, \frac{2}{7}\right)$

41. $m = \int_0^a\int_0^a\int_0^a (x^2+y^2+z^2)\,dx\,dy\,dz = \int_0^a\int_0^a\left[\frac{1}{3}x^3 + xy^2 + xz^2\right]_{x=0}^{x=a} dy\,dz = \int_0^a\int_0^a\left(\frac{1}{3}a^3 + ay^2 + az^2\right)dy\,dz$

$$= \int_0^a\left[\tfrac{1}{3}a^3y + \tfrac{1}{3}ay^3 + ayz^2\right]_{y=0}^{y=a}dz = \int_0^a\left(\tfrac{2}{3}a^4 + a^2z^2\right)dz = \left[\tfrac{2}{3}a^4z + \tfrac{1}{3}a^2z^3\right]_0^a = \tfrac{2}{3}a^5 + \tfrac{1}{3}a^5 = a^5$$

$$M_{yz} = \int_0^a\int_0^a\int_0^a\left[x^3 + x(y^2+z^2)\right]dx\,dy\,dz = \int_0^a\int_0^a\left[\tfrac{1}{4}a^4 + \tfrac{1}{2}a^2(y^2+z^2)\right]dy\,dz$$

$= \int_0^a\left(\frac{1}{4}a^5 + \frac{1}{6}a^5 + \frac{1}{2}a^3z^2\right)dz = \frac{1}{4}a^6 + \frac{1}{3}a^6 = \frac{7}{12}a^6 = M_{xz} = M_{xy}$ by symmetry of E and $\rho(x,y,z)$

Hence $(\overline{x}, \overline{y}, \overline{z}) = \left(\frac{7}{12}a, \frac{7}{12}a, \frac{7}{12}a\right)$.

42. $m = \int_0^1\int_0^{1-x}\int_0^{1-x-y} y\,dz\,dy\,dx = \int_0^1\int_0^{1-x}\left[(1-x)y - y^2\right]dy\,dx$

$$= \int_0^1\left[\tfrac{1}{2}(1-x)^3 - \tfrac{1}{3}(1-x)^3\right]dx = \tfrac{1}{6}\int_0^1(1-x)^3\,dx = \tfrac{1}{24}$$

$$M_{yz} = \int_0^1\int_0^{1-x}\int_0^{1-x-y} xy\,dz\,dy\,dx = \int_0^1\int_0^{1-x}\left[(x-x^2)y - xy^2\right]dy\,dx$$

$$= \int_0^1\left[\tfrac{1}{2}x(1-x)^3 - \tfrac{1}{3}x(1-x)^3\right]dx = \tfrac{1}{6}\int_0^1\left(x - 3x^2 + 3x^3 - x^4\right)dx = \tfrac{1}{6}\left(\tfrac{1}{2} - 1 + \tfrac{3}{4} - \tfrac{1}{5}\right) = \tfrac{1}{120}$$

$$M_{xz} = \int_0^1\int_0^{1-x}\int_0^{1-x-y} y^2\,dz\,dy\,dx = \int_0^1\int_0^{1-x}\left[(1-x)y^2 - y^3\right]dy\,dx$$

$$= \int_0^1\left[\tfrac{1}{3}(1-x)^4 - \tfrac{1}{4}(1-x)^4\right]dx = \tfrac{1}{12}\left[-\tfrac{1}{5}(1-x)^5\right]_0^1 = \tfrac{1}{60}$$

$$M_{xy} = \int_0^1\int_0^{1-x}\int_0^{1-x-y} yz\,dz\,dy\,dx = \int_0^1\int_0^{1-x}\left[\tfrac{1}{2}y(1-x-y)^2\right]dy\,dx$$

$$= \tfrac{1}{2}\int_0^1\int_0^{1-x}\left[(1-x)^2y - 2(1-x)y^2 + y^3\right]dy\,dx = \tfrac{1}{2}\int_0^1\left[\tfrac{1}{2}(1-x)^4 - \tfrac{2}{3}(1-x)^4 + \tfrac{1}{4}(1-x)^4\right]dx$$

$$= \tfrac{1}{24}\int_0^1(1-x)^4\,dx = -\tfrac{1}{24}\left[\tfrac{1}{5}(1-x)^5\right]_0^1 = \tfrac{1}{120}$$

Hence $(\overline{x}, \overline{y}, \overline{z}) = \left(\frac{1}{5}, \frac{2}{5}, \frac{1}{5}\right)$.

43. $I_x = \int_0^L\int_0^L\int_0^L k(y^2+z^2)\,dz\,dy\,dx = k\int_0^L\int_0^L\left(Ly^2 + \frac{1}{3}L^3\right)dy\,dx = k\int_0^L \frac{2}{3}L^4\,dx = \frac{2}{3}kL^5$

By symmetry, $I_x = I_y = I_z = \frac{2}{3}kL^5$.

44. $I_x = \int_{-c/2}^{c/2}\int_{-b/2}^{b/2}\int_{-a/2}^{a/2} k(y^2+z^2)\,dx\,dy\,dz = ka\int_{-c/2}^{c/2}\int_{-b/2}^{b/2}(y^2+z^2)\,dy\,dz$

$$= ak\int_{-c/2}^{c/2}\left[\tfrac{1}{3}y^3 + z^2y\right]_{y=-b/2}^{y=b/2}dz = ak\int_{-c/2}^{c/2}\left(\tfrac{1}{12}b^3 + bz^2\right)dz = ak\left[\tfrac{1}{12}b^3z + \tfrac{1}{3}bz^3\right]_{-c/2}^{c/2}$$

$$= ak\left(\tfrac{1}{12}b^3c + \tfrac{1}{12}bc^3\right) = \tfrac{1}{12}kabc(b^2+c^2)$$

By symmetry, $I_y = \frac{1}{12}kabc(a^2+c^2)$ and $I_z = \frac{1}{12}kabc(a^2+b^2)$.

45. $I_z = \iiint_E (x^2+y^2)\,\rho(x,y,z)\,dV = \iint_{x^2+y^2\le a^2} \left[\int_0^h k(x^2+y^2)\,dz\right] dA = \iint_{x^2+y^2\le a^2} k(x^2+y^2)h\,dA$

$= kh\int_0^{2\pi}\int_0^a (r^2)\,r\,dr\,d\theta = kh\int_0^{2\pi} d\theta \int_0^a r^3\,dr = kh(2\pi)\left[\frac{1}{4}r^4\right]_0^a = 2\pi kh\cdot\frac{1}{4}a^4 = \frac{1}{2}\pi kha^4$

46. $I_z = \iiint_E (x^2+y^2)\rho(x,y,z)\,dV = \iint_{x^2+y^2\le h^2}\left[\int_{\sqrt{x^2+y^2}}^h k(x^2+y^2)\,dz\right] dA$

$= \iint_{x^2+y^2\le h^2} k(x^2+y^2)\left(h-\sqrt{x^2+y^2}\right) dA = k\int_0^{2\pi}\int_0^h r^2(h-r)\,r\,dr\,d\theta$

$= k\int_0^{2\pi} d\theta\int_0^h \left(r^3h - r^4\right) dr = k(2\pi)\left[\frac{1}{4}r^4h - \frac{1}{5}r^5\right]_0^h = 2\pi k\left(\frac{1}{4}h^5 - \frac{1}{5}h^5\right) = \frac{1}{10}\pi kh^5$

47. (a) $m = \int_{-1}^1\int_{x^2}^1\int_0^{1-y}\sqrt{x^2+y^2}\,dz\,dy\,dx$

(b) $(\overline{x},\overline{y},\overline{z})$ where $\overline{x} = \frac{1}{m}\int_{-1}^1\int_{x^2}^1\int_0^{1-y} x\sqrt{x^2+y^2}\,dz\,dy\,dx$, $\overline{y} = \frac{1}{m}\int_{-1}^1\int_{x^2}^1\int_0^{1-y} y\sqrt{x^2+y^2}\,dz\,dy\,dx$, and

$\overline{z} = \frac{1}{m}\int_{-1}^1\int_{x^2}^1\int_0^{1-y} z\sqrt{x^2+y^2}\,dz\,dy\,dx.$

(c) $I_z = \int_{-1}^1\int_{x^2}^1\int_0^{1-y}(x^2+y^2)\sqrt{x^2+y^2}\,dz\,dy\,dx = \int_{-1}^1\int_{x^2}^1\int_0^{1-y}(x^2+y^2)^{3/2}\,dz\,dy\,dx$

48. (a) $m = \int_{-1}^1\int_{-\sqrt{1-y^2}}^{\sqrt{1-y^2}}\int_0^{\sqrt{1-x^2-y^2}}\sqrt{x^2+y^2+z^2}\,dz\,dx\,dy$

(b) $(\overline{x},\overline{y},\overline{z})$ where $\overline{x} = m^{-1}\int_{-1}^1\int_{-\sqrt{1-y^2}}^{\sqrt{1-y^2}}\int_0^{\sqrt{1-x^2-y^2}} x\sqrt{x^2+y^2+z^2}\,dz\,dx\,dy$,

$\overline{y} = m^{-1}\int_{-1}^1\int_{-\sqrt{1-y^2}}^{\sqrt{1-y^2}}\int_0^{\sqrt{1-x^2-y^2}} y\sqrt{x^2+y^2+z^2}\,dz\,dx\,dy$,

$\overline{z} = m^{-1}\int_{-1}^1\int_{-\sqrt{1-y^2}}^{\sqrt{1-y^2}}\int_0^{\sqrt{1-x^2-y^2}} z\sqrt{x^2+y^2+z^2}\,dz\,dx\,dy$

(c) $I_z = \int_{-1}^1\int_{-\sqrt{1-y^2}}^{\sqrt{1-y^2}}\int_0^{\sqrt{1-x^2-y^2}}(x^2+y^2)(1+x+y+z)\,dz\,dx\,dy$

49. (a) $m = \int_0^1\int_0^{\sqrt{1-x^2}}\int_0^y (1+x+y+z)\,dz\,dy\,dx = \frac{3\pi}{32}+\frac{11}{24}$

$$= \left(\frac{28}{9\pi+44}, \frac{30\pi+128}{45\pi+220}, \frac{45\pi+208}{135\pi+660}\right)$$

(c) $$I_z = \int_0^1\int_0^{\sqrt{1-x^2}}\int_0^y (x^2+y^2)(1+x+y+z)\,dz\,dy\,dx = \frac{68+15\pi}{240}$$

50. (a) $m = \int_0^1\int_{3x}^3\int_0^{\sqrt{9-y^2}}(x^2+y^2)\,dz\,dy\,dx = \frac{56}{5} = 11.2$

(b) $(\overline{x}, \overline{y}, \overline{z})$ where $\overline{x} = m^{-1} \int_0^1 \int_{3x}^3 \int_0^{\sqrt{9-y^2}} x(x^2+y^2)\,dz\,dy\,dx \approx 0.375$,

$\overline{y} = m^{-1} \int_0^1 \int_{3x}^3 \int_0^{\sqrt{9-y^2}} y(x^2+y^2)\,dz\,dy\,dx = \frac{45\pi}{64} \approx 2.209$,

$\overline{z} = m^{-1} \int_0^1 \int_{3x}^3 \int_0^{\sqrt{9-y^2}} z(x^2+y^2)\,dz\,dy\,dx = \frac{15}{16} = 0.9375$.

(c) $I_z = \int_0^1 \int_{3x}^3 \int_0^{\sqrt{9-y^2}} (x^2+y^2)^2\,dz\,dy\,dx = \frac{10{,}464}{175} \approx 59.79$

51. (a) $f(x,y,z)$ is a joint density function, so we know $\iiint_{\mathbb{R}^3} f(x,y,z)\,dV = 1$. Here we have

$$\begin{aligned}\iiint_{\mathbb{R}^3} f(x,y,z)\,dV &= \int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty} f(x,y,z)\,dz\,dy\,dx = \int_0^2\int_0^2\int_0^2 Cxyz\,dz\,dy\,dx\\ &= C\int_0^2 x\,dx \int_0^2 y\,dy \int_0^2 z\,dz = C\left[\tfrac12 x^2\right]_0^2 \left[\tfrac12 y^2\right]_0^2 \left[\tfrac12 z^2\right]_0^2 = 8C\end{aligned}$$

Then we must have $8C = 1 \quad\Rightarrow\quad C = \frac18$.

(b)
$$\begin{aligned}P(X \le 1, Y \le 1, Z \le 1) &= \int_{-\infty}^1\int_{-\infty}^1\int_{-\infty}^1 f(x,y,z)\,dz\,dy\,dx = \int_0^1\int_0^1\int_0^1 \tfrac18 xyz\,dz\,dy\,dx\\ &= \tfrac18 \int_0^1 x\,dx \int_0^1 y\,dy \int_0^1 z\,dz = \tfrac18 \left[\tfrac12 x^2\right]_0^1 \left[\tfrac12 y^2\right]_0^1 \left[\tfrac12 z^2\right]_0^1 = \tfrac18\left(\tfrac12\right)^3 = \tfrac{1}{64}\end{aligned}$$

(c) $P(X+Y+Z \le 1) = P((X,Y,Z) \in E)$ where E is the solid region in the first octant bounded by the coordinate planes and the plane $x+y+z=1$. The plane $x+y+z=1$ meets the xy-plane in the line $x+y=1$, so we have

$$\begin{aligned}P(X+Y+Z \le 1) &= \iiint_E f(x,y,z)\,dV = \int_0^1\int_0^{1-x}\int_0^{1-x-y} \tfrac18 xyz\,dz\,dy\,dx\\ &= \tfrac18\int_0^1\int_0^{1-x} xy\left[\tfrac12 z^2\right]_{z=0}^{z=1-x-y} dy\,dx = \tfrac{1}{16}\int_0^1\int_0^{1-x} xy(1-x-y)^2\,dy\,dx\\ &= \tfrac{1}{16}\int_0^1\int_0^{1-x}\left[(x^3-2x^2+x)y + (2x^2-2x)y^2 + xy^3\right] dy\,dx\\ &= \tfrac{1}{16}\int_0^1 \left[(x^3-2x^2+x)\tfrac12 y^2 + (2x^2-2x)\tfrac13 y^3 + x\left(\tfrac14 y^4\right)\right]_{y=0}^{y=1-x} dx\\ &= \tfrac{1}{192}\int_0^1 (x - 4x^2 + 6x^3 - 4x^4 + x^5)\,dx = \tfrac{1}{192}\left(\tfrac{1}{30}\right) = \tfrac{1}{5760}\end{aligned}$$

52. (a) $f(x,y,z)$ is a joint density function, so we know $\iiint_{\mathbb{R}^3} f(x,y,z)\,dV = 1$. Here we have

$$\begin{aligned}\iiint_{\mathbb{R}^3} f(x,y,z)\,dV &= \int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty} f(x,y,z)\,dz\,dy\,dx = \int_0^{\infty}\int_0^{\infty}\int_0^{\infty} Ce^{-(0.5x+0.2y+0.1z)}\,dz\,dy\,dx\\ &= C\int_0^{\infty} e^{-0.5x}\,dx \int_0^{\infty} e^{-0.2y}\,dy \int_0^{\infty} e^{-0.1z}\,dz\\ &= C\lim_{t\to\infty}\int_0^t e^{-0.5x}\,dx \lim_{t\to\infty}\int_0^t e^{-0.2y}\,dy \lim_{t\to\infty}\int_0^t e^{-0.1z}\,dz\\ &= C\lim_{t\to\infty}\left[-2e^{-0.5x}\right]_0^t \lim_{t\to\infty}\left[-5e^{-0.2y}\right]_0^t \lim_{t\to\infty}\left[-10e^{-0.1z}\right]_0^t\\ &= C\lim_{t\to\infty}\left[-2(e^{-0.5t}-1)\right] \lim_{t\to\infty}\left[-5(e^{-0.2t}-1)\right] \lim_{t\to\infty}\left[-10(e^{-0.1t}-1)\right]\\ &= C\cdot(-2)(0-1)\cdot(-5)(0-1)\cdot(-10)(0-1) = 100C\end{aligned}$$

So we must have $100C = 1 \quad\Rightarrow\quad C = \frac{1}{100}$.

(b) We have no restriction on Z, so

$$\begin{aligned}P(X \le 1, Y \le 1) &= \int_{-\infty}^1\int_{-\infty}^1\int_{-\infty}^{\infty} f(x,y,z)\,dz\,dy\,dx = \int_0^1\int_0^1\int_0^{\infty} \tfrac{1}{100} e^{-(0.5x+0.2y+0.1z)}\,dz\,dy\,dx\\ &= \tfrac{1}{100}\int_0^1 e^{-0.5x}\,dx \int_0^1 e^{-0.2y}\,dy \int_0^{\infty} e^{-0.1z}\,dz\\ &= \tfrac{1}{100}\left[-2e^{-0.5x}\right]_0^1 \left[-5e^{-0.2y}\right]_0^1 \lim_{t\to\infty}\left[-10e^{-0.1z}\right]_0^t \qquad \text{[by part (a)]}\\ &= \tfrac{1}{100}(2-2e^{-0.5})(5-5e^{-0.2})(10) = (1-e^{-0.5})(1-e^{-0.2}) \approx 0.07132\end{aligned}$$

(c) $P(X \leq 1, Y \leq 1, Z \leq 1) = \int_{-\infty}^{1}\int_{-\infty}^{1}\int_{-\infty}^{1} f(x,y,z)\,dz\,dy\,dx = \int_0^1\int_0^1\int_0^1 \frac{1}{100}e^{-(0.5x+0.2y+0.1z)}\,dz\,dy\,dx$

$$= \tfrac{1}{100}\int_0^1 e^{-0.5x}\,dx \int_0^1 e^{-0.2y}\,dy \int_0^1 e^{-0.1z}\,dz$$

$$= \tfrac{1}{100}\left[-2e^{-0.5x}\right]_0^1\left[-5e^{-0.2y}\right]_0^1\left[-10e^{-0.1z}\right]_0^1$$

$$= (1-e^{-0.5})(1-e^{-0.2})(1-e^{-0.1}) \approx 0.006787$$

53. $V(E) = L^3 \quad\Rightarrow\quad f_{\text{ave}} = \dfrac{1}{L^3}\displaystyle\int_0^L\int_0^L\int_0^L xyz\,dx\,dy\,dz = \dfrac{1}{L^3}\int_0^L x\,dx\int_0^L y\,dy\int_0^L z\,dz$

$$= \frac{1}{L^3}\left[\frac{x^2}{2}\right]_0^L\left[\frac{y^2}{2}\right]_0^L\left[\frac{z^2}{2}\right]_0^L = \frac{1}{L^3}\frac{L^2}{2}\frac{L^2}{2}\frac{L^2}{2} = \frac{L^3}{8}$$

54. The height of each point is given by its z-coordinate, so the average height of the points in $E = \left\{(x,y,z) \mid x^2+y^2+z^2 \leq 1,\ z \geq 0\right\}$ is

$$\frac{1}{V(E)}\iiint_E z\,dV$$

Here $V(E) = \frac{1}{2}\cdot\frac{4}{3}\pi(1)^3 = \frac{2}{3}\pi$ [half the volume of a sphere], so

$$\tfrac{1}{V(E)}\iiint_E z\,dV = \tfrac{1}{2\pi/3}\int_{-1}^{1}\int_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}}\int_0^{\sqrt{1-x^2-y^2}} z\,dz\,dy\,dx = \tfrac{3}{2\pi}\int_{-1}^{1}\int_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}}\left[\tfrac{1}{2}z^2\right]_{z=0}^{z=\sqrt{1-x^2-y^2}}\,dy\,dx$$

$$= \tfrac{3}{2\pi}\cdot\tfrac{1}{2}\int_{-1}^{1}\int_{-\sqrt{1-x^2}}^{\sqrt{1-x^2}}(1-x^2-y^2)\,dy\,dx = \tfrac{3}{4\pi}\int_0^{2\pi}\int_0^1(1-r^2)\,r\,dr\,d\theta$$

$$= \tfrac{3}{4\pi}\int_0^{2\pi}d\theta\int_0^1(r-r^3)\,dr = \tfrac{3}{4\pi}(2\pi)\left[\tfrac{1}{2}r^2-\tfrac{1}{4}r^4\right]_0^1 = \tfrac{3}{2}\left(\tfrac{1}{4}\right) = \tfrac{3}{8}$$

55. (a) The triple integral will attain its maximum when the integrand $1-x^2-2y^2-3z^2$ is positive in the region E and negative everywhere else. For if E contains some region F where the integrand is negative, the integral could be increased by excluding F from E, and if E fails to contain some part G of the region where the integrand is positive, the integral could be increased by including G in E. So we require that $x^2+2y^2+3z^2 \leq 1$. This describes the region bounded by the ellipsoid $x^2+2y^2+3z^2 = 1$.

(b) The maximum value of $\iiint_E(1-x^2-2y^2-3z^2)\,dV$ occurs when E is the solid region bounded by the ellipsoid $x^2+2y^2+3z^2=1$. The projection of E on the xy-plane is the planar region bounded by the ellipse $x^2+2y^2=1$, so

$$E=\left\{(x,y,z) \mid -1 \leq x \leq 1, -\sqrt{\tfrac{1}{2}(1-x^2)} \leq y \leq \sqrt{\tfrac{1}{2}(1-x^2)}, -\sqrt{\tfrac{1}{3}(1-x^2-2y^2)} \leq z \leq \sqrt{\tfrac{1}{3}(1-x^2-2y^2)}\right\}$$

and

$$\iiint_E(1-x^2-2y^2-3z^2)\,dV = \int_{-1}^{1}\int_{-\sqrt{\frac{1}{2}(1-x^2)}}^{\sqrt{\frac{1}{2}(1-x^2)}}\int_{-\sqrt{\frac{1}{3}(1-x^2-2y^2)}}^{\sqrt{\frac{1}{3}(1-x^2-2y^2)}}(1-x^2-2y^2-3z^2)\,dz\,dy\,dx = \frac{4\sqrt{6}}{45}\pi$$

using a CAS.

DISCOVERY PROJECT Volumes of Hyperspheres

In this project we use V_n to denote the n-dimensional volume of an n-dimensional hypersphere.

1. The interior of the circle is the set of points $\left\{(x,y) \mid -r \le y \le r,\ -\sqrt{r^2-y^2} \le x \le \sqrt{r^2-y^2}\right\}$. So, substituting $y = r\sin\theta$ and then using Formula 64 to evaluate the integral, we get

$$V_2 = \int_{-r}^{r}\int_{-\sqrt{r^2-y^2}}^{\sqrt{r^2-y^2}} dx\,dy = \int_{-r}^{r} 2\sqrt{r^2-y^2}\,dy = \int_{-\pi/2}^{\pi/2} 2r\sqrt{1-\sin^2\theta}\,(r\cos\theta\,d\theta)$$

$$= 2r^2\int_{-\pi/2}^{\pi/2}\cos^2\theta\,d\theta = 2r^2\left[\tfrac{1}{2}\theta + \tfrac{1}{4}\sin 2\theta\right]_{-\pi/2}^{\pi/2} = 2r^2\left(\tfrac{\pi}{2}\right) = \pi r^2$$

2. The region of integration is $\left\{(x,y,z) \mid -r \le z \le r, -\sqrt{r^2-z^2} \le y \le \sqrt{r^2-z^2}, -\sqrt{r^2-z^2-y^2} \le x \le \sqrt{r^2-z^2-y^2}\right\}$. Substituting $y = \sqrt{r^2-z^2}\sin\theta$ and using Formula 64 to integrate $\cos^2\theta$, we get

$$V_3 = \int_{-r}^{r}\int_{-\sqrt{r^2-z^2}}^{\sqrt{r^2-z^2}}\int_{-\sqrt{r^2-z^2-y^2}}^{\sqrt{r^2-z^2-y^2}} dx\,dy\,dz = \int_{-r}^{r}\int_{-\sqrt{r^2-z^2}}^{\sqrt{r^2-z^2}} 2\sqrt{r^2-z^2-y^2}\,dy\,dz$$

$$= \int_{-r}^{r}\int_{-\pi/2}^{\pi/2} 2\sqrt{r^2-z^2}\sqrt{1-\sin^2\theta}\left(\sqrt{r^2-z^2}\cos\theta\,d\theta\right)dz$$

$$= 2\left[\int_{-r}^{r}(r^2-z^2)\,dz\right]\left[\int_{-\pi/2}^{\pi/2}\cos^2\theta\,d\theta\right] = 2\left(\frac{4r^3}{3}\right)\left(\frac{\pi}{2}\right) = \frac{4\pi r^3}{3}$$

3. Here we substitute $y = \sqrt{r^2-w^2-z^2}\sin\theta$ and, later, $w = r\sin\phi$. Because $\int_{-\pi/2}^{\pi/2}\cos^p\theta\,d\theta$ seems to occur frequently in these calculations, it is useful to find a general formula for that integral. From Exercises 7.1.49-50, we have

$$\int_0^{\pi/2}\sin^{2k}x\,dx = \frac{1\cdot 3\cdot 5\cdot\cdots\cdot(2k-1)}{2\cdot 4\cdot 6\cdot\cdots\cdot 2k}\frac{\pi}{2} \qquad \text{and} \qquad \int_0^{\pi/2}\sin^{2k+1}x\,dx = \frac{2\cdot 4\cdot 6\cdot\cdots\cdot 2k}{1\cdot 3\cdot 5\cdot\cdots\cdot(2k+1)}$$

and from the symmetry of the sine and cosine functions, we can conclude that

$$\int_{-\pi/2}^{\pi/2}\cos^{2k}x\,dx = 2\int_0^{\pi/2}\sin^{2k}x\,dx = \frac{1\cdot 3\cdot 5\cdot\cdots\cdot(2k-1)\pi}{2\cdot 4\cdot 6\cdot\cdots\cdot 2k} \tag{1}$$

$$\int_{-\pi/2}^{\pi/2}\cos^{2k+1}x\,dx = 2\int_0^{\pi/2}\sin^{2k+1}x\,dx = \frac{2\cdot 2\cdot 4\cdot 6\cdot\cdots\cdot 2k}{1\cdot 3\cdot 5\cdot\cdots\cdot(2k+1)} \tag{2}$$

Thus

$$V_4 = \int_{-r}^{r}\int_{-\sqrt{r^2-w^2}}^{\sqrt{r^2-w^2}}\int_{-\sqrt{r^2-w^2-z^2}}^{\sqrt{r^2-w^2-z^2}}\int_{-\sqrt{r^2-w^2-z^2-y^2}}^{\sqrt{r^2-w^2-z^2-y^2}} dx\,dy\,dz\,dw$$

$$= 2\int_{-r}^{r}\int_{-\sqrt{r^2-w^2}}^{\sqrt{r^2-w^2}}\int_{-\sqrt{r^2-w^2-z^2}}^{\sqrt{r^2-w^2-z^2}}\sqrt{r^2-w^2-z^2-y^2}\,dy\,dz\,dw$$

$$= 2\int_{-r}^{r}\int_{-\sqrt{r^2-w^2}}^{\sqrt{r^2-w^2}}\int_{-\pi/2}^{\pi/2}(r^2-w^2-z^2)\cos^2\theta\,d\theta\,dz\,dw$$

$$= 2\left[\int_{-r}^{r}\int_{-\sqrt{r^2-w^2}}^{\sqrt{r^2-w^2}}(r^2-w^2-z^2)\,dz\,dw\right]\left[\int_{-\pi/2}^{\pi/2}\cos^2\theta\,d\theta\right]$$

$$= 2\left(\tfrac{\pi}{2}\right)\left[\int_{-r}^{r}\tfrac{4}{3}(r^2-w^2)^{3/2}\,dw\right] = \pi\left(\tfrac{4}{3}\right)\int_{-\pi/2}^{\pi/2} r^4\cos^4\phi\,d\phi = \frac{4\pi}{3}r^4\cdot\frac{1\cdot 3\cdot\pi}{2\cdot 4} = \frac{\pi^2 r^4}{2}$$

4. By using the substitutions $x_i = \sqrt{r^2 - x_n^2 - x_{n-1}^2 - \cdots - x_{i+1}^2}\cos\theta_i$ and then applying Formulas 1 and 2 from Problem 3, we can write

$$V_n = \int_{-r}^{r}\int_{-\sqrt{r^2-x_n^2}}^{\sqrt{r^2-x_n^2}}\cdots\int_{-\sqrt{r^2-x_n^2-x_{n-1}^2-\cdots-x_3^2}}^{\sqrt{r^2-x_n^2-x_{n-1}^2-\cdots-x_3^2}}\int_{-\sqrt{r^2-x_n^2-x_{n-1}^2-\cdots-x_3^2-x_2^2}}^{\sqrt{r^2-x_n^2-x_{n-1}^2-\cdots-x_3^2-x_2^2}} dx_1\,dx_2\cdots dx_{n-1}\,dx_n$$

$$= 2\left[\int_{-\pi/2}^{\pi/2}\cos^2\theta_2\,d\theta_2\right]\left[\int_{-\pi/2}^{\pi/2}\cos^3\theta_3\,d\theta_3\right]\cdots\left[\int_{-\pi/2}^{\pi/2}\cos^{n-1}\theta_{n-1}\,d\theta_{n-1}\right]\left[\int_{-\pi/2}^{\pi/2}\cos^{n}\theta_{n}\,d\theta_{n}\right]r^n$$

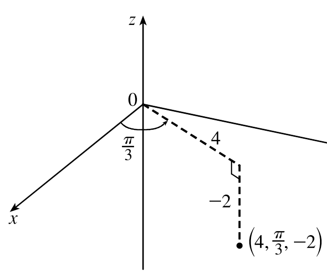
$$= \begin{cases} \left[2\cdot\dfrac{\pi}{2}\right]\left[\dfrac{2\cdot 2}{1\cdot 3}\cdot\dfrac{1\cdot 3\pi}{2\cdot 4}\right]\left[\dfrac{2\cdot 2\cdot 4}{1\cdot 3\cdot 5}\cdot\dfrac{1\cdot 3\cdot 5\pi}{2\cdot 4\cdot 6}\right]\cdots\left[\dfrac{2\cdot\cdots\cdot(n-2)}{1\cdot\cdots\cdot(n-1)}\cdot\dfrac{1\cdot\cdots\cdot(n-1)\,\pi}{2\cdot\cdots\cdot n}\right]r^n & n \text{ even} \\ 2\left[\dfrac{\pi}{2}\cdot\dfrac{2\cdot 2}{1\cdot 3}\right]\left[\dfrac{1\cdot 3\pi}{2\cdot 4}\cdot\dfrac{2\cdot 2\cdot 4}{1\cdot 3\cdot 5}\right]\cdots\left[\dfrac{1\cdot\cdots\cdot(n-2)\,\pi}{2\cdot\cdots\cdot(n-1)}\cdot\dfrac{2\cdot\cdots\cdot(n-1)}{1\cdot\cdots\cdot n}\right]r^n & n \text{ odd} \end{cases}$$

By canceling within each set of brackets, we find that

$$V_n = \begin{cases} \dfrac{2\pi}{2}\cdot\dfrac{2\pi}{4}\cdot\dfrac{2\pi}{6}\cdot\cdots\cdot\dfrac{2\pi}{n}r^n = \dfrac{(2\pi)^{n/2}}{2\cdot 4\cdot 6\cdot\cdots\cdot n}r^n = \dfrac{\pi^{n/2}}{\left(\frac{1}{2}n\right)!}r^n & n \text{ even} \\ 2\cdot\dfrac{2\pi}{3}\cdot\dfrac{2\pi}{5}\cdot\dfrac{2\pi}{7}\cdot\cdots\cdot\dfrac{2\pi}{n}r^n = \dfrac{2(2\pi)^{(n-1)/2}}{3\cdot 5\cdot 7\cdot\cdots\cdot n}r^n = \dfrac{2^n\left[\frac{1}{2}(n-1)\right]!\,\pi^{(n-1)/2}}{n!}r^n & n \text{ odd} \end{cases}$$

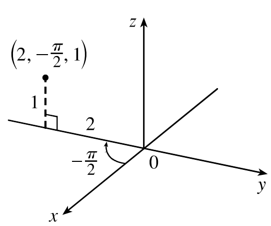
15.7 Triple Integrals in Cylindrical Coordinates

1. (a)



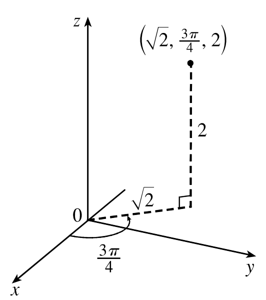
From Equations 1, $x = r\cos\theta = 4\cos\dfrac{\pi}{3} = 4\cdot\frac{1}{2} = 2$, $y = r\sin\theta = 4\sin\dfrac{\pi}{3} = 4\cdot\frac{\sqrt{3}}{2} = 2\sqrt{3}$, $z = -2$, so the point is $\left(2, 2\sqrt{3}, -2\right)$ in rectangular coordinates.

(b)



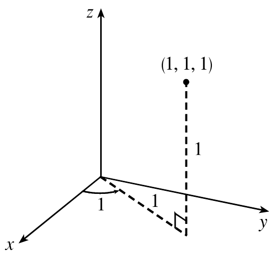
$x = 2\cos\left(-\frac{\pi}{2}\right) = 0$, $y = 2\sin\left(-\frac{\pi}{2}\right) = -2$, and $z = 1$, so the point is $(0, -2, 1)$ in rectangular coordinates.

2. (a)



$x = \sqrt{2}\cos\dfrac{3\pi}{4} = \sqrt{2}\left(-\frac{\sqrt{2}}{2}\right) = -1$, $y = \sqrt{2}\sin\dfrac{3\pi}{4} = \sqrt{2}\left(\frac{\sqrt{2}}{2}\right) = 1$, and $z = 2$, so the point is $(-1, 1, 2)$ in rectangular coordinates.

(b)



$x = 1\cos 1 = \cos 1$, $y = 1\sin 1 = \sin 1$, and $z = 1$, so the point is $(\cos 1, \sin 1, 1) \approx (0.54, 0.84, 1)$ in rectangular coordinates.

3. (a) From Equations 2 we have $r^2 = (-1)^2 + 1^2 = 2$ so $r = \sqrt{2}$; $\tan\theta = \frac{1}{-1} = -1$ and the point $(-1, 1)$ is in the second quadrant of the xy-plane, so $\theta = \frac{3\pi}{4} + 2n\pi$; $z = 1$. Thus, one set of cylindrical coordinates is $\left(\sqrt{2}, \frac{3\pi}{4}, 1\right)$.

(b) $r^2 = (-2)^2 + \left(2\sqrt{3}\right)^2 = 16$ so $r = 4$; $\tan\theta = \frac{2\sqrt{3}}{-2} = -\sqrt{3}$ and the point $\left(-2, 2\sqrt{3}\right)$ is in the second quadrant of the xy-plane, so $\theta = \frac{2\pi}{3} + 2n\pi$; $z = 3$. Thus, one set of cylindrical coordinates is $\left(4, \frac{2\pi}{3}, 3\right)$.

4. (a) $r^2 = \left(-\sqrt{2}\right)^2 + \left(\sqrt{2}\right)^2 = 4$ so $r = 2$; $\tan\theta = \frac{\sqrt{2}}{-\sqrt{2}} = -1$ and the point $\left(-\sqrt{2}, \sqrt{2}\right)$ is in the second quadrant of the xy-plane, so $\theta = \frac{3\pi}{4} + 2n\pi$; $z = 1$. Thus, one set of cylindrical coordinates is $\left(2, \frac{3\pi}{4}, 1\right)$.

(b) $r^2 = 2^2 + 2^2 = 8$ so $r = \sqrt{8} = 2\sqrt{2}$; $\tan\theta = \frac{2}{2} = 1$ and the point $(2, 2)$ is in the first quadrant of the xy-plane, so $\theta = \frac{\pi}{4} + 2n\pi$; $z = 2$. Thus, one set of cylindrical coordinates is $\left(2\sqrt{2}, \frac{\pi}{4}, 2\right)$.

5. Since $r = 2$, the distance from any point to the z-axis is 2. Because θ and z may vary, the surface is a circular cylinder with radius 2 and axis the z-axis. (See Figure 4.)
Also, $x^2 + y^2 = r^2 = 4$, which we recognize as an equation of this cylinder.

6. Since $\theta = \frac{\pi}{6}$ but r and z may vary, the surface is a vertical plane including the z-axis and intersecting the xy-plane in the line $y = \frac{1}{\sqrt{3}}x$. (Here we are assuming that r can be negative; if we restrict $r \geq 0$, then we get a half-plane.)

7. Since $r^2 + z^2 = 4$ and $r^2 = x^2 + y^2$, we have $x^2 + y^2 + z^2 = 4$, a sphere centered at the origin with radius 2.

8. $r = 2\sin\theta \quad\Rightarrow\quad r^2 = 2r\sin\theta \quad\Rightarrow\quad x^2 + y^2 = 2y \quad\Leftrightarrow\quad x^2 + (y-1)^2 = 1$. z doesn't appear in the equation, so any horizontal trace in $z = k$ is the circle $x^2 + (y-1)^2 = 1$, $z = k$, which has center $(0, 1, k)$ and radius 1. Thus the surface is a circular cylinder with radius 1 and axis the vertical line $x = 0$, $y = 1$.

9. (a) Substituting $x^2 + y^2 = r^2$ and $x = r\cos\theta$, the equation $x^2 - x + y^2 + z^2 = 1$ becomes $r^2 - r\cos\theta + z^2 = 1$ or $z^2 = 1 + r\cos\theta - r^2$.

(b) Substituting $x = r\cos\theta$ and $y = r\sin\theta$, the equation $z = x^2 - y^2$ becomes
$z = (r\cos\theta)^2 - (r\sin\theta)^2 = r^2(\cos^2\theta - \sin^2\theta)$ or $z = r^2\cos 2\theta$.

10. (a) The equation $2x^2 + 2y^2 - z^2 = 4$ can be written as $2(x^2 + y^2) - z^2 = 4$ which becomes $2r^2 - z^2 = 4$ or $z^2 = 2r^2 - 4$ in cylindrical coordinates.

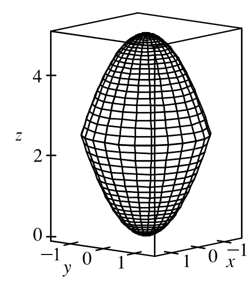
(b) Substituting $x = r\cos\theta$ and $y = r\sin\theta$, the equation $2x - y + z = 1$ becomes $2r\cos\theta - r\sin\theta + z = 1$ or $z = 1 + r(\sin\theta - 2\cos\theta)$.

11. 
$z = r^2 \quad \Leftrightarrow \quad z = x^2 + y^2$, a circular paraboloid opening upward with vertex the origin, and $z = 8 - r^2 \quad \Leftrightarrow \quad z = 8 - (x^2 + y^2)$, a circular paraboloid opening downward with vertex $(0, 0, 8)$. The paraboloids intersect when $r^2 = 8 - r^2 \quad \Leftrightarrow \quad r^2 = 4$. Thus $r^2 \leq z \leq 8 - r^2$ describes the solid above the paraboloid $z = x^2 + y^2$ and below the paraboloid $z = 8 - x^2 - y^2$ for $x^2 + y^2 \leq 4$.

12. 
$z = r = \sqrt{x^2 + y^2}$ is a cone that opens upward. Thus $r \leq z \leq 2$ is the region above this cone and beneath the horizontal plane $z = 2$. $0 \leq \theta \leq \frac{\pi}{2}$ restricts the solid to that part of this region in the first octant.

13. We can position the cylindrical shell vertically so that its axis coincides with the z-axis and its base lies in the xy-plane. If we use centimeters as the unit of measurement, then cylindrical coordinates conveniently describe the shell as $6 \leq r \leq 7$, $0 \leq \theta \leq 2\pi$, $0 \leq z \leq 20$.

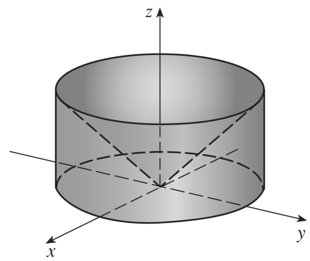
14. In cylindrical coordinates, the equations are $z = r^2$ and $z = 5 - r^2$. The curve of intersection is $r^2 = 5 - r^2$ or $r = \sqrt{5/2}$. So we graph the surfaces in cylindrical coordinates, with $0 \leq r \leq \sqrt{5/2}$. In Maple, we can use the `coords=cylindrical` option in a regular `plot3d` command. In Mathematica, we can use `RevolutionPlot3D` or `ParametricPlot3D`.



15. 
The region of integration is given in cylindrical coordinates by $E = \{(r, \theta, z) \mid -\pi/2 \leq \theta \leq \pi/2, 0 \leq r \leq 2, 0 \leq z \leq r^2\}$. This represents the solid region above quadrants I and IV of the xy-plane enclosed by the circular cylinder $r = 2$, bounded above by the circular paraboloid $z = r^2$ ($z = x^2 + y^2$), and bounded below by the xy-plane ($z = 0$).

$$\int_{-\pi/2}^{\pi/2} \int_0^2 \int_0^{r^2} r\,dz\,dr\,d\theta = \int_{-\pi/2}^{\pi/2} \int_0^2 \left[rz\right]_{z=0}^{z=r^2}\,dr\,d\theta = \int_{-\pi/2}^{\pi/2} \int_0^2 r^3\,dr\,d\theta$$
$$= \int_{-\pi/2}^{\pi/2} d\theta \int_0^2 r^3\,dr = \left[\,\theta\,\right]_{-\pi/2}^{\pi/2} \left[\tfrac{1}{4}r^4\right]_0^2$$
$$= \pi\,(4 - 0) = 4\pi$$

16.



The region of integration is given in cylindrical coordinates by $E = \{(r, \theta, z) \mid 0 \le \theta \le 2\pi, 0 \le r \le 2, 0 \le z \le r\}$. This represents the solid region enclosed by the circular cylinder $r = 2$, bounded above by the cone $z = r$, and bounded below by the xy-plane.

$$\int_0^2 \int_0^{2\pi} \int_0^r r\,dz\,d\theta\,dr = \int_0^2 \int_0^{2\pi} \left[rz\right]_{z=0}^{z=r} d\theta\,dr = \int_0^2 \int_0^{2\pi} r^2\,d\theta\,dr$$
$$= \int_0^2 r^2\,dr \int_0^{2\pi} d\theta = \left[\tfrac{1}{3}r^3\right]_0^2 \left[\,\theta\,\right]_0^{2\pi} = \tfrac{8}{3} \cdot 2\pi = \tfrac{16}{3}\pi$$

17. In cylindrical coordinates, E is given by $\{(r, \theta, z) \mid 0 \le \theta \le 2\pi, 0 \le r \le 4, -5 \le z \le 4\}$. So

$$\iiint_E \sqrt{x^2 + y^2}\,dV = \int_0^{2\pi} \int_0^4 \int_{-5}^4 \sqrt{r^2}\,r\,dz\,dr\,d\theta = \int_0^{2\pi} d\theta \int_0^4 r^2\,dr \int_{-5}^4 dz$$
$$= \left[\,\theta\,\right]_0^{2\pi} \left[\tfrac{1}{3}r^3\right]_0^4 \left[\,z\,\right]_{-5}^4 = (2\pi)\left(\tfrac{64}{3}\right)(9) = 384\pi$$

18. The paraboloid $z = x^2 + y^2 = r^2$ intersects the plane $z = 4$ in the circle $x^2 + y^2 = 4$ or $r^2 = 4 \;\Rightarrow\; r = 2$, so in cylindrical coordinates, E is given by $\left\{(r, \theta, z) \,\middle|\, 0 \le \theta \le 2\pi, 0 \le r \le 2, r^2 \le z \le 4\right\}$. Thus

$$\iiint_E z\,dV = \int_0^{2\pi} \int_0^2 \int_{r^2}^4 (z)\,r\,dz\,dr\,d\theta = \int_0^{2\pi} \int_0^2 \left[\tfrac{1}{2}rz^2\right]_{z=r^2}^{z=4} dr\,d\theta$$
$$= \int_0^{2\pi} \int_0^2 \left(8r - \tfrac{1}{2}r^5\right) dr\,d\theta = \int_0^{2\pi} d\theta \int_0^2 \left(8r - \tfrac{1}{2}r^5\right) dr = 2\pi \left[4r^2 - \tfrac{1}{12}r^6\right]_0^2$$
$$= 2\pi \left(16 - \tfrac{16}{3}\right) = \tfrac{64}{3}\pi$$

19. The paraboloid $z = 4 - x^2 - y^2 = 4 - r^2$ intersects the xy-plane in the circle $x^2 + y^2 = 4$ or $r^2 = 4 \;\Rightarrow\; r = 2$, so in cylindrical coordinates, E is given by $\left\{(r, \theta, z) \,\middle|\, 0 \le \theta \le \pi/2, 0 \le r \le 2, 0 \le z \le 4 - r^2\right\}$. Thus

$$\iiint_E (x + y + z)\,dV = \int_0^{\pi/2} \int_0^2 \int_0^{4-r^2} (r\cos\theta + r\sin\theta + z)\,r\,dz\,dr\,d\theta$$
$$= \int_0^{\pi/2} \int_0^2 \left[r^2(\cos\theta + \sin\theta)z + \tfrac{1}{2}rz^2\right]_{z=0}^{z=4-r^2} dr\,d\theta$$
$$= \int_0^{\pi/2} \int_0^2 \left[(4r^2 - r^4)(\cos\theta + \sin\theta) + \tfrac{1}{2}r(4 - r^2)^2\right] dr\,d\theta$$
$$= \int_0^{\pi/2} \left[\left(\tfrac{4}{3}r^3 - \tfrac{1}{5}r^5\right)(\cos\theta + \sin\theta) - \tfrac{1}{12}(4 - r^2)^3\right]_{r=0}^{r=2} d\theta$$
$$= \int_0^{\pi/2} \left[\tfrac{64}{15}(\cos\theta + \sin\theta) + \tfrac{16}{3}\right] d\theta = \left[\tfrac{64}{15}(\sin\theta - \cos\theta) + \tfrac{16}{3}\theta\right]_0^{\pi/2}$$
$$= \tfrac{64}{15}(1 - 0) + \tfrac{16}{3} \cdot \tfrac{\pi}{2} - \tfrac{64}{15}(0 - 1) - 0 = \tfrac{8}{3}\pi + \tfrac{128}{15}$$

20. In cylindrical coordinates E is bounded by the planes $z = 0$, $z = r\sin\theta + 4$ and the cylinders $r = 1$ and $r = 4$, so E is given by $\{(r, \theta, z) \mid 0 \le \theta \le 2\pi,\ 1 \le r \le 4,\ 0 \le z \le r\sin\theta + 4\}$. Thus

$$\iiint_E (x - y)\,dV = \int_0^{2\pi} \int_1^4 \int_0^{r\sin\theta+4} (r\cos\theta - r\sin\theta)\,r\,dz\,dr\,d\theta = \int_0^{2\pi} \int_1^4 (r^2\cos\theta - r^2\sin\theta)\left[\,z\,\right]_{z=0}^{z=r\sin\theta+4} dr\,d\theta$$
$$= \int_0^{2\pi} \int_1^4 (r^2\cos\theta - r^2\sin\theta)(r\sin\theta + 4)\,dr\,d\theta$$
$$= \int_0^{2\pi} \int_1^4 \left[r^3(\sin\theta\cos\theta - \sin^2\theta) + 4r^2(\cos\theta - \sin\theta)\right] dr\,d\theta$$
$$= \int_0^{2\pi} \left[\tfrac{1}{4}r^4(\sin\theta\cos\theta - \sin^2\theta) + \tfrac{4}{3}r^3(\cos\theta - \sin\theta)\right]_{r=1}^{r=4} d\theta$$
$$= \int_0^{2\pi} \left[\left(64 - \tfrac{1}{4}\right)(\sin\theta\cos\theta - \sin^2\theta) + \left(\tfrac{256}{3} - \tfrac{4}{3}\right)(\cos\theta - \sin\theta)\right] d\theta$$
$$= \int_0^{2\pi} \left[\tfrac{255}{4}(\sin\theta\cos\theta - \sin^2\theta) + 84(\cos\theta - \sin\theta)\right] d\theta$$
$$= \left[\tfrac{255}{4}\left(\tfrac{1}{2}\sin^2\theta - \left(\tfrac{1}{2}\theta - \tfrac{1}{4}\sin 2\theta\right)\right) + 84\,(\sin\theta + \cos\theta)\right]_0^{2\pi} = \tfrac{255}{4}(-\pi) + 84(1) - 0 - 84(1) = -\tfrac{255}{4}\pi$$

21. In cylindrical coordinates, E is bounded by the cylinder $r = 1$, the plane $z = 0$, and the cone $z = 2r$. So $E = \{(r, \theta, z) \mid 0 \le \theta \le 2\pi, 0 \le r \le 1, 0 \le z \le 2r\}$ and

$$\iiint_E x^2\,dV = \int_0^{2\pi}\int_0^1\int_0^{2r} r^2\cos^2\theta\,r\,dz\,dr\,d\theta = \int_0^{2\pi}\int_0^1 \left[r^3\cos^2\theta\,z\right]_{z=0}^{z=2r}\,dr\,d\theta = \int_0^{2\pi}\int_0^1 2r^4\cos^2\theta\,dr\,d\theta$$
$$= \int_0^{2\pi}\left[\tfrac{2}{5}r^5\cos^2\theta\right]_{r=0}^{r=1}\,d\theta = \tfrac{2}{5}\int_0^{2\pi}\cos^2\theta\,d\theta = \tfrac{2}{5}\int_0^{2\pi}\tfrac{1}{2}\left(1+\cos 2\theta\right)d\theta = \tfrac{1}{5}\left[\theta + \tfrac{1}{2}\sin 2\theta\right]_0^{2\pi} = \tfrac{2\pi}{5}$$

22. In cylindrical coordinates E is the solid region within the cylinder $r = 1$ bounded above and below by the sphere $r^2 + z^2 = 4$, so $E = \left\{(r, \theta, z) \mid 0 \le \theta \le 2\pi, 0 \le r \le 1, -\sqrt{4 - r^2} \le z \le \sqrt{4 - r^2}\right\}$. Thus the volume is

$$\iiint_E dV = \int_0^{2\pi}\int_0^1\int_{-\sqrt{4-r^2}}^{\sqrt{4-r^2}} r\,dz\,dr\,d\theta = \int_0^{2\pi}\int_0^1 2r\sqrt{4-r^2}\,dr\,d\theta$$
$$= \int_0^{2\pi}d\theta\int_0^1 2r\sqrt{4-r^2}\,dr = 2\pi\left[-\tfrac{2}{3}(4-r^2)^{3/2}\right]_0^1 = \tfrac{4}{3}\pi(8 - 3^{3/2})$$

23. In cylindrical coordinates, E is bounded below by the cone $z = r$ and above by the sphere $r^2 + z^2 = 2$ or $z = \sqrt{2 - r^2}$. The cone and the sphere intersect when $2r^2 = 2 \quad\Rightarrow\quad r = 1$, so $E = \left\{(r, \theta, z) \mid 0 \le \theta \le 2\pi, 0 \le r \le 1, r \le z \le \sqrt{2 - r^2}\right\}$ and the volume is

$$\iiint_E dV = \int_0^{2\pi}\int_0^1\int_r^{\sqrt{2-r^2}} r\,dz\,dr\,d\theta = \int_0^{2\pi}\int_0^1 \left[rz\right]_{z=r}^{z=\sqrt{2-r^2}}\,dr\,d\theta = \int_0^{2\pi}\int_0^1\left(r\sqrt{2-r^2} - r^2\right)dr\,d\theta$$
$$= \int_0^{2\pi}d\theta\int_0^1\left(r\sqrt{2-r^2} - r^2\right)dr = 2\pi\left[-\tfrac{1}{3}(2-r^2)^{3/2} - \tfrac{1}{3}r^3\right]_0^1$$
$$= 2\pi\left(-\tfrac{1}{3}\right)\left(1 + 1 - 2^{3/2}\right) = -\tfrac{2}{3}\pi\left(2 - 2\sqrt{2}\right) = \tfrac{4}{3}\pi\left(\sqrt{2} - 1\right)$$

24. In cylindrical coordinates, E is bounded below by the paraboloid $z = r^2$ and above by the sphere $r^2 + z^2 = 2$ or $z = \sqrt{2 - r^2}$. The paraboloid and the sphere intersect when $r^2 + r^4 = 2 \quad\Rightarrow\quad (r^2 + 2)(r^2 - 1) = 0 \quad\Rightarrow\quad r = 1$, so $E = \left\{(r, \theta, z) \mid 0 \le \theta \le 2\pi,\ 0 \le r \le 1,\ r^2 \le z \le \sqrt{2 - r^2}\right\}$ and the volume is

$$\iiint_E dV = \int_0^{2\pi}\int_0^1\int_{r^2}^{\sqrt{2-r^2}} r\,dz\,dr\,d\theta = \int_0^{2\pi}\int_0^1\left[rz\right]_{z=r^2}^{z=\sqrt{2-r^2}}\,dr\,d\theta = \int_0^{2\pi}\int_0^1\left(r\sqrt{2-r^2} - r^3\right)dr\,d\theta$$
$$= \int_0^{2\pi}d\theta\int_0^1\left(r\sqrt{2-r^2} - r^3\right)dr = 2\pi\left[-\tfrac{1}{3}(2-r^2)^{3/2} - \tfrac{1}{4}r^4\right]_0^1$$
$$= 2\pi(-\tfrac{1}{3} - \tfrac{1}{4} + \tfrac{1}{3}\cdot 2^{3/2} - 0) = 2\pi\left(-\tfrac{7}{12} + \tfrac{2}{3}\sqrt{2}\right) = \left(-\tfrac{7}{6} + \tfrac{4}{3}\sqrt{2}\right)\pi$$

25. (a) In cylindrical coordinates, E is bounded above by the paraboloid $z = 24 - r^2$ and below by the cone $z = 2\sqrt{r^2}$ or $z = 2r$ $(r \ge 0)$. The surfaces intersect when $24 - r^2 = 2r \quad\Rightarrow\quad r^2 + 2r - 24 = 0 \quad\Rightarrow\quad (r+6)(r-4) = 0 \quad\Rightarrow\quad r = 4$, so $E = \left\{(r, \theta, z) \mid 2r \le z \le 24 - r^2, 0 \le r \le 4, 0 \le \theta \le 2\pi\right\}$ and the volume is

$$\iiint_E dV = \int_0^{2\pi}\int_0^4\int_{2r}^{24-r^2} r\,dz\,dr\,d\theta = \int_0^{2\pi}\int_0^4 r\left(24 - r^2 - 2r\right)dr\,d\theta = \int_0^{2\pi}d\theta\int_0^4\left(24r - r^3 - 2r^2\right)dr$$
$$= 2\pi\left[12r^2 - \tfrac{1}{4}r^4 - \tfrac{2}{3}r^3\right]_0^4 = 2\pi\left(192 - 64 - \tfrac{128}{3}\right) = \tfrac{512}{3}\pi$$

(b) For constant density K, $m = KV = \frac{512}{3}\pi K$ from part (a). Since the region is homogeneous and symmetric, $M_{yz} = M_{xz} = 0$ and

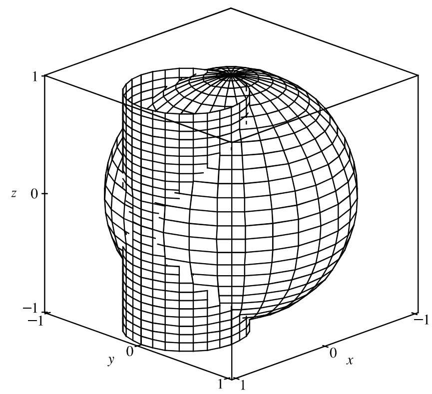
$$M_{xy} = \int_0^{2\pi}\int_0^4\int_{2r}^{24-r^2}(zK)\,r\,dz\,dr\,d\theta = K\int_0^{2\pi}\int_0^4 r\left[\tfrac{1}{2}z^2\right]_{z=2r}^{z=24-r^2}dr\,d\theta$$
$$= \tfrac{K}{2}\int_0^{2\pi}\int_0^4 r[(24-r^2)^2-4r^2]\,dr\,d\theta = \tfrac{K}{2}\int_0^{2\pi}d\theta\int_0^4(576r-52r^3+r^5)\,dr$$
$$= \tfrac{K}{2}(2\pi)\left[288r^2-13r^4+\tfrac{1}{6}r^6\right]_0^4 = \pi K\left(4608-3328+\tfrac{2048}{3}\right) = \tfrac{5888}{3}\pi K$$

Thus $(\overline{x},\overline{y},\overline{z}) = \left(\dfrac{M_{yz}}{m},\dfrac{M_{xz}}{m},\dfrac{M_{xy}}{m}\right) = \left(0,0,\frac{5888\pi K/3}{512\pi K/3}\right) = \left(0,0,\frac{23}{2}\right)$.

26. (a) $V = \int_{-\pi/2}^{\pi/2}\int_0^{a\cos\theta}\int_{-\sqrt{a^2-r^2}}^{\sqrt{a^2-r^2}} r\,dz\,dr\,d\theta$

$$= 4\int_0^{\pi/2}\int_0^{a\cos\theta}\int_0^{\sqrt{a^2-r^2}} r\,dz\,dr\,d\theta$$
$$= 4\int_0^{\pi/2}\int_0^{a\cos\theta} r\sqrt{a^2-r^2}\,dr\,d\theta$$
$$= -\tfrac{4}{3}\int_0^{\pi/2}\left[(a^2-r^2)^{3/2}\right]_{r=0}^{r=a\cos\theta}d\theta$$
$$= -\tfrac{4}{3}\int_0^{\pi/2}\left[(a^2-a^2\cos^2\theta)^{3/2}-a^3\right]d\theta$$
$$= -\tfrac{4}{3}\int_0^{\pi/2}\left[(a^2\sin^2\theta)^{3/2}-a^3\right]d\theta$$
$$= -\tfrac{4}{3}\int_0^{\pi/2}(a^3\sin^3\theta-a^3)\,d\theta$$
$$= -\frac{4a^3}{3}\int_0^{\pi/2}\left[\sin\theta\,(1-\cos^2\theta)-1\right]d\theta$$
$$= -\frac{4a^3}{3}\left[-\cos\theta+\tfrac{1}{3}\cos^3\theta-\theta\right]_0^{\pi/2} = -\frac{4a^3}{3}\left(-\tfrac{\pi}{2}+\tfrac{2}{3}\right) = \tfrac{2}{9}a^3(3\pi-4)$$

(b)



To plot the cylinder and the sphere on the same screen in Maple, we can use the sequence of commands

```
sphere:=plot3d(1,theta=0..2*Pi,phi=0..Pi,coords=spherical):
cylinder:=plot3d(cos(theta),theta=-Pi/2..Pi/2,z=-1..1,coords=cylindrical):
with(plots):
display3d({sphere,cylinder});
```

In Mathematica, we can use

```
sphere=SphericalPlot3D[1,{phi,0,Pi},{theta,0,2Pi}]
cylinder=ParametricPlot3D[{(Cos[theta])^2,Cos[theta]*Sin[theta],z},
                         {theta,-Pi/2,Pi/2},{z,-1,1}]
Show[sphere,cylinder]
```

27. The paraboloid $z = 4x^2+4y^2$ intersects the plane $z = a$ when $a = 4x^2+4y^2$ or $x^2+y^2 = \frac{1}{4}a$. So, in cylindrical coordinates, $E = \left\{(r,\theta,z)\mid 0\le r\le\frac{1}{2}\sqrt{a}, 0\le\theta\le 2\pi, 4r^2\le z\le a\right\}$. Thus

$$m = \int_0^{2\pi}\int_0^{\sqrt{a}/2}\int_{4r^2}^{a} Kr\,dz\,dr\,d\theta = K\int_0^{2\pi}\int_0^{\sqrt{a}/2}(ar-4r^3)\,dr\,d\theta$$
$$= K\int_0^{2\pi}\left[\tfrac{1}{2}ar^2-r^4\right]_{r=0}^{r=\sqrt{a}/2}d\theta = K\int_0^{2\pi}\tfrac{1}{16}a^2\,d\theta = \tfrac{1}{8}a^2\pi K$$

Since the region is homogeneous and symmetric, $M_{yz} = M_{xz} = 0$ and

$$M_{xy} = \int_0^{2\pi}\int_0^{\sqrt{a}/2}\int_{4r^2}^{a} Krz\,dz\,dr\,d\theta = K\int_0^{2\pi}\int_0^{\sqrt{a}/2}\left(\tfrac{1}{2}a^2 r - 8r^5\right)dr\,d\theta$$

$$= K\int_0^{2\pi}\left[\tfrac{1}{4}a^2r^2 - \tfrac{4}{3}r^6\right]_{r=0}^{r=\sqrt{a}/2} d\theta = K\int_0^{2\pi}\tfrac{1}{24}a^3\,d\theta = \tfrac{1}{12}a^3\pi K$$

Hence $(\overline{x}, \overline{y}, \overline{z}) = \left(0, 0, \frac{2}{3}a\right)$.

28. Since density is proportional to the distance from the z-axis, we can say $\rho(x,y,z) = K\sqrt{x^2+y^2}$. Then

$$m = 2\int_0^{2\pi}\int_0^a\int_0^{\sqrt{a^2-r^2}} Kr^2\,dz\,dr\,d\theta = 2K\int_0^{2\pi}\int_0^a r^2\sqrt{a^2-r^2}\,dr\,d\theta$$

$$= 2K\int_0^{2\pi}\left[\tfrac{1}{8}r(2r^2-a^2)\sqrt{a^2-r^2} + \tfrac{1}{8}a^4\sin^{-1}(r/a)\right]_{r=0}^{r=a} d\theta = 2K\int_0^{2\pi}\left[\left(\tfrac{1}{8}a^4\right)\left(\tfrac{\pi}{2}\right)\right]d\theta = \tfrac{1}{4}a^4\pi^2 K$$

29. The region of integration is the region above the cone $z = \sqrt{x^2+y^2}$, or $z = r$, and below the plane $z = 2$. Also, we have $-2 \le y \le 2$ with $-\sqrt{4-y^2} \le x \le \sqrt{4-y^2}$ which describes a circle of radius 2 in the xy-plane centered at $(0,0)$. Thus,

$$\int_{-2}^{2}\int_{-\sqrt{4-y^2}}^{\sqrt{4-y^2}}\int_{\sqrt{x^2+y^2}}^{2} xz\,dz\,dx\,dy = \int_0^{2\pi}\int_0^2\int_r^2 (r\cos\theta)\,z\,r\,dz\,dr\,d\theta = \int_0^{2\pi}\int_0^2\int_r^2 r^2(\cos\theta)\,z\,dz\,dr\,d\theta$$

$$= \int_0^{2\pi}\int_0^2 r^2(\cos\theta)\left[\tfrac{1}{2}z^2\right]_{z=r}^{z=2} dr\,d\theta = \tfrac{1}{2}\int_0^{2\pi}\int_0^2 r^2(\cos\theta)\left(4-r^2\right)dr\,d\theta$$

$$= \tfrac{1}{2}\int_0^{2\pi}\cos\theta\,d\theta\int_0^2\left(4r^2-r^4\right)dr = \tfrac{1}{2}\left[\sin\theta\right]_0^{2\pi}\left[\tfrac{4}{3}r^3 - \tfrac{1}{5}r^5\right]_0^2 = 0$$

30. The region of integration is the region above the plane $z = 0$ and below the paraboloid $z = 9 - x^2 - y^2$. Also, we have $-3 \le x \le 3$ with $0 \le y \le \sqrt{9-x^2}$ which describes the upper half of a circle of radius 3 in the xy-plane centered at $(0,0)$. Thus,

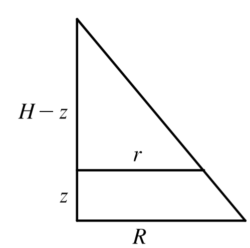
$$\int_{-3}^{3}\int_0^{\sqrt{9-x^2}}\int_0^{9-x^2-y^2}\sqrt{x^2+y^2}\,dz\,dy\,dx = \int_0^{\pi}\int_0^3\int_0^{9-r^2}\sqrt{r^2}\,r\,dz\,dr\,d\theta = \int_0^{\pi}\int_0^3\int_0^{9-r^2} r^2\,dz\,dr\,d\theta$$

$$= \int_0^{\pi}\int_0^3 r^2\left(9-r^2\right)dr\,d\theta = \int_0^{\pi}d\theta\int_0^3\left(9r^2-r^4\right)dr$$

$$= \left[\theta\right]_0^{\pi}\left[3r^3 - \tfrac{1}{5}r^5\right]_0^3 = \pi\left(81 - \tfrac{243}{5}\right) = \tfrac{162}{5}\pi$$

31. (a) The mountain comprises a solid conical region C. The work done in lifting a small volume of material ΔV with density $g(P)$ to a height $h(P)$ above sea level is $h(P)g(P)\,\Delta V$. Summing over the whole mountain we get $W = \iiint_C h(P)g(P)\,dV$.

(b) Here C is a solid right circular cone with radius $R = 62{,}000$ ft, height $H = 12{,}400$ ft, and density $g(P) = 200\text{ lb/ft}^3$ at all points P in C. We use cylindrical coordinates:



$$\frac{r}{R} = \frac{H-z}{H} = 1 - \frac{z}{H}$$

$$W = \int_0^{2\pi}\int_0^H\int_0^{R(1-z/H)} z\cdot 200r\,dr\,dz\,d\theta = 2\pi\int_0^H 200z\left[\tfrac{1}{2}r^2\right]_{r=0}^{r=R(1-z/H)} dz$$

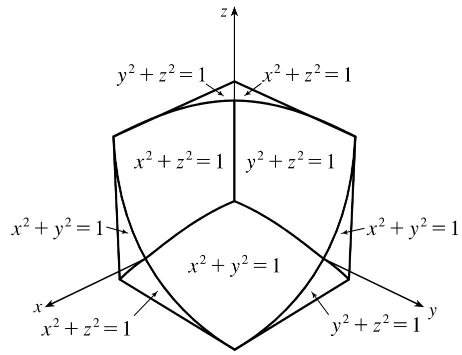
$$= 400\pi\int_0^H z\,\frac{R^2}{2}\left(1-\frac{z}{H}\right)^2 dz = 200\pi R^2\int_0^H\left(z - \frac{2z^2}{H} + \frac{z^3}{H^2}\right)dz$$

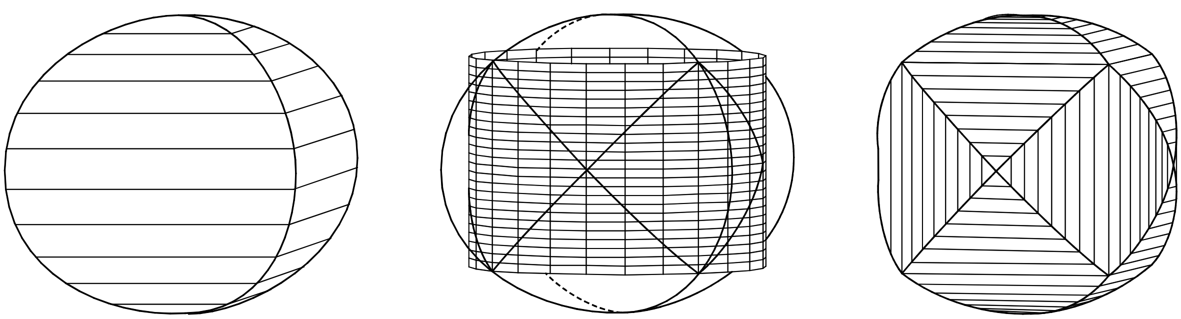
$$= 200\pi R^2\left[\frac{z^2}{2} - \frac{2z^3}{3H} + \frac{z^4}{4H^2}\right]_0^H = 200\pi R^2\left(\frac{H^2}{2} - \frac{2H^2}{3} + \frac{H^2}{4}\right)$$

$$= \tfrac{50}{3}\pi R^2H^2 = \tfrac{50}{3}\pi(62{,}000)^2(12{,}400)^2 \approx 3.1\times 10^{19}\text{ ft-lb}$$

DISCOVERY PROJECT The Intersection of Three Cylinders

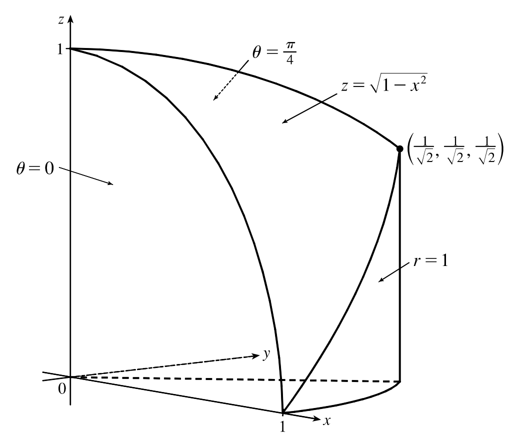
1. The three cylinders in the illustration in the text can be visualized as representing the surfaces $x^2 + y^2 = 1$, $x^2 + z^2 = 1$, and $y^2 + z^2 = 1$. Then we sketch the solid of intersection with the coordinate axes and equations indicated. To be more precise, we start by finding the bounding curves of the solid (shown in the first graph below) enclosed by the two cylinders $x^2 + z^2 = 1$ and $y^2 + z^2 = 1$: $x = \pm y = \pm\sqrt{1 - z^2}$ are the symmetric equations, and these can be expressed parametrically as $x = s, y = \pm s, z = \pm\sqrt{1 - s^2}, -1 \le s \le 1$. Now the cylinder $x^2 + y^2 = 1$ intersects these curves at the eight points $\left(\pm\frac{1}{\sqrt{2}}, \pm\frac{1}{\sqrt{2}}, \pm\frac{1}{\sqrt{2}}\right)$. The resulting solid has twelve curved faces bounded by "edges" which are arcs of circles, as shown in the third diagram. Each cylinder defines four of the twelve faces.





2. To find the volume, we split the solid into sixteen congruent pieces, one of which lies in the part of the first octant with $0 \le \theta \le \frac{\pi}{4}$. (Naturally, we use cylindrical coordinates!) This piece is described by $\left\{(r, \theta, z) \mid 0 \le r \le 1, 0 \le \theta \le \frac{\pi}{4}, 0 \le z \le \sqrt{1 - x^2}\right\}$, and so, substituting $x = r\cos\theta$, the volume of the entire solid is

$$\begin{aligned} V &= 16\int_0^{\pi/4}\int_0^1\int_0^{\sqrt{1-x^2}} r\,dz\,dr\,d\theta \\ &= 16\int_0^{\pi/4}\int_0^1 r\sqrt{1 - r^2\cos^2\theta}\,dr\,d\theta \\ &= 16 - 8\sqrt{2} \approx 4.6863 \end{aligned}$$

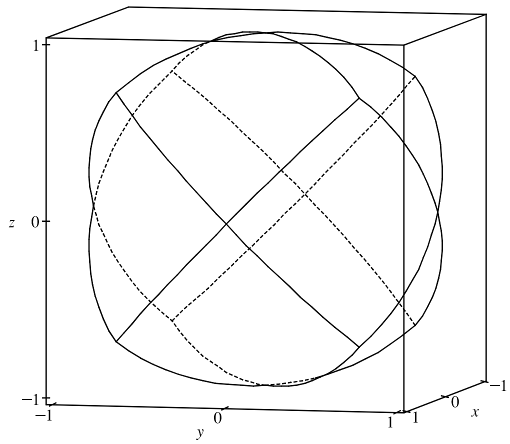


3. To graph the edges of the solid, we use parametrized curves similar to those found in Problem 1 for the intersection of two cylinders. We must restrict the parameter intervals so that each arc extends exactly to the desired vertex. One possible set of parametric equations (with all sign choices allowed) is

$x = r, y = \pm r, z = \pm\sqrt{1 - r^2}, -\frac{1}{\sqrt{2}} \le r \le \frac{1}{\sqrt{2}};$

$x = \pm s, y = \pm\sqrt{1 - s^2}, z = s, -\frac{1}{\sqrt{2}} \le s \le \frac{1}{\sqrt{2}};$

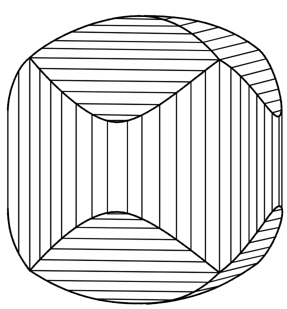
$x = \pm\sqrt{1 - t^2}, y = t, z = \pm t, -\frac{1}{\sqrt{2}} \le t \le \frac{1}{\sqrt{2}}.$



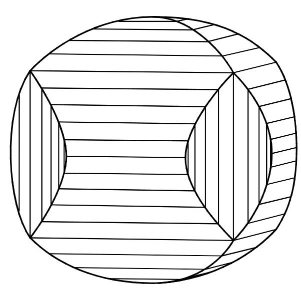
4. Let the three cylinders be $x^2 + y^2 = a^2$, $x^2 + z^2 = 1$, and $y^2 + z^2 = 1$.

If $a < 1$, then the four faces defined by the cylinder $x^2 + y^2 = 1$ in Problem 1 collapse into a single face, as in the first graph. If $1 < a < \sqrt{2}$, then each pair of vertically opposed faces, defined by one of the other two cylinders, collapse into a single face, as in the second graph. If $a \ge \sqrt{2}$, then the vertical cylinder encloses the solid of intersection of the other two cylinders completely, so the solid of intersection coincides with the solid of intersection of the two cylinders $x^2 + z^2 = 1$ and $y^2 + z^2 = 1$, as illustrated in Problem 1.

If we were to vary b or c instead of a, we would get solids with the same shape, but differently oriented.



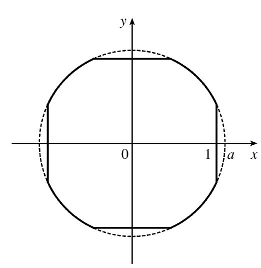
$a = 0.95, b = c = 1$

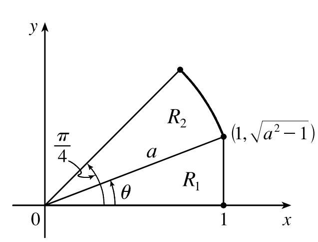


$a = 1.1, b = c = 1$

5. If $a < 1$, the solid looks similar to the first graph in Problem 4. As in Problem 2, we split the solid into sixteen congruent pieces, one of which can be described as the solid above the polar region $\left\{(r, \theta) \mid 0 \le r \le a, 0 \le \theta \le \frac{\pi}{4}\right\}$ in the xy-plane and below the surface $z = \sqrt{1 - x^2} = \sqrt{1 - r^2 \cos^2 \theta}$. Thus, the total volume is $V = 16 \int_0^{\pi/4} \int_0^a \sqrt{1 - r^2 \cos^2 \theta}\, r\, dr\, d\theta$.

If $a > 1$ and $a < \sqrt{2}$, we have a solid similar to the second graph in Problem 4. Its intersection with the xy-plane is graphed at the right. Again we split the solid into sixteen congruent pieces, one of which is the solid above the region shown in the second figure and below the surface $z = \sqrt{1 - x^2} = \sqrt{1 - r^2 \cos^2 \theta}$.





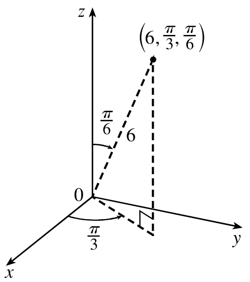
We split the region of integration where the outside boundary changes from the vertical line $x = 1$ to the circle $x^2 + y^2 = a^2$ or $r = a$. R_1 is a right triangle, so $\cos\theta = \frac{1}{a}$. Thus, the boundary between R_1 and R_2 is $\theta = \cos^{-1}\left(\frac{1}{a}\right)$ in polar coordinates, or $y = \sqrt{a^2 - 1}\,x$ in rectangular coordinates. Using rectangular coordinates for the region R_1 and polar coordinates for R_2, we find the total volume of the solid to be

$$V = 16\left[\int_0^1 \int_0^{\sqrt{a^2-1}\,x} \sqrt{1 - x^2}\,dy\,dx + \int_{\cos^{-1}(1/a)}^{\pi/4} \int_0^a \sqrt{1 - r^2\cos^2\theta}\,r\,dr\,d\theta\right]$$

If $a \geq \sqrt{2}$, the cylinder $x^2 + y^2 = 1$ completely encloses the intersection of the other two cylinders, so the solid of intersection of the three cylinders coincides with the intersection of $x^2 + z^2 = 1$ and $y^2 + z^2 = 1$ as illustrated in Exercise 15.5.24. Its volume is $V = 16\int_0^1 \int_0^x \sqrt{1 - x^2}\,dy\,dx$.

15.8 Triple Integrals in Spherical Coordinates

1. (a)

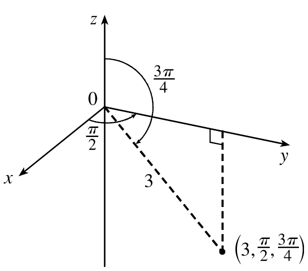


From Equations 1, $x = \rho\sin\phi\cos\theta = 6\sin\frac{\pi}{6}\cos\frac{\pi}{3} = 6\cdot\frac{1}{2}\cdot\frac{1}{2} = \frac{3}{2}$,

$y = \rho\sin\phi\sin\theta = 6\sin\frac{\pi}{6}\sin\frac{\pi}{3} = 6\cdot\frac{1}{2}\cdot\frac{\sqrt{3}}{2} = \frac{3\sqrt{3}}{2}$, and

$z = \rho\cos\phi = 6\cos\frac{\pi}{6} = 6\cdot\frac{\sqrt{3}}{2} = 3\sqrt{3}$, so the point is $\left(\frac{3}{2}, \frac{3\sqrt{3}}{2}, 3\sqrt{3}\right)$ in rectangular coordinates.

(b)

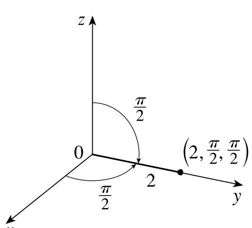


$x = 3\sin\frac{3\pi}{4}\cos\frac{\pi}{2} = 3\cdot\frac{\sqrt{2}}{2}\cdot 0 = 0$,

$y = 3\sin\frac{3\pi}{4}\sin\frac{\pi}{2} = 3\cdot\frac{\sqrt{2}}{2}\cdot 1 = \frac{3\sqrt{2}}{2}$, and

$z = 3\cos\frac{3\pi}{4} = 3\left(-\frac{\sqrt{2}}{2}\right) = -\frac{3\sqrt{2}}{2}$, so the point is $\left(0, \frac{3\sqrt{2}}{2}, -\frac{3\sqrt{2}}{2}\right)$ in rectangular coordinates.

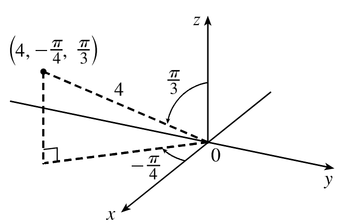
2. (a)



$x = 2\sin\frac{\pi}{2}\cos\frac{\pi}{2} = 2\cdot 1\cdot 0 = 0$, $y = 2\sin\frac{\pi}{2}\sin\frac{\pi}{2} = 2\cdot 1\cdot 1 = 2$,

$z = 2\cos\frac{\pi}{2} = 2\cdot 0 = 0$ so the point is $(0, 2, 0)$ in rectangular coordinates.

(b)



$x = 4\sin\frac{\pi}{3}\cos\left(-\frac{\pi}{4}\right) = 4\cdot\frac{\sqrt{3}}{2}\cdot\frac{\sqrt{2}}{2} = \sqrt{6}$,

$y = 4\sin\frac{\pi}{3}\sin\left(-\frac{\pi}{4}\right) = 4\left(\frac{\sqrt{3}}{2}\right)\left(-\frac{\sqrt{2}}{2}\right) = -\sqrt{6}$,

$z = 4\cos\frac{\pi}{3} = 4\cdot\frac{1}{2} = 2$ so the point is $\left(\sqrt{6}, -\sqrt{6}, 2\right)$ in rectangular coordinates.

3. (a) From Equations 1 and 2, $\rho = \sqrt{x^2+y^2+z^2} = \sqrt{0^2+(-2)^2+0^2} = 2$, $\cos\phi = \dfrac{z}{\rho} = \dfrac{0}{2} = 0 \quad\Rightarrow\quad \phi = \dfrac{\pi}{2}$, and

$\cos\theta = \dfrac{x}{\rho\sin\phi} = \dfrac{0}{2\sin(\pi/2)} = 0 \quad\Rightarrow\quad \theta = \dfrac{3\pi}{2}$ [since $y<0$]. Thus spherical coordinates are $\left(2, \dfrac{3\pi}{2}, \dfrac{\pi}{2}\right)$.

(b) $\rho = \sqrt{1+1+2} = 2$, $\cos\phi = \dfrac{z}{\rho} = \dfrac{-\sqrt{2}}{2} \quad\Rightarrow\quad \phi = \dfrac{3\pi}{4}$, and

$\cos\theta = \dfrac{x}{\rho\sin\phi} = \dfrac{-1}{2\sin(3\pi/4)} = \dfrac{-1}{2\left(\sqrt{2}/2\right)} = -\dfrac{1}{\sqrt{2}} \quad\Rightarrow\quad \theta = \dfrac{3\pi}{4}$ [since $y>0$]. Thus spherical coordinates are $\left(2, \dfrac{3\pi}{4}, \dfrac{3\pi}{4}\right)$.

4. (a) $\rho = \sqrt{x^2+y^2+z^2} = \sqrt{1+0+3} = 2$, $\cos\phi = \dfrac{z}{\rho} = \dfrac{\sqrt{3}}{2} \quad\Rightarrow\quad \phi = \dfrac{\pi}{6}$, and $\cos\theta = \dfrac{x}{\rho\sin\phi} = \dfrac{1}{2\sin(\pi/6)} = 1 \quad\Rightarrow$

$\theta = 0$. Thus spherical coordinates are $\left(2, 0, \dfrac{\pi}{6}\right)$.

(b) $\rho = \sqrt{3+1+12} = 4$, $\cos\phi = \dfrac{z}{\rho} = \dfrac{2\sqrt{3}}{4} = \dfrac{\sqrt{3}}{2} \quad\Rightarrow\quad \phi = \dfrac{\pi}{6}$, and $\cos\theta = \dfrac{x}{\rho\sin\phi} = \dfrac{\sqrt{3}}{4\sin(\pi/6)} = \dfrac{\sqrt{3}}{2} \quad\Rightarrow$

$\theta = \dfrac{11\pi}{6}$ [since $y<0$]. Thus spherical coordinates are $\left(4, \dfrac{11\pi}{6}, \dfrac{\pi}{6}\right)$.

5. Since $\phi = \frac{\pi}{3}$ but ρ and θ can vary, the surface is the top half of a right circular cone with vertex at the origin and axis the positive z-axis. (See Figure 4.)

6. $\rho^2 - 3\rho + 2 = 0 \quad\Rightarrow\quad (\rho-1)(\rho-2) = 0 \quad\Rightarrow\quad \rho = 1$ or $\rho = 2$. Thus the equation represents two surfaces. In the case $\rho = 1$, the distance from any point to the origin is 1. Because θ and ϕ can vary, the surface is a sphere centered at the origin with radius 1. (See Figure 2.) Similarly, $\rho = 2$ is a sphere centered at the origin with radius 2.

Also, $\rho = 1 \quad\Rightarrow\quad \rho^2 = 1 \quad\Rightarrow\quad x^2+y^2+z^2 = 1$ which we recognize as the equation of the unit sphere, and similarly, $\rho = 2 \quad\Rightarrow\quad \rho^2 = 4 \quad\Rightarrow\quad x^2+y^2+z^2 = 4$.

7. From Equations 1 we have $z = \rho\cos\phi$, so $\rho\cos\phi = 1 \quad\Leftrightarrow\quad z = 1$, and the surface is the horizontal plane $z = 1$.

8. $\rho = \cos\phi \quad\Rightarrow\quad \rho^2 = \rho\cos\phi \quad\Leftrightarrow\quad x^2+y^2+z^2 = z \quad\Leftrightarrow\quad x^2+y^2+z^2-z+\frac{1}{4} = \frac{1}{4} \quad\Leftrightarrow\quad x^2+y^2+(z-\frac{1}{2})^2 = \frac{1}{4}$. Therefore, the surface is a sphere of radius $\frac{1}{2}$ centered at $\left(0,0,\frac{1}{2}\right)$.

9. (a) From Equation 2 we have $\rho^2 = x^2+y^2+z^2$, so $x^2+y^2+z^2 = 9 \quad\Leftrightarrow\quad \rho^2 = 9 \quad\Rightarrow\quad \rho = 3$ (since $\rho \geq 0$).

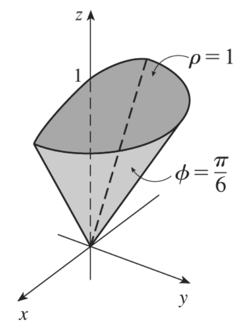
(b) From Equations 1 we have $x = \rho\sin\phi\cos\theta$, $y = \rho\sin\phi\sin\theta$, and $z = \rho\cos\phi$, so the equation $x^2-y^2-z^2 = 1$ becomes $(\rho\sin\phi\cos\theta)^2 - (\rho\sin\phi\sin\theta)^2 - (\rho\cos\phi)^2 = 1 \quad\Leftrightarrow\quad (\rho^2\sin^2\phi)(\cos^2\theta - \sin^2\theta) - \rho^2\cos^2\phi = 1 \quad\Leftrightarrow$ $\rho^2(\sin^2\phi\cos 2\theta - \cos^2\phi) = 1$.

10. (a) $x = \rho \sin \phi \cos \theta$, $y = \rho \sin \phi \sin \theta$, and $z = \rho \cos \phi$, so the equation $z = x^2 + y^2$ becomes

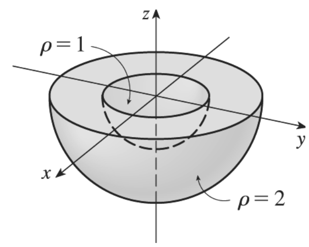
$\rho \cos \phi = (\rho \sin \phi \cos \theta)^2 + (\rho \sin \phi \sin \theta)^2$ or $\rho \cos \phi = \rho^2 \sin^2 \phi$. If $\rho \neq 0$, this becomes $\cos \phi = \rho \sin^2 \phi$ or $\rho = \cos \phi \csc^2 \phi$ or $\rho = \cot \phi \csc \phi$. ($\rho = 0$ corresponds to the origin which is included in the surface.)

(b) The equation $z = x^2 - y^2$ becomes $\rho \cos \phi = (\rho \sin \phi \cos \theta)^2 - (\rho \sin \phi \sin \theta)^2$ or $\rho \cos \phi = \rho^2 (\sin^2 \phi)(\cos^2 \theta - \sin^2 \theta) \quad \Leftrightarrow \quad \rho \cos \phi = \rho^2 \sin^2 \phi \cos 2\theta$. If $\rho \neq 0$, this becomes $\cos \phi = \rho \sin^2 \phi \cos 2\theta$. ($\rho = 0$ corresponds to the origin which is included in the surface.)

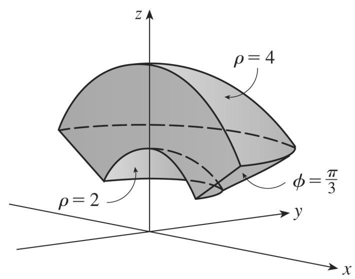
11. $\rho \leq 1$ represents the (solid) unit ball. $0 \leq \phi \leq \frac{\pi}{6}$ restricts the solid to that portion on or above the cone $\phi = \frac{\pi}{6}$, and $0 \leq \theta \leq \pi$ further restricts the solid to that portion on or to the right of the xz-plane.



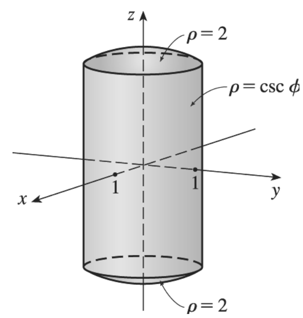
12. $1 \leq \rho \leq 2$ represents the solid region between and including the spheres of radii 1 and 2, centered at the origin. $\frac{\pi}{2} \leq \phi \leq \pi$ restricts the solid to that portion on or below the xy-plane.



13. $2 \leq \rho \leq 4$ represents the solid region between and including the spheres of radii 2 and 4, centered at the origin. $0 \leq \phi \leq \frac{\pi}{3}$ restricts the solid to that portion on or above the cone $\phi = \frac{\pi}{3}$, and $0 \leq \theta \leq \pi$ further restricts the solid to that portion on or to the right of the xz-plane.



14. $\rho \leq 2$ represents the solid sphere of radius 2 centered at the origin. Notice that $x^2 + y^2 = (\rho \sin \phi \cos \theta)^2 + (\rho \sin \phi \sin \theta)^2 = \rho^2 \sin^2 \phi$. Then $\rho = \csc \phi \quad \Rightarrow \quad \rho \sin \phi = 1 \quad \Rightarrow \quad \rho^2 \sin^2 \phi = x^2 + y^2 = 1$, so $\rho \leq \csc \phi$ restricts the solid to that portion on or inside the circular cylinder $x^2 + y^2 = 1$.

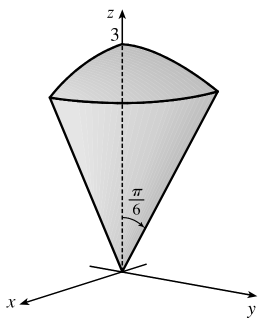


15. $z \geq \sqrt{x^2 + y^2}$ because the solid lies above the cone. Squaring both sides of this inequality gives $z^2 \geq x^2 + y^2 \Rightarrow 2z^2 \geq x^2 + y^2 + z^2 = \rho^2 \Rightarrow z^2 = \rho^2 \cos^2 \phi \geq \frac{1}{2}\rho^2 \Rightarrow \cos^2 \phi \geq \frac{1}{2}$. The cone opens upward so that the inequality is $\cos \phi \geq \frac{1}{\sqrt{2}}$, or equivalently $0 \leq \phi \leq \frac{\pi}{4}$. In spherical coordinates the sphere $z = x^2 + y^2 + z^2$ is $\rho \cos \phi = \rho^2 \Rightarrow \rho = \cos \phi$. $0 \leq \rho \leq \cos \phi$ because the solid lies below the sphere. The solid can therefore be described as the region in spherical coordinates satisfying $0 \leq \rho \leq \cos \phi$, $0 \leq \phi \leq \frac{\pi}{4}$.

16. (a) The hollow ball is a spherical shell with outer radius 15 cm and inner radius 14.5 cm. If we center the ball at the origin of the coordinate system and use centimeters as the unit of measurement, then spherical coordinates conveniently describe the hollow ball as $14.5 \leq \rho \leq 15$, $0 \leq \theta \leq 2\pi$, $0 \leq \phi \leq \pi$.

(b) If we position the ball as in part (a), one possibility is to take the half of the ball that is above the xy-plane which is described by $14.5 \leq \rho \leq 15$, $0 \leq \theta \leq 2\pi$, $0 \leq \phi \leq \pi/2$.

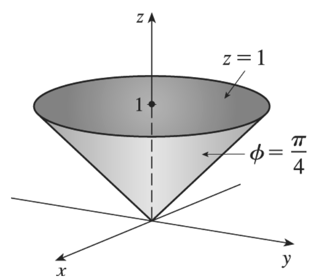
17.



The region of integration is given in spherical coordinates by $E = \{(\rho, \theta, \phi) \mid 0 \leq \rho \leq 3,\ 0 \leq \theta \leq \pi/2,\ 0 \leq \phi \leq \pi/6\}$. This represents the solid region in the first octant bounded above by the sphere $\rho = 3$ and below by the cone $\phi = \pi/6$.

$$\begin{aligned} \int_0^{\pi/6} \int_0^{\pi/2} \int_0^3 \rho^2 \sin \phi \, d\rho \, d\theta \, d\phi &= \int_0^{\pi/6} \sin \phi \, d\phi \int_0^{\pi/2} d\theta \int_0^3 \rho^2 \, d\rho \\ &= \left[-\cos \phi\right]_0^{\pi/6} \left[\theta\right]_0^{\pi/2} \left[\tfrac{1}{3}\rho^3\right]_0^3 \\ &= \left(1 - \frac{\sqrt{3}}{2}\right)\left(\frac{\pi}{2}\right)(9) = \frac{9\pi}{4}\left(2 - \sqrt{3}\right) \end{aligned}$$

18. The region of integration is given in spherical coordinates by $E = \{(\rho, \theta, \phi) \mid 0 \leq \rho \leq \sec \phi,\ 0 \leq \theta \leq 2\pi,\ 0 \leq \phi \leq \pi/4\}$. $\rho = \sec \phi \Leftrightarrow \rho \cos \phi = 1 \Leftrightarrow z = 1$, so E is the solid region above the cone $\phi = \pi/4$ and below the plane $z = 1$.



$$\begin{aligned} \int_0^{\pi/4} \int_0^{2\pi} \int_0^{\sec \phi} \rho^2 \sin \phi \, d\rho \, d\theta \, d\phi &= \int_0^{\pi/4} \int_0^{2\pi} \left[\tfrac{1}{3}\rho^3 \sin \phi\right]_{\rho=0}^{\rho=\sec \phi} d\theta \, d\phi \\ &= \int_0^{\pi/4} \int_0^{2\pi} \tfrac{1}{3} \sec^3 \phi \sin \phi \, d\theta \, d\phi = \tfrac{1}{3} \int_0^{\pi/4} \sec^3 \phi \sin \phi \, d\phi \int_0^{2\pi} d\theta \\ &= \tfrac{1}{3} \int_0^{\pi/4} \tan \phi \sec^2 \phi \, d\phi \int_0^{2\pi} d\theta = \tfrac{1}{3} \left[\tfrac{1}{2} \tan^2 \phi\right]_0^{\pi/4} \left[\theta\right]_0^{2\pi} \\ &= \tfrac{1}{3}\left(\tfrac{1}{2} - 0\right)(2\pi) = \tfrac{\pi}{3} \end{aligned}$$

19. The solid E is most conveniently described if we use cylindrical coordinates: $E = \left\{(r, \theta, z) \mid 0 \leq \theta \leq \frac{\pi}{2},\ 0 \leq r \leq 3,\ 0 \leq z \leq 2\right\}$. Then $\iiint_E f(x, y, z) \, dV = \int_0^{\pi/2} \int_0^3 \int_0^2 f(r \cos \theta, r \sin \theta, z) \, r \, dz \, dr \, d\theta$.

20. The solid E is most conveniently described if we use spherical coordinates:

$E = \left\{(\rho,\theta,\phi) \mid 1 \le \rho \le 2,\ \frac{\pi}{2} \le \theta \le 2\pi,\ 0 \le \phi \le \frac{\pi}{2}\right\}$. Then

$\iiint_E f(x,y,z)\,dV = \int_0^{\pi/2}\int_{\pi/2}^{2\pi}\int_1^2 f(\rho\sin\phi\cos\theta, \rho\sin\phi\sin\theta, \rho\cos\phi)\,\rho^2\sin\phi\,d\rho\,d\theta\,d\phi$.

21. In spherical coordinates, B is represented by $\{(\rho,\theta,\phi) \mid 0 \le \rho \le 5, 0 \le \theta \le 2\pi, 0 \le \phi \le \pi\}$. Thus

$$\begin{aligned}\iiint_B (x^2+y^2+z^2)^2\,dV &= \int_0^\pi\int_0^{2\pi}\int_0^5 (\rho^2)^2\rho^2\sin\phi\,d\rho\,d\theta\,d\phi = \int_0^\pi \sin\phi\,d\phi\,\int_0^{2\pi} d\theta\,\int_0^5 \rho^6\,d\rho \\ &= \big[-\cos\phi\big]_0^\pi\,\big[\theta\big]_0^{2\pi}\,\big[\tfrac{1}{7}\rho^7\big]_0^5 = (2)(2\pi)\big(\tfrac{78{,}125}{7}\big) \\ &= \tfrac{312{,}500}{7}\pi \approx 140{,}249.7\end{aligned}$$

22. In spherical coordinates, E is represented by $\left\{(\rho,\theta,\phi) \,\middle|\, 0 \le \rho \le 1,\ 0 \le \theta \le 2\pi,\ 0 \le \phi \le \frac{\pi}{3}\right\}$. Thus

$$\begin{aligned}\iiint_E y^2z^2\,dV &= \int_0^{\pi/3}\int_0^{2\pi}\int_0^1 (\rho\sin\phi\sin\theta)^2(\rho\cos\phi)^2\,\rho^2\sin\phi\,d\rho\,d\theta\,d\phi \\ &= \int_0^{\pi/3}\sin^3\phi\cos^2\phi\,d\phi\,\int_0^{2\pi}\sin^2\theta\,d\theta\,\int_0^1\rho^6\,d\rho \\ &= \int_0^{\pi/3}(1-\cos^2\phi)\cos^2\phi\sin\phi\,d\phi\,\int_0^{2\pi}\tfrac{1}{2}(1-\cos 2\theta)\,d\theta\,\int_0^1\rho^6\,d\rho \\ &= \big[\tfrac{1}{5}\cos^5\phi - \tfrac{1}{3}\cos^3\phi\big]_0^{\pi/3}\,\big[\tfrac{1}{2}\theta - \tfrac{1}{4}\sin 2\theta\big]_0^{2\pi}\,\big[\tfrac{1}{7}\rho^7\big]_0^1 \\ &= \left[\tfrac{1}{5}\big(\tfrac{1}{2}\big)^5 - \tfrac{1}{3}\big(\tfrac{1}{2}\big)^3 - \tfrac{1}{5} + \tfrac{1}{3}\right](\pi - 0)\left(\tfrac{1}{7} - 0\right) = \tfrac{47}{480}\cdot\pi\cdot\tfrac{1}{7} = \tfrac{47}{3360}\pi\end{aligned}$$

23. In spherical coordinates, E is represented by $\{(\rho,\theta,\phi) \mid 2 \le \rho \le 3, 0 \le \theta \le 2\pi, 0 \le \phi \le \pi\}$ and

$x^2+y^2 = \rho^2\sin^2\phi\cos^2\theta + \rho^2\sin^2\phi\sin^2\theta = \rho^2\sin^2\phi\left(\cos^2\theta+\sin^2\theta\right) = \rho^2\sin^2\phi$. Thus

$$\begin{aligned}\iiint_E (x^2+y^2)\,dV &= \int_0^\pi\int_0^{2\pi}\int_2^3 (\rho^2\sin^2\phi)\,\rho^2\sin\phi\,d\rho\,d\theta\,d\phi = \int_0^\pi\sin^3\phi\,d\phi\,\int_0^{2\pi}d\theta\,\int_2^3\rho^4\,d\rho \\ &= \int_0^\pi(1-\cos^2\phi)\,\sin\phi\,d\phi\,\big[\theta\big]_0^{2\pi}\,\big[\tfrac{1}{5}\rho^5\big]_2^3 = \big[-\cos\phi + \tfrac{1}{3}\cos^3\phi\big]_0^\pi\,(2\pi)\cdot\tfrac{1}{5}(243-32) \\ &= \left(1 - \tfrac{1}{3} + 1 - \tfrac{1}{3}\right)(2\pi)\big(\tfrac{211}{5}\big) = \tfrac{1688\pi}{15}\end{aligned}$$

24. In spherical coordinates, E is represented by $\{(\rho,\theta,\phi) \mid 0 \le \rho \le 3, 0 \le \theta \le \pi, 0 \le \phi \le \pi\}$. Thus

$$\begin{aligned}\iiint_E y^2\,dV &= \int_0^\pi\int_0^\pi\int_0^3(\rho\sin\phi\sin\theta)^2\,\rho^2\sin\phi\,d\rho\,d\theta\,d\phi = \int_0^\pi\sin^3\phi\,d\phi\,\int_0^\pi\sin^2\theta\,d\theta\,\int_0^3\rho^4\,d\rho \\ &= \int_0^\pi(1-\cos^2\phi)\,\sin\phi\,d\phi\,\int_0^\pi\tfrac{1}{2}(1-\cos 2\theta)\,d\theta\,\int_0^3\rho^4\,d\rho \\ &= \big[-\cos\phi + \tfrac{1}{3}\cos^3\phi\big]_0^\pi\,\big[\tfrac{1}{2}\big(\theta - \tfrac{1}{2}\sin 2\theta\big)\big]_0^\pi\,\big[\tfrac{1}{5}\rho^5\big]_0^3 \\ &= \left(\tfrac{2}{3}+\tfrac{2}{3}\right)\left(\tfrac{1}{2}\pi\right)\left(\tfrac{1}{5}(243)\right) = \left(\tfrac{4}{3}\right)\left(\tfrac{\pi}{2}\right)\left(\tfrac{243}{5}\right) = \tfrac{162\pi}{5}\end{aligned}$$

25. In spherical coordinates, E is represented by $\left\{(\rho,\theta,\phi) \,\middle|\, 0 \le \rho \le 1, 0 \le \theta \le \frac{\pi}{2}, 0 \le \phi \le \frac{\pi}{2}\right\}$. Thus

$$\begin{aligned}\iiint_E xe^{x^2+y^2+z^2}\,dV &= \int_0^{\pi/2}\int_0^{\pi/2}\int_0^1(\rho\sin\phi\cos\theta)e^{\rho^2}\rho^2\sin\phi\,d\rho\,d\theta\,d\phi = \int_0^{\pi/2}\sin^2\phi\,d\phi\,\int_0^{\pi/2}\cos\theta\,d\theta\,\int_0^1\rho^3e^{\rho^2}\,d\rho \\ &= \int_0^{\pi/2}\tfrac{1}{2}(1-\cos 2\phi)\,d\phi\,\int_0^{\pi/2}\cos\theta\,d\theta\left(\big[\tfrac{1}{2}\rho^2e^{\rho^2}\big]_0^1 - \int_0^1\rho e^{\rho^2}\,d\rho\right) \\ &\qquad\left[\text{integrate by parts with } u=\rho^2,\ dv=\rho e^{\rho^2}\,d\rho\right] \\ &= \big[\tfrac{1}{2}\phi - \tfrac{1}{4}\sin 2\phi\big]_0^{\pi/2}\,\big[\sin\theta\big]_0^{\pi/2}\,\big[\tfrac{1}{2}\rho^2e^{\rho^2} - \tfrac{1}{2}e^{\rho^2}\big]_0^1 = \left(\tfrac{\pi}{4}-0\right)(1-0)\left(0+\tfrac{1}{2}\right) = \tfrac{\pi}{8}\end{aligned}$$

26. In spherical coordinates, the cone $z = \sqrt{x^2 + y^2}$ is equivalent to $\phi = \pi/4$ (as in Example 4) and E is represented by $\{(\rho, \theta, \phi) \mid 1 \le \rho \le 2,\ 0 \le \theta \le 2\pi,\ 0 \le \phi \le \pi/4\}$. Also $\sqrt{x^2 + y^2 + z^2} = \sqrt{\rho^2} = \rho$, so

$$\iiint_E \sqrt{x^2 + y^2 + z^2}\, dV = \int_0^{\pi/4} \int_0^{2\pi} \int_1^2 \rho \cdot \rho^2 \sin\phi\, d\rho\, d\theta\, d\phi = \int_0^{\pi/4} \sin\phi\, d\phi \int_0^{2\pi} d\theta \int_1^2 \rho^3\, d\rho$$

$$= \left[-\cos\phi\right]_0^{\pi/4} \left[\,\theta\,\right]_0^{2\pi} \left[\tfrac{1}{4}\rho^4\right]_1^2 = \left(-\tfrac{\sqrt{2}}{2} + 1\right)(2\pi) \cdot \tfrac{1}{4}(16 - 1) = \tfrac{15}{2}\pi\left(1 - \tfrac{\sqrt{2}}{2}\right)$$

27. The solid region is given by $E = \left\{(\rho, \theta, \phi) \mid 0 \le \rho \le a, 0 \le \theta \le 2\pi, \frac{\pi}{6} \le \phi \le \frac{\pi}{3}\right\}$ and its volume is

$$V = \iiint_E dV = \int_{\pi/6}^{\pi/3} \int_0^{2\pi} \int_0^a \rho^2 \sin\phi\, d\rho\, d\theta\, d\phi = \int_{\pi/6}^{\pi/3} \sin\phi\, d\phi \int_0^{2\pi} d\theta \int_0^a \rho^2\, d\rho$$

$$= \left[-\cos\phi\right]_{\pi/6}^{\pi/3} \left[\theta\right]_0^{2\pi} \left[\tfrac{1}{3}\rho^3\right]_0^a = \left(-\tfrac{1}{2} + \tfrac{\sqrt{3}}{2}\right)(2\pi)\left(\tfrac{1}{3}a^3\right) = \tfrac{\sqrt{3}-1}{3}\pi a^3$$

28. If we center the ball at the origin, then the ball is given by $B = \{(\rho, \theta, \phi) \mid 0 \le \rho \le a, 0 \le \theta \le 2\pi, 0 \le \phi \le \pi\}$ and the distance from any point (x, y, z) in the ball to the center $(0, 0, 0)$ is $\sqrt{x^2 + y^2 + z^2} = \rho$. Thus the average distance is

$$\frac{1}{V(B)} \iiint_B \rho\, dV = \frac{1}{\frac{4}{3}\pi a^3} \int_0^{\pi} \int_0^{2\pi} \int_0^a \rho \cdot \rho^2 \sin\phi\, d\rho\, d\theta\, d\phi = \frac{3}{4\pi a^3} \int_0^{\pi} \sin\phi\, d\phi \int_0^{2\pi} d\theta \int_0^a \rho^3\, d\rho$$

$$= \frac{3}{4\pi a^3} \left[-\cos\phi\right]_0^{\pi} \left[\,\theta\,\right]_0^{2\pi} \left[\tfrac{1}{4}\rho^4\right]_0^a = \frac{3}{4\pi a^3}(2)(2\pi)\left(\tfrac{1}{4}a^4\right) = \tfrac{3}{4}a$$

29. (a) Since $\rho = 4\cos\phi$ implies $\rho^2 = 4\rho\cos\phi \quad\Leftrightarrow\quad x^2 + y^2 + z^2 = 4z \quad\Leftrightarrow\quad x^2 + y^2 + (z-2)^2 = 4$, the equation is that of a sphere of radius 2 with center at $(0, 0, 2)$. Thus

$$V = \int_0^{2\pi} \int_0^{\pi/3} \int_0^{4\cos\phi} \rho^2 \sin\phi\, d\rho\, d\phi\, d\theta = \int_0^{2\pi} \int_0^{\pi/3} \left[\tfrac{1}{3}\rho^3\right]_{\rho=0}^{\rho=4\cos\phi} \sin\phi\, d\phi\, d\theta = \int_0^{2\pi} \int_0^{\pi/3} \left(\tfrac{64}{3}\cos^3\phi\right) \sin\phi\, d\phi\, d\theta$$

$$= \int_0^{2\pi} \left[-\tfrac{16}{3}\cos^4\phi\right]_{\phi=0}^{\phi=\pi/3} d\theta = \int_0^{2\pi} -\tfrac{16}{3}\left(\tfrac{1}{16} - 1\right) d\theta = 5\theta\Big]_0^{2\pi} = 10\pi$$

(b) By the symmetry of the problem $M_{yz} = M_{xz} = 0$. Then

$$M_{xy} = \int_0^{2\pi} \int_0^{\pi/3} \int_0^{4\cos\phi} \rho^3 \cos\phi \sin\phi\, d\rho\, d\phi\, d\theta = \int_0^{2\pi} \int_0^{\pi/3} \cos\phi \sin\phi \left(64\cos^4\phi\right) d\phi\, d\theta$$

$$= \int_0^{2\pi} 64\left[-\tfrac{1}{6}\cos^6\phi\right]_{\phi=0}^{\phi=\pi/3} d\theta = \int_0^{2\pi} \tfrac{21}{2}\, d\theta = 21\pi$$

Hence $(\overline{x}, \overline{y}, \overline{z}) = (0, 0, 21\pi/(10\pi)) = (0, 0, 2.1)$.

30. In spherical coordinates, the sphere $x^2 + y^2 + z^2 = 4$ is equivalent to $\rho = 2$ and the cone $z = \sqrt{x^2 + y^2}$ is represented by $\phi = \frac{\pi}{4}$ (as in Example 4). Thus, the solid is given by $\left\{(\rho, \theta, \phi) \,\middle|\, 0 \le \rho \le 2,\ 0 \le \theta \le 2\pi,\ \frac{\pi}{4} \le \phi \le \frac{\pi}{2}\right\}$ and

$$V = \int_{\pi/4}^{\pi/2} \int_0^{2\pi} \int_0^2 \rho^2 \sin\phi\, d\rho\, d\theta\, d\phi = \int_{\pi/4}^{\pi/2} \sin\phi\, d\phi \int_0^{2\pi} d\theta \int_0^2 \rho^2\, d\rho$$

$$= \left[-\cos\phi\right]_{\pi/4}^{\pi/2} \left[\,\theta\,\right]_0^{2\pi} \left[\tfrac{1}{3}\rho^3\right]_0^2 = \left(\tfrac{\sqrt{2}}{2}\right)(2\pi)\left(\tfrac{8}{3}\right) = \tfrac{8\sqrt{2}\,\pi}{3}$$

31. (a) By the symmetry of the region, $M_{yz} = 0$ and $M_{xz} = 0$. Assuming constant density K,

$m = \iiint_E K\,dV = K \iiint_E dV = \frac{\pi}{8}K$ (from Example 4). Then

$$M_{xy} = \iiint_E z\,K\,dV = K\int_0^{2\pi}\int_0^{\pi/4}\int_0^{\cos\phi}(\rho\cos\phi)\,\rho^2\sin\phi\,d\rho\,d\phi\,d\theta = K\int_0^{2\pi}\int_0^{\pi/4}\sin\phi\cos\phi\left[\tfrac{1}{4}\rho^4\right]_{\rho=0}^{\rho=\cos\phi}d\phi\,d\theta$$
$$= \tfrac{1}{4}K\int_0^{2\pi}\int_0^{\pi/4}\sin\phi\cos\phi\left(\cos^4\phi\right)d\phi\,d\theta = \tfrac{1}{4}K\int_0^{2\pi}d\theta\int_0^{\pi/4}\cos^5\phi\sin\phi\,d\phi$$
$$= \tfrac{1}{4}K\left[\theta\right]_0^{2\pi}\left[-\tfrac{1}{6}\cos^6\phi\right]_0^{\pi/4} = \tfrac{1}{4}K(2\pi)\left(-\tfrac{1}{6}\right)\left[\left(\tfrac{\sqrt{2}}{2}\right)^6 - 1\right] = -\tfrac{\pi}{12}K\left(-\tfrac{7}{8}\right) = \tfrac{7\pi}{96}K$$

Thus the centroid is $(\overline{x},\overline{y},\overline{z}) = \left(\dfrac{M_{yz}}{m},\dfrac{M_{xz}}{m},\dfrac{M_{xy}}{m}\right) = \left(0,0,\dfrac{7\pi K/96}{\pi K/8}\right) = \left(0,0,\frac{7}{12}\right)$.

(b) As in Exercise 23, $x^2+y^2 = \rho^2\sin^2\phi$ and

$$I_z = \iiint_E (x^2+y^2)\,K\,dV = K\int_0^{2\pi}\int_0^{\pi/4}\int_0^{\cos\phi}(\rho^2\sin^2\phi)\,\rho^2\sin\phi\,d\rho\,d\phi\,d\theta = K\int_0^{2\pi}\int_0^{\pi/4}\sin^3\phi\left[\tfrac{1}{5}\rho^5\right]_{\rho=0}^{\rho=\cos\phi}d\phi\,d\theta$$
$$= \tfrac{1}{5}K\int_0^{2\pi}\int_0^{\pi/4}\sin^3\phi\cos^5\phi\,d\phi\,d\theta = \tfrac{1}{5}K\int_0^{2\pi}d\theta\int_0^{\pi/4}\cos^5\phi\left(1-\cos^2\phi\right)\sin\phi\,d\phi$$
$$= \tfrac{1}{5}K\left[\theta\right]_0^{2\pi}\left[-\tfrac{1}{6}\cos^6\phi + \tfrac{1}{8}\cos^8\phi\right]_0^{\pi/4}$$
$$= \tfrac{1}{5}K(2\pi)\left[-\tfrac{1}{6}\left(\tfrac{\sqrt{2}}{2}\right)^6 + \tfrac{1}{8}\left(\tfrac{\sqrt{2}}{2}\right)^8 + \tfrac{1}{6} - \tfrac{1}{8}\right] = \tfrac{2\pi}{5}K\left(\tfrac{11}{384}\right) = \tfrac{11\pi}{960}K$$

32. (a) Placing the center of the base at $(0,0,0)$, $\rho(x,y,z) = K\sqrt{x^2+y^2+z^2}$ is the density function. So

$$m = \int_0^{2\pi}\int_0^{\pi/2}\int_0^a K\rho^3\sin\phi\,d\rho\,d\phi\,d\theta = K\int_0^{2\pi}d\theta\int_0^{\pi/2}\sin\phi\,d\phi\int_0^a\rho^3\,d\rho$$
$$= K\left[\theta\right]_0^{2\pi}\left[-\cos\phi\right]_0^{\pi/2}\left[\tfrac{1}{4}\rho^4\right]_0^a = K(2\pi)(1)\left(\tfrac{1}{4}a^4\right) = \tfrac{1}{2}\pi K a^4$$

(b) By the symmetry of the problem $M_{yz} = M_{xz} = 0$. Then

$$M_{xy} = \int_0^{2\pi}\int_0^{\pi/2}\int_0^a K\rho^4\sin\phi\cos\phi\,d\rho\,d\phi\,d\theta = K\int_0^{2\pi}d\theta\int_0^{\pi/2}\sin\phi\cos\phi\,d\phi\int_0^a\rho^4\,d\rho$$
$$= K\left[\theta\right]_0^{2\pi}\left[\tfrac{1}{2}\sin^2\phi\right]_0^{\pi/2}\left[\tfrac{1}{5}\rho^5\right]_0^a = K(2\pi)\left(\tfrac{1}{2}\right)\left(\tfrac{1}{5}a^5\right) = \tfrac{1}{5}\pi K a^5$$

Hence $(\overline{x},\overline{y},\overline{z}) = \left(0,0,\frac{2}{5}a\right)$.

(c) $I_z = \int_0^{2\pi}\int_0^{\pi/2}\int_0^a (K\rho^3\sin\phi)(\rho^2\sin^2\phi)\,d\rho\,d\phi\,d\theta = K\int_0^{2\pi}d\theta\int_0^{\pi/2}\sin^3\phi\,d\phi\int_0^a\rho^5\,d\rho$

$$= K\left[\theta\right]_0^{2\pi}\left[-\cos\phi + \tfrac{1}{3}\cos^3\phi\right]_0^{\pi/2}\left[\tfrac{1}{6}\rho^6\right]_0^a = K(2\pi)\left(\tfrac{2}{3}\right)\left(\tfrac{1}{6}a^6\right) = \tfrac{2}{9}\pi K a^6$$

33. (a) The density function is $\rho(x,y,z) = K$, a constant, and by the symmetry of the problem $M_{xz} = M_{yz} = 0$. Then

$M_{xy} = \int_0^{2\pi}\int_0^{\pi/2}\int_0^a K\rho^3\sin\phi\,\cos\phi\,d\rho\,d\phi\,d\theta = \frac{1}{2}\pi K a^4\int_0^{\pi/2}\sin\phi\,\cos\phi\,d\phi = \frac{1}{8}\pi K a^4$. But the mass is K(volume of the hemisphere) $= \frac{2}{3}\pi K a^3$, so the centroid is $\left(0,0,\frac{3}{8}a\right)$.

(b) Place the center of the base at $(0,0,0)$; the density function is $\rho(x,y,z) = K$. By symmetry, the moments of inertia about any two such diameters will be equal, so we just need to find I_x:

$$I_x = \int_0^{2\pi}\int_0^{\pi/2}\int_0^a (K\rho^2\sin\phi)\,\rho^2\left(\sin^2\phi\,\sin^2\theta + \cos^2\phi\right)d\rho\,d\phi\,d\theta$$
$$= K\int_0^{2\pi}\int_0^{\pi/2}\left(\sin^3\phi\,\sin^2\theta + \sin\phi\,\cos^2\phi\right)\left(\tfrac{1}{5}a^5\right)d\phi\,d\theta$$
$$= \tfrac{1}{5}Ka^5\int_0^{2\pi}\left[\sin^2\theta\left(-\cos\phi + \tfrac{1}{3}\cos^3\phi\right) + \left(-\tfrac{1}{3}\cos^3\phi\right)\right]_{\phi=0}^{\phi=\pi/2}d\theta = \tfrac{1}{5}Ka^5\int_0^{2\pi}\left[\tfrac{2}{3}\sin^2\theta + \tfrac{1}{3}\right]d\theta$$
$$= \tfrac{1}{5}Ka^5\left[\tfrac{2}{3}\left(\tfrac{1}{2}\theta - \tfrac{1}{4}\sin 2\theta\right) + \tfrac{1}{3}\theta\right]_0^{2\pi} = \tfrac{1}{5}Ka^5\left[\tfrac{2}{3}(\pi - 0) + \tfrac{1}{3}(2\pi - 0)\right] = \tfrac{4}{15}Ka^5\pi$$

34. Place the center of the base at $(0,0,0)$, then the density is $\rho(x,y,z) = Kz$, K a constant. Then

$m = \int_0^{2\pi}\int_0^{\pi/2}\int_0^a (K\rho\cos\phi)\,\rho^2\sin\phi\,d\rho\,d\phi\,d\theta = 2\pi K\int_0^{\pi/2}\cos\phi\sin\phi\cdot\frac{1}{4}a^4\,d\phi = \frac{1}{2}\pi K a^4\left[-\frac{1}{4}\cos 2\phi\right]_0^{\pi/2} = \frac{\pi}{4}Ka^4.$

By the symmetry of the problem $M_{xz} = M_{yz} = 0$, and

$M_{xy} = \int_0^{2\pi}\int_0^{\pi/2}\int_0^a K\rho^4\cos^2\phi\sin\phi\,d\rho\,d\phi\,d\theta = \frac{2}{5}\pi K a^5\int_0^{\pi/2}\cos^2\phi\sin\phi\,d\phi = \frac{2}{5}\pi K a^5\left[-\frac{1}{3}\cos^3\theta\right]_0^{\pi/2} = \frac{2}{15}\pi K a^5.$

Hence $(\overline{x},\overline{y},\overline{z}) = \left(0,0,\frac{8}{15}a\right)$.

35. In spherical coordinates $z = \sqrt{x^2+y^2}$ becomes $\phi = \frac{\pi}{4}$ (as in Example 4). Then

$V = \int_0^{2\pi}\int_0^{\pi/4}\int_0^1 \rho^2\sin\phi\,d\rho\,d\phi\,d\theta = \int_0^{2\pi}d\theta\int_0^{\pi/4}\sin\phi\,d\phi\int_0^1\rho^2\,d\rho = 2\pi\left(-\frac{\sqrt{2}}{2}+1\right)\left(\frac{1}{3}\right) = \frac{1}{3}\pi\left(2-\sqrt{2}\right),$

$M_{xy} = \int_0^{2\pi}\int_0^{\pi/4}\int_0^1 \rho^3\sin\phi\cos\phi\,d\rho\,d\phi\,d\theta = 2\pi\left[-\frac{1}{4}\cos 2\phi\right]_0^{\pi/4}\left(\frac{1}{4}\right) = \frac{\pi}{8}$ and by symmetry $M_{yz} = M_{xz} = 0$.

Hence $(\overline{x},\overline{y},\overline{z}) = \left(0,0,\dfrac{3}{8\left(2-\sqrt{2}\right)}\right)$.

36. Place the center of the sphere at $(0,0,0)$, let the diameter of intersection be along the z-axis, one of the planes be the xz-plane and the other be the plane whose angle with the xz-plane is $\theta = \frac{\pi}{6}$. Then in spherical coordinates the volume is given by

$V = \int_0^{\pi/6}\int_0^{\pi}\int_0^a \rho^2\sin\phi\,d\rho\,d\phi\,d\theta = \int_0^{\pi/6}d\theta\int_0^{\pi}\sin\phi\,d\phi\int_0^a\rho^2\,d\rho = \frac{\pi}{6}(2)\left(\frac{1}{3}a^3\right) = \frac{1}{9}\pi a^3.$

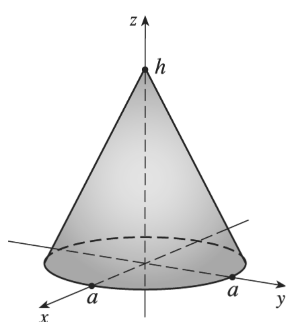
37. (a) If we orient the cylinder so that its axis is the z-axis and its base lies in the xy-plane, then the cylinder is described, in cylindrical coordinates, by $E = \{(r,\theta,z) \mid 0 \le r \le a,\ 0 \le \theta \le 2\pi,\ 0 \le z \le h\}$. Assuming constant density K, the moment of inertia about its axis (the z-axis) is

$$\begin{aligned} I_z &= \iiint_E (x^2+y^2)\,\rho(x,y,z)\,dV = \int_0^{2\pi}\int_0^a\int_0^h K(r^2)\,r\,dz\,dr\,d\theta = K\int_0^{2\pi}d\theta\int_0^a r^3\,dr\int_0^h dz \\ &= K\left[\theta\right]_0^{2\pi}\left[\tfrac{1}{4}r^4\right]_0^a\left[z\right]_0^h = K(2\pi)\left(\tfrac{1}{4}a^4\right)(h) = \tfrac{1}{2}\pi K a^4 h \end{aligned}$$

(b) By symmetry, the moments of inertia about any two diameters of the base will be equal, and one of the diameters lies on the x-axis, so we compute:

$$\begin{aligned} I_x &= \iiint_E (y^2+z^2)\,\rho(x,y,z)\,dV = \int_0^{2\pi}\int_0^a\int_0^h K(r^2\sin^2\theta+z^2)\,r\,dz\,dr\,d\theta \\ &= K\int_0^{2\pi}\int_0^a\int_0^h r^3\sin^2\theta\,dz\,dr\,d\theta + K\int_0^{2\pi}\int_0^a\int_0^h rz^2\,dz\,dr\,d\theta \\ &= K\int_0^{2\pi}\sin^2\theta\,d\theta\int_0^a r^3\,dr\int_0^h dz + K\int_0^{2\pi}d\theta\int_0^a r\,dr\int_0^h z^2\,dz \\ &= K\left[\tfrac{1}{2}\theta-\tfrac{1}{4}\sin 2\theta\right]_0^{2\pi}\left[\tfrac{1}{4}r^4\right]_0^a\left[z\right]_0^h + K\left[\theta\right]_0^{2\pi}\left[\tfrac{1}{2}r^2\right]_0^a\left[\tfrac{1}{3}z^3\right]_0^h \\ &= K(\pi)\left(\tfrac{1}{4}a^4\right)(h) + K(2\pi)\left(\tfrac{1}{2}a^2\right)\left(\tfrac{1}{3}h^3\right) = \tfrac{1}{12}\pi K a^2 h(3a^2+4h^2) \end{aligned}$$

38.



Orient the cone so that its axis is the z-axis and its base lies in the xy-plane, as shown in the figure. (Then the z-axis is the axis of the cone and the x-axis contains a diameter of the base.) A right circular cone with axis the z-axis and vertex at the origin has equation $z^2 = c^2(x^2+y^2)$. Here we have the bottom frustum, shifted upward h units, and with $c^2 = h^2/a^2$ so that the cone includes the point $(a,0,0)$. Thus an equation of the cone in rectangular coordinates is $z = h - \frac{h}{a}\sqrt{x^2+y^2}$, $0 \le z \le h$. In cylindrical coordinates, the cone is described by

$$E = \left\{(r,\theta,z) \mid 0 \le r \le a,\ 0 \le \theta \le 2\pi,\ 0 \le z \le h\left(1 - \tfrac{1}{a}r\right)\right\}$$

(a) Assuming constant density K, the moment of inertia about its axis (the z-axis) is

$$\begin{aligned} I_z &= \iiint_E (x^2+y^2)\,\rho(x,y,z)\,dV = \int_0^{2\pi}\int_0^a\int_0^{h(1-r/a)} K(r^2)\,r\,dz\,dr\,d\theta \\ &= K\int_0^{2\pi}\int_0^a \left[r^3 z\right]_{z=0}^{z=h(1-r/a)}\,dr\,d\theta = K\int_0^{2\pi}\int_0^a r^3 h\left(1-\tfrac{1}{a}r\right)\,dr\,d\theta \\ &= Kh\int_0^{2\pi} d\theta\int_0^a \left(r^3 - \tfrac{1}{a}r^4\right)dr = Kh\left[\,\theta\,\right]_0^{2\pi}\left[\tfrac{1}{4}r^4 - \tfrac{1}{5a}r^5\right]_0^a \\ &= Kh\,(2\pi)\left(\tfrac{1}{4}a^4 - \tfrac{1}{5}a^4\right) = \tfrac{1}{10}\pi K a^4 h \end{aligned}$$

(b) By symmetry, the moments of inertia about any two diameters of the base will be equal, and one of the diameters lies on the x-axis, so we compute:

$$\begin{aligned} I_x &= \iiint_E (y^2+z^2)\,\rho(x,y,z)\,dV = \int_0^{2\pi}\int_0^a\int_0^{h(1-r/a)} K(r^2\sin^2\theta + z^2)\,r\,dz\,dr\,d\theta \\ &= K\int_0^{2\pi}\int_0^a \left[(r^3\sin^2\theta)z + \tfrac{1}{3}rz^3\right]_{z=0}^{z=h(1-r/a)}\,dr\,d\theta \\ &= K\int_0^{2\pi}\int_0^a \left[(r^3\sin^2\theta)\left(h\left(1-\tfrac{1}{a}r\right)\right) + \tfrac{1}{3}r\left(h\left(1-\tfrac{1}{a}r\right)\right)^3\right]dr\,d\theta \\ &= Kh\int_0^{2\pi}\int_0^a (r^3\sin^2\theta)\left(1-\tfrac{1}{a}r\right)dr\,d\theta + Kh^3\int_0^{2\pi}\int_0^a \tfrac{1}{3}r\left(1-\tfrac{1}{a}r\right)^3 dr\,d\theta \\ &= Kh\int_0^{2\pi}\sin^2\theta\,d\theta\int_0^a\left(r^3 - \tfrac{1}{a}r^4\right)dr + \tfrac{1}{3}Kh^3\int_0^{2\pi}d\theta\int_0^a\left(r - \tfrac{3}{a}r^2 + \tfrac{3}{a^2}r^3 - \tfrac{1}{a^3}r^4\right)dr \\ &= Kh\left[\tfrac{1}{2}\theta - \tfrac{1}{4}\sin 2\theta\right]_0^{2\pi}\left[\tfrac{1}{4}r^4 - \tfrac{1}{5a}r^5\right]_0^a + \tfrac{1}{3}Kh^3\left[\,\theta\,\right]_0^{2\pi}\left[\tfrac{1}{2}r^2 - \tfrac{1}{a}r^3 + \tfrac{3}{4a^2}r^4 - \tfrac{1}{5a^3}r^5\right]_0^a \\ &= Kh\,(\pi)\left(\tfrac{1}{4}a^4 - \tfrac{1}{5}a^4\right) + \tfrac{1}{3}Kh^3\,(2\pi)\left(\tfrac{1}{2}a^2 - a^2 + \tfrac{3}{4}a^2 - \tfrac{1}{5}a^2\right) \\ &= \pi Kh\left(\tfrac{1}{20}a^4\right) + \tfrac{2}{3}\pi Kh^3\left(\tfrac{1}{20}a^2\right) = \pi K a^2 h\left(\tfrac{1}{20}a^2 + \tfrac{1}{30}h^2\right) \end{aligned}$$

39. In cylindrical coordinates the paraboloid is given by $z = r^2$ and the plane by $z = 2r\sin\theta$ and the projection of the intersection onto the xy-plane is the circle $r = 2\sin\theta$. Then $\iiint_E z\,dV = \int_0^{\pi}\int_0^{2\sin\theta}\int_{r^2}^{2r\sin\theta} rz\,dz\,dr\,d\theta = \frac{5\pi}{6}$ [using a CAS].

40. (a) The region enclosed by the torus is $\{(\rho,\theta,\phi) \mid 0 \le \theta \le 2\pi,\ 0 \le \phi \le \pi,\ 0 \le \rho \le \sin\phi\}$, so its volume is

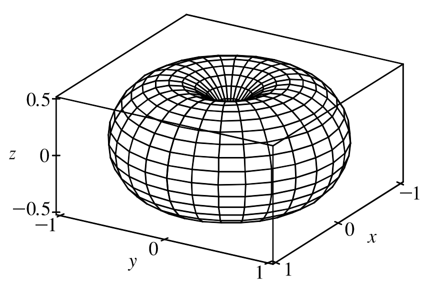
$V = \int_0^{2\pi}\int_0^{\pi}\int_0^{\sin\phi} \rho^2\sin\phi\,d\rho\,d\phi\,d\theta = 2\pi\int_0^{\pi}\tfrac{1}{3}\sin^4\phi\,d\phi = \tfrac{2}{3}\pi\left[\tfrac{3}{8}\phi - \tfrac{1}{4}\sin 2\phi + \tfrac{1}{16}\sin 4\phi\right]_0^{\pi} = \tfrac{1}{4}\pi^2.$

(b) In Maple, we can plot the torus using the command

```
plot3d(sin(phi),theta=0..2*Pi,
       phi=0..Pi,coords=spherical);.
```

In Mathematica, use

```
SphericalPlot3D[Sin[phi],{phi,0,Pi},{theta,0,2Pi}].
```



41. The region E of integration is the region above the cone $z = \sqrt{x^2+y^2}$ and below the sphere $x^2+y^2+z^2 = 2$ in the first octant. Because E is in the first octant we have $0 \le \theta \le \frac{\pi}{2}$. The cone has equation $\phi = \frac{\pi}{4}$ (as in Example 4), so $0 \le \phi \le \frac{\pi}{4}$, and $0 \le \rho \le \sqrt{2}$. Then the integral becomes

$$\int_0^{\pi/4}\int_0^{\pi/2}\int_0^{\sqrt{2}} (\rho\sin\phi\cos\theta)(\rho\sin\phi\sin\theta)\,\rho^2\sin\phi\,d\rho\,d\theta\,d\phi$$

$$= \int_0^{\pi/4}\sin^3\phi\,d\phi\int_0^{\pi/2}\sin\theta\cos\theta\,d\theta\int_0^{\sqrt{2}}\rho^4\,d\rho = \left(\int_0^{\pi/4}\left(1-\cos^2\phi\right)\sin\phi\,d\phi\right)\left[\tfrac{1}{2}\sin^2\theta\right]_0^{\pi/2}\left[\tfrac{1}{5}\rho^5\right]_0^{\sqrt{2}}$$

$$= \left[\tfrac{1}{3}\cos^3\phi - \cos\phi\right]_0^{\pi/4}\cdot\tfrac{1}{2}\cdot\tfrac{1}{5}\left(\sqrt{2}\right)^5 = \left[\tfrac{\sqrt{2}}{12} - \tfrac{\sqrt{2}}{2} - \left(\tfrac{1}{3}-1\right)\right]\cdot\tfrac{2\sqrt{2}}{5} = \tfrac{4\sqrt{2}-5}{15}$$

42. The region of integration is the solid sphere $x^2+y^2+z^2 \le a^2$, so $0 \le \theta \le 2\pi$, $0 \le \phi \le \pi$, and $0 \le \rho \le a$. Also $x^2z + y^2z + z^3 = (x^2+y^2+z^2)z = \rho^2 z = \rho^3\cos\phi$, so the integral becomes

$$\int_0^{\pi}\int_0^{2\pi}\int_0^{a}\left(\rho^3\cos\phi\right)\rho^2\sin\phi\,d\rho\,d\theta\,d\phi = \int_0^{\pi}\sin\phi\cos\phi\,d\phi\int_0^{2\pi}d\theta\int_0^{a}\rho^5\,d\rho = \left[\tfrac{1}{2}\sin^2\phi\right]_0^{\pi}\left[\theta\right]_0^{2\pi}\left[\tfrac{1}{6}\rho^6\right]_0^{a} = 0$$

43. The region of integration is the solid sphere $x^2+y^2+(z-2)^2 \le 4$ or equivalently $\rho^2\sin^2\phi + (\rho\cos\phi - 2)^2 = \rho^2 - 4\rho\cos\phi + 4 \le 4 \quad\Rightarrow\quad \rho \le 4\cos\phi$, so $0 \le \theta \le 2\pi$, $0 \le \phi \le \frac{\pi}{2}$, and $0 \le \rho \le 4\cos\phi$. Also $(x^2+y^2+z^2)^{3/2} = (\rho^2)^{3/2} = \rho^3$, so the integral becomes

$$\int_0^{\pi/2}\int_0^{2\pi}\int_0^{4\cos\phi}\left(\rho^3\right)\rho^2\sin\phi\,d\rho\,d\theta\,d\phi = \int_0^{\pi/2}\int_0^{2\pi}\sin\phi\left[\tfrac{1}{6}\rho^6\right]_{\rho=0}^{\rho=4\cos\phi}d\theta\,d\phi$$

$$= \tfrac{1}{6}\int_0^{\pi/2}\int_0^{2\pi}\sin\phi\left(4096\cos^6\phi\right)d\theta\,d\phi$$

$$= \tfrac{1}{6}(4096)\int_0^{\pi/2}\cos^6\phi\sin\phi\,d\phi\int_0^{2\pi}d\theta = \tfrac{2048}{3}\left[-\tfrac{1}{7}\cos^7\phi\right]_0^{\pi/2}\left[\theta\right]_0^{2\pi}$$

$$= \tfrac{2048}{3}\left(\tfrac{1}{7}\right)(2\pi) = \tfrac{4096\pi}{21}$$

44. The solid region between the ground and an altitude of 5 km (5000 m) is given by

$$E = \left\{(\rho,\theta,\phi) \mid 6.370\times10^6 \le \rho \le 6.375\times10^6, 0 \le \theta \le 2\pi, 0 \le \phi \le \pi\right\}.$$

Then the mass of the atmosphere in this region is

$$m = \iiint_E \delta\,dV = \int_0^{2\pi}\int_0^{\pi}\int_{6.370\times10^6}^{6.375\times10^6}(619.09 - 0.000097\rho)\,\rho^2\sin\phi\,d\rho\,d\phi\,d\theta$$

$$= \int_0^{2\pi}d\theta\int_0^{\pi}\sin\phi\,d\phi\int_{6.370\times10^6}^{6.375\times10^6}\left(619.09\rho^2 - 0.000097\rho^3\right)d\rho$$

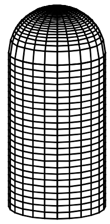
$$= \left[\theta\right]_0^{2\pi}\left[-\cos\phi\right]_0^{\pi}\left[\tfrac{619.09}{3}\rho^3 - \tfrac{0.000097}{4}\rho^4\right]_{6.370\times10^6}^{6.375\times10^6}$$

$$= (2\pi)(2)\left[\tfrac{619.09}{3}\left((6.375\times10^6)^3 - (6.370\times10^6)^3\right) - \tfrac{0.000097}{4}\left((6.375\times10^6)^4 - (6.370\times10^6)^4\right)\right]$$

$$\approx 4\pi\left(1.944\times10^{17}\right) \approx 2.44\times10^{18}\text{ kg}$$

45. In cylindrical coordinates, the equation of the cylinder is $r = 3$, $0 \le z \le 10$.

The hemisphere is the upper part of the sphere radius 3, center $(0,0,10)$, equation $r^2 + (z-10)^2 = 3^2$, $z \ge 10$. In Maple, we can use the `coords=cylindrical` option in a regular `plot3d` command. In Mathematica, we can use `ParametricPlot3D`.



46. We begin by finding the positions of Los Angeles and Montréal in spherical coordinates, using the method described in the exercise:

Montréal	Los Angeles
$\rho = 3960$ mi	$\rho = 3960$ mi
$\theta = 360° - 73.60° = 286.40°$	$\theta = 360° - 118.25° = 241.75°$
$\phi = 90° - 45.50° = 44.50°$	$\phi = 90° - 34.06° = 55.94°$

Now we change the above to Cartesian coordinates using $x = \rho\cos\theta\sin\phi$, $y = \rho\sin\theta\sin\phi$ and $z = \rho\cos\phi$ to get two position vectors of length 3960 mi (since both cities must lie on the surface of the earth). In particular:

Montréal: $\langle 783.67, -2662.67, 2824.47\rangle$ Los Angeles: $\langle -1552.80, -2889.91, 2217.84\rangle$

To find the angle γ between these two vectors we use the dot product:

$\langle 783.67, -2662.67, 2824.47\rangle \cdot \langle -1552.80, -2889.91, 2217.84\rangle = (3960)^2\cos\gamma \Rightarrow \cos\gamma \approx 0.8126 \Rightarrow$ $\gamma \approx 0.6223$ rad. The great circle distance between the cities is $s = \rho\gamma \approx 3960(0.6223) \approx 2464$ mi.

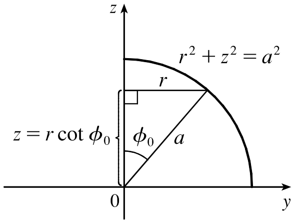
47. If E is the solid enclosed by the surface $\rho = 1 + \frac{1}{5}\sin 6\theta\,\sin 5\phi$, it can be described in spherical coordinates as $E = \left\{(\rho,\theta,\phi) \mid 0 \le \rho \le 1 + \frac{1}{5}\sin 6\theta\sin 5\phi, 0 \le \theta \le 2\pi, 0 \le \phi \le \pi\right\}$. Its volume is given by $V(E) = \iiint_E dV = \int_0^\pi \int_0^{2\pi} \int_0^{1+(\sin 6\theta\sin 5\phi)/5} \rho^2\sin\phi\,d\rho\,d\theta\,d\phi = \frac{136\pi}{99}$ [using a CAS].

48. The given integral is equal to $\lim\limits_{R\to\infty}\int_0^{2\pi}\int_0^\pi\int_0^R \rho e^{-\rho^2}\rho^2\sin\phi\,d\rho\,d\phi\,d\theta = \lim\limits_{R\to\infty}\int_0^{2\pi}d\theta\int_0^\pi\sin\phi\,d\phi\int_0^R\rho^3e^{-\rho^2}\,d\rho$. Now use integration by parts with $u = \rho^2$, $dv = \rho e^{-\rho^2}\,d\rho$ to get

$$\lim_{R\to\infty}2\pi(2)\left(\rho^2\left(-\tfrac{1}{2}\right)e^{-\rho^2}\Big]_0^R - \int_0^R 2\rho\left(-\tfrac{1}{2}\right)e^{-\rho^2}\,d\rho\right) = \lim_{R\to\infty}4\pi\left(-\tfrac{1}{2}R^2e^{-R^2} + \left[-\tfrac{1}{2}e^{-\rho^2}\right]_0^R\right)$$
$$= 4\pi\lim_{R\to\infty}\left[-\tfrac{1}{2}R^2e^{-R^2} - \tfrac{1}{2}e^{-R^2} + \tfrac{1}{2}\right] = 4\pi\left(\tfrac{1}{2}\right) = 2\pi$$

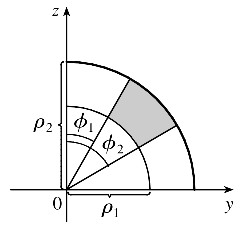
(Note that $R^2e^{-R^2} \to 0$ as $R \to \infty$ by l'Hospital's Rule.)

49. (a) From the diagram, $z = r\cot\phi_0$ to $z = \sqrt{a^2 - r^2}$, $r = 0$ to $r = a\sin\phi_0$ (or use $a^2 - r^2 = r^2\cot^2\phi_0$). Thus



$$\begin{aligned}V &= \int_0^{2\pi}\int_0^{a\sin\phi_0}\int_{r\cot\phi_0}^{\sqrt{a^2-r^2}} r\,dz\,dr\,d\theta \\ &= 2\pi\int_0^{a\sin\phi_0}\left(r\sqrt{a^2-r^2} - r^2\cot\phi_0\right)dr \\ &= \tfrac{2\pi}{3}\left[-(a^2-r^2)^{3/2} - r^3\cot\phi_0\right]_0^{a\sin\phi_0} \\ &= \tfrac{2\pi}{3}\left[-\left(a^2 - a^2\sin^2\phi_0\right)^{3/2} - a^3\sin^3\phi_0\cot\phi_0 + a^3\right] \\ &= \tfrac{2}{3}\pi a^3\left[1 - \left(\cos^3\phi_0 + \sin^2\phi_0\cos\phi_0\right)\right] = \tfrac{2}{3}\pi a^3(1 - \cos\phi_0)\end{aligned}$$

(b) The wedge in question is the shaded area rotated from $\theta = \theta_1$ to $\theta = \theta_2$.



Letting

V_{ij} = volume of the region bounded by the sphere of radius ρ_i and the cone with angle ϕ_j ($\theta = \theta_1$ to θ_2)

and letting V be the volume of the wedge, we have

$$\begin{aligned}V &= (V_{22} - V_{21}) - (V_{12} - V_{11}) \\ &= \tfrac{1}{3}(\theta_2 - \theta_1)\left[\rho_2^3(1-\cos\phi_2) - \rho_2^3(1-\cos\phi_1) - \rho_1^3(1-\cos\phi_2) + \rho_1^3(1-\cos\phi_1)\right] \\ &= \tfrac{1}{3}(\theta_2 - \theta_1)\left[\left(\rho_2^3 - \rho_1^3\right)(1-\cos\phi_2) - \left(\rho_2^3 - \rho_1^3\right)(1-\cos\phi_1)\right] = \tfrac{1}{3}(\theta_2 - \theta_1)\left[\left(\rho_2^3 - \rho_1^3\right)(\cos\phi_1 - \cos\phi_2)\right]\end{aligned}$$

Or: Show that $V = \int_{\theta_1}^{\theta_2} \int_{\rho_1 \sin\phi_1}^{\rho_2 \sin\phi_2} \int_{r\cot\phi_2}^{r\cot\phi_1} r\,dz\,dr\,d\theta$.

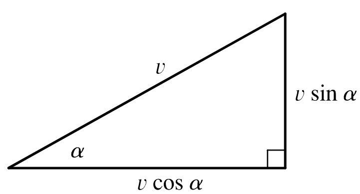
(c) By the Mean Value Theorem with $f(\rho) = \rho^3$ there exists some $\tilde{\rho}$ with $\rho_1 \le \tilde{\rho} \le \rho_2$ such that $f(\rho_2) - f(\rho_1) = f'(\tilde{\rho})(\rho_2 - \rho_1)$ or $\rho_1^3 - \rho_2^3 = 3\tilde{\rho}^2\Delta\rho$. Similarly there exists ϕ with $\phi_1 \le \tilde{\phi} \le \phi_2$ such that $\cos\phi_2 - \cos\phi_1 = \left(-\sin\tilde{\phi}\right)\,\Delta\phi$. Substituting into the result from (b) gives $\Delta V = (\tilde{\rho}^2\,\Delta\rho)(\theta_2 - \theta_1)(\sin\tilde{\phi})\;\Delta\phi = \tilde{\rho}^2 \sin\tilde{\phi}\,\Delta\rho\,\Delta\phi\,\Delta\theta$.

APPLIED PROJECT Roller Derby

1. $mgh = \frac{1}{2}mv^2 + \frac{1}{2}I\omega^2 = \frac{1}{2}(m + I/r^2)v^2$, so $v^2 = \dfrac{2mgh}{m + I/r^2} = \dfrac{2gh}{1 + I^*}$.

2. The vertical component of the speed is $v\sin\alpha$, so

$$\frac{dy}{dt} = \sqrt{\frac{2gy}{1+I^*}}\sin\alpha = \sqrt{\frac{2g}{1+I^*}}\sin\alpha\,\sqrt{y}.$$



3. Solving the separable differential equation, we get $\dfrac{dy}{\sqrt{y}} = \sqrt{\dfrac{2g}{1+I^*}}\sin\alpha\,dt \quad\Rightarrow\quad 2\sqrt{y} = \sqrt{\dfrac{2g}{1+I^*}}\,(\sin\alpha)t + C$.

But $y = 0$ when $t = 0$, so $C = 0$ and we have $2\sqrt{y} = \sqrt{\dfrac{2g}{1+I^*}}\,(\sin\alpha)t$. Solving for t when $y = h$ gives

$$T = \frac{2\sqrt{h}}{\sin\alpha}\sqrt{\frac{1+I^*}{2g}} = \sqrt{\frac{2h(1+I^*)}{g\sin^2\alpha}}.$$

4. Assume that the length of each cylinder is ℓ. Then the density of the solid cylinder is $\dfrac{m}{\pi r^2 \ell}$, and from Formulas 15.6.16, its moment of inertia (using cylindrical coordinates) is

$$I_z = \iiint \frac{m}{\pi r^2\ell}\,(x^2+y^2)\,dV = \int_0^\ell \int_0^{2\pi} \int_0^r \frac{m}{\pi r^2\ell}\,R^2 R\,dR\,d\theta\,dz = \frac{m}{\pi r^2\ell}\,2\pi\ell\left[\tfrac{1}{4}R^4\right]_0^r = \frac{mr^2}{2}$$

and so $I^* = \dfrac{I_z}{mr^2} = \dfrac{1}{2}$.

[continued]

For the hollow cylinder, we consider its entire mass to lie a distance r from the axis of rotation, so $x^2 + y^2 = r^2$ is a constant. We express the density in terms of mass per unit area as $\rho = \dfrac{m}{2\pi r\ell}$, and then the moment of inertia is calculated as a double integral: $I_z = \iint (x^2 + y^2)\,\dfrac{m}{2\pi r\ell}\,dA = \dfrac{mr^2}{2\pi r\ell}\iint dA = mr^2$, so $I^* = \dfrac{I_z}{mr^2} = 1$.

5. The volume of such a ball is $\frac{4}{3}\pi(r^3 - a^3) = \frac{4}{3}\pi r(1 - b^3)$, and so its density is $\dfrac{m}{\frac{4}{3}\pi r^3(1 - b^3)}$. Using Formula 15.8.3, we get

$$\begin{aligned} I_z &= \iiint (x^2 + y^2)\,\frac{m}{\frac{4}{3}\pi r^3(1 - b^3)}\,dV \\ &= \frac{m}{\frac{4}{3}\pi r^3(1 - b^3)} \int_a^r \int_0^{2\pi} \int_0^{\pi} (\rho^2 \sin^2\phi)(\rho^2 \sin\phi)\,d\phi\,d\theta\,d\rho \\ &= \frac{m}{\frac{4}{3}\pi r^3(1 - b^3)} \cdot 2\pi \left[-\frac{(2 + \sin^2\phi)\cos\phi}{3}\right]_0^{\pi} \left[\frac{\rho^5}{5}\right]_a^r \qquad \text{[from the Table of Integrals]} \\ &= \frac{m}{\frac{4}{3}\pi r^3(1 - b^3)} \cdot 2\pi \cdot \frac{4}{3} \cdot \frac{r^5 - a^5}{5} = \frac{2mr^5(1 - b^5)}{5r^3(1 - b^3)} = \frac{2(1 - b^5)mr^2}{5(1 - b^3)} \end{aligned}$$

Therefore $I^* = \dfrac{2(1 - b^5)}{5(1 - b^3)}$. Since a represents the inner radius, $a \to 0$ corresponds to a solid ball, and $a \to r$ corresponds to a hollow ball.

6. For a solid ball, $a \to 0 \quad\Rightarrow\quad b \to 0$, so $I^* = \lim\limits_{b \to 0} \dfrac{2(1 - b^5)}{5(1 - b^3)} = \dfrac{2}{5}$. For a hollow ball, $a \to r \quad\Rightarrow\quad b \to 1$, so

$$I^* = \lim_{b \to 1} \frac{2(1 - b^5)}{5(1 - b^3)} = \frac{2}{5} \lim_{b \to 1} \frac{-5b^4}{-3b^2} = \frac{2}{5}\left(\frac{5}{3}\right) = \frac{2}{3} \qquad \text{[by l'Hospital's Rule]}$$

Note: We could instead have calculated $I^* = \lim\limits_{b \to 1} \dfrac{2(1 - b)(1 + b + b^2 + b^3 + b^4)}{5(1 - b)(1 + b + b^2)} = \dfrac{2 \cdot 5}{5 \cdot 3} = \dfrac{2}{3}$.

Thus the objects finish in the following order: solid ball $\left(I^* = \frac{2}{5}\right)$, solid cylinder $\left(I^* = \frac{1}{2}\right)$, hollow ball $\left(I^* = \frac{2}{3}\right)$, hollow cylinder $(I^* = 1)$.

15.9 Change of Variables in Multiple Integrals

1. $x = 2u + v,\ y = 4u - v.$

The Jacobian is $\dfrac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \partial x/\partial u & \partial x/\partial v \\ \partial y/\partial u & \partial y/\partial v \end{vmatrix} = \begin{vmatrix} 2 & 1 \\ 4 & -1 \end{vmatrix} = (2)(-1) - (1)(4) = -6.$

2. $x = u^2 + uv,\ y = uv^2.$

$$\frac{\partial(x, y)}{\partial(u, v)} = \begin{vmatrix} \partial x/\partial u & \partial x/\partial v \\ \partial y/\partial u & \partial y/\partial v \end{vmatrix} = \begin{vmatrix} 2u + v & u \\ v^2 & 2uv \end{vmatrix} = (2u + v)(2uv) - u(v^2) = 4u^2v + 2uv^2 - uv^2 = 4u^2v + uv^2$$

3. $x = s\cos t,\ y = s\sin t.$

$$\frac{\partial(x, y)}{\partial(s, t)} = \begin{vmatrix} \partial x/\partial s & \partial x/\partial t \\ \partial y/\partial s & \partial y/\partial t \end{vmatrix} = \begin{vmatrix} \cos t & -s\sin t \\ \sin t & s\cos t \end{vmatrix} = s\cos^2 t - (-s\sin^2 t) = s(\cos^2 t + \sin^2 t) = s$$

4. $x = pe^q,\ y = qe^p.$

$$\frac{\partial(x,y)}{\partial(p,q)} = \begin{vmatrix} \partial x/\partial p & \partial x/\partial q \\ \partial y/\partial p & \partial y/\partial q \end{vmatrix} = \begin{vmatrix} e^q & pe^q \\ qe^p & e^p \end{vmatrix} = e^q e^p - pe^q \cdot qe^p = e^{p+q} - pqe^{p+q} = (1-pq)e^{p+q}$$

5. $x = uv,\ y = vw,\ z = wu.$

$$\frac{\partial(x,y,z)}{\partial(u,v,w)} = \begin{vmatrix} \partial x/\partial u & \partial x/\partial v & \partial x/\partial w \\ \partial y/\partial u & \partial y/\partial v & \partial y/\partial w \\ \partial z/\partial u & \partial z/\partial v & \partial z/\partial w \end{vmatrix} = \begin{vmatrix} v & u & 0 \\ 0 & w & v \\ w & 0 & u \end{vmatrix} = v\begin{vmatrix} w & v \\ 0 & u \end{vmatrix} - u\begin{vmatrix} 0 & v \\ w & u \end{vmatrix} + 0\begin{vmatrix} 0 & w \\ w & 0 \end{vmatrix}$$

$$= v(uw - 0) - u(0 - vw) + 0 = uvw + uvw = 2uvw$$

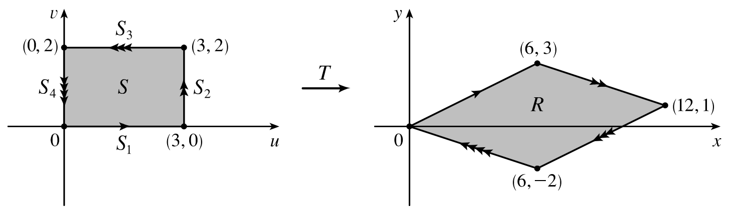
6. $x = u + vw,\ y = v + wu,\ z = w + uv.$

$$\frac{\partial(x,y,z)}{\partial(u,v,w)} = \begin{vmatrix} 1 & w & v \\ w & 1 & u \\ v & u & 1 \end{vmatrix} = 1\begin{vmatrix} 1 & u \\ u & 1 \end{vmatrix} - w\begin{vmatrix} w & u \\ v & 1 \end{vmatrix} + v\begin{vmatrix} w & 1 \\ v & u \end{vmatrix} = 1(1-u^2) - w\,(w - uv) + v\,(uw - v)$$

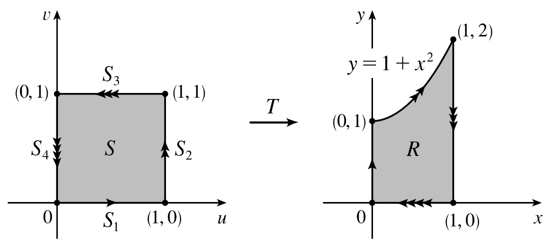
$$= 1 - u^2 - w^2 + uvw + uvw - v^2 = 1 + 2uvw - u^2 - v^2 - w^2$$

7. The transformation maps the boundary of S to the boundary of the image R, so we first look at side S_1 in the uv-plane. S_1 is described by $v = 0$, $0 \le u \le 3$, so $x = 2u + 3v = 2u$ and $y = u - v = u$. Eliminating u, we have $x = 2y$, $0 \le x \le 6$. S_2 is the line segment $u = 3$, $0 \le v \le 2$, so $x = 6 + 3v$ and $y = 3 - v$. Then $v = 3 - y \;\Rightarrow\; x = 6 + 3(3 - y) = 15 - 3y$, $6 \le x \le 12$. S_3 is the line segment $v = 2$, $0 \le u \le 3$, so $x = 2u + 6$ and $y = u - 2$, giving $u = y + 2 \;\Rightarrow\; x = 2y + 10$, $6 \le x \le 12$. Finally, S_4 is the segment $u = 0$, $0 \le v \le 2$, so $x = 3v$ and $y = -v \;\Rightarrow\; x = -3y$, $0 \le x \le 6$.

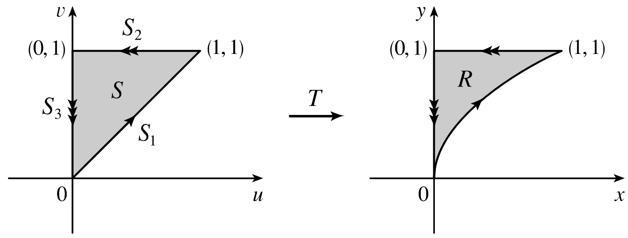
The image of set S is the region R shown in the xy-plane, a parallelogram bounded by these four segments.



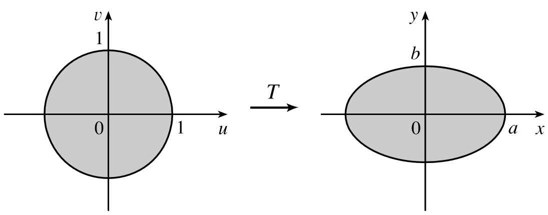
8. S_1 is the line segment $v = 0$, $0 \le u \le 1$, so $x = v = 0$ and $y = u(1 + v^2) = u$. Since $0 \le u \le 1$, the image is the line segment $x = 0$, $0 \le y \le 1$. S_2 is the segment $u = 1$, $0 \le v \le 1$, so $x = v$ and $y = u(1 + v^2) = 1 + x^2$. Thus the image is the portion of the parabola $y = 1 + x^2$ for $0 \le x \le 1$. S_3 is the segment $v = 1$, $0 \le u \le 1$, so $x = 1$ and $y = 2u$. The image is the segment $x = 1$, $0 \le y \le 2$. S_4 is described by $u = 0$, $0 \le v \le 1$, so $0 \le x = v \le 1$ and $y = u(1 + v^2) = 0$. The image is the line segment $y = 0$, $0 \le x \le 1$. Thus, the image of S is the region R bounded by the parabola $y = 1 + x^2$, the x-axis, and the lines $x = 0$, $x = 1$.



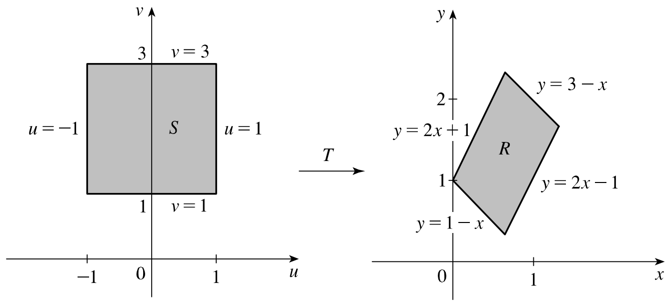
9. S_1 is the line segment $u = v$, $0 \le u \le 1$, so $y = v = u$ and $x = u^2 = y^2$. Since $0 \le u \le 1$, the image is the portion of the parabola $x = y^2$, $0 \le y \le 1$. S_2 is the segment $v = 1$, $0 \le u \le 1$, thus $y = v = 1$ and $x = u^2$, so $0 \le x \le 1$. The image is the line segment $y = 1$, $0 \le x \le 1$. S_3 is the segment $u = 0$, $0 \le v \le 1$, so $x = u^2 = 0$ and $y = v \Rightarrow 0 \le y \le 1$. The image is the segment $x = 0$, $0 \le y \le 1$. Thus, the image of S is the region R in the first quadrant bounded by the parabola $x = y^2$, the y-axis, and the line $y = 1$.



10. Substituting $u = \dfrac{x}{a}$, $v = \dfrac{y}{b}$ into $u^2 + v^2 \le 1$ gives $\dfrac{x^2}{a^2} + \dfrac{y^2}{b^2} \le 1$, so the image of $u^2 + v^2 \le 1$ is the elliptical region $\dfrac{x^2}{a^2} + \dfrac{y^2}{b^2} \le 1$.

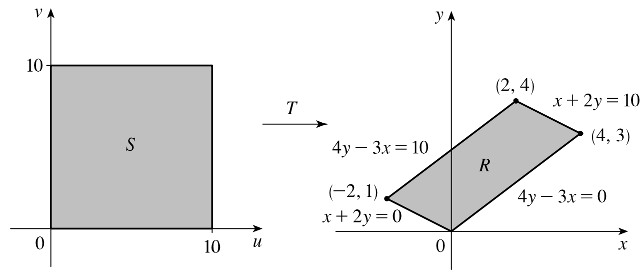


11. R is a parallelogram enclosed by the parallel lines $y = 2x - 1$, $y = 2x + 1$ and the parallel lines $y = 1 - x$, $y = 3 - x$. The first pair of equations can be written as $y - 2x = -1$, $y - 2x = 1$. If we let $u = y - 2x$ then these lines are mapped to the vertical lines $u = -1$, $u = 1$ in the uv-plane. Similarly, the second pair of equations can be written as $x + y = 1$, $x + y = 3$, and setting $v = x + y$ maps these lines to the horizontal lines $v = 1$, $v = 3$ in the uv-plane. Boundary curves are mapped to boundary curves under a transformation, so here the equations $u = y - 2x$, $v = x + y$ define a transformation T^{-1} that maps R in the xy-plane to the square S enclosed by the lines $u = -1$, $u = 1$, $v = 1$, $v = 3$ in the uv-plane. To find the transformation T that maps S to R we solve $u = y - 2x$, $v = x + y$ for x, y: Subtracting the first equation from the second gives $v - u = 3x \Rightarrow x = \frac{1}{3}(v - u)$ and adding twice the second equation to the first gives $u + 2v = 3y \Rightarrow y = \frac{1}{3}(u + 2v)$. Thus one possible transformation T (there are many) is given by $x = \frac{1}{3}(v - u)$, $y = \frac{1}{3}(u + 2v)$.

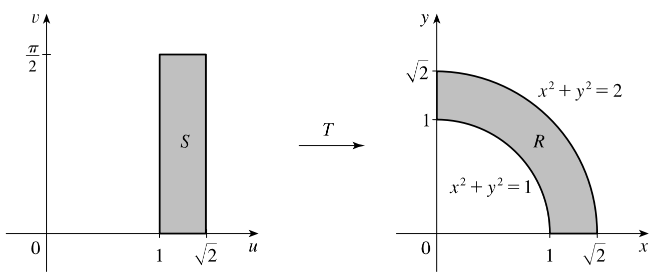


12. The boundaries of the parallelogram R are the lines $y = \frac{3}{4}x$ or $4y - 3x = 0$, $y = \frac{3}{4}x + \frac{5}{2}$ or $4y - 3x = 10$, $y = -\frac{1}{2}x$ or $x + 2y = 0$, $y = -\frac{1}{2}x + 5$ or $x + 2y = 10$. Setting $u = 4y - 3x$ and $v = x + 2y$ defines a transformation T^{-1} that maps R

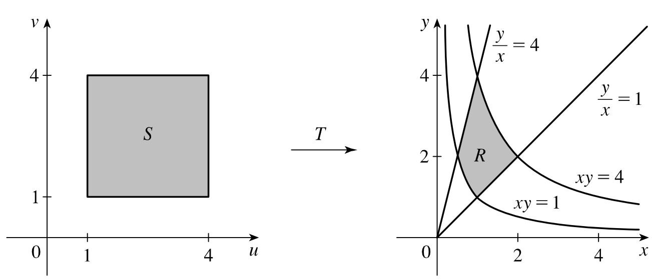
in the xy-plane to the square S enclosed by the lines $u = 0$, $u = 10$, $v = 0$, $v = 10$ in the uv-plane. Solving $u = 4y - 3x$, $v = x + 2y$ for x and y gives $2v - u = 5x \Rightarrow x = \frac{1}{5}(2v - u)$, $u + 3v = 10y \Rightarrow y = \frac{1}{10}(u + 3v)$. Thus one possible transformation T is given by $x = \frac{1}{5}(2v - u)$, $y = \frac{1}{10}(u + 3v)$.



13. R is a portion of an annular region (see the figure) that is easily described in polar coordinates as $R = \{(r, \theta) \mid 1 \le r \le \sqrt{2},\ 0 \le \theta \le \pi/2\}$. If we converted a double integral over R to polar coordinates the resulting region of integration is a rectangle (in the $r\theta$-plane), so we can create a transformation T here by letting u play the role of r and v the role of θ. Thus T is defined by $x = u \cos v$, $y = u \sin v$ and T maps the rectangle $S = \{(u, v) \mid 1 \le u \le \sqrt{2},\ 0 \le v \le \pi/2\}$ in the uv-plane to R in the xy-plane.



14. The boundaries of the region R are the curves $y = 1/x$ or $xy = 1$, $y = 4/x$ or $xy = 4$, $y = x$ or $y/x = 1$, $y = 4x$ or $y/x = 4$. Setting $u = xy$ and $v = y/x$ defines a transformation T^{-1} that maps R in the xy-plane to the square S enclosed by the lines $u = 1$, $u = 4$, $v = 1$, $v = 4$ in the uv-plane. Solving $u = xy$, $v = y/x$ for x and y gives $x^2 = u/v \Rightarrow x = \sqrt{u/v}$ [since x, y, u, v are all positive], $y^2 = uv \Rightarrow y = \sqrt{uv}$. Thus one possible transformation T is given by $x = \sqrt{u/v}$, $y = \sqrt{uv}$.



15. $\dfrac{\partial(x,y)}{\partial(u,v)} = \begin{vmatrix} 2 & 1 \\ 1 & 2 \end{vmatrix} = 3$ and $x - 3y = (2u + v) - 3(u + 2v) = -u - 5v$. To find the region S in the uv-plane that corresponds to R we first find the corresponding boundary under the given transformation. The line through $(0,0)$ and $(2,1)$ is $y = \frac{1}{2}x$ which is the image of $u + 2v = \frac{1}{2}(2u + v) \quad\Rightarrow\quad v = 0$; the line through $(2,1)$ and $(1,2)$ is $x + y = 3$ which is the image of $(2u + v) + (u + 2v) = 3 \quad\Rightarrow\quad u + v = 1$; the line through $(0,0)$ and $(1,2)$ is $y = 2x$ which is the image of $u + 2v = 2(2u + v) \quad\Rightarrow\quad u = 0$. Thus S is the triangle $0 \le v \le 1 - u$, $0 \le u \le 1$ in the uv-plane and

$$\begin{aligned}\iint_R (x - 3y)\,dA &= \int_0^1 \int_0^{1-u} (-u - 5v)\,|3|\;dv\,du = -3\int_0^1 \left[uv + \tfrac{5}{2}v^2\right]_{v=0}^{v=1-u}\,du \\ &= -3\int_0^1 \left(u - u^2 + \tfrac{5}{2}(1-u)^2\right)du = -3\left[\tfrac{1}{2}u^2 - \tfrac{1}{3}u^3 - \tfrac{5}{6}(1-u)^3\right]_0^1 = -3\left(\tfrac{1}{2} - \tfrac{1}{3} + \tfrac{5}{6}\right) = -3\end{aligned}$$

16. $\dfrac{\partial(x,y)}{\partial(u,v)} = \begin{vmatrix} 1/4 & 1/4 \\ -3/4 & 1/4 \end{vmatrix} = \dfrac{1}{4}$, $4x + 8y = 4 \cdot \frac{1}{4}(u + v) + 8 \cdot \frac{1}{4}(v - 3u) = 3v - 5u$. R is a parallelogram bounded by the lines $x - y = -4$, $x - y = 4$, $3x + y = 0$, $3x + y = 8$. Since $u = x - y$ and $v = 3x + y$, R is the image of the rectangle enclosed by the lines $u = -4$, $u = 4$, $v = 0$, and $v = 8$. Thus

$$\begin{aligned}\iint_R (4x + 8y)\,dA &= \int_{-4}^4 \int_0^8 (3v - 5u)\left|\tfrac{1}{4}\right|\,dv\,du = \tfrac{1}{4}\int_{-4}^4 \left[\tfrac{3}{2}v^2 - 5uv\right]_{v=0}^{v=8}\,du \\ &= \tfrac{1}{4}\int_{-4}^4 (96 - 40u)\,du = \tfrac{1}{4}\left[96u - 20u^2\right]_{-4}^4 = 192\end{aligned}$$

17. $\dfrac{\partial(x,y)}{\partial(u,v)} = \begin{vmatrix} 2 & 0 \\ 0 & 3 \end{vmatrix} = 6$, $x^2 = 4u^2$ and the planar ellipse $9x^2 + 4y^2 \le 36$ is the image of the disk $u^2 + v^2 \le 1$. Thus

$$\begin{aligned}\iint_R x^2\,dA &= \iint_{u^2+v^2\le 1} (4u^2)(6)\,du\,dv = \int_0^{2\pi}\int_0^1 (24r^2\cos^2\theta)\,r\,dr\,d\theta = 24\int_0^{2\pi}\cos^2\theta\,d\theta\int_0^1 r^3\,dr \\ &= 24\left[\tfrac{1}{2}x + \tfrac{1}{4}\sin 2x\right]_0^{2\pi}\left[\tfrac{1}{4}r^4\right]_0^1 = 24(\pi)\left(\tfrac{1}{4}\right) = 6\pi\end{aligned}$$

18. $\dfrac{\partial(x,y)}{\partial(u,v)} = \begin{vmatrix} \sqrt{2} & -\sqrt{2/3} \\ \sqrt{2} & \sqrt{2/3} \end{vmatrix} = \dfrac{4}{\sqrt{3}}$, $x^2 - xy + y^2 = 2u^2 + 2v^2$ and the planar ellipse $x^2 - xy + y^2 \le 2$ is the image of the disk $u^2 + v^2 \le 1$. Thus

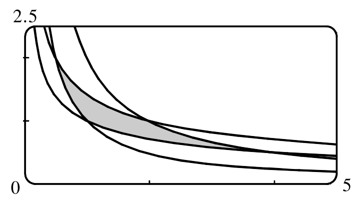
$$\iint_R (x^2 - xy + y^2)\,dA = \iint_{u^2+v^2\le 1} (2u^2 + 2v^2)\left(\tfrac{4}{\sqrt{3}}\,du\,dv\right) = \int_0^{2\pi}\int_0^1 \tfrac{8}{\sqrt{3}}r^3\,dr\,d\theta = \tfrac{4\pi}{\sqrt{3}}$$

19. $\dfrac{\partial(x,y)}{\partial(u,v)} = \begin{vmatrix} 1/v & -u/v^2 \\ 0 & 1 \end{vmatrix} = \dfrac{1}{v}$, $xy = u$, $y = x$ is the image of the parabola $v^2 = u$, $y = 3x$ is the image of the parabola $v^2 = 3u$, and the hyperbolas $xy = 1$, $xy = 3$ are the images of the lines $u = 1$ and $u = 3$ respectively. Thus

$$\iint_R xy\,dA = \int_1^3 \int_{\sqrt{u}}^{\sqrt{3u}} u\left(\frac{1}{v}\right)dv\,du = \int_1^3 u\left(\ln\sqrt{3u} - \ln\sqrt{u}\right)du = \int_1^3 u\ln\sqrt{3}\,du = 4\ln\sqrt{3} = 2\ln 3.$$

20. Here $y = \dfrac{v}{u}$, $x = \dfrac{u^2}{v}$ so $\dfrac{\partial(x,y)}{\partial(u,v)} = \begin{vmatrix} 2u/v & -u^2/v^2 \\ -v/u^2 & 1/u \end{vmatrix} = \dfrac{1}{v}$ and R is the image of the square with vertices $(1,1)$, $(2,1)$, $(2,2)$, and $(1,2)$. So

$$\iint_R y^2\,dA = \int_1^2\int_1^2 \frac{v^2}{u^2}\left(\frac{1}{v}\right)du\,dv = \int_1^2 \frac{v}{2}\,dv = \frac{3}{4}$$



21. (a) $\dfrac{\partial(x,y,z)}{\partial(u,v,w)} = \begin{vmatrix} a & 0 & 0 \\ 0 & b & 0 \\ 0 & 0 & c \end{vmatrix} = abc$ and since $u = \dfrac{x}{a}$, $v = \dfrac{y}{b}$, $w = \dfrac{z}{c}$ the solid enclosed by the ellipsoid is the image of the ball $u^2 + v^2 + w^2 \le 1$. So

$$\iiint_E dV = \iiint_{u^2+v^2+w^2 \le 1} abc\, du\, dv\, dw = (abc)(\text{volume of the ball}) = \tfrac{4}{3}\pi abc$$

(b) If we approximate the surface of the earth by the ellipsoid $\dfrac{x^2}{6378^2} + \dfrac{y^2}{6378^2} + \dfrac{z^2}{6356^2} = 1$, then we can estimate the volume of the earth by finding the volume of the solid E enclosed by the ellipsoid. From part (a), this is $\iiint_E dV = \frac{4}{3}\pi(6378)(6378)(6356) \approx 1.083 \times 10^{12}\ \text{km}^3$.

(c) The moment of intertia about the z-axis is $I_z = \iiint_E \left(x^2 + y^2\right) \rho(x,y,z)\, dV$, where E is the solid enclosed by $\dfrac{x^2}{a^2} + \dfrac{y^2}{b^2} + \dfrac{z^2}{c^2} = 1$. As in part (a), we use the transformation $x = au$, $y = bv$, $z = cw$, so $\left|\dfrac{\partial(x,y,z)}{\partial(u,v,w)}\right| = abc$ and

$$\begin{aligned}
I_z &= \iiint_E \left(x^2 + y^2\right) k\, dV = \iiint_{u^2+v^2+w^2 \le 1} k(a^2u^2 + b^2v^2)(abc)\, du\, dv\, dw \\
&= abck \int_0^\pi \int_0^{2\pi} \int_0^1 (a^2\rho^2 \sin^2\phi \cos^2\theta + b^2\rho^2 \sin^2\phi \sin^2\theta)\, \rho^2 \sin\phi\, d\rho\, d\theta\, d\phi \\
&= abck \left[a^2 \int_0^\pi \int_0^{2\pi} \int_0^1 (\rho^2 \sin^2\phi \cos^2\theta)\, \rho^2 \sin\phi\, d\rho\, d\theta\, d\phi + b^2 \int_0^\pi \int_0^{2\pi} \int_0^1 (\rho^2 \sin^2\phi \sin^2\theta)\, \rho^2 \sin\phi\, d\rho\, d\theta\, d\phi\right] \\
&= a^3bck \int_0^\pi \sin^3\phi\, d\phi \int_0^{2\pi} \cos^2\theta\, d\theta \int_0^1 \rho^4\, d\rho + ab^3ck \int_0^\pi \sin^3\phi\, d\phi \int_0^{2\pi} \sin^2\theta\, d\theta \int_0^1 \rho^4\, d\rho \\
&= a^3bck \left[\tfrac{1}{3}\cos^3\phi - \cos\phi\right]_0^\pi \left[\tfrac{1}{2}\theta + \tfrac{1}{4}\sin 2\theta\right]_0^{2\pi} \left[\tfrac{1}{5}\rho^5\right]_0^1 + ab^3ck \left[\tfrac{1}{3}\cos^3\phi - \cos\phi\right]_0^\pi \left[\tfrac{1}{2}\theta - \tfrac{1}{4}\sin 2\theta\right]_0^{2\pi} \left[\tfrac{1}{5}\rho^5\right]_0^1 \\
&= a^3bck\left(\tfrac{4}{3}\right)(\pi)\left(\tfrac{1}{5}\right) + ab^3ck\left(\tfrac{4}{3}\right)(\pi)\left(\tfrac{1}{5}\right) = \tfrac{4}{15}\pi(a^2 + b^2)abck
\end{aligned}$$

22. R is the region enclosed by the curves $xy = a$, $xy = b$, $xy^{1.4} = c$, and $xy^{1.4} = d$, so if we let $u = xy$ and $v = xy^{1.4}$ then R is the image of the rectangle enclosed by the lines $u = a$, $u = b$ $(a < b)$ and $v = c$, $v = d$ $(c < d)$. Now

$x = u/y \quad \Rightarrow \quad v = (u/y)y^{1.4} = uy^{0.4} \quad \Rightarrow \quad y^{0.4} = u^{-1}v \quad \Rightarrow \quad y = (u^{-1}v)^{1/0.4} = u^{-2.5}v^{2.5}$ and

$x = uy^{-1} = u(u^{-2.5}v^{2.5})^{-1} = u^{3.5}v^{-2.5}$, so

$\dfrac{\partial(x,y)}{\partial(u,v)} = \begin{vmatrix} 3.5u^{2.5}v^{-2.5} & -2.5u^{3.5}v^{-3.5} \\ -2.5u^{-3.5}v^{2.5} & 2.5u^{-2.5}v^{1.5} \end{vmatrix} = 8.75v^{-1} - 6.25v^{-1} = 2.5v^{-1}$. Thus the area of R, and the work done by the engine, is

$$\iint_R dA = \int_a^b \int_c^d \left|2.5v^{-1}\right| dv\, du = 2.5 \int_a^b du \int_c^d (1/v)\, dv = 2.5\big[u\big]_a^b \big[\ln|v|\,\big]_c^d = 2.5(b-a)(\ln d - \ln c) = 2.5(b-a)\ln\frac{d}{c}.$$

23. Letting $u = x - 2y$ and $v = 3x - y$, we have $x = \frac{1}{5}(2v - u)$ and $y = \frac{1}{5}(v - 3u)$. Then $\dfrac{\partial(x,y)}{\partial(u,v)} = \begin{vmatrix} -1/5 & 2/5 \\ -3/5 & 1/5 \end{vmatrix} = \dfrac{1}{5}$ and R is the image of the rectangle enclosed by the lines $u = 0$, $u = 4$, $v = 1$, and $v = 8$. Thus

$$\iint_R \frac{x - 2y}{3x - y}\, dA = \int_0^4 \int_1^8 \frac{u}{v} \left|\frac{1}{5}\right| dv\, du = \frac{1}{5} \int_0^4 u\, du \int_1^8 \frac{1}{v}\, dv = \tfrac{1}{5}\left[\tfrac{1}{2}u^2\right]_0^4 \big[\ln|v|\,\big]_1^8 = \tfrac{8}{5}\ln 8.$$

24. Letting $u = x + y$ and $v = x - y$, we have $x = \frac{1}{2}(u + v)$ and $y = \frac{1}{2}(u - v)$. Then $\dfrac{\partial(x,y)}{\partial(u,v)} = \begin{vmatrix} 1/2 & 1/2 \\ 1/2 & -1/2 \end{vmatrix} = -\dfrac{1}{2}$ and R is the image of the rectangle enclosed by the lines $u = 0$, $u = 3$, $v = 0$, and $v = 2$. Thus

$$\iint_R (x+y)\,e^{x^2-y^2}\,dA = \int_0^3\int_0^2 ue^{uv}\left|-\tfrac{1}{2}\right|dv\,du = \tfrac{1}{2}\int_0^3\left[e^{uv}\right]_{v=0}^{v=2}du = \tfrac{1}{2}\int_0^3(e^{2u}-1)\,du$$
$$= \tfrac{1}{2}\left[\tfrac{1}{2}e^{2u}-u\right]_0^3 = \tfrac{1}{2}\left(\tfrac{1}{2}e^6 - 3 - \tfrac{1}{2}\right) = \tfrac{1}{4}(e^6 - 7)$$

25. Letting $u = y - x$, $v = y + x$, we have $y = \frac{1}{2}(u + v)$, $x = \frac{1}{2}(v - u)$. Then $\dfrac{\partial(x,y)}{\partial(u,v)} = \begin{vmatrix} -1/2 & 1/2 \\ 1/2 & 1/2 \end{vmatrix} = -\dfrac{1}{2}$ and R is the image of the trapezoidal region with vertices $(-1,1)$, $(-2,2)$, $(2,2)$, and $(1,1)$. Thus

$$\iint_R \cos\left(\frac{y-x}{y+x}\right)dA = \int_1^2\int_{-v}^{v}\cos\frac{u}{v}\left|-\frac{1}{2}\right|du\,dv = \frac{1}{2}\int_1^2\left[v\sin\frac{u}{v}\right]_{u=-v}^{u=v}dv = \frac{1}{2}\int_1^2 2v\sin(1)\,dv = \tfrac{3}{2}\sin 1$$

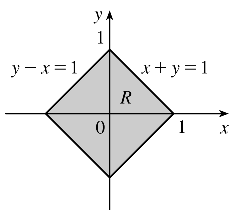
26. Letting $u = 3x$, $v = 2y$, we have $9x^2 + 4y^2 = u^2 + v^2$, $x = \frac{1}{3}u$, and $y = \frac{1}{2}v$. Then $\dfrac{\partial(x,y)}{\partial(u,v)} = \dfrac{1}{6}$ and R is the image of the quarter-disk D given by $u^2 + v^2 \le 1$, $u \ge 0$, $v \ge 0$. Thus

$$\iint_R \sin(9x^2+4y^2)\,dA = \iint_D \tfrac{1}{6}\sin(u^2+v^2)\,du\,dv = \int_0^{\pi/2}\int_0^1 \tfrac{1}{6}\sin(r^2)\,r\,dr\,d\theta = \tfrac{\pi}{12}\left[-\tfrac{1}{2}\cos r^2\right]_0^1 = \tfrac{\pi}{24}(1-\cos 1)$$

27. Let $u = x + y$ and $v = -x + y$. Then $u + v = 2y \Rightarrow y = \frac{1}{2}(u + v)$ and $u - v = 2x \Rightarrow x = \frac{1}{2}(u - v)$.

$\dfrac{\partial(x,y)}{\partial(u,v)} = \begin{vmatrix} 1/2 & -1/2 \\ 1/2 & 1/2 \end{vmatrix} = \dfrac{1}{2}$. Now $|u| = |x + y| \le |x| + |y| \le 1 \Rightarrow -1 \le u \le 1$, and $|v| = |-x + y| \le |x| + |y| \le 1 \Rightarrow -1 \le v \le 1$. R is the image of the square region with vertices $(1,1)$, $(1,-1)$, $(-1,-1)$, and $(-1,1)$.

So $\iint_R e^{x+y}\,dA = \frac{1}{2}\int_{-1}^1\int_{-1}^1 e^u\,du\,dv = \frac{1}{2}\left[e^u\right]_{-1}^1\left[v\right]_{-1}^1 = e - e^{-1}$.



28. Let $u = x + y$ and $v = y$, then $x = u - v$, $y = v$, $\dfrac{\partial(x,y)}{\partial(u,v)} = 1$ and R is the image under T of the triangular region with vertices $(0,0)$, $(1,0)$ and $(1,1)$. Thus

$$\iint_R f(x+y)\,dA = \int_0^1\int_0^u (1)\,f(u)\,dv\,du = \int_0^1 f(u)\left[\,v\,\right]_{v=0}^{v=u}du = \int_0^1 uf(u)\,du \quad \text{as desired.}$$

15 Review

TRUE-FALSE QUIZ

1. This is true by Fubini's Theorem.

2. False. $\int_0^1\int_0^x \sqrt{x+y^2}\,dy\,dx$ describes the region of integration as a Type I region. To reverse the order of integration, we must consider the region as a Type II region: $\int_0^1\int_y^1 \sqrt{x+y^2}\,dx\,dy$.

3. True by Equation 15.1.11.

4. $\int_{-1}^{1}\int_{0}^{1} e^{x^2+y^2}\sin y\,dx\,dy = \left(\int_0^1 e^{x^2}\,dx\right)\left(\int_{-1}^{1} e^{y^2}\sin y\,dy\right) = \left(\int_0^1 e^{x^2}\,dx\right)(0) = 0$, since $e^{y^2}\sin y$ is an odd function. Therefore the statement is true.

5. True. By Equation 15.1.11 we can write $\int_0^1\int_0^1 f(x)\,f(y)\,dy\,dx = \int_0^1 f(x)\,dx\int_0^1 f(y)\,dy$. But $\int_0^1 f(y)\,dy = \int_0^1 f(x)\,dx$ so this becomes $\int_0^1 f(x)\,dx\int_0^1 f(x)\,dx = \left[\int_0^1 f(x)\,dx\right]^2$.

6. This statement is true because in the given region, $\left(x^2+\sqrt{y}\right)\sin(x^2y^2) \le (1+2)(1) = 3$, so $\int_1^4\int_0^1 \left(x^2+\sqrt{y}\right)\sin(x^2y^2)\,dx\,dy \le \int_1^4\int_0^1 3\,dA = 3A(D) = 3(3) = 9$.

7. True: $\iint_D \sqrt{4-x^2-y^2}\,dA =$ the volume under the surface $x^2+y^2+z^2=4$ and above the xy-plane

$= \frac{1}{2}\left(\text{the volume of the sphere } x^2+y^2+z^2=4\right) = \frac{1}{2}\cdot\frac{4}{3}\pi(2)^3 = \frac{16}{3}\pi$

8. True. The moment of inertia about the z-axis of a solid E with constant density k is

$I_z = \iiint_E (x^2+y^2)\rho(x,y,z)\,dV = \iiint_E (kr^2)\,r\,dz\,dr\,d\theta = \iiint_E kr^3\,dz\,dr\,d\theta$.

9. The volume enclosed by the cone $z=\sqrt{x^2+y^2}$ and the plane $z=2$ is, in cylindrical coordinates, $V = \int_0^{2\pi}\int_0^2\int_r^2 r\,dz\,dr\,d\theta \ne \int_0^{2\pi}\int_0^2\int_r^2 dz\,dr\,d\theta$, so the assertion is false.

EXERCISES

1. As shown in the contour map, we divide R into 9 equally sized subsquares, each with area $\Delta A = 1$. Then we approximate $\iint_R f(x,y)\,dA$ by a Riemann sum with $m=n=3$ and the sample points the upper right corners of each square, so

$$\iint_R f(x,y)\,dA \approx \sum_{i=1}^{3}\sum_{j=1}^{3} f(x_i,y_j)\,\Delta A$$
$$= \Delta A\,[f(1,1)+f(1,2)+f(1,3)+f(2,1)+f(2,2)+f(2,3)+f(3,1)+f(3,2)+f(3,3)]$$

Using the contour lines to estimate the function values, we have

$$\iint_R f(x,y)\,dA \approx 1[2.7+4.7+8.0+4.7+6.7+10.0+6.7+8.6+11.9] \approx 64.0$$

2. As in Exercise 1, we have $m=n=3$ and $\Delta A = 1$. Using the contour map to estimate the value of f at the center of each subsquare, we have

$$\iint_R f(x,y)\,dA \approx \sum_{i=1}^{3}\sum_{j=1}^{3} f\left(\overline{x}_i,\overline{y}_j\right)\Delta A$$
$$= \Delta A\,[f(0.5,0.5)+(0.5,1.5)+(0.5,2.5)+(1.5,0.5)+f(1.5,1.5)$$
$$+f(1.5,2.5)+(2.5,0.5)+f(2.5,1.5)+f(2.5,2.5)]$$
$$\approx 1[1.2+2.5+5.0+3.2+4.5+7.1+5.2+6.5+9.0] = 44.2$$

3. $\int_1^2\int_0^2 (y+2xe^y)\,dx\,dy = \int_1^2 \left[xy+x^2e^y\right]_{x=0}^{x=2}dy = \int_1^2 (2y+4e^y)\,dy = \left[y^2+4e^y\right]_1^2$

$= 4+4e^2-1-4e = 4e^2-4e+3$

4. $\int_0^1 \int_0^1 ye^{xy}\,dx\,dy = \int_0^1 \left[e^{xy}\right]_{x=0}^{x=1} dy = \int_0^1 (e^y - 1)\,dy = \left[e^y - y\right]_0^1 = e - 2$

5. $\int_0^1 \int_0^x \cos(x^2)\,dy\,dx = \int_0^1 \left[\cos(x^2)y\right]_{y=0}^{y=x} dx = \int_0^1 x\cos(x^2)\,dx = \frac{1}{2}\sin(x^2)\Big]_0^1 = \frac{1}{2}\sin 1$

6. $\int_0^1 \int_x^{e^x} 3xy^2\,dy\,dx = \int_0^1 \left[xy^3\right]_{y=x}^{y=e^x} dx = \int_0^1 (xe^{3x} - x^4)\,dx = \frac{1}{3}xe^{3x}\Big]_0^1 - \int_0^1 \frac{1}{3}e^{3x}\,dx - \left[\frac{1}{5}x^5\right]_0^1$ [integrate by parts in the first term]

$= \frac{1}{3}e^3 - \left[\frac{1}{9}e^{3x}\right]_0^1 - \frac{1}{5} = \frac{2}{9}e^3 - \frac{4}{45}$

7. $\int_0^\pi \int_0^1 \int_0^{\sqrt{1-y^2}} y\sin x\,dz\,dy\,dx = \int_0^\pi \int_0^1 \left[(y\sin x)z\right]_{z=0}^{z=\sqrt{1-y^2}} dy\,dx = \int_0^\pi \int_0^1 y\sqrt{1-y^2}\sin x\,dy\,dx$

$= \int_0^\pi \left[-\frac{1}{3}(1-y^2)^{3/2}\sin x\right]_{y=0}^{y=1} dx = \int_0^\pi \frac{1}{3}\sin x\,dx = -\frac{1}{3}\cos x\Big]_0^\pi = \frac{2}{3}$

8. $\int_0^1 \int_0^y \int_x^1 6xyz\,dz\,dx\,dy = \int_0^1 \int_0^y \left[3xyz^2\right]_{z=x}^{z=1} dx\,dy = \int_0^1 \int_0^y (3xy - 3x^3y)\,dx\,dy$

$= \int_0^1 \left[\frac{3}{2}x^2y - \frac{3}{4}x^4y\right]_{x=0}^{x=y} dy = \int_0^1 \left(\frac{3}{2}y^3 - \frac{3}{4}y^5\right) dy = \left[\frac{3}{8}y^4 - \frac{1}{8}y^6\right]_0^1 = \frac{1}{4}$

9. The region R is more easily described by polar coordinates: $R = \{(r,\theta) \mid 2 \le r \le 4, 0 \le \theta \le \pi\}$. Thus $\iint_R f(x,y)\,dA = \int_0^\pi \int_2^4 f(r\cos\theta, r\sin\theta)\,r\,dr\,d\theta$.

10. The region R is a type II region that can be described as the region enclosed by the lines $y = 4 - x$, $y = 4 + x$, and the x-axis. So using rectangular coordinates, we can say $R = \{(x,y) \mid 0 \le y \le 4, y - 4 \le x \le 4 - y\}$ and $\iint_R f(x,y)\,dA = \int_0^4 \int_{y-4}^{4-y} f(x,y)\,dx\,dy$.

11. $x = r\cos\theta = 2\sqrt{3}\cos\frac{\pi}{3} = 2\sqrt{3}\cdot\frac{1}{2} = \sqrt{3}$, $y = r\sin\theta = 2\sqrt{3}\sin\frac{\pi}{3} = 2\sqrt{3}\cdot\frac{\sqrt{3}}{2} = 3$, $z = 2$, so in rectangular coordinates the point is $(\sqrt{3}, 3, 2)$. $\rho = \sqrt{r^2 + z^2} = \sqrt{12 + 4} = 4$, $\theta = \frac{\pi}{3}$, and $\cos\phi = z/\rho = \frac{1}{2}$, so $\phi = \frac{\pi}{3}$ and spherical coordinates are $\left(4, \frac{\pi}{3}, \frac{\pi}{3}\right)$.

12. $r = \sqrt{4+4} = 2\sqrt{2}$; $z = -1$; $\tan\theta = \frac{2}{2} = 1$ and the point $(2,2)$ is in the first quadrant of the xy-plane, so $\theta = \frac{\pi}{4}$. Thus in cylindrical coordinates the point is $\left(2\sqrt{2}, \frac{\pi}{4}, -1\right)$. $\rho = \sqrt{4+4+1} = 3$, $\cos\phi = z/\rho = -\frac{1}{3}$, so the spherical coordinates are $\left(3, \frac{\pi}{4}, \cos^{-1}\left(-\frac{1}{3}\right)\right)$.

13. $x = \rho\sin\phi\cos\theta = 8\sin\frac{\pi}{6}\cos\frac{\pi}{4} = 8\cdot\frac{1}{2}\cdot\frac{\sqrt{2}}{2} = 2\sqrt{2}$, $y = \rho\sin\phi\sin\theta = 8\sin\frac{\pi}{6}\sin\frac{\pi}{4} = 2\sqrt{2}$, and $z = \rho\cos\phi = 8\cos\frac{\pi}{6} = 8\cdot\frac{\sqrt{3}}{2} = 4\sqrt{3}$. Thus rectangular coordinates for the point are $\left(2\sqrt{2}, 2\sqrt{2}, 4\sqrt{3}\right)$.

$r^2 = x^2 + y^2 = 8 + 8 = 16 \quad\Rightarrow\quad r = 4$, $\theta = \frac{\pi}{4}$, and $z = 4\sqrt{3}$, so cylindrical coordinates are $\left(4, \frac{\pi}{4}, 4\sqrt{3}\right)$.

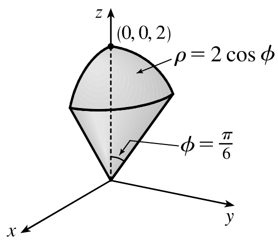
14. (a) $\theta = \frac{\pi}{4}$. In cylindrical coordinates (assuming that r can be negative), this is a vertical plane that includes the z-axis and intersects the xy-plane in the line $y = x$. In spherical coordinates, because $\rho \ge 0$ and $0 \le \phi \le \pi$, we get a vertical half-plane that includes the z-axis and intersects the xy-plane in the half-line $y = x$, $x \ge 0$.

(b) $\phi = \frac{\pi}{4}$. In spherical coordinates, this is one frustum of a circular cone with vertex the origin and axis the positive z-axis.

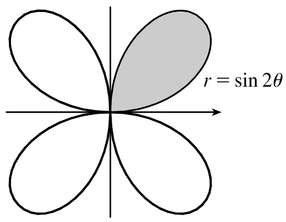
15. (a) $x^2+y^2+z^2=4$. In cylindrical coordinates, this becomes $r^2+z^2=4$. In spherical coordinates, it becomes $\rho^2=4$ or $\rho=2$.

(b) $x^2+y^2=4$. In cylindrical coordinates: $r^2=4$ or $r=2$. In spherical coordinates: $\rho^2-z^2=4$ or $\rho^2-\rho^2\cos^2\phi=4$ or $\rho^2\sin^2\phi=4$ or $\rho\sin\phi=2$.

16. $\rho=2\cos\phi \quad\Rightarrow\quad \rho^2=2\rho\cos\phi \quad\Rightarrow\quad x^2+y^2+z^2=2z \quad\Rightarrow$ $x^2+y^2+(z-1)^2=1$. This is the equation of a sphere with radius 1, centered at $(0,0,1)$. Therefore, $0\le\rho\le 2\cos\phi$ is the solid ball whose boundary is this sphere. $0\le\theta\le\frac{\pi}{2}$ and $0\le\phi\le\frac{\pi}{6}$ restrict the solid to the section of this ball that lies above the cone $\phi=\frac{\pi}{6}$ and is in the first octant.



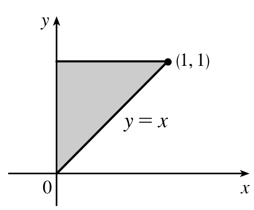
17.



The region whose area is given by $\int_0^{\pi/2}\int_0^{\sin 2\theta} r\,dr\,d\theta$ is $\left\{(r,\theta)\mid 0\le\theta\le\frac{\pi}{2}, 0\le r\le \sin 2\theta\right\}$, which is the region contained in the loop in the first quadrant of the four-leaved rose $r=\sin 2\theta$.

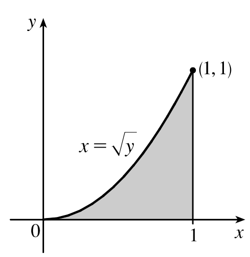
18. The solid is $\left\{(\rho,\theta,\phi)\mid 1\le\rho\le 2,\ 0\le\theta\le\frac{\pi}{2},\ 0\le\phi\le\frac{\pi}{2}\right\}$ which is the region in the first octant on or between the two spheres $\rho=1$ and $\rho=2$.

19.



$$\begin{aligned}\int_0^1\int_x^1 \cos(y^2)\,dy\,dx &= \int_0^1\int_0^y \cos(y^2)\,dx\,dy \\ &= \int_0^1 \cos(y^2)\left[\,x\,\right]_{x=0}^{x=y}\,dy = \int_0^1 y\cos(y^2)\,dy \\ &= \left[\tfrac{1}{2}\sin(y^2)\right]_0^1 = \tfrac{1}{2}\sin 1\end{aligned}$$

20.



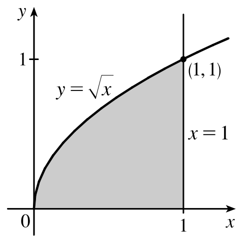
$$\begin{aligned}\int_0^1\int_{\sqrt{y}}^1 \frac{ye^{x^2}}{x^3}\,dx\,dy &= \int_0^1\int_0^{x^2}\frac{ye^{x^2}}{x^3}\,dy\,dx = \int_0^1 \frac{e^{x^2}}{x^3}\left[\tfrac{1}{2}y^2\right]_{y=0}^{y=x^2}\,dx \\ &= \int_0^1 \tfrac{1}{2}xe^{x^2}\,dx = \tfrac{1}{4}e^{x^2}\Big]_0^1 = \tfrac{1}{4}(e-1)\end{aligned}$$

21. $\iint_R ye^{xy}\,dA = \int_0^3\int_0^2 ye^{xy}\,dx\,dy = \int_0^3\left[e^{xy}\right]_{x=0}^{x=2}\,dy = \int_0^3(e^{2y}-1)\,dy = \left[\frac{1}{2}e^{2y}-y\right]_0^3 = \frac{1}{2}e^6-3-\frac{1}{2} = \frac{1}{2}e^6-\frac{7}{2}$

22. $\iint_D xy\,dA = \int_0^1\int_{y^2}^{y+2} xy\,dx\,dy = \int_0^1 y\left[\frac{1}{2}x^2\right]_{x=y^2}^{x=y+2}\,dy = \frac{1}{2}\int_0^1 y\left[(y+2)^2-y^4\right]dy$

$= \frac{1}{2}\int_0^1 (y^3+4y^2+4y-y^5)\,dy = \frac{1}{2}\left[\frac{1}{4}y^4+\frac{4}{3}y^3+2y^2-\frac{1}{6}y^6\right]_0^1 = \frac{41}{24}$

23.



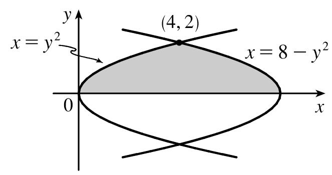
$$\iint_D \frac{y}{1+x^2}\,dA = \int_0^1 \int_0^{\sqrt{x}} \frac{y}{1+x^2}\,dy\,dx = \int_0^1 \frac{1}{1+x^2}\left[\tfrac{1}{2}y^2\right]_{y=0}^{y=\sqrt{x}}\,dx$$

$$= \tfrac{1}{2}\int_0^1 \frac{x}{1+x^2}\,dx = \left[\tfrac{1}{4}\ln(1+x^2)\right]_0^1 = \tfrac{1}{4}\ln 2$$

24. $\displaystyle\iint_D \frac{1}{1+x^2}\,dA = \int_0^1\int_x^1 \frac{1}{1+x^2}\,dy\,dx = \int_0^1 \frac{1}{1+x^2}\left[\,y\,\right]_{y=x}^{y=1}\,dx = \int_0^1 \frac{1-x}{1+x^2}\,dx = \int_0^1 \left(\frac{1}{1+x^2} - \frac{x}{1+x^2}\right)dx$

$$= \left[\tan^{-1}x - \tfrac{1}{2}\ln(1+x^2)\right]_0^1 = \tan^{-1}1 - \tfrac{1}{2}\ln 2 - \left(\tan^{-1}0 - \tfrac{1}{2}\ln 1\right) = \tfrac{\pi}{4} - \tfrac{1}{2}\ln 2$$

25.

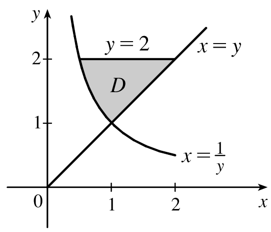


$$\iint_D y\,dA = \int_0^2\int_{y^2}^{8-y^2} y\,dx\,dy$$

$$= \int_0^2 y\left[x\right]_{x=y^2}^{x=8-y^2}\,dy = \int_0^2 y(8-y^2-y^2)\,dy$$

$$= \int_0^2 (8y-2y^3)\,dy = \left[4y^2 - \tfrac{1}{2}y^4\right]_0^2 = 8$$

26.

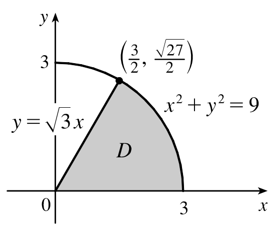


$$\iint_D y\,dA = \int_1^2\int_{1/y}^{y} y\,dx\,dy = \int_1^2 y\left(y - \frac{1}{y}\right)dy$$

$$= \int_1^2 (y^2-1)\,dy = \left[\tfrac{1}{3}y^3 - y\right]_1^2$$

$$= \left(\tfrac{8}{3} - 2\right) - \left(\tfrac{1}{3} - 1\right) = \tfrac{4}{3}$$

27.



$$\iint_D \left(x^2+y^2\right)^{3/2} dA = \int_0^{\pi/3}\int_0^3 (r^2)^{3/2}\,r\,dr\,d\theta$$

$$= \int_0^{\pi/3} d\theta \int_0^3 r^4\,dr = \left[\,\theta\,\right]_0^{\pi/3}\left[\tfrac{1}{5}r^5\right]_0^3$$

$$= \frac{\pi}{3}\,\frac{3^5}{5} = \frac{81\pi}{5}$$

28. $\iint_D x\,dA = \int_0^{\pi/2}\int_1^{\sqrt{2}} (r\cos\theta)\,r\,dr\,d\theta = \int_0^{\pi/2}\cos\theta\,d\theta\,\int_1^{\sqrt{2}} r^2\,dr = \left[\sin\theta\right]_0^{\pi/2}\left[\tfrac{1}{3}r^3\right]_1^{\sqrt{2}}$

$$= 1\cdot\tfrac{1}{3}(2^{3/2}-1) = \tfrac{1}{3}(2^{3/2}-1)$$

29. $\iiint_E xy\,dV = \int_0^3\int_0^x\int_0^{x+y} xy\,dz\,dy\,dx = \int_0^3\int_0^x xy\left[\,z\,\right]_{z=0}^{z=x+y}\,dy\,dx = \int_0^3\int_0^x xy(x+y)\,dy\,dx$

$$= \int_0^3\int_0^x (x^2y+xy^2)\,dy\,dx = \int_0^3 \left[\tfrac{1}{2}x^2y^2 + \tfrac{1}{3}xy^3\right]_{y=0}^{y=x}\,dx = \int_0^3 \left(\tfrac{1}{2}x^4 + \tfrac{1}{3}x^4\right)dx$$

$$= \tfrac{5}{6}\int_0^3 x^4\,dx = \left[\tfrac{1}{6}x^5\right]_0^3 = \tfrac{81}{2} = 40.5$$

30. $\iiint_T xy\,dV = \int_0^{1/3}\int_0^{1-3x}\int_0^{1-3x-y} xy\,dz\,dy\,dx = \int_0^{1/3}\int_0^{1-3x} xy(1-3x-y)\,dy\,dx$

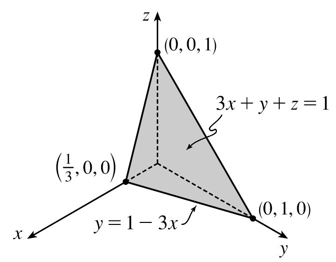
$= \int_0^{1/3}\int_0^{1-3x}(xy - 3x^2y - xy^2)\,dy\,dx$

$= \int_0^{1/3}\left[\frac{1}{2}xy^2 - \frac{3}{2}x^2y^2 - \frac{1}{3}xy^3\right]_{y=0}^{y=1-3x} dx$

$= \int_0^{1/3}\left[\frac{1}{2}x(1-3x)^2 - \frac{3}{2}x^2(1-3x)^2 - \frac{1}{3}x(1-3x)^3\right] dx$

$= \int_0^{1/3}\left(\frac{1}{6}x - \frac{3}{2}x^2 + \frac{9}{2}x^3 - \frac{9}{2}x^4\right) dx$

$= \left.\frac{1}{12}x^2 - \frac{1}{2}x^3 + \frac{9}{8}x^4 - \frac{9}{10}x^5\right]_0^{1/3} = \frac{1}{1080}$



31. $\iiint_E y^2z^2\,dV = \int_{-1}^{1}\int_{-\sqrt{1-y^2}}^{\sqrt{1-y^2}}\int_0^{1-y^2-z^2} y^2z^2\,dx\,dz\,dy = \int_{-1}^{1}\int_{-\sqrt{1-y^2}}^{\sqrt{1-y^2}} y^2z^2(1-y^2-z^2)\,dz\,dy$

$= \int_0^{2\pi}\int_0^1 (r^2\cos^2\theta)(r^2\sin^2\theta)(1-r^2)\,r\,dr\,d\theta = \int_0^{2\pi}\left(\frac{1}{2}\sin 2\theta\right)^2 d\theta \int_0^1 (r^5 - r^7)\,dr$

$= \int_0^{2\pi}\frac{1}{4}\left[\frac{1}{2}(1-\cos 4\theta)\right] d\theta \int_0^1 (r^5-r^7)\,dr = \frac{1}{8}\left[\theta - \frac{1}{4}\sin 4\theta\right]_0^{2\pi}\left[\frac{1}{6}r^6 - \frac{1}{8}r^8\right]_0^1$

$= \frac{1}{8}(2\pi)\left(\frac{1}{6}-\frac{1}{8}\right) = \frac{\pi}{4}\cdot\frac{1}{24} = \frac{\pi}{96}$

32. $\iiint_E z\,dV = \int_0^1\int_0^{\sqrt{1-y^2}}\int_0^{2-y} z\,dx\,dz\,dy = \int_0^1\int_0^{\sqrt{1-y^2}}(2-y)z\,dz\,dy = \int_0^1 \frac{1}{2}(2-y)(1-y^2)\,dy$

$= \int_0^1 \frac{1}{2}(2 - y - 2y^2 + y^3)\,dy = \frac{13}{24}$

33. $\iiint_E yz\,dV = \int_{-2}^{2}\int_0^{\sqrt{4-x^2}}\int_0^y yz\,dz\,dy\,dx = \int_{-2}^{2}\int_0^{\sqrt{4-x^2}}\left[\frac{1}{2}yz^2\right]_{z=0}^{z=y} dy\,dx = \frac{1}{2}\int_{-2}^{2}\int_0^{\sqrt{4-x^2}} y^3\,dy\,dx$

$= \frac{1}{2}\int_0^{\pi}\int_0^2 (r\sin\theta)^3\,r\,dr\,d\theta = \frac{1}{2}\int_0^{\pi}\sin^3\theta\,d\theta\int_0^2 r^4\,dr = \frac{1}{2}\int_0^{\pi}(1-\cos^2\theta)\sin\theta\,d\theta\int_0^2 r^4\,dr$

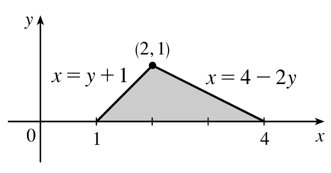
$= \frac{1}{2}\left[-\cos\theta + \frac{1}{3}\cos^3\theta\right]_0^{\pi}\left[\frac{1}{5}r^5\right]_0^2 = \frac{1}{2}\left(\frac{2}{3}+\frac{2}{3}\right)\left(\frac{32}{5}\right) = \frac{64}{15}$

34. $\iiint_H z^3\sqrt{x^2+y^2+z^2}\,dV = \int_0^{2\pi}\int_0^{\pi/2}\int_0^1 (\rho^3\cos^3\phi)\rho(\rho^2\sin\phi)\,d\rho\,d\phi\,d\theta$

$= \int_0^{2\pi} d\theta \int_0^{\pi/2}\cos^3\phi\sin\phi\,d\phi \int_0^1 \rho^6\,d\rho = 2\pi\left[-\frac{1}{4}\cos^4\phi\right]_0^{\pi/2}\left(\frac{1}{7}\right) = \frac{\pi}{14}$

35. $V = \int_0^2\int_1^4 (x^2+4y^2)\,dy\,dx = \int_0^2\left[x^2y + \frac{4}{3}y^3\right]_{y=1}^{y=4} dx = \int_0^2 (3x^2+84)\,dx = \left.x^3 + 84x\right]_0^2 = 176$

36.

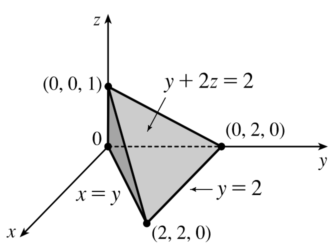


$V = \int_0^1\int_{y+1}^{4-2y}\int_0^{x^2y} dz\,dx\,dy = \int_0^1\int_{y+1}^{4-2y} x^2y\,dx\,dy$

$= \int_0^1 \frac{1}{3}\left[(4-2y)^3y - (y+1)^3y\right] dy$

$= \int_0^1 3(-y^4 + 5y^3 - 11y^2 + 7y)\,dy = 3\left(-\frac{1}{5} + \frac{5}{4} - \frac{11}{3} + \frac{7}{2}\right) = \frac{53}{20}$

37.



$V = \int_0^2\int_0^y\int_0^{(2-y)/2} dz\,dx\,dy = \int_0^2\int_0^y \left(1 - \frac{1}{2}y\right) dx\,dy$

$= \int_0^2\left(y - \frac{1}{2}y^2\right) dy = \left.\frac{1}{2}y^2 - \frac{1}{6}y^3\right]_0^2 = \frac{2}{3}$

38. $V = \int_0^{2\pi}\int_0^2\int_0^{3-r\sin\theta} r\,dz\,dr\,d\theta = \int_0^{2\pi}\int_0^2 (3r - r^2\sin\theta)\,dr\,d\theta = \int_0^{2\pi}\left[6 - \frac{8}{3}\sin\theta\right]d\theta = 6\theta + \frac{8}{3}\cos\theta\Big]_0^{2\pi} = 12\pi$

39. Using the wedge above the plane $z = 0$ and below the plane $z = mx$ and noting that we have the same volume for $m < 0$ as for $m > 0$ (so use $m > 0$), we have

$V = 2\int_0^{a/3}\int_0^{\sqrt{a^2-9y^2}} mx\,dx\,dy = 2\int_0^{a/3}\frac{1}{2}m(a^2 - 9y^2)\,dy = m\left[a^2y - 3y^3\right]_0^{a/3} = m\left(\frac{1}{3}a^3 - \frac{1}{9}a^3\right) = \frac{2}{9}ma^3.$

40. The paraboloid and the half-cone intersect when $x^2 + y^2 = \sqrt{x^2+y^2}$, that is when $x^2 + y^2 = 1$ or 0. So

$V = \iint_{x^2+y^2\le 1}\int_{x^2+y^2}^{\sqrt{x^2+y^2}} dz\,dA = \int_0^{2\pi}\int_0^1\int_{r^2}^{r} r\,dz\,dr\,d\theta = \int_0^{2\pi}\int_0^1 (r^2 - r^3)\,dr\,d\theta = \int_0^{2\pi}\left(\frac{1}{3} - \frac{1}{4}\right)d\theta = \frac{1}{12}(2\pi) = \frac{\pi}{6}.$

41. (a) $m = \int_0^1\int_0^{1-y^2} y\,dx\,dy = \int_0^1 (y - y^3)\,dy = \frac{1}{2} - \frac{1}{4} = \frac{1}{4}$

(b) $M_y = \int_0^1\int_0^{1-y^2} xy\,dx\,dy = \int_0^1 \frac{1}{2}y(1-y^2)^2\,dy = -\frac{1}{12}(1-y^2)^3\Big]_0^1 = \frac{1}{12},$

$M_x = \int_0^1\int_0^{1-y^2} y^2\,dx\,dy = \int_0^1 (y^2 - y^4)\,dy = \frac{2}{15}$. Hence $(\overline{x},\overline{y}) = \left(\frac{1}{3}, \frac{8}{15}\right)$.

(c) $I_x = \int_0^1\int_0^{1-y^2} y^3\,dx\,dy = \int_0^1 (y^3 - y^5)\,dy = \frac{1}{12},$

$I_y = \int_0^1\int_0^{1-y^2} yx^2\,dx\,dy = \int_0^1 \frac{1}{3}y(1-y^2)^3\,dy = -\frac{1}{24}(1-y^2)^4\Big]_0^1 = \frac{1}{24},$

$\overline{\overline{y}}^2 = I_x/m = \frac{1/12}{1/4} = \frac{1}{3} \;\Rightarrow\; \overline{\overline{y}} = \frac{1}{\sqrt{3}}$, and $\overline{\overline{x}}^2 = I_y/m = \frac{1/24}{1/4} = \frac{1}{6} \;\Rightarrow\; \overline{\overline{x}} = \frac{1}{\sqrt{6}}$.

42. (a) In polar coordinates, the lamina occupies the region $D = \{(r,\theta) \mid 0 \le r \le a, 0 \le \theta \le \pi/2\}$. Assuming constant density K, then $m = K\,A(D) = K\cdot\frac{1}{4}\pi a^2 = \frac{1}{4}\pi K a^2$,

$M_y = \iint_D Kx\,dA = K\int_0^{\pi/2}\int_0^a (r\cos\theta)\,r\,dr\,d\theta = K\int_0^{\pi/2}\cos\theta\,d\theta\int_0^a r^2\,dr = K\left[\sin\theta\right]_0^{\pi/2}\left[\frac{1}{3}r^3\right]_0^a = \frac{1}{3}Ka^3$, and

$M_x = \iint_D Ky\,dA = K\int_0^{\pi/2}\sin\theta\,d\theta\int_0^a r^2\,dr = K\left[-\cos\theta\right]_0^{\pi/2}\left[\frac{1}{3}r^3\right]_0^a = \frac{1}{3}Ka^3$ [by symmetry $M_y = M_x$].

Thus the centroid is $(\overline{x},\overline{y}) = (M_y/m, M_x/m) = \left(\frac{4}{3\pi}a, \frac{4}{3\pi}a\right)$.

(b) $m = \iint_D \rho(x,y)\,dA = \iint_D xy^2\,dA = \int_0^{\pi/2}\int_0^a (r\cos\theta)(r\sin\theta)^2\,r\,dr\,d\theta$

$= \int_0^{\pi/2}\sin^2\theta\,\cos\theta\,d\theta\int_0^a r^4\,dr = \left[\frac{1}{3}\sin^3\theta\right]_0^{\pi/2}\left[\frac{1}{5}r^5\right]_0^a = \frac{1}{15}a^5,$

$M_y = \int_0^{\pi/2}\int_0^a r^5\cos^2\theta\sin^2\theta\,dr\,d\theta = \frac{1}{8}\left[\theta - \frac{1}{4}\sin 4\theta\right]_0^{\pi/2}\left[\frac{1}{6}r^6\right]_0^a = \frac{1}{96}\pi a^6$, and

$M_x = \int_0^{\pi/2}\int_0^a r^5\cos\theta\sin^3\theta\,dr\,d\theta = \left[\frac{1}{4}\sin^4\theta\right]_0^{\pi/2}\left[\frac{1}{6}r^6\right]_0^a = \frac{1}{24}a^6$. Hence $(\overline{x},\overline{y}) = \left(\frac{5}{32}\pi a, \frac{5}{8}a\right)$.

43. (a) A right circular cone with axis the z-axis and vertex at the origin has equation $z^2 = c^2(x^2 + y^2)$. Here we have the bottom frustum, shifted upward h units, and with $c^2 = h^2/a^2$ so that the cone includes the point $(a, 0, 0)$. Thus an equation of the cone in rectangular coordinates is $z = h - \frac{h}{a}\sqrt{x^2+y^2}$, $0 \le z \le h$. In cylindrical coordinates, the cone is described by $E = \left\{(r,\theta,z) \mid 0 \le r \le a,\ 0 \le \theta \le 2\pi,\ 0 \le z \le h\left(1 - \frac{1}{a}r\right)\right\}$, and its volume is $V = \frac{1}{3}\pi a^2 h$. By symmetry

$M_{yz} = M_{xz} = 0$, and

$$M_{xy} = \int_0^{2\pi}\int_0^a\int_0^{h(1-r/a)} z \cdot r\,dz\,dr\,d\theta = \int_0^{2\pi}\int_0^a \left[\frac{1}{2}rz^2\right]_{z=0}^{z=h(1-r/a)} dr\,d\theta$$
$$= \frac{1}{2}\int_0^{2\pi}\int_0^a rh^2\left(1-\frac{r}{a}\right)^2 dr\,d\theta = \frac{1}{2}h^2\int_0^{2\pi} d\theta \int_0^a \left(r - \frac{2}{a}r^2 + \frac{1}{a^2}r^3\right) dr$$
$$= \tfrac{1}{2}h^2\left[\,\theta\,\right]_0^{2\pi}\left[\tfrac{1}{2}r^2 - \tfrac{2}{3a}r^3 + \tfrac{1}{4a^2}r^4\right]_0^a = \tfrac{1}{2}h^2(2\pi)\left(\tfrac{1}{2}a^2 - \tfrac{2}{3}a^2 + \tfrac{1}{4}a^2\right)$$
$$= \pi h^2\left(\tfrac{1}{12}a^2\right) = \tfrac{1}{12}\pi a^2 h^2$$

Hence the centroid is $(\overline{x}, \overline{y}, \overline{z}) = \left(0, 0, [\pi a^2h^2/12]/[\pi a^2 h/3]\right) = \left(0, 0, \tfrac{1}{4}h\right)$.

(b) The density function is $\rho = \sqrt{x^2+y^2} = \sqrt{r^2} = r$, so the moment of inertia about the cone's axis (the z-axis) is

$$I_z = \iiint_E (x^2+y^2)\,\rho(x,y,z)\,dV = \int_0^{2\pi}\int_0^a\int_0^{h(1-r/a)}(r^2)(r)\,r\,dz\,dr\,d\theta$$
$$= \int_0^{2\pi}\int_0^a \left[r^4 z\right]_{z=0}^{z=h(1-r/a)} dr\,d\theta = \int_0^{2\pi}\int_0^a r^4 h\left(1-\tfrac{1}{a}r\right) dr\,d\theta$$
$$= h\int_0^{2\pi} d\theta \int_0^a \left(r^4 - \tfrac{1}{a}r^5\right) dr = h\left[\,\theta\,\right]_0^{2\pi}\left[\tfrac{1}{5}r^5 - \tfrac{1}{6a}r^6\right]_0^a$$
$$= h\,(2\pi)\left(\tfrac{1}{5}a^5 - \tfrac{1}{6}a^5\right) = \tfrac{1}{15}\pi a^5 h$$

44. $1 \le z^2 \le 4 \quad \Rightarrow \quad 1/a^2 \le x^2+y^2 \le 4/a^2$. Let $D = \left\{(x,y) \mid 1/a^2 \le x^2+y^2 \le 4/a^2\right\}$. $z = f(x,y) = a\sqrt{x^2+y^2}$, so $f_x(x,y) = ax(x^2+y^2)^{-1/2}$, $f_y(x,y) = ay(x^2+y^2)^{-1/2}$, and

$$A(S) = \iint_D \sqrt{\frac{a^2x^2+a^2y^2}{x^2+y^2}+1}\,dA = \iint_D \sqrt{a^2+1}\,dA = \sqrt{a^2+1}\,A(D)$$
$$= \sqrt{a^2+1}\left[\pi\left(\frac{2}{a}\right)^2 - \pi\left(\frac{1}{a}\right)^2\right] = \frac{3\pi}{a^2}\sqrt{a^2+1}$$

45. Let D represent the given triangle; then D can be described as the area enclosed by the x- and y-axes and the line $y = 2-2x$, or equivalently $D = \{(x,y) \mid 0 \le x \le 1, 0 \le y \le 2-2x\}$. We want to find the surface area of the part of the graph of $z = x^2 + y$ that lies over D, so using Equation 15.5.3 we have

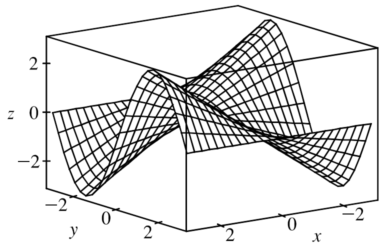
$$A(S) = \iint_D \sqrt{1 + \left(\frac{\partial z}{\partial x}\right)^2 + \left(\frac{\partial z}{\partial y}\right)^2}\,dA = \iint_D \sqrt{1+(2x)^2+(1)^2}\,dA = \int_0^1\int_0^{2-2x}\sqrt{2+4x^2}\,dy\,dx$$
$$= \int_0^1 \sqrt{2+4x^2}\left[\,y\,\right]_{y=0}^{y=2-2x} dx = \int_0^1 (2-2x)\sqrt{2+4x^2}\,dx = \int_0^1 2\sqrt{2+4x^2}\,dx - \int_0^1 2x\sqrt{2+4x^2}\,dx$$

Using Formula 21 in the Table of Integrals with $a = \sqrt{2}$, $u = 2x$, and $du = 2\,dx$, we have

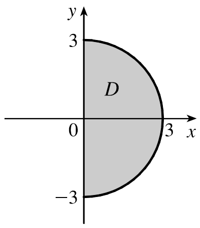
$\int 2\sqrt{2+4x^2}\,dx = x\sqrt{2+4x^2} + \ln\left(2x + \sqrt{2+4x^2}\right)$. If we substitute $u = 2+4x^2$ in the second integral, then $du = 8x\,dx$ and $\int 2x\sqrt{2+4x^2}\,dx = \frac{1}{4}\int\sqrt{u}\,du = \frac{1}{4}\cdot\frac{2}{3}u^{3/2} = \frac{1}{6}(2+4x^2)^{3/2}$. Thus

$$A(S) = \left[x\sqrt{2+4x^2} + \ln\left(2x+\sqrt{2+4x^2}\right) - \tfrac{1}{6}(2+4x^2)^{3/2}\right]_0^1$$
$$= \sqrt{6} + \ln\left(2+\sqrt{6}\right) - \tfrac{1}{6}(6)^{3/2} - \ln\sqrt{2} + \tfrac{\sqrt{2}}{3} = \ln\tfrac{2+\sqrt{6}}{\sqrt{2}} + \tfrac{\sqrt{2}}{3}$$
$$= \ln\left(\sqrt{2}+\sqrt{3}\right) + \tfrac{\sqrt{2}}{3} \approx 1.6176$$

46. Using Formula 15.5.3 with $\partial z/\partial x = \sin y$, $\partial z/\partial y = x\cos y$, we get $S = \int_{-\pi}^{\pi}\int_{-3}^{3}\sqrt{1+\sin^2 y + x^2\cos^2 y}\,dx\,dy \approx 62.9714$.



47.



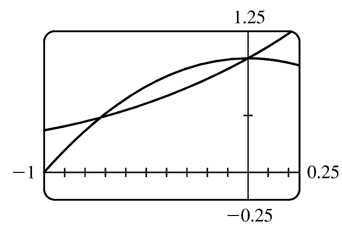
$$\int_0^3\int_{-\sqrt{9-x^2}}^{\sqrt{9-x^2}}(x^3+xy^2)\,dy\,dx = \int_0^3\int_{-\sqrt{9-x^2}}^{\sqrt{9-x^2}}x(x^2+y^2)\,dy\,dx$$
$$= \int_{-\pi/2}^{\pi/2}\int_0^3(r\cos\theta)(r^2)\,r\,dr\,d\theta$$
$$= \int_{-\pi/2}^{\pi/2}\cos\theta\,d\theta\int_0^3 r^4\,dr$$
$$= \big[\sin\theta\big]_{-\pi/2}^{\pi/2}\left[\tfrac{1}{5}r^5\right]_0^3 = 2\cdot\tfrac{1}{5}(243) = \tfrac{486}{5} = 97.2$$

48. The region of integration is the solid hemisphere $x^2+y^2+z^2 \le 4$, $x \ge 0$.

$$\int_{-2}^{2}\int_0^{\sqrt{4-y^2}}\int_{-\sqrt{4-x^2-y^2}}^{\sqrt{4-x^2-y^2}} y^2\sqrt{x^2+y^2+z^2}\,dz\,dx\,dy$$
$$= \int_{-\pi/2}^{\pi/2}\int_0^{\pi}\int_0^2(\rho\sin\phi\sin\theta)^2\left(\sqrt{\rho^2}\right)\rho^2\sin\phi\,d\rho\,d\phi\,d\theta = \int_{-\pi/2}^{\pi/2}\sin^2\theta\,d\theta\int_0^{\pi}\sin^3\phi\,d\phi\int_0^2\rho^5\,d\rho$$
$$= \left[\tfrac{1}{2}\theta - \tfrac{1}{4}\sin 2\theta\right]_{-\pi/2}^{\pi/2}\left[-\cos\phi + \tfrac{1}{3}\cos^3\phi\right]_0^{\pi}\left[\tfrac{1}{6}\rho^6\right]_0^2 = \left(\tfrac{\pi}{2}\right)\left(\tfrac{2}{3}+\tfrac{2}{3}\right)\left(\tfrac{32}{3}\right) = \tfrac{64}{9}\pi$$

49. From the graph, it appears that $1-x^2 = e^x$ at $x \approx -0.71$ and at $x = 0$, with $1-x^2 > e^x$ on $(-0.71, 0)$. So the desired integral is

$$\iint_D y^2\,dA \approx \int_{-0.71}^{0}\int_{e^x}^{1-x^2} y^2\,dy\,dx$$
$$= \tfrac{1}{3}\int_{-0.71}^{0}\left[(1-x^2)^3 - e^{3x}\right]dx$$
$$= \tfrac{1}{3}\left[x - x^3 + \tfrac{3}{5}x^5 - \tfrac{1}{7}x^7 - \tfrac{1}{3}e^{3x}\right]_{-0.71}^{0} \approx 0.0512$$



50. Let the tetrahedron be called T. The front face of T is given by the plane $x + \frac{1}{2}y + \frac{1}{3}z = 1$, or $z = 3 - 3x - \frac{3}{2}y$, which intersects the xy-plane in the line $y = 2 - 2x$. So the total mass is

$m = \iiint_T \rho(x,y,z)\,dV = \int_0^1\int_0^{2-2x}\int_0^{3-3x-3y/2}(x^2+y^2+z^2)\,dz\,dy\,dx = \frac{7}{5}$. The center of mass is

$(\overline{x},\overline{y},\overline{z}) = \left(m^{-1}\iiint_T x\rho(x,y,z)\,dV, m^{-1}\iiint_T y\rho(x,y,z)\,dV, m^{-1}\iiint_T z\rho(x,y,z)\,dV\right) = \left(\frac{4}{21}, \frac{11}{21}, \frac{8}{7}\right)$.

51. (a) $f(x,y)$ is a joint density function, so we know that $\iint_{\mathbb{R}^2} f(x,y)\,dA = 1$. Since $f(x,y) = 0$ outside the rectangle $[0,3]\times[0,2]$, we can say

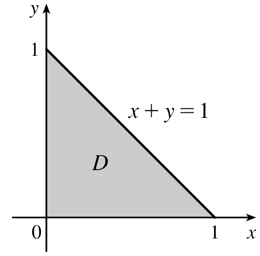
$$\iint_{\mathbb{R}^2} f(x,y)\,dA = \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} f(x,y)\,dy\,dx = \int_0^3\int_0^2 C(x+y)\,dy\,dx$$
$$= C\int_0^3\left[xy + \tfrac{1}{2}y^2\right]_{y=0}^{y=2}dx = C\int_0^3(2x+2)\,dx = C\left[x^2+2x\right]_0^3 = 15C$$

Then $15C = 1 \quad\Rightarrow\quad C = \frac{1}{15}$.

(b) $P(X \le 2, Y \ge 1) = \int_{-\infty}^{2} \int_{1}^{\infty} f(x,y)\,dy\,dx = \int_0^2 \int_1^2 \frac{1}{15}(x,y)\,dy\,dx = \frac{1}{15}\int_0^2 \left[xy + \frac{1}{2}y^2\right]_{y=1}^{y=2}\,dx$

$$= \frac{1}{15}\int_0^2 \left(x + \frac{3}{2}\right) dx = \frac{1}{15}\left[\frac{1}{2}x^2 + \frac{3}{2}x\right]_0^2 = \frac{1}{3}$$

(c) $P(X + Y \le 1) = P((X,Y) \in D)$ where D is the triangular region shown in the figure. Thus



$$\begin{aligned} P(X+Y \le 1) &= \iint_D f(x,y)\,dA = \int_0^1 \int_0^{1-x} \tfrac{1}{15}(x+y)\,dy\,dx \\ &= \tfrac{1}{15}\int_0^1 \left[xy + \tfrac{1}{2}y^2\right]_{y=0}^{y=1-x}\,dx \\ &= \tfrac{1}{15}\int_0^1 \left[x(1-x) + \tfrac{1}{2}(1-x)^2\right] dx \\ &= \tfrac{1}{30}\int_0^1 (1-x^2)\,dx = \tfrac{1}{30}\left[x - \tfrac{1}{3}x^3\right]_0^1 = \tfrac{1}{45} \end{aligned}$$

52. Each lamp has exponential density function

$$f(t) = \begin{cases} 0 & \text{if } t < 0 \\ \frac{1}{800}e^{-t/800} & \text{if } t \ge 0 \end{cases}$$

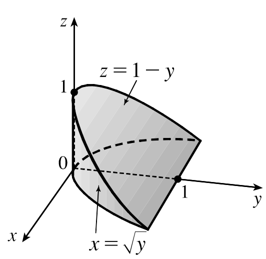
If X, Y, and Z are the lifetimes of the individual bulbs, then X, Y, and Z are independent, so the joint density function is the product of the individual density functions:

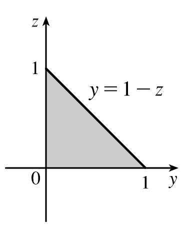
$$f(x,y,z) = \begin{cases} \frac{1}{800^3}e^{-(x+y+z)/800} & \text{if } x \ge 0, y \ge 0, z \ge 0 \\ 0 & \text{otherwise} \end{cases}$$

The probability that all three bulbs fail within a total of 1000 hours is $P(X + Y + Z \le 1000)$, or equivalently $P((X,Y,Z) \in E)$ where E is the solid region in the first octant bounded by the coordinate planes and the plane $x + y + z = 1000$. The plane $x + y + z = 1000$ meets the xy-plane in the line $x + y = 1000$, so we have

$$\begin{aligned} P(X+Y+Z \le 1000) &= \iiint_E f(x,y,z)\,dV = \int_0^{1000}\int_0^{1000-x}\int_0^{1000-x-y} \tfrac{1}{800^3}e^{-(x+y+z)/800}\,dz\,dy\,dx \\ &= \tfrac{1}{800^3}\int_0^{1000}\int_0^{1000-x} -800\left[e^{-(x+y+z)/800}\right]_{z=0}^{z=1000-x-y}\,dy\,dx \\ &= \tfrac{-1}{800^2}\int_0^{1000}\int_0^{1000-x}\left[e^{-5/4} - e^{-(x+y)/800}\right] dy\,dx \\ &= \tfrac{-1}{800^2}\int_0^{1000}\left[e^{-5/4}y + 800e^{-(x+y)/800}\right]_{y=0}^{y=1000-x}\,dx \\ &= \tfrac{-1}{800^2}\int_0^{1000}\left[e^{-5/4}(1800-x) - 800e^{-x/800}\right] dx \\ &= \tfrac{-1}{800^2}\left[-\tfrac{1}{2}e^{-5/4}(1800-x)^2 + 800^2e^{-x/800}\right]_0^{1000} \\ &= \tfrac{-1}{800^2}\left[-\tfrac{1}{2}e^{-5/4}(800)^2 + 800^2e^{-5/4} + \tfrac{1}{2}e^{-5/4}(1800)^2 - 800^2\right] \\ &= 1 - \tfrac{97}{32}e^{-5/4} \approx 0.1315 \end{aligned}$$

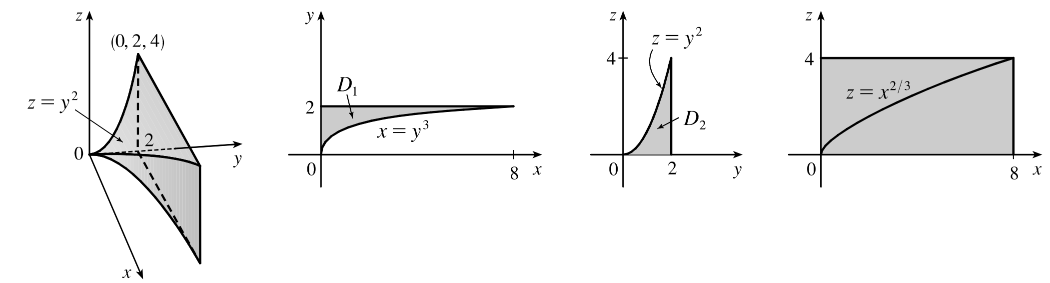
53.





$$\int_{-1}^{1}\int_{x^2}^{1}\int_0^{1-y} f(x,y,z)\,dz\,dy\,dx = \int_0^1\int_0^{1-z}\int_{-\sqrt{y}}^{\sqrt{y}} f(x,y,z)\,dx\,dy\,dz$$

54.



$\int_0^2 \int_0^{y^3} \int_0^{y^2} f(x,y,z)\,dz\,dx\,dy = \iiint_E f(x,y,z)\,dV$ where $E = \left\{(x,y,z) \mid 0 \le y \le 2, 0 \le x \le y^3, 0 \le z \le y^2\right\}$.

If D_1, D_2, and D_3 are the projections of E onto the xy-, yz-, and xz-planes, then

$D_1 = \left\{(x,y) \mid 0 \le y \le 2, 0 \le x \le y^3\right\} = \{(x,y) \mid 0 \le x \le 8, \sqrt[3]{x} \le y \le 2\}$,

$D_2 = \{(y,z) \mid 0 \le z \le 4, \sqrt{z} \le y \le 2\} = \left\{(y,z) \mid 0 \le y \le 2, 0 \le z \le y^2\right\}$, $D_3 = \{(x,z) \mid 0 \le x \le 8, 0 \le z \le 4\}$.

Therefore we have

$$\begin{aligned}
\int_0^2 \int_0^{y^3} \int_0^{y^2} f(x,y,z)\,dz\,dx\,dy &= \int_0^8 \int_{\sqrt[3]{x}}^2 \int_0^{y^2} f(x,y,z)\,dz\,dy\,dx = \int_0^4 \int_{\sqrt{z}}^2 \int_0^{y^3} f(x,y,z)\,dx\,dy\,dz \\
&= \int_0^2 \int_0^{y^2} \int_0^{y^3} f(x,y,z)\,dx\,dz\,dy \\
&= \int_0^8 \int_0^{x^{2/3}} \int_{\sqrt[3]{x}}^2 f(x,y,z)\,dy\,dz\,dx + \int_0^8 \int_{x^{2/3}}^4 \int_{\sqrt{z}}^2 f(x,y,z)\,dy\,dz\,dx \\
&= \int_0^4 \int_0^{z^{3/2}} \int_{\sqrt{z}}^2 f(x,y,z)\,dy\,dx\,dz + \int_0^4 \int_{z^{3/2}}^8 \int_{\sqrt[3]{x}}^2 f(x,y,z)\,dy\,dx\,dz
\end{aligned}$$

55. Since $u = x - y$ and $v = x + y$, $x = \frac{1}{2}(u+v)$ and $y = \frac{1}{2}(v-u)$. Thus $\dfrac{\partial(x,y)}{\partial(u,v)} = \begin{vmatrix} 1/2 & 1/2 \\ -1/2 & 1/2 \end{vmatrix} = \dfrac{1}{2}$.

R is the image under this transformation of the square with vertices $(u,v) = (-2,2)$, $(0,2)$, $(0,4)$, and $(-2,4)$. So

$$\begin{aligned}
\iint_R \frac{x-y}{x+y}\,dA &= \int_2^4 \int_{-2}^0 \frac{u}{v}\left(\frac{1}{2}\right) du\,dv = \frac{1}{2}\int_2^4 \left[\frac{u^2}{2v}\right]_{u=-2}^{u=0} dv = \frac{1}{2}\int_2^4 \left(-\frac{2}{v}\right) dv \\
&= -\ln v\Big]_2^4 = -\ln 4 + \ln 2 = -2\ln 2 + \ln 2 = -\ln 2.
\end{aligned}$$

56. $\dfrac{\partial(x,y,z)}{\partial(u,v,w)} = \begin{vmatrix} 2u & 0 & 0 \\ 0 & 2v & 0 \\ 0 & 0 & 2w \end{vmatrix} = 8uvw$, so

$$\begin{aligned}
V = \iiint_E dV &= \int_0^1 \int_0^{1-u} \int_0^{1-u-v} 8uvw\,dw\,dv\,du = \int_0^1 \int_0^{1-u} 4uv(1-u-v)^2\,du \\
&= \int_0^1 \int_0^{1-u} \left[4u(1-u)^2 v - 8u(1-u)v^2 + 4uv^3\right] dv\,du \\
&= \int_0^1 \left[2u(1-u)^4 - \tfrac{8}{3}u(1-u)^4 + u(1-u)^4\right] du = \int_0^1 \tfrac{1}{3}u(1-u)^4 du \\
&= \int_0^1 \tfrac{1}{3}\left[(1-u)^4 - (1-u)^5\right] du = \tfrac{1}{3}\left[-\tfrac{1}{5}(1-u)^5 + \tfrac{1}{6}(1-u)^6\right]_0^1 = \tfrac{1}{3}\left(-\tfrac{1}{6} + \tfrac{1}{5}\right) = \tfrac{1}{90}
\end{aligned}$$

57. Let $u = y - x$ and $v = y + x$ so $x = y - u = (v - x) - u \quad \Rightarrow \quad x = \frac{1}{2}(v-u)$ and $y = v - \frac{1}{2}(v-u) = \frac{1}{2}(v+u)$.

$\left|\dfrac{\partial(x,y)}{\partial(u,v)}\right| = \left|\dfrac{\partial x}{\partial u}\dfrac{\partial y}{\partial v} - \dfrac{\partial x}{\partial v}\dfrac{\partial y}{\partial u}\right| = \left|-\frac{1}{2}\left(\frac{1}{2}\right) - \frac{1}{2}\left(\frac{1}{2}\right)\right| = \left|-\frac{1}{2}\right| = \frac{1}{2}$. R is the image under this transformation of the square with vertices $(u,v) = (0,0)$, $(-2,0)$, $(0,2)$, and $(-2,2)$. So

$$\iint_R xy\,dA = \int_0^2 \int_{-2}^0 \frac{v^2-u^2}{4}\left(\frac{1}{2}\right) du\,dv = \tfrac{1}{8}\int_0^2 \left[v^2u - \tfrac{1}{3}u^3\right]_{u=-2}^{u=0} dv = \tfrac{1}{8}\int_0^2 \left(2v^2 - \tfrac{8}{3}\right) dv = \tfrac{1}{8}\left[\tfrac{2}{3}v^3 - \tfrac{8}{3}v\right]_0^2 = 0$$

This result could have been anticipated by symmetry, since the integrand is an odd function of y and R is symmetric about the x-axis.

58. By the Extreme Value Theorem (14.7.8), f has an absolute minimum value m and an absolute maximum value M in D. Then by Property 15.2.11, $mA(D) \le \iint_D f(x,y)\,dA \le MA(D)$. Dividing through by the positive number $A(D)$, we get $m \le \dfrac{1}{A(D)}\iint_D f(x,y)\,dA \le M$. This says that the average value of f over D lies between m and M. But f is continuous on D and takes on the values m and M, and so by the Intermediate Value Theorem must take on all values between m and M. Specifically, there exists a point (x_0, y_0) in D such that $f(x_0,y_0) = \dfrac{1}{A(D)}\iint_D f(x,y)\,dA$ or equivalently $\iint_D f(x,y)\,dA = f(x_0,y_0)\,A(D)$.

59. For each r such that D_r lies within the domain, $A(D_r) = \pi r^2$, and by the Mean Value Theorem for Double Integrals there exists (x_r, y_r) in D_r such that $f(x_r,y_r) = \dfrac{1}{\pi r^2}\iint_{D_r} f(x,y)\,dA$. But $\lim\limits_{r\to 0^+}(x_r,y_r) = (a,b)$, so $\lim\limits_{r\to 0^+}\dfrac{1}{\pi r^2}\iint_{D_r} f(x,y)\,dA = \lim\limits_{r\to 0^+} f(x_r,y_r) = f(a,b)$ by the continuity of f.

60. (a) $$\iint_D \frac{1}{(x^2+y^2)^{n/2}}\,dA = \int_0^{2\pi}\int_r^R \frac{1}{(t^2)^{n/2}}\,t\,dt\,d\theta = 2\pi\int_r^R t^{1-n}\,dt$$

$$= \begin{cases} \left.\dfrac{2\pi}{2-n}t^{2-n}\right]_r^R = \dfrac{2\pi}{2-n}\left(R^{2-n} - r^{2-n}\right) & \text{if } n \ne 2 \\ 2\pi\ln(R/r) & \text{if } n = 2 \end{cases}$$

(b) The integral in part (a) has a limit as $r \to 0^+$ for all values of n such that $2 - n > 0 \;\Leftrightarrow\; n < 2$.

(c) $$\iiint_E \frac{1}{(x^2+y^2+z^2)^{n/2}}\,dV = \int_r^R\int_0^\pi\int_0^{2\pi}\frac{1}{(\rho^2)^{n/2}}\rho^2\sin\phi\,d\theta\,d\phi\,d\rho = 2\pi\int_r^R\int_0^\pi \rho^{2-n}\sin\phi\,d\phi\,d\rho$$

$$= \begin{cases} \left.\dfrac{4\pi}{3-n}\rho^{3-n}\right]_r^R = \dfrac{4\pi}{3-n}\left(R^{3-n} - r^{3-n}\right) & \text{if } n \ne 3 \\ 4\pi\ln(R/r) & \text{if } n = 3 \end{cases}$$

(d) As $r \to 0^+$, the above integral has a limit, provided that $3 - n > 0 \;\Leftrightarrow\; n < 3$.

☐ PROBLEMS PLUS

1. 
Let $R = \bigcup_{i=1}^{5} R_i$, where

$R_i = \{(x, y) \mid x + y \geq i + 2, x + y < i + 3, 1 \leq x \leq 3, 2 \leq y \leq 5\}$.

$\iint_R [\![x+y]\!]\, dA = \sum\limits_{i=1}^{5} \iint_{R_i} [\![x+y]\!]\, dA = \sum\limits_{i=1}^{5} [\![x+y]\!] \iint_{R_i} dA$, since

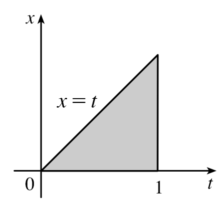
$[\![x+y]\!] = \text{constant} = i + 2$ for $(x, y) \in R_i$. Therefore

$$\begin{aligned} \iint_R [\![x+y]\!]\, dA &= \textstyle\sum_{i=1}^{5} (i+2)\, [A(R_i)] \\ &= 3A(R_1) + 4A(R_2) + 5A(R_3) + 6A(R_4) + 7A(R_5) \\ &= 3\left(\tfrac{1}{2}\right) + 4\left(\tfrac{3}{2}\right) + 5(2) + 6\left(\tfrac{3}{2}\right) + 7\left(\tfrac{1}{2}\right) = 30 \end{aligned}$$

2. 
Let $R = \{(x, y) \mid 0 \leq x, y \leq 1\}$. For $x, y \in R$, $\max\{x^2, y^2\} = x^2$ if $x \geq y$, and $\max\{x^2, y^2\} = y^2$ if $x \leq y$. Therefore we divide R into two regions: $R = R_1 \cup R_2$, where $R_1 = \{(x, y) \mid 0 \leq x \leq 1, 0 \leq y \leq x\}$ and $R_2 = \{(x, y) \mid 0 \leq y \leq 1, 0 \leq x \leq y\}$. Now $\max\{x^2, y^2\} = x^2$ for $(x, y) \in R_1$, and $\max\{x^2, y^2\} = y^2$ for $(x, y) \in R_2$ $\Rightarrow$

$$\begin{aligned} \int_0^1 \int_0^1 e^{\max\{x^2, y^2\}}\, dy\, dx &= \iint_R e^{\max\{x^2, y^2\}}\, dA = \iint_{R_1} e^{\max\{x^2, y^2\}}\, dA + \iint_{R_2} e^{\max\{x^2, y^2\}}\, dA \\ &= \int_0^1 \int_0^x e^{x^2}\, dy\, dx + \int_0^1 \int_0^y e^{y^2}\, dx\, dy = \int_0^1 x e^{x^2}\, dx + \int_0^1 y e^{y^2}\, dy = e^{x^2}\Big]_0^1 = e - 1 \end{aligned}$$

3. $f_{\text{ave}} = \dfrac{1}{b-a} \displaystyle\int_a^b f(x)\, dx = \dfrac{1}{1-0} \int_0^1 \left[\int_x^1 \cos(t^2)\, dt\right] dx$



$= \int_0^1 \int_x^1 \cos(t^2)\, dt\, dx = \int_0^1 \int_0^t \cos(t^2)\, dx\, dt$ [changing the order of integration]

$= \int_0^1 t \cos(t^2)\, dt = \frac{1}{2} \sin(t^2)\big]_0^1 = \frac{1}{2} \sin 1$

4. Let $u = \mathbf{a} \cdot \mathbf{r}$, $v = \mathbf{b} \cdot \mathbf{r}$, $w = \mathbf{c} \cdot \mathbf{r}$, where $\mathbf{a} = \langle a_1, a_2, a_3 \rangle$, $\mathbf{b} = \langle b_1, b_2, b_3 \rangle$, $\mathbf{c} = \langle c_1, c_2, c_3 \rangle$. Under this change of variables, E corresponds to the rectangular box $0 \leq u \leq \alpha$, $0 \leq v \leq \beta$, $0 \leq w \leq \gamma$. So, by Formula 15.9.13,

$\displaystyle\int_0^\gamma \int_0^\beta \int_0^\alpha uvw\, du\, dv\, dw = \iiint_E (\mathbf{a} \cdot \mathbf{r})(\mathbf{b} \cdot \mathbf{r})(\mathbf{c} \cdot \mathbf{r}) \left| \frac{\partial(u, v, w)}{\partial(x, y, z)} \right| dV$. But

$$\left| \frac{\partial(u, v, w)}{\partial(x, y, z)} \right| = \left\| \begin{matrix} a_1 & a_2 & a_3 \\ b_1 & b_2 & b_3 \\ c_1 & c_2 & c_3 \end{matrix} \right\| = |\mathbf{a} \cdot (\mathbf{b} \times \mathbf{c})| \quad \Rightarrow$$

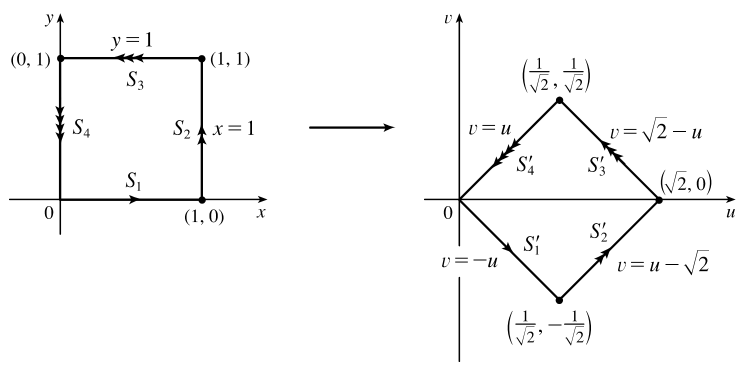
$$\begin{aligned} \iiint_E (\mathbf{a} \cdot \mathbf{r})(\mathbf{b} \cdot \mathbf{r})(\mathbf{c} \cdot \mathbf{r})\, dV &= \frac{1}{|\mathbf{a} \cdot (\mathbf{b} \times \mathbf{c})|} \int_0^\gamma \int_0^\beta \int_0^\alpha uvw\, du\, dv\, dw \\ &= \frac{1}{|\mathbf{a} \cdot (\mathbf{b} \times \mathbf{c})|} \left(\frac{\alpha^2}{2}\right)\left(\frac{\beta^2}{2}\right)\left(\frac{\gamma^2}{2}\right) = \frac{(\alpha\beta\gamma)^2}{8\, |\mathbf{a} \cdot (\mathbf{b} \times \mathbf{c})|} \end{aligned}$$

5. Since $|xy| < 1$, except at $(1, 1)$, the formula for the sum of a geometric series gives $\dfrac{1}{1-xy} = \sum\limits_{n=0}^{\infty} (xy)^n$, so

$$\int_0^1\int_0^1 \tfrac{1}{1-xy}\,dx\,dy = \int_0^1\int_0^1 \sum_{n=0}^{\infty}(xy)^n\,dx\,dy = \sum_{n=0}^{\infty}\int_0^1\int_0^1 (xy)^n\,dx\,dy = \sum_{n=0}^{\infty}\left[\int_0^1 x^n\,dx\right]\left[\int_0^1 y^n\,dy\right]$$

$$= \sum_{n=0}^{\infty} \tfrac{1}{n+1}\cdot\tfrac{1}{n+1} = \sum_{n=0}^{\infty}\tfrac{1}{(n+1)^2} = \tfrac{1}{1^2}+\tfrac{1}{2^2}+\tfrac{1}{3^2}+\cdots = \textstyle\sum_{n=1}^{\infty}\tfrac{1}{n^2}$$

6. Let $x = \dfrac{u-v}{\sqrt{2}}$ and $y = \dfrac{u+v}{\sqrt{2}}$. We know the region of integration in the xy-plane, so to find its image in the uv-plane we get u and v in terms of x and y, and then use the methods of Section 15.9. $x + y = \dfrac{u-v}{\sqrt{2}} + \dfrac{u+v}{\sqrt{2}} = \sqrt{2}\,u$, so $u = \dfrac{x+y}{\sqrt{2}}$, and similarly $v = \dfrac{y-x}{\sqrt{2}}$. S_1 is given by $y = 0$, $0 \le x \le 1$, so from the equations derived above, the image of S_1 is S_1': $u = \frac{1}{\sqrt{2}}x$, $v = -\frac{1}{\sqrt{2}}x$, $0 \le x \le 1$, that is, $v = -u$, $0 \le u \le \frac{1}{\sqrt{2}}$. Similarly, the image of S_2 is S_2': $v = u - \sqrt{2}$, $\frac{1}{\sqrt{2}} \le u \le \sqrt{2}$, the image of S_3 is S_3': $v = \sqrt{2} - u$, $\frac{1}{\sqrt{2}} \le u \le \sqrt{2}$, and the image of S_4 is S_4': $v - u$, $0 \le u \le \frac{1}{\sqrt{2}}$.



The Jacobian of the transformation is $\dfrac{\partial(x,y)}{\partial(u,v)} = \begin{vmatrix} \partial x/\partial u & \partial x/\partial v \\ \partial y/\partial u & \partial y/\partial v \end{vmatrix} = \begin{vmatrix} \frac{1}{\sqrt{2}} & -\frac{1}{\sqrt{2}} \\ \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \end{vmatrix} = 1$. From the diagram, we see that we must evaluate two integrals: one over the region $\left\{(u,v) \mid 0 \le u \le \frac{1}{\sqrt{2}},\ -u \le v \le u\right\}$ and the other over $\left\{(u,v) \mid \frac{1}{\sqrt{2}} \le u \le \sqrt{2},\ -\sqrt{2}+u \le v \le \sqrt{2}-u\right\}$. So

$$\int_0^1\int_0^1 \frac{dx\,dy}{1-xy} = \int_0^{\sqrt{2}/2}\int_{-u}^{u} \frac{dv\,du}{1-\left[\frac{1}{\sqrt{2}}(u+v)\right]\left[\frac{1}{\sqrt{2}}(u-v)\right]} + \int_{\sqrt{2}/2}^{\sqrt{2}}\int_{-\sqrt{2}+u}^{\sqrt{2}-u} \frac{dv\,du}{1-\left[\frac{1}{\sqrt{2}}(u+v)\right]\left[\frac{1}{\sqrt{2}}(u-v)\right]}$$

$$= \int_0^{\sqrt{2}/2}\int_{-u}^{u}\frac{2\,dv\,du}{2-u^2+v^2} + \int_{\sqrt{2}/2}^{\sqrt{2}}\int_{-\sqrt{2}+u}^{\sqrt{2}-u}\frac{2\,dv\,du}{2-u^2+v^2}$$

$$= 2\left[\int_0^{\sqrt{2}/2}\frac{1}{\sqrt{2-u^2}}\left[\arctan\frac{v}{\sqrt{2-u^2}}\right]_{-u}^{u} du + \int_{\sqrt{2}/2}^{\sqrt{2}}\frac{1}{\sqrt{2-u^2}}\left[\arctan\frac{v}{\sqrt{2-u^2}}\right]_{-\sqrt{2}+u}^{\sqrt{2}-u} du\right]$$

$$= 4\left[\int_0^{\sqrt{2}/2}\frac{1}{\sqrt{2-u^2}}\arctan\frac{u}{\sqrt{2-u^2}}\,du + \int_{\sqrt{2}/2}^{\sqrt{2}}\frac{1}{\sqrt{2-u^2}}\arctan\frac{\sqrt{2}-u}{\sqrt{2-u^2}}\,du\right]$$

Now let $u = \sqrt{2}\sin\theta$, so $du = \sqrt{2}\cos\theta\,d\theta$ and the limits change to 0 and $\frac{\pi}{6}$ (in the first integral) and $\frac{\pi}{6}$ and $\frac{\pi}{2}$ (in the second integral). Continuing:

$$\int_0^1\int_0^1 \frac{dx\,dy}{1-xy} = 4\left[\int_0^{\pi/6} \frac{1}{\sqrt{2-2\sin^2\theta}} \arctan\left(\frac{\sqrt{2}\sin\theta}{\sqrt{2-2\sin^2\theta}}\right)\left(\sqrt{2}\cos\theta\,d\theta\right) + \int_{\pi/6}^{\pi/2} \frac{1}{\sqrt{2-2\sin^2\theta}} \arctan\left(\frac{\sqrt{2}-\sqrt{2}\sin\theta}{\sqrt{2-2\sin^2\theta}}\right)\left(\sqrt{2}\cos\theta\,d\theta\right)\right]$$

$$= 4\left[\int_0^{\pi/6} \frac{\sqrt{2}\cos\theta}{\sqrt{2}\cos\theta} \arctan\left(\frac{\sqrt{2}\sin\theta}{\sqrt{2}\cos\theta}\right)d\theta + \int_{\pi/6}^{\pi/2} \frac{\sqrt{2}\cos\theta}{\sqrt{2}\cos\theta} \arctan\left(\frac{\sqrt{2}\,(1-\sin\theta)}{\sqrt{2}\cos\theta}\right)d\theta\right]$$

$$= 4\left[\int_0^{\pi/6} \arctan(\tan\theta)\,d\theta + \int_{\pi/6}^{\pi/2} \arctan\left(\frac{1-\sin\theta}{\cos\theta}\right)d\theta\right]$$

But (following the hint)

$$\frac{1-\sin\theta}{\cos\theta} = \frac{1-\cos\left(\frac{\pi}{2}-\theta\right)}{\sin\left(\frac{\pi}{2}-\theta\right)} = \frac{1-\left[1-2\sin^2\left(\frac{1}{2}\left(\frac{\pi}{2}-\theta\right)\right)\right]}{2\sin\left(\frac{1}{2}\left(\frac{\pi}{2}-\theta\right)\right)\cos\left(\frac{1}{2}\left(\frac{\pi}{2}-\theta\right)\right)} \quad \text{[half-angle formulas]}$$

$$= \frac{2\sin^2\left(\frac{1}{2}\left(\frac{\pi}{2}-\theta\right)\right)}{2\sin\left(\frac{1}{2}\left(\frac{\pi}{2}-\theta\right)\right)\cos\left(\frac{1}{2}\left(\frac{\pi}{2}-\theta\right)\right)} = \tan\left(\frac{1}{2}\left(\frac{\pi}{2}-\theta\right)\right)$$

Continuing:

$$\int_0^1\int_0^1 \frac{dx\,dy}{1-xy} = 4\left[\int_0^{\pi/6} \arctan(\tan\theta)\,d\theta + \int_{\pi/6}^{\pi/2} \arctan\left(\tan\left(\frac{1}{2}\left(\frac{\pi}{2}-\theta\right)\right)\right)d\theta\right]$$

$$= 4\left[\int_0^{\pi/6} \theta\,d\theta + \int_{\pi/6}^{\pi/2}\left[\frac{1}{2}\left(\frac{\pi}{2}-\theta\right)\right]d\theta\right] = 4\left(\left[\frac{\theta^2}{2}\right]_0^{\pi/6} + \left[\frac{\pi\theta}{4}-\frac{\theta^2}{4}\right]_{\pi/6}^{\pi/2}\right) = 4\left(\frac{3\pi^2}{72}\right) = \frac{\pi^2}{6}$$

7. (a) Since $|xyz| < 1$ except at $(1,1,1)$, the formula for the sum of a geometric series gives $\frac{1}{1-xyz} = \sum_{n=0}^{\infty}(xyz)^n$, so

$$\int_0^1\int_0^1\int_0^1 \frac{1}{1-xyz}\,dx\,dy\,dz = \int_0^1\int_0^1\int_0^1 \sum_{n=0}^{\infty}(xyz)^n\,dx\,dy\,dz = \sum_{n=0}^{\infty}\int_0^1\int_0^1\int_0^1 (xyz)^n\,dx\,dy\,dz$$

$$= \sum_{n=0}^{\infty}\left[\int_0^1 x^n\,dx\right]\left[\int_0^1 y^n\,dy\right]\left[\int_0^1 z^n\,dz\right] = \sum_{n=0}^{\infty}\frac{1}{n+1}\cdot\frac{1}{n+1}\cdot\frac{1}{n+1}$$

$$= \sum_{n=0}^{\infty}\frac{1}{(n+1)^3} = \frac{1}{1^3}+\frac{1}{2^3}+\frac{1}{3^3}+\cdots = \sum_{n=1}^{\infty}\frac{1}{n^3}$$

(b) Since $|-xyz| < 1$, except at $(1,1,1)$, the formula for the sum of a geometric series gives $\frac{1}{1+xyz} = \sum_{n=0}^{\infty}(-xyz)^n$, so

$$\int_0^1\int_0^1\int_0^1 \frac{1}{1+xyz}\,dx\,dy\,dz = \int_0^1\int_0^1\int_0^1 \sum_{n=0}^{\infty}(-xyz)^n\,dx\,dy\,dz = \sum_{n=0}^{\infty}\int_0^1\int_0^1\int_0^1 (-xyz)^n\,dx\,dy\,dz$$

$$= \sum_{n=0}^{\infty}(-1)^n\left[\int_0^1 x^n\,dx\right]\left[\int_0^1 y^n\,dy\right]\left[\int_0^1 z^n\,dz\right] = \sum_{n=0}^{\infty}(-1)^n\frac{1}{n+1}\cdot\frac{1}{n+1}\cdot\frac{1}{n+1}$$

$$= \sum_{n=0}^{\infty}\frac{(-1)^n}{(n+1)^3} = \frac{1}{1^3}-\frac{1}{2^3}+\frac{1}{3^3}-\cdots = \sum_{n=0}^{\infty}\frac{(-1)^{n-1}}{n^3}$$

To evaluate this sum, we first write out a few terms: $s = 1-\frac{1}{2^3}+\frac{1}{3^3}-\frac{1}{4^3}+\frac{1}{5^3}-\frac{1}{6^3} \approx 0.8998$. Notice that $a_7 = \frac{1}{7^3} < 0.003$. By the Alternating Series Estimation Theorem from Section 11.5, we have $|s-s_6| \le a_7 < 0.003$. This error of 0.003 will not affect the second decimal place, so we have $s \approx 0.90$.

8. $\displaystyle\int_0^\infty \frac{\arctan \pi x - \arctan x}{x}\,dx = \int_0^\infty \left[\frac{\arctan yx}{x}\right]_{y=1}^{y=\pi} dx = \int_0^\infty \int_1^\pi \frac{1}{1+y^2x^2}\,dy\,dx = \int_1^\pi \int_0^\infty \frac{1}{1+y^2x^2}\,dx\,dy$

$$= \int_1^\pi \lim_{t\to\infty}\left[\frac{\arctan yx}{y}\right]_{x=0}^{x=t} dy = \int_1^\pi \frac{\pi}{2y}\,dy = \frac{\pi}{2}\left[\ln y\right]_1^\pi = \frac{\pi}{2}\ln\pi$$

9. (a) $x = r\cos\theta,\ y = r\sin\theta,\ z = z.$ Then $\dfrac{\partial u}{\partial r} = \dfrac{\partial u}{\partial x}\dfrac{\partial x}{\partial r} + \dfrac{\partial u}{\partial y}\dfrac{\partial y}{\partial r} + \dfrac{\partial u}{\partial z}\dfrac{\partial z}{\partial r} = \dfrac{\partial u}{\partial x}\cos\theta + \dfrac{\partial u}{\partial y}\sin\theta$ and

$$\frac{\partial^2 u}{\partial r^2} = \cos\theta\left[\frac{\partial^2 u}{\partial x^2}\frac{\partial x}{\partial r} + \frac{\partial^2 u}{\partial y\,\partial x}\frac{\partial y}{\partial r} + \frac{\partial^2 u}{\partial z\,\partial x}\frac{\partial z}{\partial r}\right] + \sin\theta\left[\frac{\partial^2 u}{\partial y^2}\frac{\partial y}{\partial r} + \frac{\partial^2 u}{\partial x\,\partial y}\frac{\partial x}{\partial r} + \frac{\partial^2 u}{\partial z\,\partial y}\frac{\partial z}{\partial r}\right]$$
$$= \frac{\partial^2 u}{\partial x^2}\cos^2\theta + \frac{\partial^2 u}{\partial y^2}\sin^2\theta + 2\,\frac{\partial^2 u}{\partial y\,\partial x}\cos\theta\,\sin\theta$$

Similarly $\dfrac{\partial u}{\partial \theta} = -\dfrac{\partial u}{\partial x}\,r\sin\theta + \dfrac{\partial u}{\partial y}\,r\cos\theta$ and

$\dfrac{\partial^2 u}{\partial \theta^2} = \dfrac{\partial^2 u}{\partial x^2}\,r^2\sin^2\theta + \dfrac{\partial^2 u}{\partial y^2}\,r^2\cos^2\theta - 2\,\dfrac{\partial^2 u}{\partial y\,\partial x}\,r^2\sin\theta\,\cos\theta - \dfrac{\partial u}{\partial x}\,r\cos\theta - \dfrac{\partial u}{\partial y}\,r\sin\theta$. So

$$\frac{\partial^2 u}{\partial r^2} + \frac{1}{r}\frac{\partial u}{\partial r} + \frac{1}{r^2}\frac{\partial^2 u}{\partial \theta^2} + \frac{\partial^2 u}{\partial z^2} = \frac{\partial^2 u}{\partial x^2}\cos^2\theta + \frac{\partial^2 u}{\partial y^2}\sin^2\theta + 2\,\frac{\partial^2 u}{\partial y\,\partial x}\cos\theta\,\sin\theta + \frac{\partial u}{\partial x}\frac{\cos\theta}{r} + \frac{\partial u}{\partial y}\frac{\sin\theta}{r}$$
$$+ \frac{\partial^2 u}{\partial x^2}\sin^2\theta + \frac{\partial^2 u}{\partial y^2}\cos^2\theta - 2\,\frac{\partial^2 u}{\partial y\,\partial x}\sin\theta\,\cos\theta$$
$$- \frac{\partial u}{\partial x}\frac{\cos\theta}{r} - \frac{\partial u}{\partial y}\frac{\sin\theta}{r} + \frac{\partial^2 u}{\partial z^2}$$
$$= \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2}$$

(b) $x = \rho\sin\phi\cos\theta$, $y = \rho\sin\phi\sin\theta$, $z = \rho\cos\phi$. Then

$\dfrac{\partial u}{\partial \rho} = \dfrac{\partial u}{\partial x}\dfrac{\partial x}{\partial \rho} + \dfrac{\partial u}{\partial y}\dfrac{\partial y}{\partial \rho} + \dfrac{\partial u}{\partial z}\dfrac{\partial z}{\partial \rho} = \dfrac{\partial u}{\partial x}\sin\phi\,\cos\theta + \dfrac{\partial u}{\partial y}\sin\phi\,\sin\theta + \dfrac{\partial u}{\partial z}\cos\phi$, and

$$\frac{\partial^2 u}{\partial \rho^2} = \sin\phi\cos\theta\left[\frac{\partial^2 u}{\partial x^2}\frac{\partial x}{\partial \rho} + \frac{\partial^2 u}{\partial y\,\partial x}\frac{\partial y}{\partial \rho} + \frac{\partial^2 u}{\partial z\,\partial x}\frac{\partial z}{\partial \rho}\right]$$
$$+ \sin\phi\sin\theta\left[\frac{\partial^2 u}{\partial y^2}\frac{\partial y}{\partial \rho} + \frac{\partial^2 u}{\partial x\,\partial y}\frac{\partial x}{\partial \rho} + \frac{\partial^2 u}{\partial z\,\partial y}\frac{\partial z}{\partial \rho}\right]$$
$$+ \cos\phi\left[\frac{\partial^2 u}{\partial z^2}\frac{\partial z}{\partial \rho} + \frac{\partial^2 u}{\partial x\,\partial z}\frac{\partial x}{\partial \rho} + \frac{\partial^2 u}{\partial y\,\partial z}\frac{\partial y}{\partial \rho}\right]$$
$$= 2\,\frac{\partial^2 u}{\partial y\,\partial x}\sin^2\phi\,\sin\theta\,\cos\theta + 2\,\frac{\partial^2 u}{\partial z\,\partial x}\sin\phi\,\cos\phi\,\cos\theta + 2\,\frac{\partial^2 u}{\partial y\,\partial z}\sin\phi\,\cos\phi\,\sin\theta$$
$$+ \frac{\partial^2 u}{\partial x^2}\sin^2\phi\cos^2\theta + \frac{\partial^2 u}{\partial y^2}\sin^2\phi\sin^2\theta + \frac{\partial^2 u}{\partial z^2}\cos^2\phi$$

Similarly $\dfrac{\partial u}{\partial \phi} = \dfrac{\partial u}{\partial x}\,\rho\cos\phi\cos\theta + \dfrac{\partial u}{\partial y}\,\rho\cos\phi\sin\theta - \dfrac{\partial u}{\partial z}\,\rho\sin\phi$, and

$$\frac{\partial^2 u}{\partial\phi^2} = 2\,\frac{\partial^2 u}{\partial y\,\partial x}\,\rho^2\cos^2\phi\,\sin\theta\,\cos\theta - 2\,\frac{\partial^2 u}{\partial x\,\partial z}\,\rho^2\sin\phi\,\cos\phi\,\cos\theta - 2\,\frac{\partial^2 u}{\partial y\,\partial z}\,\rho^2\sin\phi\,\cos\phi\,\sin\theta + \frac{\partial^2 u}{\partial x^2}\,\rho^2\cos^2\phi\,\cos^2\theta + \frac{\partial^2 u}{\partial y^2}\,\rho^2\cos^2\phi\,\sin^2\theta + \frac{\partial^2 u}{\partial z^2}\,\rho^2\sin^2\phi - \frac{\partial u}{\partial x}\,\rho\sin\phi\,\cos\theta - \frac{\partial u}{\partial y}\,\rho\sin\phi\,\sin\theta - \frac{\partial u}{\partial z}\,\rho\cos\phi$$

And $\dfrac{\partial u}{\partial\theta} = -\dfrac{\partial u}{\partial x}\,\rho\sin\phi\sin\theta + \dfrac{\partial u}{\partial y}\,\rho\sin\phi\cos\theta$, while

$$\frac{\partial^2 u}{\partial\theta^2} = -2\,\frac{\partial^2 u}{\partial y\,\partial x}\,\rho^2\sin^2\phi\,\cos\theta\,\sin\theta + \frac{\partial^2 u}{\partial x^2}\,\rho^2\sin^2\phi\,\sin^2\theta + \frac{\partial^2 u}{\partial y^2}\,\rho^2\sin^2\phi\cos^2\theta - \frac{\partial u}{\partial x}\,\rho\sin\phi\,\cos\theta - \frac{\partial u}{\partial y}\,\rho\sin\phi\,\sin\theta$$

Therefore

$$\frac{\partial^2 u}{\partial\rho^2} + \frac{2}{\rho}\frac{\partial u}{\partial\rho} + \frac{\cot\phi}{\rho^2}\frac{\partial u}{\partial\phi} + \frac{1}{\rho^2}\frac{\partial^2 u}{\partial\phi^2} + \frac{1}{\rho^2\sin^2\phi}\frac{\partial^2 u}{\partial\theta^2}$$

$$= \frac{\partial^2 u}{\partial x^2}\left[(\sin^2\phi\,\cos^2\theta) + (\cos^2\phi\,\cos^2\theta) + \sin^2\theta\right] + \frac{\partial^2 u}{\partial y^2}\left[(\sin^2\phi\,\sin^2\theta) + (\cos^2\phi\,\sin^2\theta) + \cos^2\theta\right] + \frac{\partial^2 u}{\partial z^2}\left[\cos^2\phi + \sin^2\phi\right] + \frac{\partial u}{\partial x}\left[\frac{2\sin^2\phi\,\cos\theta + \cos^2\phi\,\cos\theta - \sin^2\phi\,\cos\theta - \cos\theta}{\rho\sin\phi}\right] + \frac{\partial u}{\partial y}\left[\frac{2\sin^2\phi\,\sin\theta + \cos^2\phi\,\sin\theta - \sin^2\phi\,\sin\theta - \sin\theta}{\rho\sin\phi}\right]$$

But $2\sin^2\phi\cos\theta + \cos^2\phi\cos\theta - \sin^2\phi\cos\theta - \cos\theta = (\sin^2\phi + \cos^2\phi - 1)\,\cos\theta = 0$ and similarly the coefficient of $\partial u/\partial y$ is 0. Also $\sin^2\phi\cos^2\theta + \cos^2\phi\cos^2\theta + \sin^2\theta = \cos^2\theta\,(\sin^2\phi + \cos^2\phi) + \sin^2\theta = 1$, and similarly the coefficient of $\partial^2 u/\partial y^2$ is 1. So Laplace's Equation in spherical coordinates is as stated.

10. (a) Consider a polar division of the disk, similar to that in Figure 15.3.4, where $0 = \theta_0 < \theta_1 < \theta_2 < \cdots < \theta_n = 2\pi$, $0 = r_1 < r_2 < \cdots < r_m = R$, and where the polar subrectangle R_{ij}, as well as r_i^*, θ_j^*, Δr and $\Delta\theta$ are the same as in that figure. Thus $\Delta A_i = r_i^*\,\Delta r\,\Delta\theta$. The mass of R_{ij} is $\rho\,\Delta A_i$, and its distance from m is $s_{ij} \approx \sqrt{(r_i^*)^2 + d^2}$. According to Newton's Law of Gravitation, the force of attraction experienced by m due to this polar subrectangle is in the direction from m towards R_{ij} and has magnitude $\dfrac{Gm\rho\,\Delta A_i}{s_{ij}^2}$. The symmetry of the lamina with respect to the x- and y-axes and the position of m are such that all horizontal components of the gravitational force cancel, so that the total force is simply in the z-direction. Thus, we need only be concerned with the components of this vertical force; that is, $\dfrac{Gm\rho\,\Delta A_i}{s_{ij}^2}\sin\alpha$, where α is the angle between the origin, r_i^* and the mass m. Thus $\sin\alpha = \dfrac{d}{s_{ij}}$ and the previous result becomes

$\dfrac{Gm\rho d\,\Delta A_i}{s_{ij}^3}$. The total attractive force is just the Riemann sum $\displaystyle\sum_{i=1}^{m}\sum_{j=1}^{n}\frac{Gm\rho d\,\Delta A_i}{s_{ij}^3}=\sum_{i=1}^{m}\sum_{j=1}^{n}\frac{Gm\rho d(r_i^*)\,\Delta r\,\Delta\theta}{\left[(r_i^*)^2+d^2\right]^{3/2}}$

which becomes $\displaystyle\int_0^R\int_0^{2\pi}\frac{Gm\rho d}{(r^2+d^2)^{3/2}}\,r\,d\theta\,dr$ as $m\to\infty$ and $n\to\infty$. Therefore,

$$F=2\pi Gm\rho d\int_0^R\frac{r}{(r^2+d^2)^{3/2}}\,dr=2\pi Gm\rho d\left[-\frac{1}{\sqrt{r^2+d^2}}\right]_0^R=2\pi Gm\rho d\left(\frac{1}{d}-\frac{1}{\sqrt{R^2+d^2}}\right)$$

(b) This is just the result of part (a) in the limit as $R\to\infty$. In this case $\dfrac{1}{\sqrt{R^2+d^2}}\to 0$, and we are left with

$$F=2\pi Gm\rho d\left(\frac{1}{d}-0\right)=2\pi Gm\rho.$$

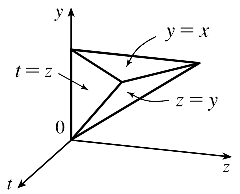
11. $\int_0^x\int_0^y\int_0^z f(t)\,dt\,dz\,dy=\iiint_E f(t)\,dV$, where

$E=\{(t,z,y)\mid 0\le t\le z, 0\le z\le y, 0\le y\le x\}$.

If we let D be the projection of E on the yt-plane then

$D=\{(y,t)\mid 0\le t\le x, t\le y\le x\}$. And we see from the diagram

that $E=\{(t,z,y)\mid t\le z\le y, t\le y\le x, 0\le t\le x\}$. So



$$\begin{aligned}\int_0^x\int_0^y\int_0^z f(t)\,dt\,dz\,dy&=\int_0^x\int_t^x\int_t^y f(t)\,dz\,dy\,dt=\int_0^x\left[\int_t^x(y-t)\,f(t)\,dy\right]dt\\&=\int_0^x\left[\left(\tfrac12 y^2-ty\right)f(t)\right]_{y=t}^{y=x}dt=\int_0^x\left[\tfrac12x^2-tx-\tfrac12t^2+t^2\right]f(t)\,dt\\&=\int_0^x\left[\tfrac12x^2-tx+\tfrac12t^2\right]f(t)\,dt=\int_0^x\left(\tfrac12x^2-2tx+t^2\right)f(t)\,dt\\&=\tfrac12\int_0^x(x-t)^2\,f(t)\,dt\end{aligned}$$

12. $\displaystyle n^{-2}\sum_{i=1}^{n}\sum_{j=1}^{n^2}\frac{1}{\sqrt{n^2+ni+j}}=\sum_{i=1}^{n}\sum_{j=1}^{n^2}\frac{1}{\frac1n\sqrt{n^2+ni+j}}\cdot\frac{1}{n^3}=\sum_{i=1}^{n}\sum_{j=1}^{n^2}\frac{1}{\sqrt{1+\frac{i}{n}+\frac{j}{n^2}}}\cdot\frac{1}{n^3}$ can be considered a double

Riemann sum of the function $f(x,y)=\dfrac{1}{\sqrt{1+x+y}}$ where the square region $R=\{(x,y)\mid 0\le x\le1, 0\le y\le1\}$ is divided into subrectangles by dividing the interval $[0,1]$ on the x-axis into n subintervals, each of width $\frac1n$, and $[0,1]$ on the y-axis is divided into n^2 subintervals, each of width $\frac{1}{n^2}$. Then the area of each subrectangle is $\Delta A=\frac{1}{n^3}$, and if we take the upper right corners of the subrectangles as sample points, we have $(x_{ij}^*,y_{ij}^*)=\left(\frac{i}{n},\frac{j}{n^2}\right)$. Finally, note that $n^2\to\infty$ as $n\to\infty$, so

$$\lim_{n\to\infty}n^{-2}\sum_{i=1}^{n}\sum_{j=1}^{n^2}\frac{1}{\sqrt{n^2+ni+j}}=\lim_{n,n^2\to\infty}\sum_{i=1}^{n}\sum_{j=1}^{n^2}\frac{1}{\sqrt{1+\frac{i}{n}+\frac{j}{n^2}}}\cdot\frac{1}{n^3}=\lim_{n,n^2\to\infty}\sum_{i=1}^{n}\sum_{j=1}^{n^2}f(x_{ij}^*,y_{ij}^*)\,\Delta A$$

But by Definition 15.1.5 this is equal to $\iint_R f(x,y)\,dA$, so

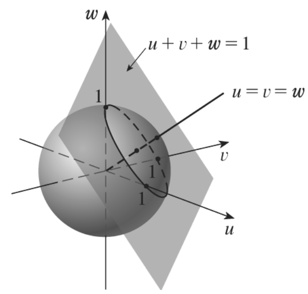
$$\lim_{n\to\infty} n^{-2}\sum_{i=1}^{n}\sum_{j=1}^{n^2}\frac{1}{\sqrt{n^2+ni+j}} = \iint_R f(x,y)\,dA = \int_0^1\int_0^1 \frac{1}{\sqrt{1+x+y}}\,dy\,dx$$

$$= \int_0^1 \left[2(1+x+y)^{1/2}\right]_{y=0}^{y=1} dx = 2\int_0^1 \left(\sqrt{2+x}-\sqrt{1+x}\right) dx$$

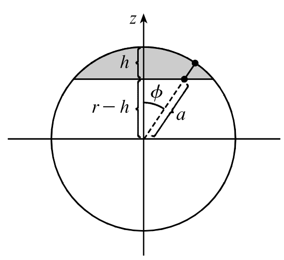
$$= 2\left[\tfrac{2}{3}(2+x)^{3/2} - \tfrac{2}{3}(1+x)^{3/2}\right]_0^1 = \tfrac{4}{3}(3^{3/2}-2^{3/2}-2^{3/2}+1)$$

$$= \tfrac{4}{3}(3\sqrt{3}-4\sqrt{2}+1) = 4\sqrt{3}-\tfrac{16}{3}\sqrt{2}+\tfrac{4}{3}$$

13. The volume is $V=\iiint_R dV$ where R is the solid region given. From Exercise 15.9.21(a), the transformation $x=au$, $y=bv$, $z=cw$ maps the unit ball $u^2+v^2+w^2\le 1$ to the solid ellipsoid $\dfrac{x^2}{a^2}+\dfrac{y^2}{b^2}+\dfrac{z^2}{c^2}\le 1$ with $\dfrac{\partial(x,y,z)}{\partial(u,v,w)}=abc$. The same transformation maps the plane $u+v+w=1$ to $\dfrac{x}{a}+\dfrac{y}{b}+\dfrac{z}{c}=1$. Thus the region R in xyz-space corresponds to the region S in uvw-space consisting of the smaller piece of the unit ball cut off by the plane $u+v+w=1$, a "cap of a sphere" (see the figure).



We will need to compute the volume of S, but first consider the general case where a horizontal plane slices the upper portion of a sphere of radius r to produce a cap of height h. We use spherical coordinates. From the figure, a line through the origin at angle ϕ from the z-axis intersects the plane when $\cos\phi=(r-h)/a \Rightarrow a=(r-h)/\cos\phi$, and the line passes through the outer rim of the cap when $a=r \Rightarrow \cos\phi=(r-h)/r \Rightarrow \phi=\cos^{-1}((r-h)/r)$. Thus the cap is described by $\{(\rho,\theta,\phi)\mid (r-h)/\cos\phi\le\rho\le r, 0\le\theta\le 2\pi, 0\le\phi\le\cos^{-1}((r-h)/r)\}$ and its volume is



$$V=\int_0^{2\pi}\int_0^{\cos^{-1}((r-h)/r)}\int_{(r-h)/\cos\phi}^{r}\rho^2\sin\phi\,d\rho\,d\phi\,d\theta$$

$$=\int_0^{2\pi}\int_0^{\cos^{-1}((r-h)/r)}\left[\tfrac{1}{3}\rho^3\sin\phi\right]_{\rho=(r-h)/\cos\phi}^{\rho=r} d\phi\,d\theta$$

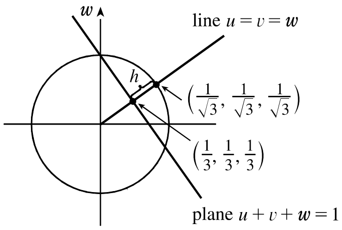
$$=\frac{1}{3}\int_0^{2\pi}\int_0^{\cos^{-1}((r-h)/r)}\left[r^3\sin\phi-\frac{(r-h)^3}{\cos^3\phi}\sin\phi\right]d\phi\,d\theta$$

$$=\tfrac{1}{3}\int_0^{2\pi}\left[-r^3\cos\phi-\tfrac{1}{2}(r-h)^3\cos^{-2}\phi\right]_{\phi=0}^{\phi=\cos^{-1}((r-h)/r)} d\theta$$

$$=\frac{1}{3}\int_0^{2\pi}\left[-r^3\left(\frac{r-h}{r}\right)-\frac{1}{2}(r-h)^3\left(\frac{r-h}{r}\right)^{-2}+r^3+\frac{1}{2}(r-h)^3\right]d\theta$$

$$=\tfrac{1}{3}\int_0^{2\pi}\left(\tfrac{3}{2}rh^2-\tfrac{1}{2}h^3\right)d\theta=\tfrac{1}{3}\left(\tfrac{3}{2}rh^2-\tfrac{1}{2}h^3\right)(2\pi)=\pi h^2\left(r-\tfrac{1}{3}h\right)$$

(This volume can also be computed by treating the cap as a solid of revolution and using the single variable disk method; see Exercise 5.2.49 [ET 6.2.49].)



To determine the height h of the cap cut from the unit ball by the plane $u + v + w = 1$, note that the line $u = v = w$ passes through the origin with direction vector $\langle 1, 1, 1 \rangle$ which is perpendicular to the plane. Therefore this line coincides with a radius of the sphere that passes through the center of the cap and h is measured along this line. The line intersects the plane at $\left(\frac{1}{3}, \frac{1}{3}, \frac{1}{3}\right)$ and the sphere at $\left(\frac{1}{\sqrt{3}}, \frac{1}{\sqrt{3}}, \frac{1}{\sqrt{3}}\right)$. (See the figure.)

The distance between these points is $h = \sqrt{3\left(\frac{1}{\sqrt{3}} - \frac{1}{3}\right)^2} = \sqrt{3}\left(\frac{1}{\sqrt{3}} - \frac{1}{3}\right) = 1 - \frac{1}{\sqrt{3}}$. Thus the volume of R is

$$V = \iiint_R dV = \iiint_S \left| \frac{\partial(x,y,z)}{\partial(u,v,w)} \right| dV = abc \iiint_S dV = abc\, V(S)$$

$$= abc \cdot \pi h^2 (r - \tfrac{1}{3}h) = abc \cdot \pi \left(1 - \frac{1}{\sqrt{3}}\right)^2 \left[1 - \frac{1}{3}\left(1 - \frac{1}{\sqrt{3}}\right)\right]$$

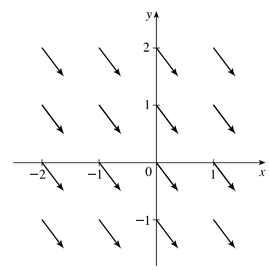
$$= abc\pi \left(\frac{4}{3} - \frac{2}{\sqrt{3}}\right)\left(\frac{2}{3} + \frac{1}{3\sqrt{3}}\right) = abc\pi\left(\frac{2}{3} - \frac{8}{9\sqrt{3}}\right) \approx 0.482abc$$

16 ☐ VECTOR CALCULUS

16.1 Vector Fields

1. $\mathbf{F}(x, y) = 0.3\,\mathbf{i} - 0.4\,\mathbf{j}$

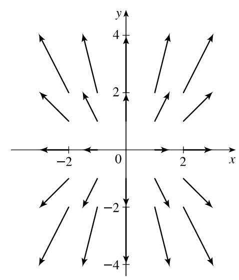
All vectors in this field are identical, with length 0.5 and parallel to $\langle 3, -4 \rangle$.



2. $\mathbf{F}(x, y) = \frac{1}{2}x\,\mathbf{i} + y\,\mathbf{j}$

The length of the vector $\frac{1}{2}x\,\mathbf{i} + y\,\mathbf{j}$ is $\sqrt{\frac{1}{4}x^2 + y^2}$.

Vectors point roughly away from the origin and vectors farther from the origin are longer.

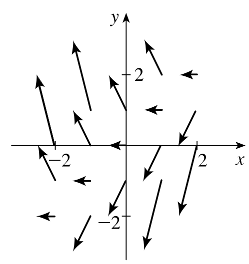


3. $\mathbf{F}(x, y) = -\frac{1}{2}\,\mathbf{i} + (y - x)\,\mathbf{j}$

The length of the vector $-\frac{1}{2}\,\mathbf{i} + (y - x)\,\mathbf{j}$ is

$\sqrt{\frac{1}{4} + (y - x)^2}$. Vectors along the line $y = x$ are

horizontal with length $\frac{1}{2}$.



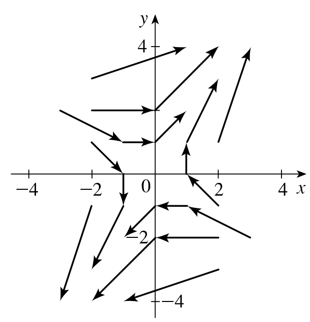
4. $\mathbf{F}(x, y) = y\,\mathbf{i} + (x + y)\,\mathbf{j}$

The length of the vector $y\,\mathbf{i} + (x + y)\,\mathbf{j}$ is

$\sqrt{y^2 + (x + y)^2}$. Vectors along the x-axis are vertical,

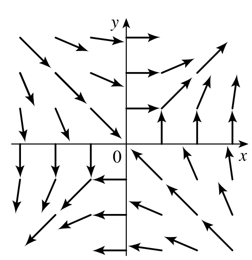
and vectors along the line $y = -x$ are horizontal with

length $|y|$.



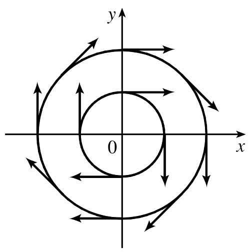
5. $\mathbf{F}(x, y) = \dfrac{y\,\mathbf{i} + x\,\mathbf{j}}{\sqrt{x^2 + y^2}}$

The length of the vector $\dfrac{y\,\mathbf{i} + x\,\mathbf{j}}{\sqrt{x^2 + y^2}}$ is 1.



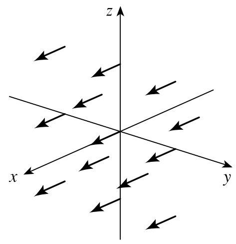
6. $\mathbf{F}(x,y) = \dfrac{y\,\mathbf{i} - x\,\mathbf{j}}{\sqrt{x^2+y^2}}$

All the vectors $\mathbf{F}(x,y)$ are unit vectors tangent to circles centered at the origin with radius $\sqrt{x^2+y^2}$.



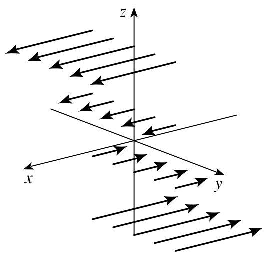
7. $\mathbf{F}(x,y) = \mathbf{i}$

All vectors in this field are identical, with length 1 and pointing in the direction of the positive x-axis.



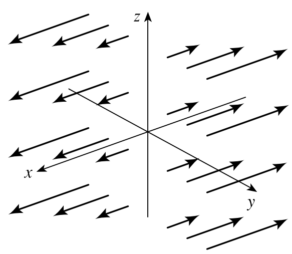
8. $\mathbf{F}(x,y,z) = z\,\mathbf{i}$

At each point (x,y,z), $\mathbf{F}(x,y,z)$ is a vector of length $|z|$. For $z > 0$, all point in the direction of the positive x-axis, while for $z < 0$, all are in the direction of the negative x-axis. In each plane $z = k$, all the vectors are identical.



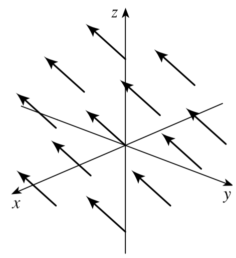
9. $\mathbf{F}(x,y,z) = -y\,\mathbf{i}$

At each point (x,y,z), $\mathbf{F}(x,y,z)$ is a vector of length $|y|$. For $y > 0$, all point in the direction of the negative x-axis, while for $y < 0$, all are in the direction of the positive x-axis. In each plane $y = k$, all the vectors are identical.



10. $\mathbf{F}(x,y,z) = \mathbf{i} + \mathbf{k}$

All vectors in this field have length $\sqrt{2}$ and point in the same direction, parallel to the xz-plane.



11. $\mathbf{F}(x,y) = \langle x, -y \rangle$ corresponds to graph IV. In the first quadrant all the vectors have positive x-components and negative y-components, in the second quadrant all vectors have negative x- and y-components, in the third quadrant all vectors have negative x-components and positive y-components, and in the fourth quadrant all vectors have positive x- and y-components. In addition, the vectors get shorter as we approach the origin.

12. $\mathbf{F}(x,y) = \langle y, x-y\rangle$ corresponds to graph III. All vectors in quadrants I and II have positive x-components while all vectors in quadrants III and IV have negative x-components. In addition, vectors along the line $y = x$ are horizontal, and vectors get shorter as we approach the origin.

13. $\mathbf{F}(x,y) = \langle y, y+2\rangle$ corresponds to graph I. As in Exercise 12, all vectors in quadrants I and II have positive x-components while all vectors in quadrants III and IV have negative x-components. Vectors along the line $y = -2$ are horizontal, and the vectors are independent of x (vectors along horizontal lines are identical).

14. $\mathbf{F}(x,y) = \langle \cos(x+y), x\rangle$ corresponds to graph II. All vectors in quadrants I and IV have positive y-components while all vectors in quadrants II and III have negative y-components. Also, the y-components of vectors along any vertical line remain constant while the x-component oscillates.

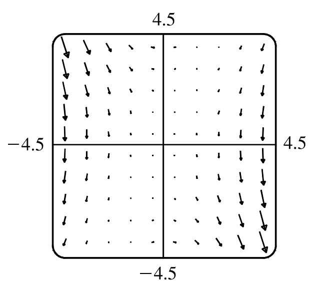
15. $\mathbf{F}(x,y,z) = \mathbf{i} + 2\,\mathbf{j} + 3\,\mathbf{k}$ corresponds to graph IV, since all vectors have identical length and direction.

16. $\mathbf{F}(x,y,z) = \mathbf{i} + 2\,\mathbf{j} + z\,\mathbf{k}$ corresponds to graph I, since the horizontal vector components remain constant, but the vectors above the xy-plane point generally upward while the vectors below the xy-plane point generally downward.

17. $\mathbf{F}(x,y,z) = x\,\mathbf{i} + y\,\mathbf{j} + 3\,\mathbf{k}$ corresponds to graph III; the projection of each vector onto the xy-plane is $x\,\mathbf{i} + y\,\mathbf{j}$, which points away from the origin, and the vectors point generally upward because their z-components are all 3.

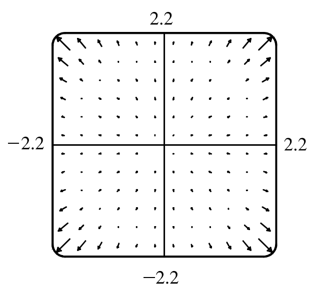
18. $\mathbf{F}(x,y,z) = x\,\mathbf{i} + y\,\mathbf{j} + z\,\mathbf{k}$ corresponds to graph II; each vector $\mathbf{F}(x,y,z)$ has the same length and direction as the position vector of the point (x,y,z), and therefore the vectors all point directly away from the origin.

19.



The vector field seems to have very short vectors near the line $y = 2x$. For $\mathbf{F}(x,y) = \langle 0,0\rangle$ we must have $y^2 - 2xy = 0$ and $3xy - 6x^2 = 0$. The first equation holds if $y = 0$ or $y = 2x$, and the second holds if $x = 0$ or $y = 2x$. So both equations hold [and thus $\mathbf{F}(x,y) = \mathbf{0}$] along the line $y = 2x$.

20.



From the graph, it appears that all of the vectors in the field lie on lines through the origin, and that the vectors have very small magnitudes near the circle $|\mathbf{x}| = 2$ and near the origin. Note that $\mathbf{F}(\mathbf{x}) = \mathbf{0} \quad\Leftrightarrow\quad r(r-2) = 0 \quad\Leftrightarrow\quad r = 0$ or 2, so as we suspected, $\mathbf{F}(\mathbf{x}) = \mathbf{0}$ for $|\mathbf{x}| = 2$ and for $|\mathbf{x}| = 0$. Note that where $r^2 - r < 0$, the vectors point towards the origin, and where $r^2 - r > 0$, they point away from the origin.

21. $f(x,y) = y\sin(xy) \quad\Rightarrow$

$$\begin{aligned}\nabla f(x,y) &= f_x(x,y)\,\mathbf{i} + f_y(x,y)\,\mathbf{j} = (y\cos(xy)\cdot y)\,\mathbf{i} + [y\cdot x\cos(xy) + \sin(xy)\cdot 1]\,\mathbf{j} \\ &= y^2\cos(xy)\,\mathbf{i} + [xy\cos(xy) + \sin(xy)]\,\mathbf{j}\end{aligned}$$

22. $f(s,t) = \sqrt{2s+3t} \quad \Rightarrow$

$$\nabla f(s,t) = f_s(s,t)\,\mathbf{i} + f_t(s,t)\,\mathbf{j} = \left[\tfrac{1}{2}(2s+3t)^{-1/2} \cdot 2\right]\mathbf{i} + \left[\tfrac{1}{2}(2s+3t)^{-1/2} \cdot 3\right]\mathbf{j} = \frac{1}{\sqrt{2s+3t}}\,\mathbf{i} + \frac{3}{2\sqrt{2s+3t}}\,\mathbf{j}$$

23. $f(x,y,z) = \sqrt{x^2+y^2+z^2} \quad \Rightarrow$

$$\begin{aligned} \nabla f(x,y,z) &= f_x(x,y,z)\,\mathbf{i} + f_y(x,y,z)\,\mathbf{j} + f_z(x,y,z)\,\mathbf{k} \\ &= \tfrac{1}{2}(x^2+y^2+z^2)^{-1/2}(2x)\,\mathbf{i} + \tfrac{1}{2}(x^2+y^2+z^2)^{-1/2}(2y)\,\mathbf{j} + \tfrac{1}{2}(x^2+y^2+z^2)^{-1/2}(2z)\,\mathbf{k} \\ &= \frac{x}{\sqrt{x^2+y^2+z^2}}\,\mathbf{i} + \frac{y}{\sqrt{x^2+y^2+z^2}}\,\mathbf{j} + \frac{z}{\sqrt{x^2+y^2+z^2}}\,\mathbf{k} \end{aligned}$$

24. $f(x,y,z) = x^2 y e^{y/z} \quad \Rightarrow$

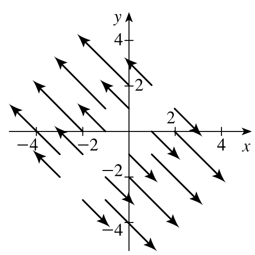
$$\begin{aligned} \nabla f(x,y,z) &= f_x(x,y,z)\,\mathbf{i} + f_y(x,y,z)\,\mathbf{j} + f_z(x,y,z)\,\mathbf{k} \\ &= 2xye^{y/z}\,\mathbf{i} + x^2\left[y \cdot e^{yz}(1/z) + e^{y/z} \cdot 1\right]\mathbf{j} + \left[x^2 y e^{y/z}(-y/z^2)\right]\mathbf{k} \\ &= 2xye^{y/z}\,\mathbf{i} + x^2 e^{y/z}\left(\frac{y}{z} + 1\right)\mathbf{j} - \frac{x^2y^2}{z^2}e^{y/z}\,\mathbf{k} \end{aligned}$$

25. $f(x,y) = \frac{1}{2}(x-y)^2 \quad \Rightarrow$

$\nabla f(x,y) = (x-y)(1)\,\mathbf{i} + (x-y)(-1)\,\mathbf{j} = (x-y)\,\mathbf{i} + (y-x)\,\mathbf{j}$.

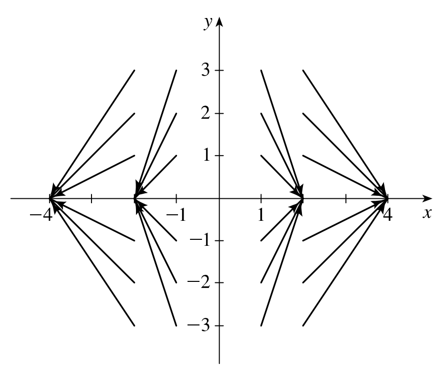
The length of $\nabla f(x,y)$ is $\sqrt{(x-y)^2+(y-x)^2} = \sqrt{2}\,|x-y|$.

The vectors are $\mathbf{0}$ along the line $y = x$. Elsewhere the vectors point away from the line $y = x$ with length that increases as the distance from the line increases.



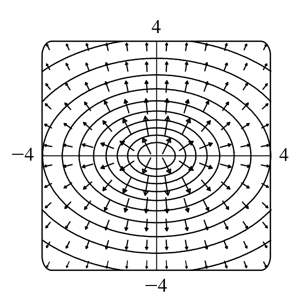
26. $f(x,y) = \frac{1}{2}(x^2 - y^2) \quad \Rightarrow \quad \nabla f(x,y) = x\,\mathbf{i} - y\,\mathbf{j}$.

The length of $\nabla f(x,y)$ is $\sqrt{x^2+y^2}$. The lengths of the vectors increase as the distance from the origin increases, and the terminal point of each vector lies on the x-axis.

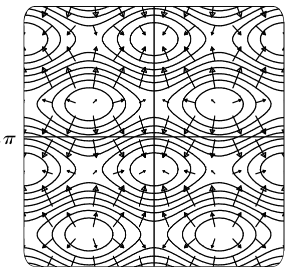


27. We graph $\nabla f(x,y) = \dfrac{2x}{1+x^2+2y^2}\,\mathbf{i} + \dfrac{4y}{1+x^2+2y^2}\,\mathbf{j}$ along with a contour map of f.

The graph shows that the gradient vectors are perpendicular to the level curves. Also, the gradient vectors point in the direction in which f is increasing and are longer where the level curves are closer together.



28. We graph $\nabla f(x,y) = -\sin x\,\mathbf{i} - 2\cos y\,\mathbf{j}$ along with a contour map of f.



The graph shows that the gradient vectors are perpendicular to the level curves. Also, the gradient vectors point in the direction in which f is increasing and are longer where the level curves are closer together.

29. $f(x,y) = x^2 + y^2 \quad\Rightarrow\quad \nabla f(x,y) = 2x\,\mathbf{i} + 2y\,\mathbf{j}$. Thus, each vector $\nabla f(x,y)$ has the same direction and twice the length of the position vector of the point (x,y), so the vectors all point directly away from the origin and their lengths increase as we move away from the origin. Hence, ∇f is graph III.

30. $f(x,y) = x(x+y) = x^2 + xy \quad\Rightarrow\quad \nabla f(x,y) = (2x+y)\,\mathbf{i} + x\,\mathbf{j}$. The y-component of each vector is x, so the vectors point upward in quadrants I and IV and downward in quadrants II and III. Also, the x-component of each vector is 0 along the line $y = -2x$ so the vectors are vertical there. Thus, ∇f is graph IV.

31. $f(x,y) = (x+y)^2 \quad\Rightarrow\quad \nabla f(x,y) = 2(x+y)\,\mathbf{i} + 2(x+y)\,\mathbf{j}$. The x- and y-components of each vector are equal, so all vectors are parallel to the line $y = x$. The vectors are $\mathbf{0}$ along the line $y = -x$ and their length increases as the distance from this line increases. Thus, ∇f is graph II.

32. $f(x,y) = \sin\sqrt{x^2+y^2} \quad\Rightarrow$

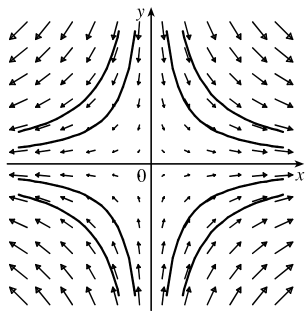
$$\begin{aligned}\nabla f(x,y) &= \left[\cos\sqrt{x^2+y^2}\cdot\tfrac{1}{2}(x^2+y^2)^{-1/2}(2x)\right]\mathbf{i} + \left[\cos\sqrt{x^2+y^2}\cdot\tfrac{1}{2}(x^2+y^2)^{-1/2}(2y)\right]\mathbf{j} \\ &= \frac{\cos\sqrt{x^2+y^2}}{\sqrt{x^2+y^2}}\,x\,\mathbf{i} + \frac{\cos\sqrt{x^2+y^2}}{\sqrt{x^2+y^2}}\,y\,\mathbf{j} \text{ or } \frac{\cos\sqrt{x^2+y^2}}{\sqrt{x^2+y^2}}\,(x\,\mathbf{i} + y\,\mathbf{j})\end{aligned}$$

Thus each vector is a scalar multiple of its position vector, so the vectors point toward or away from the origin with length that changes in a periodic fashion as we move away from the origin. ∇f is graph I.

33. At $t = 3$ the particle is at $(2,1)$ so its velocity is $\mathbf{V}(2,1) = \langle 4,3\rangle$. After 0.01 units of time, the particle's change in location should be approximately $0.01\,\mathbf{V}(2,1) = 0.01\,\langle 4,3\rangle = \langle 0.04, 0.03\rangle$, so the particle should be approximately at the point $(2.04, 1.03)$.

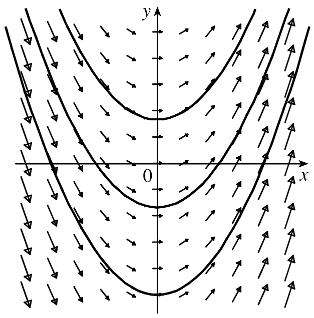
34. At $t = 1$ the particle is at $(1,3)$ so its velocity is $\mathbf{F}(1,3) = \langle 1,-1\rangle$. After 0.05 units of time, the particle's change in location should be approximately $0.05\,\mathbf{F}(1,3) = 0.05\,\langle 1,-1\rangle = \langle 0.05, -0.05\rangle$, so the particle should be approximately at the point $(1.05, 2.95)$.

35. (a) We sketch the vector field $\mathbf{F}(x, y) = x\,\mathbf{i} - y\,\mathbf{j}$ along with several approximate flow lines. The flow lines appear to be hyperbolas with shape similar to the graph of $y = \pm 1/x$, so we might guess that the flow lines have equations $y = C/x$.



(b) If $x = x(t)$ and $y = y(t)$ are parametric equations of a flow line, then the velocity vector of the flow line at the point (x, y) is $x'(t)\,\mathbf{i} + y'(t)\,\mathbf{j}$. Since the velocity vectors coincide with the vectors in the vector field, we have $x'(t)\,\mathbf{i} + y'(t)\,\mathbf{j} = x\,\mathbf{i} - y\,\mathbf{j} \;\Rightarrow\; dx/dt = x,\, dy/dt = -y$. To solve these differential equations, we know $dx/dt = x \;\Rightarrow\; dx/x = dt \;\Rightarrow\; \ln|x| = t + C \;\Rightarrow\; x = \pm e^{t+C} = Ae^t$ for some constant A, and $dy/dt = -y \;\Rightarrow\; dy/y = -dt \;\Rightarrow\; \ln|y| = -t + K \;\Rightarrow\; y = \pm e^{-t+K} = Be^{-t}$ for some constant B. Therefore $xy = Ae^tBe^{-t} = AB =$ constant. If the flow line passes through $(1, 1)$ then $(1)(1) =$ constant $= 1 \;\Rightarrow\; xy = 1 \;\Rightarrow\; y = 1/x,\, x > 0$.

36. (a) We sketch the vector field $\mathbf{F}(x, y) = \mathbf{i} + x\,\mathbf{j}$ along with several approximate flow lines. The flow lines appear to be parabolas.



(b) If $x = x(t)$ and $y = y(t)$ are parametric equations of a flow line, then the velocity vector of the flow line at the point (x, y) is $x'(t)\,\mathbf{i} + y'(t)\,\mathbf{j}$. Since the velocity vectors coincide with the vectors in the vector field, we have $x'(t)\,\mathbf{i} + y'(t)\,\mathbf{j} = \mathbf{i} + x\,\mathbf{j} \;\Rightarrow\; \dfrac{dx}{dt} = 1,\, \dfrac{dy}{dt} = x$. Thus $\dfrac{dy}{dx} = \dfrac{dy/dt}{dx/dt} = \dfrac{x}{1} = x$.

(c) From part (b), $dy/dx = x$. Integrating, we have $y = \frac{1}{2}x^2 + c$. Since the particle starts at the origin, we know $(0, 0)$ is on the curve, so $0 = 0 + c \;\Rightarrow\; c = 0$ and the path the particle follows is $y = \frac{1}{2}x^2$.

16.2 Line Integrals

1. $x = t^2$ and $y = 2t$, $0 \le t \le 3$, so by Formula 3

$$\int_C y\,ds = \int_0^3 2t\sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2}\,dt = \int_0^3 2t\,\sqrt{(2t)^2 + (2)^2}\,dt = \int_0^3 2t\,\sqrt{4t^2 + 4}\,dt$$

$$= \int_0^3 4t\,\sqrt{t^2 + 1}\,dt = 2 \cdot \tfrac{2}{3}\left(t^2 + 1\right)^{3/2}\Big]_0^3 = \tfrac{4}{3}(10^{3/2} - 1) \;\text{ or }\; \tfrac{4}{3}(10\sqrt{10} - 1)$$

2. $x = t^3$ and $y = t^4$, $1 \le t \le 2$, so by Formula 3

$$\int_C (x/y)\,ds = \int_1^2 (t^3/t^4)\sqrt{(3t^2)^2 + (4t^3)^2}\,dt = \int_1^2 (1/t)\cdot t^2\sqrt{9+16t^2}\,dt = \int_1^2 t\sqrt{9+16t^2}\,dt$$
$$= \tfrac{1}{32}\cdot\tfrac{2}{3}\left(9+16t^2\right)^{3/2}\Big]_1^2 = \tfrac{1}{48}(73^{3/2} - 25^{3/2}) \text{ or } \tfrac{1}{48}(73\sqrt{73} - 125)$$

3. Parametric equations for C are $x = 4\cos t$, $y = 4\sin t$, $-\frac{\pi}{2} \le t \le \frac{\pi}{2}$. Then

$$\int_C xy^4\,ds = \int_{-\pi/2}^{\pi/2} (4\cos t)(4\sin t)^4\sqrt{(-4\sin t)^2 + (4\cos t)^2}\,dt = \int_{-\pi/2}^{\pi/2} 4^5\cos t\,\sin^4 t\,\sqrt{16(\sin^2 t + \cos^2 t)}\,dt$$
$$= 4^5\int_{-\pi/2}^{\pi/2} (\sin^4 t\cos t)(4)\,dt = (4)^6\left[\tfrac{1}{5}\sin^5 t\right]_{-\pi/2}^{\pi/2} = 4^6\cdot\tfrac{2}{5} = 1638.4$$

4. Parametric equations for C are $x = 2+3t$, $y = 4t$, $0 \le t \le 1$. Then

$$\int_C xe^y\,ds = \int_0^1 (2+3t)\,e^{4t}\sqrt{3^2+4^2}\,dt = 5\int_0^1 (2+3t)\,e^{4t}\,dt$$

Integrating by parts with $u = 2+3t \;\Rightarrow\; du = 3\,dt$, $dv = e^{4t}\,dt \;\Rightarrow\; v = \frac{1}{4}e^{4t}$ gives

$$\int_C xe^y\,ds = 5\left[\tfrac{1}{4}(2+3t)e^{4t} - \tfrac{3}{16}e^{4t}\right]_0^1 = 5\left[\tfrac{5}{4}e^4 - \tfrac{3}{16}e^4 - \tfrac{1}{2} + \tfrac{3}{16}\right] = \tfrac{85}{16}e^4 - \tfrac{25}{16}$$

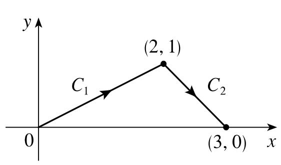
5. If we choose x as the parameter, parametric equations for C are $x = x$, $y = x^2$ for $0 \le x \le \pi$ and by Equations 7

$$\int_C \left(x^2y + \sin x\right)dy = \int_0^\pi \left[x^2(x^2) + \sin x\right]\cdot 2x\,dx = 2\int_0^\pi \left(x^5 + x\sin x\right)dx$$
$$= 2\left[\tfrac{1}{6}x^6 - x\cos x + \sin x\right]_0^\pi \quad \left[\begin{array}{c}\text{where we integrated by parts}\\ \text{in the second term}\end{array}\right]$$
$$= 2\left[\tfrac{1}{6}\pi^6 + \pi + 0 - 0\right] = \tfrac{1}{3}\pi^6 + 2\pi$$

6. Choosing y as the parameter, we have $x = y^3$, $y = y$, $-1 \le y \le 1$. Then

$$\int_C e^x\,dx = \int_{-1}^1 e^{y^3}\cdot 3y^2\,dy = e^{y^3}\Big]_{-1}^1 = e^1 - e^{-1} = e - \tfrac{1}{e}.$$

7.



$C = C_1 + C_2$

On C_1: $x = x, y = \frac{1}{2}x \;\Rightarrow\; dy = \frac{1}{2}\,dx$, $0 \le x \le 2$.

On C_2: $x = x, y = 3 - x \;\Rightarrow\; dy = -dx$, $2 \le x \le 3$.

Then

$$\int_C (x+2y)\,dx + x^2\,dy = \int_{C_1} (x+2y)\,dx + x^2\,dy + \int_{C_2} (x+2y)\,dx + x^2\,dy$$
$$= \int_0^2 \left[x + 2\left(\tfrac{1}{2}x\right) + x^2\left(\tfrac{1}{2}\right)\right]dx + \int_2^3 \left[x + 2(3-x) + x^2(-1)\right]dx$$
$$= \int_0^2 \left(2x + \tfrac{1}{2}x^2\right)dx + \int_2^3 \left(6 - x - x^2\right)dx$$
$$= \left[x^2 + \tfrac{1}{6}x^3\right]_0^2 + \left[6x - \tfrac{1}{2}x^2 - \tfrac{1}{3}x^3\right]_2^3 = \tfrac{16}{3} - 0 + \tfrac{9}{2} - \tfrac{22}{3} = \tfrac{5}{2}$$

8. 
$C = C_1 + C_2$

On C_1: $x = 2\cos t \;\Rightarrow\; dx = -2\sin t\,dt,\;\; y = 2\sin t \;\Rightarrow$
$dy = 2\cos t\;dt,\;\; 0 \le t \le \frac{\pi}{2}$.

On C_2: $x = 4t \;\Rightarrow\; dx = 4\,dt, y = 2 + t \;\Rightarrow$
$dy = dt,\;\; 0 \le t \le 1$.

Then

$$\begin{aligned}\int_C x^2\,dx + y^2\,dy &= \int_{C_1} x^2\,dx + y^2\,dy + \int_{C_2} x^2\,dx + y^2\,dy \\ &= \int_0^{\pi/2} (2\cos t)^2(-2\sin t\,dt) + (2\sin t)^2(2\cos t\,dt) + \int_0^1 (4t)^2(4\,dt) + (2+t)^2\,dt \\ &= 8\int_0^{\pi/2} (-\cos^2 t\sin t + \sin^2 t\cos t)\,dt + \int_0^1 (65t^2 + 4t + 4)\,dt \\ &= 8\left[\tfrac{1}{3}\cos^3 t + \tfrac{1}{3}\sin^3 t\right]_0^{\pi/2} + \left[\tfrac{65}{3}t^3 + 2t^2 + 4t\right]_0^1 = 8\left(\tfrac{1}{3} - \tfrac{1}{3}\right) + \tfrac{65}{3} + 2 + 4 = \tfrac{83}{3}\end{aligned}$$

9. $x = \cos t,\;\; y = \sin t,\;\; z = t,\;\; 0 \le t \le \pi/2$. Then by Formula 9,

$$\begin{aligned}\int_C x^2 y\,ds &= \int_0^{\pi/2} (\cos t)^2(\sin t)\sqrt{\left(\tfrac{dx}{dt}\right)^2 + \left(\tfrac{dy}{dt}\right)^2 + \left(\tfrac{dz}{dt}\right)^2}\,dt \\ &= \int_0^{\pi/2} \cos^2 t\sin t\,\sqrt{(-\sin t)^2 + (\cos t)^2 + (1)^2}\,dt = \int_0^{\pi/2} \cos^2 t\sin t\,\sqrt{\sin^2 t + \cos^2 t + 1}\,dt \\ &= \sqrt{2}\int_0^{\pi/2} \cos^2 t\sin t\,dt = \sqrt{2}\left[-\tfrac{1}{3}\cos^3 t\right]_0^{\pi/2} = \sqrt{2}\left(0 + \tfrac{1}{3}\right) = \tfrac{\sqrt{2}}{3}\end{aligned}$$

10. Parametric equations for C are $x = 3 - 2t,\; y = 1 + t,\; z = 2 + 3t,\; 0 \le t \le 1$. Then

$$\begin{aligned}\int_C y^2 z\,ds &= \int_0^1 (1+t)^2(2+3t)\sqrt{(-2)^2 + 1^2 + 3^2}\,dt = \sqrt{14}\int_0^1 (3t^3 + 8t^2 + 7t + 2)\,dt \\ &= \sqrt{14}\left[\tfrac{3}{4}t^4 + \tfrac{8}{3}t^3 + \tfrac{7}{2}t^2 + 2t\right]_0^1 = \sqrt{14}\left(\tfrac{3}{4} + \tfrac{8}{3} + \tfrac{7}{2} + 2\right) = \tfrac{107}{12}\sqrt{14}\end{aligned}$$

11. Parametric equations for C are $x = t,\; y = 2t,\; z = 3t,\; 0 \le t \le 1$. Then

$$\int_C xe^{yz}\,ds = \int_0^1 te^{(2t)(3t)}\sqrt{1^2 + 2^2 + 3^2}\,dt = \sqrt{14}\int_0^1 te^{6t^2}\,dt = \sqrt{14}\left[\tfrac{1}{12}e^{6t^2}\right]_0^1 = \tfrac{\sqrt{14}}{12}(e^6 - 1).$$

12. $\sqrt{(dx/dt)^2 + (dy/dt)^2 + (dz/dt)^2} = \sqrt{1^2 + (-2\sin 2t)^2 + (2\cos 2t)^2} = \sqrt{1 + 4(\sin^2 2t + \cos^2 2t)} = \sqrt{5}$. Then

$$\begin{aligned}\int_C (x^2 + y^2 + z^2)\,ds &= \int_0^{2\pi} (t^2 + \cos^2 2t + \sin^2 2t)\sqrt{5}\,dt = \sqrt{5}\int_0^{2\pi} (t^2 + 1)\,dt \\ &= \sqrt{5}\left[\tfrac{1}{3}t^3 + t\right]_0^{2\pi} = \sqrt{5}\left[\tfrac{1}{3}(8\pi^3) + 2\pi\right] = \sqrt{5}\left(\tfrac{8}{3}\pi^3 + 2\pi\right)\end{aligned}$$

13. $\int_C xye^{yz}\,dy = \int_0^1 (t)(t^2)e^{(t^2)(t^3)}\cdot 2t\,dt = \int_0^1 2t^4e^{t^5}\,dt = \tfrac{2}{5}e^{t^5}\Big]_0^1 = \tfrac{2}{5}(e^1 - e^0) = \tfrac{2}{5}(e - 1)$

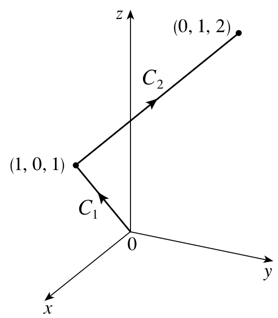
14. $\int_C y\,dx + z\,dy + x\,dz = \int_1^4 t\cdot\tfrac{1}{2}t^{-1/2}\,dt + t^2\cdot dt + \sqrt{t}\cdot 2t\,dt = \int_1^4 \left(\tfrac{1}{2}t^{1/2} + t^2 + 2t^{3/2}\right)dt$

$$= \left[\tfrac{1}{3}t^{3/2} + \tfrac{1}{3}t^3 + \tfrac{4}{5}t^{5/2}\right]_1^4 = \tfrac{8}{3} + \tfrac{64}{3} + \tfrac{128}{5} - \tfrac{1}{3} - \tfrac{1}{3} - \tfrac{4}{5} = \tfrac{722}{15}$$

15. Parametric equations for C are $x = 1 + 3t$, $y = t$, $z = 2t$, $0 \le t \le 1$. Then

$$\int_C z^2\,dx + x^2\,dy + y^2\,dz = \int_0^1 (2t)^2 \cdot 3\,dt + (1+3t)^2\,dt + t^2 \cdot 2\,dt = \int_0^1 \left(23t^2 + 6t + 1\right)dt$$
$$= \left[\tfrac{23}{3}t^3 + 3t^2 + t\right]_0^1 = \tfrac{23}{3} + 3 + 1 = \tfrac{35}{3}$$

16.



On C_1: $x = t \Rightarrow dx = dt$, $y = 0 \Rightarrow dy = 0\,dt$, $z = t \Rightarrow dz = dt$, $0 \le t \le 1$.

On C_2: $x = 1 - t \Rightarrow dx = -dt$, $y = t \Rightarrow dy = dt$, $z = 1 + t \Rightarrow dz = dt$, $0 \le t \le 1$.

Then

$$\int_C (y+z)\,dx + (x+z)\,dy + (x+y)\,dz$$
$$= \int_{C_1} (y+z)\,dx + (x+z)\,dy + (x+y)\,dz + \int_{C_2} (y+z)\,dx + (x+z)\,dy + (x+y)\,dz$$
$$= \int_0^1 (0+t)\,dt + (t+t)\cdot 0\,dt + (t+0)\,dt + \int_0^1 (t+1+t)(-dt) + (1-t+1+t)\,dt + (1-t+t)\,dt$$
$$= \int_0^1 2t\,dt + \int_0^1 (-2t+2)\,dt = \left[t^2\right]_0^1 + \left[-t^2 + 2t\right]_0^1 = 1 + 1 = 2$$

17. (a) Along the line $x = -3$, the vectors of $\mathbf{F}$ have positive y-components, so since the path goes upward, the integrand $\mathbf{F} \cdot \mathbf{T}$ is always positive. Therefore $\int_{C_1} \mathbf{F} \cdot d\mathbf{r} = \int_{C_1} \mathbf{F} \cdot \mathbf{T}\,ds$ is positive.

(b) All of the (nonzero) field vectors along the circle with radius 3 are pointed in the clockwise direction, that is, opposite the direction to the path. So $\mathbf{F} \cdot \mathbf{T}$ is negative, and therefore $\int_{C_2} \mathbf{F} \cdot d\mathbf{r} = \int_{C_2} \mathbf{F} \cdot \mathbf{T}\,ds$ is negative.

18. Vectors starting on C_1 point in roughly the same direction as C_1, so the tangential component $\mathbf{F} \cdot \mathbf{T}$ is positive. Then $\int_{C_1} \mathbf{F} \cdot d\mathbf{r} = \int_{C_1} \mathbf{F} \cdot \mathbf{T}\,ds$ is positive. On the other hand, no vectors starting on C_2 point in the same direction as C_2, while some vectors point in roughly the opposite direction, so we would expect $\int_{C_2} \mathbf{F} \cdot d\mathbf{r} = \int_{C_2} \mathbf{F} \cdot \mathbf{T}\,ds$ to be negative.

19. $\mathbf{r}(t) = t^3\,\mathbf{i} + t^2\,\mathbf{j}$, so $\mathbf{F}(\mathbf{r}(t)) = (t^3)(t^2)^2\,\mathbf{i} - (t^3)^2\,\mathbf{j} = t^7\,\mathbf{i} - t^6\,\mathbf{j}$ and $\mathbf{r}'(t) = 3t^2\,\mathbf{i} + 2t\,\mathbf{j}$. Then

$$\int_C \mathbf{F} \cdot d\mathbf{r} = \int_0^1 \mathbf{F}(\mathbf{r}(t)) \cdot \mathbf{r}'(t)\,dt = \int_0^1 (t^7 \cdot 3t^2 - t^6 \cdot 2t)\,dt = \int_0^1 (3t^9 - 2t^7)\,dt = \left[\tfrac{3}{10}t^{10} - \tfrac{1}{4}t^8\right]_0^1 = \tfrac{3}{10} - \tfrac{1}{4} = \tfrac{1}{20}.$$

20. $\mathbf{F}(\mathbf{r}(t)) = \left(t^2 + (t^3)^2\right)\mathbf{i} + (t^2)(-2t)\,\mathbf{j} + (t^3 - 2t)\,\mathbf{k} = (t^2 + t^6)\,\mathbf{i} - 2t^3\,\mathbf{j} + (t^3 - 2t)\,\mathbf{k}$, $\mathbf{r}'(t) = 2t\,\mathbf{i} + 3t^2\,\mathbf{j} - 2\,\mathbf{k}$. Then

$$\int_C \mathbf{F} \cdot d\mathbf{r} = \int_0^2 \mathbf{F}(\mathbf{r}(t)) \cdot \mathbf{r}'(t)\,dt = \int_0^2 (2t^3 + 2t^7 - 6t^5 - 2t^3 + 4t)\,dt = \int_0^2 (2t^7 - 6t^5 + 4t)\,dt$$
$$= \left[\tfrac{1}{4}t^8 - t^6 + 2t^2\right]_0^2 = 64 - 64 + 8 = 8$$

21. $$\int_C \mathbf{F} \cdot d\mathbf{r} = \int_0^1 \left\langle \sin t^3, \cos(-t^2), t^4 \right\rangle \cdot \left\langle 3t^2, -2t, 1 \right\rangle dt$$
$$= \int_0^1 (3t^2 \sin t^3 - 2t\cos t^2 + t^4)\,dt = \left[-\cos t^3 - \sin t^2 + \tfrac{1}{5}t^5\right]_0^1 = \tfrac{6}{5} - \cos 1 - \sin 1$$

22. $\int_C \mathbf{F} \cdot d\mathbf{r} = \int_0^\pi \langle \cos t, \sin t, \cos t \sin t \rangle \cdot \langle -\sin t, \cos t, 1 \rangle \, dt = \int_0^\pi \sin t \cos t \, dt = \frac{1}{2} \sin^2 t \big]_0^\pi = 0$

23. $\mathbf{F}(\mathbf{r}(t)) = \sqrt{\sin^2 t + \sin t \cos t}\ \mathbf{i} + \left[(\sin t \cos t)/\sin^2 t\right] \mathbf{j} = \sqrt{\sin^2 t + \sin t \cos t}\ \mathbf{i} + \cot t \, \mathbf{j}$,

$\mathbf{r}'(t) = 2 \sin t \cos t \, \mathbf{i} + (\cos^2 t - \sin^2 t) \, \mathbf{j}$. Then

$$\begin{aligned} \int_C \mathbf{F} \cdot d\mathbf{r} &= \int_{\pi/6}^{\pi/3} \mathbf{F}(\mathbf{r}(t)) \cdot \mathbf{r}'(t) \, dt = \int_{\pi/6}^{\pi/3} \left[2 \sin t \cos t \sqrt{\sin^2 t + \sin t \cos t} + (\cot t)(\cos^2 t - \sin^2 t)\right] dt \\ &\approx 0.5424 \end{aligned}$$

24. $$\begin{aligned} \mathbf{F}(\mathbf{r}(t)) &= (\cos t \tan t) e^{\sin t} \, \mathbf{i} + (\tan t \sin t) e^{\cos t} \, \mathbf{j} + (\sin t \cos t) e^{\tan t} \, \mathbf{k} \\ &= (\sin t) e^{\sin t} \, \mathbf{i} + (\tan t \sin t) e^{\cos t} \, \mathbf{j} + (\sin t \cos t) e^{\tan t} \, \mathbf{k}, \end{aligned}$$

$\mathbf{r}'(t) = \cos t \, \mathbf{i} - \sin t \, \mathbf{j} + \sec^2 t \, \mathbf{k}$. Then

$$\int_C \mathbf{F} \cdot d\mathbf{r} = \int_0^{\pi/4} \mathbf{F}(\mathbf{r}(t)) \cdot \mathbf{r}'(t) \, dt = \int_0^{\pi/4} \left[(\sin t \cos t) e^{\sin t} - (\tan t \sin^2 t) e^{\cos t} + (\tan t) e^{\tan t}\right] dt \approx 0.8527$$

25. $x = t^2, \ \ y = t^3, \ \ z = \sqrt{t}$ so by Formula 9,

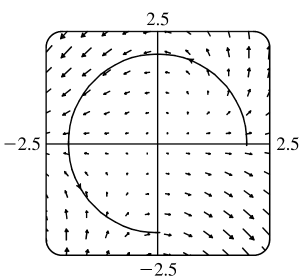
$$\begin{aligned} \int_C xy \arctan z \, ds &= \int_1^2 (t^2)(t^3) \arctan \sqrt{t} \cdot \sqrt{(2t)^2 + (3t^2)^2 + \left[1/(2\sqrt{t}\,)\right]^2} \, dt \\ &= \int_1^2 t^5 \sqrt{4t^2 + 9t^4 + 1/(4t)} \, \arctan \sqrt{t} \, dt \approx 94.8231 \end{aligned}$$

26. $x = 1 + 3t, \ \ y = 2 + t^2, \ \ z = t^4$ so by Formula 9,

$$\begin{aligned} \int_C z \ln(x + y) \, ds &= \int_{-1}^1 t^4 \ln(1 + 3t + 2 + t^2) \cdot \sqrt{(3)^2 + (2t)^2 + (4t^3)^2} \, dt \\ &= \int_{-1}^1 t^4 \sqrt{9 + 4t^2 + 16t^6} \, \ln(3 + 3t + t^2) \, dt \approx 1.7260 \end{aligned}$$

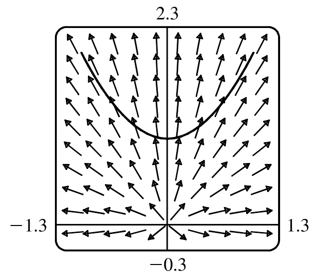
27. We graph $\mathbf{F}(x, y) = (x - y) \, \mathbf{i} + xy \, \mathbf{j}$ and the curve C. We see that most of the vectors starting on C point in roughly the same direction as C, so for these portions of C the tangential component $\mathbf{F} \cdot \mathbf{T}$ is positive. Although some vectors in the third quadrant which start on C point in roughly the opposite direction, and hence give negative tangential components, it seems reasonable that the effect of these portions of C is outweighed by the positive tangential components. Thus, we would expect $\int_C \mathbf{F} \cdot d\mathbf{r} = \int_C \mathbf{F} \cdot \mathbf{T} \, ds$ to be positive.

To verify, we evaluate $\int_C \mathbf{F} \cdot d\mathbf{r}$. The curve C can be represented by $\mathbf{r}(t) = 2 \cos t \, \mathbf{i} + 2 \sin t \, \mathbf{j}, \ \ 0 \leq t \leq \frac{3\pi}{2}$, so $\mathbf{F}(\mathbf{r}(t)) = (2 \cos t - 2 \sin t) \, \mathbf{i} + 4 \cos t \sin t \, \mathbf{j}$ and $\mathbf{r}'(t) = -2 \sin t \, \mathbf{i} + 2 \cos t \, \mathbf{j}$. Then



$$\begin{aligned} \int_C \mathbf{F} \cdot d\mathbf{r} &= \int_0^{3\pi/2} \mathbf{F}(\mathbf{r}(t)) \cdot \mathbf{r}'(t) \, dt \\ &= \int_0^{3\pi/2} [-2 \sin t (2 \cos t - 2 \sin t) + 2 \cos t (4 \cos t \sin t)] \, dt \\ &= 4 \int_0^{3\pi/2} (\sin^2 t - \sin t \cos t + 2 \sin t \cos^2 t) \, dt \\ &= 3\pi + \tfrac{2}{3} \qquad \text{[using a CAS]} \end{aligned}$$

28. We graph $\mathbf{F}(x,y) = \dfrac{x}{\sqrt{x^2+y^2}}\,\mathbf{i} + \dfrac{y}{\sqrt{x^2+y^2}}\,\mathbf{j}$ and the curve C. In the first quadrant, each vector starting on C points in roughly the same direction as C, so the tangential component $\mathbf{F}\cdot\mathbf{T}$ is positive. In the second quadrant, each vector starting on C points in roughly the direction opposite to C, so $\mathbf{F}\cdot\mathbf{T}$ is negative. Here, it appears that the tangential components in the first and second quadrants counteract each other, so it seems reasonable to guess that $\int_C \mathbf{F}\cdot d\mathbf{r} = \int_C \mathbf{F}\cdot\mathbf{T}\,ds$ is zero. To verify, we evaluate $\int_C \mathbf{F}\cdot d\mathbf{r}$. The curve C can be represented by



$\mathbf{r}(t) = t\,\mathbf{i} + (1+t^2)\,\mathbf{j}$, $-1 \le t \le 1$, so $\mathbf{F}(\mathbf{r}(t)) = \dfrac{t}{\sqrt{t^2+(1+t^2)^2}}\,\mathbf{i} + \dfrac{1+t^2}{\sqrt{t^2+(1+t^2)^2}}\,\mathbf{j}$ and $\mathbf{r}'(t) = \mathbf{i} + 2t\,\mathbf{j}$. Then

$$\int_C \mathbf{F}\cdot d\mathbf{r} = \int_{-1}^{1} \mathbf{F}(\mathbf{r}(t))\cdot\mathbf{r}'(t)\,dt = \int_{-1}^{1}\left(\frac{t}{\sqrt{t^2+(1+t^2)^2}} + \frac{2t(1+t^2)}{\sqrt{t^2+(1+t^2)^2}}\right)dt$$

$$= \int_{-1}^{1} \frac{t(3+2t^2)}{\sqrt{t^4+3t^2+1}}\,dt = 0 \qquad \text{[since the integrand is an odd function]}$$

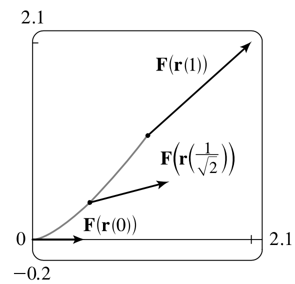
29. (a) $\int_C \mathbf{F}\cdot d\mathbf{r} = \int_0^1 \left\langle e^{t^2-1}, t^5\right\rangle \cdot \langle 2t, 3t^2\rangle\,dt = \int_0^1 \left(2te^{t^2-1} + 3t^7\right)dt = \left[e^{t^2-1} + \frac{3}{8}t^8\right]_0^1 = \frac{11}{8} - 1/e$

(b) $\mathbf{r}(0) = \mathbf{0}$, $\mathbf{F}(\mathbf{r}(0)) = \langle e^{-1}, 0\rangle$;

$\mathbf{r}\left(\frac{1}{\sqrt{2}}\right) = \left\langle \frac{1}{2}, \frac{1}{2\sqrt{2}}\right\rangle$, $\mathbf{F}\left(\mathbf{r}\left(\frac{1}{\sqrt{2}}\right)\right) = \left\langle e^{-1/2}, \frac{1}{4\sqrt{2}}\right\rangle$;

$\mathbf{r}(1) = \langle 1, 1\rangle$, $\mathbf{F}(\mathbf{r}(1)) = \langle 1, 1\rangle$.

In order to generate the graph with Maple, we use the `line` command in the `plottools` package to define each of the vectors. For example,

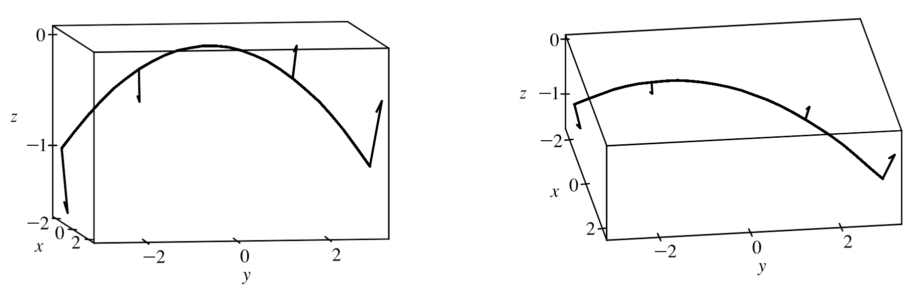


```
v1:=line([0,0],[exp(-1),0]):
```

generates the vector from the vector field at the point $(0,0)$ (but without an arrowhead) and gives it the name `v1`. To show everything on the same screen, we use the `display` command. In Mathematica, we use `ListPlot` (with the `PlotJoined -> True` option) to generate the vectors, and then `Show` to show everything on the same screen.

30. (a) $\int_C \mathbf{F}\cdot d\mathbf{r} = \int_{-1}^{1} \langle 2t, t^2, 3t\rangle \cdot \langle 2, 3, -2t\rangle\,dt = \int_{-1}^{1}(4t + 3t^2 - 6t^2)\,dt = \left[2t^2 - t^3\right]_{-1}^{1} = -2$

(b) Now $\mathbf{F}(\mathbf{r}(t)) = \langle 2t, t^2, 3t\rangle$, so $\mathbf{F}(\mathbf{r}(-1)) = \langle -2, 1, -3\rangle$, $\mathbf{F}\left(\mathbf{r}\left(-\frac{1}{2}\right)\right) = \left\langle -1, \frac{1}{4}, -\frac{3}{2}\right\rangle$, $\mathbf{F}\left(\mathbf{r}\left(\frac{1}{2}\right)\right) = \left\langle 1, \frac{1}{4}, \frac{3}{2}\right\rangle$, and $\mathbf{F}(\mathbf{r}(1)) = \langle 2, 1, 3\rangle$.



31. $x = e^{-t}\cos 4t,\;\; y = e^{-t}\sin 4t,\;\; z = e^{-t},\;\; 0 \le t \le 2\pi$.

Then $\dfrac{dx}{dt} = e^{-t}(-\sin 4t)(4) - e^{-t}\cos 4t = -e^{-t}(4\sin 4t + \cos 4t)$,

$\dfrac{dy}{dt} = e^{-t}(\cos 4t)(4) - e^{-t}\sin 4t = -e^{-t}(-4\cos 4t + \sin 4t)$, and $\dfrac{dz}{dt} = -e^{-t}$, so

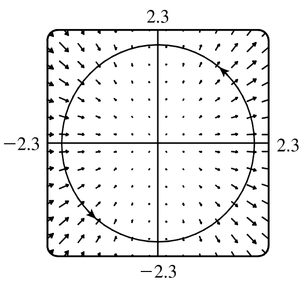
$$\sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2 + \left(\frac{dz}{dt}\right)^2} = \sqrt{(-e^{-t})^2[(4\sin 4t + \cos 4t)^2 + (-4\cos 4t + \sin 4t)^2 + 1]}$$
$$= e^{-t}\sqrt{16(\sin^2 4t + \cos^2 4t) + \sin^2 4t + \cos^2 4t + 1} = 3\sqrt{2}\,e^{-t}$$

Therefore $$\int_C x^3y^2z\,ds = \int_0^{2\pi}(e^{-t}\cos 4t)^3(e^{-t}\sin 4t)^2(e^{-t})\,(3\sqrt{2}\,e^{-t})\,dt$$
$$= \int_0^{2\pi} 3\sqrt{2}\,e^{-7t}\cos^3 4t\sin^2 4t\,dt = \tfrac{172{,}704}{5{,}632{,}705}\sqrt{2}\,(1 - e^{-14\pi})$$

32. (a) We parametrize the circle C as $\mathbf{r}(t) = 2\cos t\,\mathbf{i} + 2\sin t\,\mathbf{j},\;\; 0 \le t \le 2\pi$. So $\mathbf{F}(\mathbf{r}(t)) = \langle 4\cos^2 t, 4\cos t\sin t\rangle$,

$\mathbf{r}'(t) = \langle -2\sin t, 2\cos t\rangle$, and $W = \int_C \mathbf{F}\cdot d\mathbf{r} = \int_0^{2\pi}(-8\cos^2 t\sin t + 8\cos^2 t\sin t)\,dt = 0$.

(b)



From the graph, we see that all of the vectors in the field are perpendicular to the path. This indicates that the field does no work on the particle, since the field never pulls the particle in the direction in which it is going. In other words, at any point along C, $\mathbf{F}\cdot\mathbf{T} = 0$, and so certainly $\int_C \mathbf{F}\cdot d\mathbf{r} = 0$.

33. We use the parametrization $x = 2\cos t$, $y = 2\sin t$, $-\frac{\pi}{2} \le t \le \frac{\pi}{2}$. Then

$ds = \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2}dt = \sqrt{(-2\sin t)^2 + (2\cos t)^2}\,dt = 2\,dt$, so $m = \int_C k\,ds = 2k\int_{-\pi/2}^{\pi/2} dt = 2k(\pi)$,

$\overline{x} = \frac{1}{2\pi k}\int_C xk\,ds = \frac{1}{2\pi}\int_{-\pi/2}^{\pi/2}(2\cos t)2\,dt = \frac{1}{2\pi}\left[4\sin t\right]_{-\pi/2}^{\pi/2} = \frac{4}{\pi}$, $\overline{y} = \frac{1}{2\pi k}\int_C yk\,ds = \frac{1}{2\pi}\int_{-\pi/2}^{\pi/2}(2\sin t)2\,dt = 0$.

Hence $(\overline{x}, \overline{y}) = \left(\frac{4}{\pi}, 0\right)$.

34. We use the parametrization $x = a\cos t,\;\; y = a\sin t,\;\; 0 \le t \le \frac{\pi}{2}$. Then

$ds = \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2}dt = \sqrt{(-a\sin t)^2 + (a\cos t)^2}\,dt = a\,dt$, so

$m = \int_C \rho(x,y)\,ds = \int_C kxy\,ds = \int_0^{\pi/2} k(a\cos t)(a\sin t)\,a\,dt = ka^3\int_0^{\pi/2}\cos t\sin t\,dt = ka^3\left[\frac{1}{2}\sin^2 t\right]_0^{\pi/2} = \frac{1}{2}ka^3$,

$$\overline{x} = \frac{1}{ka^3/2}\int_C x(kxy)\,ds = \frac{2}{ka^3}\int_0^{\pi/2} k(a\cos t)^2(a\sin t)a\,dt = \frac{2}{ka^3}\cdot ka^4\int_0^{\pi/2}\cos^2 t\,\sin t\,dt$$
$$= 2a\left[-\tfrac{1}{3}\cos^3 t\right]_0^{\pi/2} = 2a\left(0 + \tfrac{1}{3}\right) = \tfrac{2}{3}a, \text{ and}$$

$$\overline{y} = \frac{1}{ka^3/2}\int_C y(kxy)\,ds = \frac{2}{ka^3}\int_0^{\pi/2} k(a\cos t)(a\sin t)^2a\,dt = \frac{2}{ka^3}\cdot ka^4\int_0^{\pi/2}\sin^2 t\,\cos t\,dt$$
$$= 2a\left[\tfrac{1}{3}\sin^3 t\right]_0^{\pi/2} = 2a\left(\tfrac{1}{3} - 0\right) = \tfrac{2}{3}a.$$

Therefore the mass is $\frac{1}{2}ka^3$ and the center of mass is $(\overline{x}, \overline{y}) = \left(\frac{2}{3}a, \frac{2}{3}a\right)$.

35. (a) $\overline{x} = \dfrac{1}{m}\displaystyle\int_C x\rho(x,y,z)\,ds$, $\overline{y} = \dfrac{1}{m}\displaystyle\int_C y\rho(x,y,z)\,ds$, $\overline{z} = \dfrac{1}{m}\displaystyle\int_C z\rho(x,y,z)\,ds$ where $m = \int_C \rho(x,y,z)\,ds$.

(b) $m = \int_C k\,ds = k\int_0^{2\pi}\sqrt{4\sin^2 t + 4\cos^2 t + 9}\,dt = k\sqrt{13}\int_0^{2\pi} dt = 2\pi k\sqrt{13}$,

$$\overline{x} = \frac{1}{2\pi k\sqrt{13}}\int_0^{2\pi} 2k\sqrt{13}\,\sin t\,dt = 0,\ \overline{y} = \frac{1}{2\pi k\sqrt{13}}\int_0^{2\pi} 2k\sqrt{13}\,\cos t\,dt = 0,$$

$$\overline{z} = \frac{1}{2\pi k\sqrt{13}}\int_0^{2\pi}\left(k\sqrt{13}\right)(3t)\,dt = \frac{3}{2\pi}\left(2\pi^2\right) = 3\pi.$$ Hence $(\overline{x},\overline{y},\overline{z}) = (0,0,3\pi)$.

36. $m = \int_C (x^2+y^2+z^2)\,ds = \int_0^{2\pi}(t^2+1)\sqrt{(1)^2+(-\sin t)^2+(\cos t)^2}\,dt = \int_0^{2\pi}(t^2+1)\sqrt{2}\,dt = \sqrt{2}\left(\frac{8}{3}\pi^3+2\pi\right)$,

$$\overline{x} = \frac{1}{\sqrt{2}\left(\frac{8}{3}\pi^3+2\pi\right)}\int_0^{2\pi}\sqrt{2}\,(t^3+t)\,dt = \frac{4\pi^4+2\pi^2}{\frac{8}{3}\pi^3+2\pi} = \frac{3\pi\left(2\pi^2+1\right)}{4\pi^2+3},$$

$$\overline{y} = \frac{3}{2\sqrt{2}\,\pi(4\pi^2+3)}\int_0^{2\pi}\left(\sqrt{2}\cos t\right)(t^2+1)\,dt = 0, \text{ and}$$

$$\overline{z} = \frac{3}{2\sqrt{2}\,\pi(4\pi^2+3)}\int_0^{2\pi}\left(\sqrt{2}\sin t\right)(t^2+1)\,dt = 0.$$ Hence $(\overline{x},\overline{y},\overline{z}) = \left(\dfrac{3\pi(2\pi^2+1)}{4\pi^2+3}, 0, 0\right)$.

37. From Example 3, $\rho(x,y) = k(1-y)$, $x = \cos t$, $y = \sin t$, and $ds = dt$, $0 \le t \le \pi \Rightarrow$

$$\begin{aligned} I_x &= \textstyle\int_C y^2\rho(x,y)\,ds = \int_0^\pi \sin^2 t\,[k(1-\sin t)]\,dt = k\int_0^\pi(\sin^2 t - \sin^3 t)\,dt \\ &= \tfrac{1}{2}k\textstyle\int_0^\pi(1-\cos 2t)\,dt - k\int_0^\pi(1-\cos^2 t)\sin t\,dt \qquad \left[\begin{array}{c}\text{Let } u=\cos t,\ du=-\sin t\,dt\\ \text{in the second integral}\end{array}\right] \\ &= k\left[\tfrac{\pi}{2} + \textstyle\int_1^{-1}(1-u^2)\,du\right] = k\left(\tfrac{\pi}{2}-\tfrac{4}{3}\right) \end{aligned}$$

$$\begin{aligned} I_y &= \textstyle\int_C x^2\rho(x,y)\,ds = k\int_0^\pi \cos^2 t\,(1-\sin t)\,dt = \frac{k}{2}\int_0^\pi(1+\cos 2t)\,dt - k\int_0^\pi\cos^2 t\sin t\,dt \\ &= k\left(\tfrac{\pi}{2}-\tfrac{2}{3}\right) \end{aligned}$$, using the same substitution as above.

38. The wire is given as $x = 2\sin t$, $y = 2\cos t$, $z = 3t$, $0 \le t \le 2\pi$ with $\rho(x,y,z) = k$. Then

$ds = \sqrt{(2\cos t)^2 + (-2\sin t)^2 + 3^2}\,dt = \sqrt{4(\cos^2 t + \sin^2 t) + 9}\,dt = \sqrt{13}\,dt$ and

$$\begin{aligned} I_x &= \textstyle\int_C (y^2+z^2)\rho(x,y,z)\,ds = \int_0^{2\pi}(4\cos^2 t + 9t^2)(k)\sqrt{13}\,dt = \sqrt{13}\,k\left[4\left(\frac{1}{2}t+\frac{1}{4}\sin 2t\right)+3t^3\right]_0^{2\pi} \\ &= \sqrt{13}\,k(4\pi+24\pi^3) = 4\sqrt{13}\,\pi k(1+6\pi^2) \end{aligned}$$

$$\begin{aligned} I_y &= \textstyle\int_C (x^2+z^2)\rho(x,y,z)\,ds = \int_0^{2\pi}\left(4\sin^2 t + 9t^2\right)(k)\sqrt{13}\,dt = \sqrt{13}\,k\left[4\left(\frac{1}{2}t-\frac{1}{4}\sin 2t\right)+3t^3\right]_0^{2\pi} \\ &= \sqrt{13}\,k(4\pi+24\pi^3) = 4\sqrt{13}\,\pi k(1+6\pi^2) \end{aligned}$$

$$I_z = \textstyle\int_C (x^2+y^2)\rho(x,y,z)\,ds = \int_0^{2\pi}(4\sin^2 t + 4\cos^2 t)(k)\sqrt{13}\,dt = 4\sqrt{13}\,k\int_0^{2\pi}dt = 8\pi\sqrt{13}\,k$$

39.
$$\begin{aligned} W &= \textstyle\int_C \mathbf{F}\cdot d\mathbf{r} = \int_0^{2\pi}\langle t-\sin t, 3-\cos t\rangle\cdot\langle 1-\cos t, \sin t\rangle\,dt \\ &= \textstyle\int_0^{2\pi}(t - t\cos t - \sin t + \sin t\cos t + 3\sin t - \sin t\cos t)\,dt \\ &= \textstyle\int_0^{2\pi}(t - t\cos t + 2\sin t)\,dt = \left[\frac{1}{2}t^2 - (t\sin t + \cos t) - 2\cos t\right]_0^{2\pi} \qquad \left[\begin{array}{c}\text{integrate by parts}\\ \text{in the second term}\end{array}\right] \\ &= 2\pi^2 \end{aligned}$$

40. Choosing y as the parameter, the curve C is parametrized by $x = y^2 + 1$, $y = y$, $0 \le y \le 1$. Then

$$W = \int_C \mathbf{F} \cdot d\mathbf{r} = \int_0^1 \left\langle \left(y^2+1\right)^2, ye^{y^2+1} \right\rangle \cdot \langle 2y, 1 \rangle \, dy = \int_0^1 \left[2y\left(y^2+1\right)^2 + ye^{y^2+1}\right] dy$$
$$= \left[\tfrac{1}{3}\left(y^2+1\right)^3 + \tfrac{1}{2}e^{y^2+1}\right]_0^1 = \tfrac{8}{3} + \tfrac{1}{2}e^2 - \tfrac{1}{3} - \tfrac{1}{2}e = \tfrac{1}{2}e^2 - \tfrac{1}{2}e + \tfrac{7}{3}$$

41. $\mathbf{r}(t) = \langle 2t, t, 1-t \rangle$, $0 \le t \le 1$.

$$W = \int_C \mathbf{F} \cdot d\mathbf{r} = \int_0^1 \left\langle 2t - t^2, t - (1-t)^2, 1 - t - (2t)^2 \right\rangle \cdot \langle 2, 1, -1 \rangle \, dt$$
$$= \int_0^1 (4t - 2t^2 + t - 1 + 2t - t^2 - 1 + t + 4t^2) \, dt = \int_0^1 (t^2 + 8t - 2) \, dt = \left[\tfrac{1}{3}t^3 + 4t^2 - 2t\right]_0^1 = \tfrac{7}{3}$$

42. $\mathbf{r}(t) = 2\,\mathbf{i} + t\,\mathbf{j} + 5t\,\mathbf{k}$, $0 \le t \le 1$. Therefore

$$W = \int_C \mathbf{F} \cdot d\mathbf{r} = \int_0^1 \frac{K\langle 2, t, 5t \rangle}{(4 + 26t^2)^{3/2}} \cdot \langle 0, 1, 5 \rangle \, dt = K \int_0^1 \frac{26t}{(4 + 26t^2)^{3/2}} \, dt = K\left[-(4 + 26t^2)^{-1/2}\right]_0^1 = K\left(\tfrac{1}{2} - \tfrac{1}{\sqrt{30}}\right).$$

43. (a) $\mathbf{r}(t) = at^2\,\mathbf{i} + bt^3\,\mathbf{j} \Rightarrow \mathbf{v}(t) = \mathbf{r}'(t) = 2at\,\mathbf{i} + 3bt^2\,\mathbf{j} \Rightarrow \mathbf{a}(t) = \mathbf{v}'(t) = 2a\,\mathbf{i} + 6bt\,\mathbf{j}$, and force is mass times acceleration: $\mathbf{F}(t) = m\,\mathbf{a}(t) = 2ma\,\mathbf{i} + 6mbt\,\mathbf{j}$.

(b) $W = \int_C \mathbf{F} \cdot d\mathbf{r} = \int_0^1 (2ma\,\mathbf{i} + 6mbt\,\mathbf{j}) \cdot (2at\,\mathbf{i} + 3bt^2\,\mathbf{j}) \, dt = \int_0^1 (4ma^2t + 18mb^2t^3) \, dt$

$= \left[2ma^2t^2 + \tfrac{9}{2}mb^2t^4\right]_0^1 = 2ma^2 + \tfrac{9}{2}mb^2$

44. $\mathbf{r}(t) = a\sin t\,\mathbf{i} + b\cos t\,\mathbf{j} + ct\,\mathbf{k} \Rightarrow \mathbf{v}(t) = \mathbf{r}'(t) = a\cos t\,\mathbf{i} - b\sin t\,\mathbf{j} + c\,\mathbf{k} \Rightarrow \mathbf{a}(t) = \mathbf{v}'(t) = -a\sin t\,\mathbf{i} - b\cos t\,\mathbf{j}$ and $\mathbf{F}(t) = m\,\mathbf{a}(t) = -ma\sin t\,\mathbf{i} - mb\cos t\,\mathbf{j}$. Thus

$$W = \int_C \mathbf{F} \cdot d\mathbf{r} = \int_0^{\pi/2} (-ma\sin t\,\mathbf{i} - mb\cos t\,\mathbf{j}) \cdot (a\cos t\,\mathbf{i} - b\sin t\,\mathbf{j} + c\,\mathbf{k}) \, dt$$
$$= \int_0^{\pi/2} (-ma^2\sin t\cos t + mb^2\sin t\cos t) \, dt = m(b^2 - a^2)\left[\tfrac{1}{2}\sin^2 t\right]_0^{\pi/2} = \tfrac{1}{2}m(b^2 - a^2)$$

45. The combined weight of the man and the paint is 185 lb, so the force exerted (equal and opposite to that exerted by gravity) is $\mathbf{F} = 185\,\mathbf{k}$. To parametrize the staircase, let $x = 20\cos t$, $y = 20\sin t$, $z = \frac{90}{6\pi}t = \frac{15}{\pi}t$, $0 \le t \le 6\pi$. Then the work done is

$$W = \int_C \mathbf{F} \cdot d\mathbf{r} = \int_0^{6\pi} \langle 0, 0, 185 \rangle \cdot \left\langle -20\sin t, 20\cos t, \tfrac{15}{\pi} \right\rangle dt = (185)\tfrac{15}{\pi}\int_0^{6\pi} dt = (185)\left(\tfrac{15}{\pi}\right)(6\pi) \approx 1.67 \times 10^4 \text{ ft-lb}$$

46. This time m is a function of t: $m = 185 - \frac{9}{6\pi}t = 185 - \frac{3}{2\pi}t$. So let $\mathbf{F} = \left(185 - \frac{3}{2\pi}t\right)\mathbf{k}$. To parametrize the staircase, let $x = 20\cos t$, $y = 20\sin t$, $z = \frac{90}{6\pi}t = \frac{15}{\pi}t$, $0 \le t \le 6\pi$. Therefore

$$W = \int_C \mathbf{F} \cdot d\mathbf{r} = \int_0^{6\pi} \left\langle 0, 0, 185 - \tfrac{3}{2\pi}t \right\rangle \cdot \left\langle -20\sin t, 20\cos t, \tfrac{15}{\pi} \right\rangle dt = \tfrac{15}{\pi}\int_0^{6\pi} \left(185 - \tfrac{3}{2\pi}t\right) dt$$
$$= \tfrac{15}{\pi}\left[185t - \tfrac{3}{4\pi}t^2\right]_0^{6\pi} = 90\left(185 - \tfrac{9}{2}\right) \approx 1.62 \times 10^4 \text{ ft-lb}$$

47. (a) $\mathbf{r}(t) = \langle \cos t, \sin t \rangle$, $0 \le t \le 2\pi$, and let $\mathbf{F} = \langle a, b \rangle$. Then

$$W = \int_C \mathbf{F} \cdot d\mathbf{r} = \int_0^{2\pi} \langle a, b \rangle \cdot \langle -\sin t, \cos t \rangle \, dt = \int_0^{2\pi} (-a\sin t + b\cos t) \, dt = \left[a\cos t + b\sin t\right]_0^{2\pi}$$
$$= a + 0 - a + 0 = 0$$

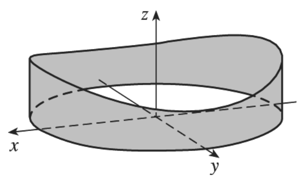
(b) Yes. $\mathbf{F}(x, y) = k\,\mathbf{x} = \langle kx, ky \rangle$ and

$$W = \int_C \mathbf{F} \cdot d\mathbf{r} = \int_0^{2\pi} \langle k\cos t, k\sin t \rangle \cdot \langle -\sin t, \cos t \rangle \, dt = \int_0^{2\pi} (-k\sin t\,\cos t + k\sin t\,\cos t) \, dt = \int_0^{2\pi} 0 \, dt = 0.$$

48. Consider the base of the fence in the xy-plane, centered at the origin, with the height given by $z = h(x, y)$. To graph the fence, observe that the fence is highest when $y = 0$ (where the height is 5 m) and lowest when $x = 0$ (a height of 3 m). When $y = \pm x$, the height is 4 m.

Also, the fence can be graphed using parametric equations (see Section 16.6): $x = 10\cos u$, $y = 10\sin u$,

$$\begin{aligned} z &= v\left[4 + 0.01((10\cos u)^2 - (10\sin u)^2)\right] = v(4 + \cos^2 u - \sin^2 u) \\ &= v(4 + \cos 2u),\ 0 \le u \le 2\pi,\ 0 \le v \le 1. \end{aligned}$$



The area of the fence is $\int_C h(x,y)\,ds$ where C, the base of the fence, is given by $x = 10\cos t$, $y = 10\sin t$, $0 \le t \le 2\pi$. Then

$$\begin{aligned} \int_C h(x,y)\,ds &= \int_0^{2\pi} \left[4 + 0.01((10\cos t)^2 - (10\sin t)^2)\right] \sqrt{(-10\sin t)^2 + (10\cos t)^2}\,dt \\ &= \int_0^{2\pi} (4 + \cos 2t)\sqrt{100}\,dt = 10\left[4t + \tfrac{1}{2}\sin 2t\right]_0^{2\pi} = 10(8\pi) = 80\pi \text{ m}^2 \end{aligned}$$

If we paint both sides of the fence, the total surface area to cover is 160π m^2, and since 1 L of paint covers 100 m^2, we require $\frac{160\pi}{100} = 1.6\pi \approx 5.03$ L of paint.

49. Let $\mathbf{r}(t) = \langle x(t), y(t), z(t)\rangle$ and $\mathbf{v} = \langle v_1, v_2, v_3\rangle$. Then

$$\begin{aligned} \int_C \mathbf{v}\cdot d\mathbf{r} &= \int_a^b \langle v_1, v_2, v_3\rangle \cdot \langle x'(t), y'(t), z'(t)\rangle\,dt = \int_a^b \left[v_1\,x'(t) + v_2\,y'(t) + v_3\,z'(t)\right]dt \\ &= \left[v_1\,x(t) + v_2\,y(t) + v_3\,z(t)\right]_a^b = \left[v_1\,x(b) + v_2\,y(b) + v_3\,z(b)\right] - \left[v_1\,x(a) + v_2\,y(a) + v_3\,z(a)\right] \\ &= v_1\left[x(b) - x(a)\right] + v_2\left[y(b) - y(a)\right] + v_3\left[z(b) - z(a)\right] \\ &= \langle v_1, v_2, v_3\rangle \cdot \langle x(b) - x(a), y(b) - y(a), z(b) - z(a)\rangle \\ &= \langle v_1, v_2, v_3\rangle \cdot \left[\langle x(b), y(b), z(b)\rangle - \langle x(a), y(a), z(a)\rangle\right] = \mathbf{v}\cdot\left[\mathbf{r}(b) - \mathbf{r}(a)\right] \end{aligned}$$

50. If $\mathbf{r}(t) = \langle x(t), y(t), z(t)\rangle$ then

$$\begin{aligned} \int_C \mathbf{r}\cdot d\mathbf{r} &= \int_a^b \langle x(t), y(t), z(t)\rangle \cdot \langle x'(t), y'(t), z'(t)\rangle\,dt = \int_a^b \left[x(t)\,x'(t) + y(t)\,y'(t) + z(t)\,z'(t)\right]dt \\ &= \left[\tfrac{1}{2}[x(t)]^2 + \tfrac{1}{2}[y(t)]^2 + \tfrac{1}{2}[z(t)]^2\right]_a^b \\ &= \tfrac{1}{2}\left\{\left([x(b)]^2 + [y(b)]^2 + [z(b)]^2\right) - \left([x(a)]^2 + [y(a)]^2 + [z(a)]^2\right)\right\} \\ &= \tfrac{1}{2}\left[|\mathbf{r}(b)|^2 - |\mathbf{r}(a)|^2\right] \end{aligned}$$

51. The work done in moving the object is $\int_C \mathbf{F}\cdot d\mathbf{r} = \int_C \mathbf{F}\cdot\mathbf{T}\,ds$. We can approximate this integral by dividing C into 7 segments of equal length $\Delta s = 2$ and approximating $\mathbf{F}\cdot\mathbf{T}$, that is, the tangential component of force, at a point (x_i^*, y_i^*) on each segment. Since C is composed of straight line segments, $\mathbf{F}\cdot\mathbf{T}$ is the scalar projection of each force vector onto C. If we choose (x_i^*, y_i^*) to be the point on the segment closest to the origin, then the work done is

$\int_C \mathbf{F}\cdot\mathbf{T}\,ds \approx \sum\limits_{i=1}^{7}\left[\mathbf{F}(x_i^*,y_i^*)\cdot\mathbf{T}(x_i^*,y_i^*)\right]\Delta s = [2+2+2+2+1+1+1](2) = 22$. Thus, we estimate the work done to be approximately 22 J.

52. Use the orientation pictured in the figure. Then since $\mathbf{B}$ is tangent to any circle that lies in the plane perpendicular to the wire, $\mathbf{B} = |\mathbf{B}|\,\mathbf{T}$ where $\mathbf{T}$ is the unit tangent to the circle C: $x = r\cos\theta,\ \ y = r\sin\theta$. Thus $\mathbf{B} = |\mathbf{B}|\,\langle -\sin\theta,\cos\theta\rangle$. Then $\int_C \mathbf{B}\cdot d\mathbf{r} = \int_0^{2\pi}|\mathbf{B}|\,\langle -\sin\theta,\cos\theta\rangle\cdot\langle -r\sin\theta, r\cos\theta\rangle\,d\theta = \int_0^{2\pi}|\mathbf{B}|\,r\,d\theta = 2\pi r\,|\mathbf{B}|$. (Note that $|\mathbf{B}|$ here is the magnitude of the field at a distance r from the wire's center.) But by Ampere's Law $\int_C \mathbf{B}\cdot d\mathbf{r} = \mu_0 I$. Hence $|\mathbf{B}| = \mu_0 I/(2\pi r)$.

16.3 The Fundamental Theorem for Line Integrals

1. C appears to be a smooth curve, and since ∇f is continuous, we know f is differentiable. Then Theorem 2 says that the value of $\int_C \nabla f\cdot d\mathbf{r}$ is simply the difference of the values of f at the terminal and initial points of C. From the graph, this is $50 - 10 = 40$.

2. C is represented by the vector function $\mathbf{r}(t) = (t^2+1)\,\mathbf{i} + (t^3+t)\,\mathbf{j}$, $0 \le t \le 1$, so $\mathbf{r}'(t) = 2t\,\mathbf{i} + (3t^2+1)\,\mathbf{j}$. Since $3t^2 + 1 \neq 0$, we have $\mathbf{r}'(t) \neq \mathbf{0}$, thus C is a smooth curve. ∇f is continuous, and hence f is differentiable, so by Theorem 2 we have $\int_C \nabla f\cdot d\mathbf{r} = f(\mathbf{r}(1)) - f(\mathbf{r}(0)) = f(2,2) - f(1,0) = 9 - 3 = 6$.

3. Let $P(x,y) = xy + y^2$ and $Q(x,y) = x^2 + 2xy$. Then $\partial P/\partial y = x + 2y$ and $\partial Q/\partial x = 2x + 2y$. Since $\partial P/\partial y \neq \partial Q/\partial x$, $\mathbf{F}(x,y) = P\,\mathbf{i} + Q\,\mathbf{j}$ is not conservative by Theorem 5.

4. $\partial(y^2 - 2x)/\partial y = 2y = \partial(2xy)/\partial x$ and the domain of $\mathbf{F}$ is $\mathbb{R}^2$ which is open and simply-connected, so $\mathbf{F}$ is conservative by Theorem 6. Thus, there exists a function f such that $\nabla f = \mathbf{F}$, that is, $f_x(x,y) = y^2 - 2x$ and $f_y(x,y) = 2xy$. But $f_x(x,y) = y^2 - 2x$ implies $f(x,y) = xy^2 - x^2 + g(y)$ and differentiating both sides of this equation with respect to y gives $f_y(x,y) = 2xy + g'(y)$. Thus $2xy = 2xy + g'(y)$ so $g'(y) = 0$ and $g(y) = K$ where K is a constant. Hence $f(x,y) = xy^2 - x^2 + K$ is a potential function for $\mathbf{F}$.

5. $\dfrac{\partial}{\partial y}\left(y^2 e^{xy}\right) = y^2\cdot xe^{xy} + 2ye^{xy} = (xy^2 + 2y)e^{xy}$,

$\dfrac{\partial}{\partial x}\left[(1+xy)e^{xy}\right] = (1+xy)\cdot ye^{xy} + ye^{xy} = ye^{xy} + xy^2e^{xy} + ye^{xy} = (xy^2+2y)e^{xy}$.

Since these partial derivatives are equal and the domain of $\mathbf{F}$ is $\mathbb{R}^2$ which is open and simply-connected, $\mathbf{F}$ is conservative by Theorem 6. Thus, there exists a function f such that $\nabla f = \mathbf{F}$, that is, $f_x(x,y) = y^2e^{xy}$ and $f_y(x,y) = (1+xy)e^{xy}$. But $f_x(x,y) = y^2e^{xy}$ implies $f(x,y) = ye^{xy} + g(y)$ and differentiating both sides of this equation with respect to y gives $f_y(x,y) = (1+xy)e^{xy} + g'(y)$. Thus $(1+xy)e^{xy} = (1+xy)e^{xy} + g'(y)$ so $g'(y) = 0$ and $g(y) = K$ where K is a constant. Hence $f(x,y) = ye^{xy} + K$ is a potential function for $\mathbf{F}$.

6. $\partial(ye^x)/\partial y = e^x = \partial(e^x + e^y)/\partial x$ and the domain of $\mathbf{F}$ is $\mathbb{R}^2$ which is open and simply-connected, so $\mathbf{F}$ is conservative. Hence there exists a function f such that $\nabla f = \mathbf{F}$. Here $f_x(x,y) = ye^x$ implies $f(x,y) = ye^x + g(y)$ and then $f_y(x,y) = e^x + g'(y)$. But $f_y(x,y) = e^x + e^y$ so $g'(y) = e^y \Rightarrow g(y) = e^y + K$ and $f(x,y) = ye^x + e^y + K$ is a potential function for $\mathbf{F}$.

7. $\partial(ye^x + \sin y)/\partial y = e^x + \cos y = \partial(e^x + x\cos y)/\partial x$ and the domain of $\mathbf{F}$ is $\mathbb{R}^2$. Hence $\mathbf{F}$ is conservative so there exists a function f such that $\nabla f = \mathbf{F}$. Then $f_x(x,y) = ye^x + \sin y$ implies $f(x,y) = ye^x + x\sin y + g(y)$ and $f_y(x,y) = e^x + x\cos y + g'(y)$. But $f_y(x,y) = e^x + x\cos y$ so $g(y) = K$ and $f(x,y) = ye^x + x\sin y + K$ is a potential function for $\mathbf{F}$.

8. $\partial(2xy + y^{-2})/\partial y = 2x - 2y^{-3} = \partial(x^2 - 2xy^{-3})/\partial x$ and the domain of $\mathbf{F}$ is $\{(x,y) \mid y > 0\}$ which is open and simply-connected. Hence $\mathbf{F}$ is conservative, so there exists a function f such that $\nabla f = \mathbf{F}$. Then $f_x(x,y) = 2xy + y^{-2}$ implies $f(x,y) = x^2y + xy^{-2} + g(y)$ and $f_y(x,y) = x^2 - 2xy^{-3} + g'(y)$. But $f_y(x,y) = x^2 - 2xy^{-3}$ so $g'(y) = 0 \Rightarrow g(y) = K$. Then $f(x,y) = x^2y + xy^{-2} + K$ is a potential function for $\mathbf{F}$.

9. $\partial(y^2\cos x + \cos y)/\partial y = 2y\cos x - \sin y = \partial(2y\sin x - x\sin y)/\partial x$ and the domain of $\mathbf{F}$ is $\mathbb{R}^2$ which is open and simply connected. Hence $\mathbf{F}$ is conservative so there exists a function f such that $\nabla f = \mathbf{F}$. Then $f_x(x,y) = y^2\cos x + \cos y$ implies $f(x,y) = y^2\sin x + x\cos y + g(y)$ and $f_y(x,y) = 2y\sin x - x\sin y + g'(y)$. But $f_y(x,y) = 2y\sin x - x\sin y$ so $g'(y) = 0 \Rightarrow g(y) = K$ and $f(x,y) = y^2\sin x + x\cos y + K$ is a potential function for $\mathbf{F}$.

10. $\partial(\ln y + y/x)/\partial y = 1/y + 1/x = \partial(\ln x + x/y)/\partial x$ and the domain of $\mathbf{F}$ is $\{(x,y) \mid x > 0,\ y > 0\}$ which is open and simply connected. Hence $\mathbf{F}$ is conservative so there exists a function f such that $\nabla f = \mathbf{F}$. Then $f_x(x,y) = \ln y + y/x$ implies $f(x,y) = x\ln y + y\ln x + g(y)$ and $f_y(x,y) = x/y + \ln x + g'(y)$. But $f_y(x,y) = \ln x + x/y$ so $g'(y) = 0 \Rightarrow g(y) = K$ and $f(x,y) = x\ln y + y\ln x + K$ is a potential function for $\mathbf{F}$.

11. (a) $\mathbf{F}$ has continuous first-order partial derivatives and $\dfrac{\partial}{\partial y}(2xy) = 2x = \dfrac{\partial}{\partial x}(x^2)$ on $\mathbb{R}^2$, which is open and simply-connected. Thus, $\mathbf{F}$ is conservative by Theorem 6. Then we know that the line integral of $\mathbf{F}$ is independent of path; in particular, the value of $\int_C \mathbf{F} \cdot d\mathbf{r}$ depends only on the endpoints of C. Since all three curves have the same initial and terminal points, $\int_C \mathbf{F} \cdot d\mathbf{r}$ will have the same value for each curve.

(b) We first find a potential function f, so that $\nabla f = \mathbf{F}$. We know $f_x(x,y) = 2xy$ and $f_y(x,y) = x^2$. Integrating $f_x(x,y)$ with respect to x, we have $f(x,y) = x^2y + g(y)$. Differentiating both sides with respect to y gives $f_y(x,y) = x^2 + g'(y)$, so we must have $x^2 + g'(y) = x^2 \Rightarrow g'(y) = 0 \Rightarrow g(y) = K$, a constant.
Thus $f(x,y) = x^2y + K$, and we can take $K = 0$. All three curves start at $(1,2)$ and end at $(3,2)$, so by Theorem 2, $\int_C \mathbf{F} \cdot d\mathbf{r} = f(3,2) - f(1,2) = 18 - 2 = 16$ for each curve.

12. (a) If $\mathbf{F} = \nabla f$ then $f_x(x,y) = 3 + 2xy^2$ and $f_y(x,y) = 2x^2y$.

$f_x(x,y) = 3 + 2xy^2$ implies $f(x,y) = 3x + x^2y^2 + g(y)$ and $f_y(x,y) = 2x^2y + g'(y)$. But $f_y(x,y) = 2x^2y$ so $g'(y) = 0 \Rightarrow g(y) = K$. We can take $K = 0$, so $f(x,y) = 3x + x^2y^2$.

(b) C is a smooth curve with initial point $(1,1)$ and terminal point $\left(4, \frac{1}{4}\right)$, so by Theorem 2

$\int_C \mathbf{F} \cdot d\mathbf{r} = \int_C \nabla f \cdot d\mathbf{r} = f\left(4, \frac{1}{4}\right) - f(1,1) = (12+1) - (3+1) = 9$.

13. (a) If $\mathbf{F} = \nabla f$ then $f_x(x,y) = x^2y^3$ and $f_y(x,y) = x^3y^2$.

$f_x(x,y) = x^2y^3$ implies $f(x,y) = \frac{1}{3}x^3y^3 + g(y)$ and $f_y(x,y) = x^3y^2 + g'(y)$. But $f_y(x,y) = x^3y^2$ so $g'(y) = 0 \Rightarrow g(y) = K$, a constant. We can take $K = 0$, so $f(x,y) = \frac{1}{3}x^3y^3$.

(b) C is a smooth curve with initial point $\mathbf{r}(0) = (0,0)$ and terminal point $\mathbf{r}(1) = (-1,3)$, so by Theorem 2

$\int_C \mathbf{F} \cdot d\mathbf{r} = \int_C \nabla f \cdot d\mathbf{r} = f(-1,3) - f(0,0) = -9 - 0 = -9$.

14. (a) $f_y(x,y) = x^2e^{xy}$ implies $f(x,y) = xe^{xy} + g(x) \Rightarrow f_x(x,y) = xye^{xy} + e^{xy} + g'(x) = (1+xy)e^{xy} + g'(x)$. But $f_x(x,y) = (1+xy)e^{xy}$ so $g'(x) = 0 \Rightarrow g(x) = K$. We can take $K = 0$, so $f(x,y) = xe^{xy}$.

(b) The initial point of C is $\mathbf{r}(0) = (1,0)$ and the terminal point is $\mathbf{r}(\pi/2) = (0,2)$, so

$\int_C \mathbf{F} \cdot d\mathbf{r} = f(0,2) - f(1,0) = 0 - e^0 = -1$.

15. (a) $f_x(x,y,z) = yz$ implies $f(x,y,z) = xyz + g(y,z)$ and so $f_y(x,y,z) = xz + g_y(y,z)$. But $f_y(x,y,z) = xz$ so $g_y(y,z) = 0 \Rightarrow g(y,z) = h(z)$. Thus $f(x,y,z) = xyz + h(z)$ and $f_z(x,y,z) = xy + h'(z)$. But $f_z(x,y,z) = xy + 2z$, so $h'(z) = 2z \Rightarrow h(z) = z^2 + K$. Hence $f(x,y,z) = xyz + z^2$ (taking $K = 0$).

(b) $\int_C \mathbf{F} \cdot d\mathbf{r} = f(4,6,3) - f(1,0,-2) = 81 - 4 = 77$.

16. (a) $f_x(x,y,z) = y^2z + 2xz^2$ implies $f(x,y,z) = xy^2z + x^2z^2 + g(y,z)$ and so $f_y(x,y,z) = 2xyz + g_y(y,z)$. But $f_y(x,y,z) = 2xyz$ so $g_y(y,z) = 0 \Rightarrow g(y,z) = h(z)$. Thus $f(x,y,z) = xy^2z + x^2z^2 + h(z)$ and $f_z(x,y,z) = xy^2 + 2x^2z + h'(z)$. But $f_z(x,y,z) = xy^2 + 2x^2z$, so $h'(z) = 0 \Rightarrow h(z) = K$. Hence $f(x,y,z) = xy^2z + x^2z^2$ (taking $K = 0$).

(b) $t = 0$ corresponds to the point $(0,1,0)$ and $t = 1$ corresponds to $(1,2,1)$, so

$\int_C \mathbf{F} \cdot d\mathbf{r} = f(1,2,1) - f(0,1,0) = 5 - 0 = 5$.

17. (a) $f_x(x,y,z) = yze^{xz}$ implies $f(x,y,z) = ye^{xz} + g(y,z)$ and so $f_y(x,y,z) = e^{xz} + g_y(y,z)$. But $f_y(x,y,z) = e^{xz}$ so $g_y(y,z) = 0 \Rightarrow g(y,z) = h(z)$. Thus $f(x,y,z) = ye^{xz} + h(z)$ and $f_z(x,y,z) = xye^{xz} + h'(z)$. But $f_z(x,y,z) = xye^{xz}$, so $h'(z) = 0 \Rightarrow h(z) = K$. Hence $f(x,y,z) = ye^{xz}$ (taking $K = 0$).

(b) $\mathbf{r}(0) = \langle 1,-1,0 \rangle$, $\mathbf{r}(2) = \langle 5,3,0 \rangle$ so $\int_C \mathbf{F} \cdot d\mathbf{r} = f(5,3,0) - f(1,-1,0) = 3e^0 + e^0 = 4$.

18. (a) $f_x(x,y,z) = \sin y$ implies $f(x,y,z) = x\sin y + g(y,z)$ and so $f_y(x,y,z) = x\cos y + g_y(y,z)$. But $f_y(x,y,z) = x\cos y + \cos z$ so $g_y(y,z) = \cos z \quad\Rightarrow\quad g(y,z) = y\cos z + h(z)$. Thus $f(x,y,z) = x\sin y + y\cos z + h(z)$ and $f_z(x,y,z) = -y\sin z + h'(z)$. But $f_z(x,y,z) = -y\sin z$, so $h'(z) = 0 \quad\Rightarrow$ $h(z) = K$. Hence $f(x,y,z) = x\sin y + y\cos z$ (taking $K = 0$).

(b) $\mathbf{r}(0) = \langle 0,0,0\rangle$, $\mathbf{r}(\pi/2) = \langle 1,\pi/2,\pi\rangle$ so $\int_C \mathbf{F}\cdot d\mathbf{r} = f(1,\pi/2,\pi) - f(0,0,0) = 1 - \frac{\pi}{2} - 0 = 1 - \frac{\pi}{2}$.

19. The functions $2xe^{-y}$ and $2y - x^2e^{-y}$ have continuous first-order derivatives on $\mathbb{R}^2$ and $\dfrac{\partial}{\partial y}\left(2xe^{-y}\right) = -2xe^{-y} = \dfrac{\partial}{\partial x}\left(2y - x^2e^{-y}\right)$, so $\mathbf{F}(x,y) = 2xe^{-y}\,\mathbf{i} + \left(2y - x^2e^{-y}\right)\mathbf{j}$ is a conservative vector field by Theorem 6 and hence the line integral is independent of path. Thus a potential function f exists, and $f_x(x,y) = 2xe^{-y}$ implies $f(x,y) = x^2e^{-y} + g(y)$ and $f_y(x,y) = -x^2e^{-y} + g'(y)$. But $f_y(x,y) = 2y - x^2e^{-y}$ so $g'(y) = 2y \quad\Rightarrow\quad g(y) = y^2 + K$. We can take $K = 0$, so $f(x,y) = x^2e^{-y} + y^2$. Then $\int_C 2xe^{-y}\,dx + (2y - x^2e^{-y})\,dy = f(2,1) - f(1,0) = 4e^{-1} + 1 - 1 = 4/e$.

20. The functions $\sin y$ and $x\cos y - \sin y$ have continuous first-order derivatives on $\mathbb{R}^2$ and $\dfrac{\partial}{\partial y}(\sin y) = \cos y = \dfrac{\partial}{\partial x}(x\cos y - \sin y)$, so $\mathbf{F}(x,y) = \sin y\,\mathbf{i} + (x\cos y - \sin y)\,\mathbf{j}$ is a conservative vector field by Theorem 6 and hence the line integral is independent of path. Thus a potential function f exists, and $f_x(x,y) = \sin y$ implies $f(x,y) = x\sin y + g(y)$ and $f_y(x,y) = x\cos y + g'(y)$. But $f_y(x,y) = x\cos y - \sin y$ so $g'(y) = -\sin y \quad\Rightarrow\quad g(y) = \cos y + K$. We can take $K = 0$, so $f(x,y) = x\sin y + \cos y$. Then $\int_C \sin y\,dx + (x\cos y - \sin y)\,dy = f(1,\pi) - f(2,0) = -1 - 1 = -2$.

21. If $\mathbf{F}$ is conservative, then $\int_C \mathbf{F}\cdot d\mathbf{r}$ is independent of path. This means that the work done along all piecewise-smooth curves that have the described initial and terminal points is the same. Your reply: It doesn't matter which curve is chosen.

22. The curves C_1 and C_2 connect the same two points but $\int_{C_1} \mathbf{F}\cdot d\mathbf{r} \neq \int_{C_2} \mathbf{F}\cdot d\mathbf{r}$. Thus $\mathbf{F}$ is not independent of path, and therefore is not conservative.

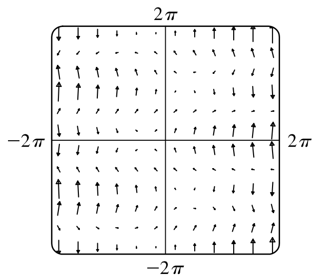
23. $\mathbf{F}(x,y) = x^3\,\mathbf{i} + y^3\,\mathbf{j}$, $W = \int_C \mathbf{F}\cdot d\mathbf{r}$. Since $\partial(x^3)/\partial y = 0 = \partial(y^3)/\partial x$, there exists a function f such that $\nabla f = \mathbf{F}$. In fact, $f_x(x,y) = x^3 \quad\Rightarrow\quad f(x,y) = \frac{1}{4}x^4 + g(y) \quad\Rightarrow\quad f_y(x,y) = 0 + g'(y)$. But $f_y(x,y) = y^3$ so $g'(y) = y^3 \quad\Rightarrow\quad g(y) = \frac{1}{4}y^4 + K$. We can take $K = 0 \quad\Rightarrow\quad f(x,y) = \frac{1}{4}x^4 + \frac{1}{4}y^4$. Thus $W = \int_C \mathbf{F}\cdot d\mathbf{r} = f(2,2) - f(1,0) = (4+4) - \left(\frac{1}{4} + 0\right) = \frac{31}{4}$.

24. $\mathbf{F}(x,y) = (2x+y)\,\mathbf{i} + x\,\mathbf{j}$, $W = \int_C \mathbf{F}\cdot d\mathbf{r}$. Since $\partial(2x+y)/\partial y = 1 = \partial(x)/\partial x$, there exists a function f such that $\nabla f = \mathbf{F}$. In fact, $f_x(x,y) = 2x + y \quad\Rightarrow\quad f(x,y) = x^2 + xy + g(y) \quad\Rightarrow\quad f_y(x,y) = x + g'(y)$. But $f_y(x,y) = x$ so $g'(y) = 0 \quad\Rightarrow\quad g(y) = K$. We can take $K = 0 \quad\Rightarrow\quad f(x,y) = x^2 + xy$. Thus $W = \int_C \mathbf{F}\cdot d\mathbf{r} = f(4,3) - f(1,1) = (16+12) - (1+1) = 26$.

25. We know that if the vector field (call it $\mathbf{F}$) is conservative, then around any closed path C, $\int_C \mathbf{F} \cdot d\mathbf{r} = 0$. But take C to be a circle centered at the origin, oriented counterclockwise. All of the field vectors that start on C are roughly in the direction of motion along C, so the integral around C will be positive. Therefore the field is not conservative.

26. If a vector field $\mathbf{F}$ is conservative, then around any closed path C, $\int_C \mathbf{F} \cdot d\mathbf{r} = 0$. For any closed path we draw in the field, it appears that some vectors on the curve point in approximately the same direction as the curve and a similar number point in roughly the opposite direction. (Some appear perpendicular to the curve as well.) Therefore it is plausible that $\int_C \mathbf{F} \cdot d\mathbf{r} = 0$ for every closed curve C which means $\mathbf{F}$ is conservative.

27.



From the graph, it appears that $\mathbf{F}$ is conservative, since around all closed paths, the number and size of the field vectors pointing in directions similar to that of the path seem to be roughly the same as the number and size of the vectors pointing in the opposite direction. To check, we calculate $\dfrac{\partial}{\partial y}(\sin y) = \cos y = \dfrac{\partial}{\partial x}(1 + x\cos y)$. Thus $\mathbf{F}$ is conservative, by Theorem 6.

28. $\nabla f(x, y) = \cos(x - 2y)\,\mathbf{i} - 2\cos(x - 2y)\,\mathbf{j}$

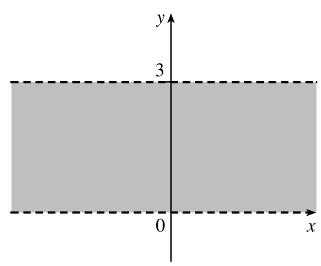
(a) We use Theorem 2: $\int_{C_1} \mathbf{F} \cdot d\mathbf{r} = \int_{C_1} \nabla f \cdot d\mathbf{r} = f(\mathbf{r}(b)) - f(\mathbf{r}(a))$ where C_1 starts at $t = a$ and ends at $t = b$. So because $f(0, 0) = \sin 0 = 0$ and $f(\pi, \pi) = \sin(\pi - 2\pi) = 0$, one possible curve C_1 is the straight line from $(0, 0)$ to (π, π); that is, $\mathbf{r}(t) = \pi t\,\mathbf{i} + \pi t\,\mathbf{j},\ 0 \le t \le 1$.

(b) From (a), $\int_{C_2} \mathbf{F} \cdot d\mathbf{r} = f(\mathbf{r}(b)) - f(\mathbf{r}(a))$. So because $f(0, 0) = \sin 0 = 0$ and $f\left(\frac{\pi}{2}, 0\right) = 1$, one possible curve C_2 is $\mathbf{r}(t) = \frac{\pi}{2} t\,\mathbf{i}$, $0 \le t \le 1$, the straight line from $(0, 0)$ to $\left(\frac{\pi}{2}, 0\right)$.

29. Since $\mathbf{F}$ is conservative, there exists a function f such that $\mathbf{F} = \nabla f$, that is, $P = f_x$, $Q = f_y$, and $R = f_z$. Since P, Q, and R have continuous first order partial derivatives, Clairaut's Theorem says that $\partial P/\partial y = f_{xy} = f_{yx} = \partial Q/\partial x$, $\partial P/\partial z = f_{xz} = f_{zx} = \partial R/\partial x$, and $\partial Q/\partial z = f_{yz} = f_{zy} = \partial R/\partial y$.

30. Here $\mathbf{F}(x, y, z) = y\,\mathbf{i} + x\,\mathbf{j} + xyz\,\mathbf{k}$. Then using the notation of Exercise 29, $\partial P/\partial z = 0$ while $\partial R/\partial x = yz$. Since these aren't equal, $\mathbf{F}$ is not conservative. Thus by Theorem 4, the line integral of $\mathbf{F}$ is not independent of path.

31. $D = \{(x, y) \mid 0 < y < 3\}$ consists of those points between, but not on, the horizontal lines $y = 0$ and $y = 3$.

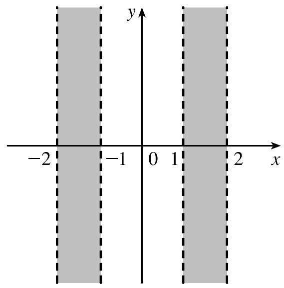


(a) Since D does not include any of its boundary points, it is open. More formally, at any point in D there is a disk centered at that point that lies entirely in D.

(b) Any two points chosen in D can always be joined by a path that lies entirely in D, so D is connected. (D consists of just one "piece.")

(c) D is connected and it has no holes, so it's simply-connected. (Every simple closed curve in D encloses only points that are in D.)

32. $D = \{(x, y) \mid 1 < |x| < 2\}$ consists of those points between, but not on, the vertical lines $x = 1$ and $x = 2$, together with the points between the vertical lines $x = -1$ and $x = -2$.

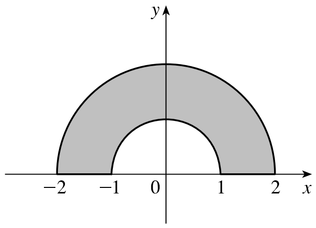


(a) The region does not include any of its boundary points, so it is open.

(b) D consists of two separate pieces, so it is not connected. [For instance, both the points $(-1.5, 0)$ and $(1.5, 0)$ lie in D but they cannot be joined by a path that lies entirely in D.]

(c) Because D is not connected, it's not simply-connected.

33. $D = \{(x, y) \mid 1 \leq x^2 + y^2 \leq 4,\ y \geq 0\}$ is the semiannular region in the upper half-plane between circles centered at the origin of radii 1 and 2 (including all boundary points).

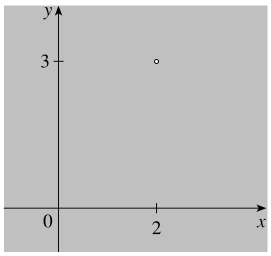


(a) D includes boundary points, so it is not open. [Note that at any boundary point, $(1, 0)$ for instance, any disk centered there cannot lie entirely in D.]

(b) The region consists of one piece, so it's connected.

(c) D is connected and has no holes, so it's simply-connected.

34. $D = \{(x, y) \mid (x, y) \neq (2, 3)\}$ consists of all points in the xy-plane except for $(2, 3)$.



(a) D has only one boundary point, namely $(2, 3)$, which is not included, so the region is open.

(b) D is connected, as it consists of only one piece.

(c) D is not simply-connected, as it has a hole at $(2, 3)$. Thus any simple closed curve that encloses $(2, 3)$ lies in D but includes a point that is not in D.

35. (a) $P = -\dfrac{y}{x^2 + y^2}$, $\dfrac{\partial P}{\partial y} = \dfrac{y^2 - x^2}{(x^2 + y^2)^2}$ and $Q = \dfrac{x}{x^2 + y^2}$, $\dfrac{\partial Q}{\partial x} = \dfrac{y^2 - x^2}{(x^2 + y^2)^2}$. Thus $\dfrac{\partial P}{\partial y} = \dfrac{\partial Q}{\partial x}$.

(b) C_1: $x = \cos t$, $y = \sin t$, $0 \leq t \leq \pi$, C_2: $x = \cos t$, $y = \sin t$, $t = 2\pi$ to $t = \pi$. Then

$$\int_{C_1} \mathbf{F} \cdot d\mathbf{r} = \int_0^{\pi} \frac{(-\sin t)(-\sin t) + (\cos t)(\cos t)}{\cos^2 t + \sin^2 t}\, dt = \int_0^{\pi} dt = \pi \text{ and } \int_{C_2} \mathbf{F} \cdot d\mathbf{r} = \int_{2\pi}^{\pi} dt = -\pi$$

Since these aren't equal, the line integral of $\mathbf{F}$ isn't independent of path. (Or notice that $\int_{C_3} \mathbf{F} \cdot d\mathbf{r} = \int_0^{2\pi} dt = 2\pi$ where C_3 is the circle $x^2 + y^2 = 1$, and apply the contrapositive of Theorem 3.) This doesn't contradict Theorem 6, since the domain of $\mathbf{F}$, which is $\mathbb{R}^2$ except the origin, isn't simply-connected.

36. (a) Here $\mathbf{F}(\mathbf{r}) = c\mathbf{r}/|\mathbf{r}|^3$ and $\mathbf{r} = x\,\mathbf{i} + y\,\mathbf{j} + z\,\mathbf{k}$. Then $f(\mathbf{r}) = -c/|\mathbf{r}|$ is a potential function for $\mathbf{F}$, that is, $\nabla f = \mathbf{F}$. (See the discussion of gradient fields in Section 16.1.) Hence $\mathbf{F}$ is conservative and its line integral is independent of path. Let $P_1 = (x_1, y_1, z_1)$ and $P_2 = (x_2, y_2, z_2)$.

$$W = \int_C \mathbf{F} \cdot d\mathbf{r} = f(P_2) - f(P_1) = -\frac{c}{(x_2^2 + y_2^2 + z_2^2)^{1/2}} + \frac{c}{(x_1^2 + y_1^2 + z_1^2)^{1/2}} = c\left(\frac{1}{d_1} - \frac{1}{d_2}\right).$$

(b) In this case, $c = -(mMG) \quad \Rightarrow$

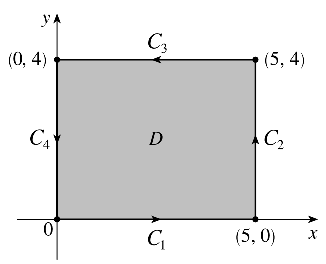
$$W = -mMG\left(\frac{1}{1.52 \times 10^{11}} - \frac{1}{1.47 \times 10^{11}}\right)$$
$$= -(5.97 \times 10^{24})(1.99 \times 10^{30})(6.67 \times 10^{-11})(-2.2377 \times 10^{-13}) \approx 1.77 \times 10^{32}\text{ J}$$

(c) In this case, $c = \epsilon qQ \quad \Rightarrow$

$$W = \epsilon qQ\left(\frac{1}{10^{-12}} - \frac{1}{5 \times 10^{-13}}\right) = \left(8.985 \times 10^9\right)(1)\left(-1.6 \times 10^{-19}\right)\left(-10^{12}\right) \approx 1400\text{ J}.$$

16.4 Green's Theorem

1. (a)



C_1: $x = t \;\Rightarrow\; dx = dt,\; y = 0 \;\Rightarrow\; dy = 0\,dt,\; 0 \le t \le 5.$

C_2: $x = 5 \;\Rightarrow\; dx = 0\,dt,\; y = t \;\Rightarrow\; dy = dt,\; 0 \le t \le 4.$

C_3: $x = 5 - t \;\Rightarrow\; dx = -dt,\; y = 4 \;\Rightarrow\; dy = 0\,dt,\; 0 \le t \le 5.$

C_4: $x = 0 \;\Rightarrow\; dx = 0\,dt,\; y = 4 - t \;\Rightarrow\; dy = -dt,\; 0 \le t \le 4$

Thus $$\oint_C y^2\,dx + x^2 y\,dy = \oint_{C_1 + C_2 + C_3 + C_4} y^2\,dx + x^2 y\,dy = \int_0^5 0\,dt + \int_0^4 25t\,dt + \int_0^5 (-16 + 0)\,dt + \int_0^4 0\,dt$$
$$= 0 + \left[\tfrac{25}{2}t^2\right]_0^4 + \left[-16t\right]_0^5 + 0 = 200 + (-80) = 120$$

(b) Note that C as given in part (a) is a positively oriented, piecewise-smooth, simple closed curve. Then by Green's Theorem,

$$\oint_C y^2\,dx + x^2 y\,dy = \iint_D \left[\tfrac{\partial}{\partial x}\left(x^2 y\right) - \tfrac{\partial}{\partial y}\left(y^2\right)\right] dA = \int_0^5 \int_0^4 (2xy - 2y)\,dy\,dx = \int_0^5 \left[xy^2 - y^2\right]_{y=0}^{y=4} dx$$
$$= \int_0^5 (16x - 16)\,dx = \left[8x^2 - 16x\right]_0^5 = 200 - 80 = 120$$

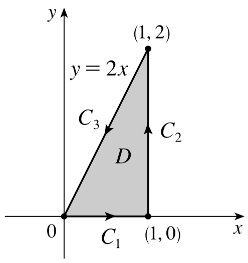
2. (a) Parametric equations for C are $x = 4\cos t,\;\; y = 4\sin t,\;\; 0 \le t \le 2\pi$. Then $dx = -4\sin t\,dt,\; dy = 4\cos t\,dt$ and

$$\oint_C y\,dx - x\,dy = \int_0^{2\pi} [(4\sin t)(-4\sin t) - (4\cos t)(4\cos t)]\,dt$$
$$= -16\int_0^{2\pi} (\sin^2 t + \cos^2 t)\,dt = -16\int_0^{2\pi} 1\,dt = -16(2\pi) = -32\pi$$

(b) Note that C as given in part (a) is a positively oriented, smooth, simple closed curve. Then by Green's Theorem,

$$\oint_C y\,dx - x\,dy = \iint_D \left[\tfrac{\partial}{\partial x}(-x) - \tfrac{\partial}{\partial y}(y)\right] dA = \iint_D (-1 - 1)\,dA = -2\iint_D dA$$
$$= -2(\text{area of } D) = -2 \cdot \pi(4)^2 = -32\pi$$

3. (a)



C_1: $x = t \;\Rightarrow\; dx = dt,\; y = 0 \;\Rightarrow\; dy = 0\,dt,\; 0 \le t \le 1.$

C_2: $x = 1 \;\Rightarrow\; dx = 0\,dt,\; y = t \;\Rightarrow\; dy = dt,\; 0 \le t \le 2.$

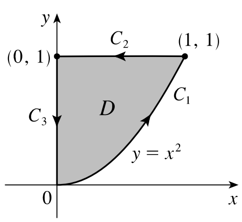
C_3: $x = 1 - t \;\Rightarrow\; dx = -dt,\; y = 2 - 2t \;\Rightarrow\; dy = -2\,dt,\; 0 \le t \le 1.$

Thus

$$\begin{aligned}\oint_C xy\,dx + x^2y^3\,dy &= \oint_{C_1+C_2+C_3} xy\,dx + x^2y^3\,dy \\ &= \int_0^1 0\,dt + \int_0^2 t^3\,dt + \int_0^1 \left[-(1-t)(2-2t) - 2(1-t)^2(2-2t)^3\right] dt \\ &= 0 + \left[\tfrac{1}{4}t^4\right]_0^2 + \int_0^1 \left[-2(1-t)^2 - 16(1-t)^5\right] dt \\ &= 4 + \left[\tfrac{2}{3}(1-t)^3 + \tfrac{8}{3}(1-t)^6\right]_0^1 = 4 + 0 - \tfrac{10}{3} = \tfrac{2}{3}\end{aligned}$$

(b) $$\begin{aligned}\oint_C xy\,dx + x^2y^3\,dy &= \iint_D \left[\frac{\partial}{\partial x}(x^2y^3) - \frac{\partial}{\partial y}(xy)\right] dA = \int_0^1 \int_0^{2x} (2xy^3 - x)\,dy\,dx \\ &= \int_0^1 \left[\tfrac{1}{2}xy^4 - xy\right]_{y=0}^{y=2x} dx = \int_0^1 (8x^5 - 2x^2)\,dx = \tfrac{4}{3} - \tfrac{2}{3} = \tfrac{2}{3}\end{aligned}$$

4. (a)



C_1: $x = t \;\Rightarrow\; dx = dt,\; y = t^2 \;\Rightarrow\; dy = 2t\,dt,\; 0 \le t \le 1$

C_2: $x = 1 - t \;\Rightarrow\; dx = -dt,\; y = 1 \;\Rightarrow\; dy = 0\,dt,\; 0 \le t \le 1$

C_3: $x = 0 \;\Rightarrow\; dx = 0\,dt,\; y = 1 - t \;\Rightarrow\; dy = -dt,\; 0 \le t \le 1$

Thus

$$\begin{aligned}\oint_C x^2y^2\,dx + xy\,dy &= \oint_{C_1+C_2+C_3} x^2y^2\,dx + xy\,dy \\ &= \int_0^1 \left[t^2(t^2)^2\,dt + t(t^2)(2t\,dt)\right] + \int_0^1 \left[(1-t)^2(1)^2(-dt) + (1-t)(1)(0\,dt)\right] \\ &\qquad + \int_0^1 \left[(0)^2(1-t)^2(0\,dt) + (0)(1-t)(-dt)\right] \\ &= \int_0^1 \left(t^6 + 2t^4\right) dt + \int_0^1 \left(-1 + 2t - t^2\right) dt + \int_0^1 0\,dt \\ &= \left[\tfrac{1}{7}t^7 + \tfrac{2}{5}t^5\right]_0^1 + \left[-t + t^2 - \tfrac{1}{3}t^3\right]_0^1 + 0 = \left(\tfrac{1}{7} + \tfrac{2}{5}\right) + \left(-1 + 1 - \tfrac{1}{3}\right) = \tfrac{22}{105}\end{aligned}$$

(b) $$\begin{aligned}\oint_C x^2y^2\,dx + xy\,dy &= \iint_D \left[\frac{\partial}{\partial x}(xy) - \frac{\partial}{\partial y}(x^2y^2)\right] dA = \int_0^1 \int_{x^2}^1 (y - 2x^2y)\,dy\,dx \\ &= \int_0^1 \left[\tfrac{1}{2}y^2 - x^2y^2\right]_{y=x^2}^{y=1} dx = \int_0^1 \left(\tfrac{1}{2} - x^2 - \tfrac{1}{2}x^4 + x^6\right) dx \\ &= \left[\tfrac{1}{2}x - \tfrac{1}{3}x^3 - \tfrac{1}{10}x^5 + \tfrac{1}{7}x^7\right]_0^1 = \tfrac{1}{2} - \tfrac{1}{3} - \tfrac{1}{10} + \tfrac{1}{7} = \tfrac{22}{105}\end{aligned}$$

5. The region D enclosed by C is $[0, 3] \times [0, 4]$, so

$$\begin{aligned}\int_C ye^x\,dx + 2e^x\,dy &= \iint_D \left[\frac{\partial}{\partial x}(2e^x) - \frac{\partial}{\partial y}(ye^x)\right] dA = \int_0^3 \int_0^4 (2e^x - e^x)\,dy\,dx \\ &= \int_0^3 e^x\,dx \int_0^4 dy = \left[e^x\right]_0^3 \left[y\right]_0^4 = (e^3 - e^0)(4 - 0) = 4(e^3 - 1)\end{aligned}$$

6. 
The region D enclosed by C is given by $\{(x,y) \mid 0 \le y \le 1,\ 0 \le x \le 2y\}$, so

$$\begin{aligned}\int_C (x^2+y^2)\,dx + (x^2-y^2)\,dy &= \iint_D \left[\frac{\partial}{\partial x}(x^2-y^2) - \frac{\partial}{\partial y}(x^2+y^2)\right] dA \\ &= \int_0^1 \int_0^{2y} (2x-2y)\,dx\,dy \\ &= \int_0^1 \left[x^2 - 2xy\right]_{x=0}^{x=2y} dy \\ &= \int_0^1 (4y^2 - 4y^2)\,dy = \int_0^1 0\,dy = 0\end{aligned}$$

7. $$\begin{aligned}\int_C \left(y + e^{\sqrt{x}}\right) dx + (2x + \cos y^2)\,dy &= \iint_D \left[\frac{\partial}{\partial x}(2x+\cos y^2) - \frac{\partial}{\partial y}\left(y + e^{\sqrt{x}}\right)\right] dA \\ &= \int_0^1 \int_{x^2}^{\sqrt{x}} (2-1)\,dy\,dx = \int_0^1 (\sqrt{x} - x^2)\,dx = \left[\tfrac{2}{3}x^{3/2} - \tfrac{1}{3}x^3\right]_0^1 = \tfrac{1}{3}\end{aligned}$$

8. $$\begin{aligned}\int_C y^4\,dx + 2xy^3\,dy &= \iint_D \left[\frac{\partial}{\partial x}(2xy^3) - \frac{\partial}{\partial y}(y^4)\right] dA = \iint_D (2y^3 - 4y^3)\,dA \\ &= -2\iint_D y^3\,dA = 0\end{aligned}$$

because $f(x,y) = y^3$ is an odd function with respect to y and D is symmetric about the x-axis.

9. $$\begin{aligned}\int_C y^3\,dx - x^3\,dy &= \iint_D \left[\frac{\partial}{\partial x}(-x^3) - \frac{\partial}{\partial y}(y^3)\right] dA = \iint_D (-3x^2 - 3y^2)\,dA = \int_0^{2\pi}\int_0^2 (-3r^2)\,r\,dr\,d\theta \\ &= -3\int_0^{2\pi} d\theta \int_0^2 r^3\,dr = -3\big[\theta\big]_0^{2\pi}\left[\tfrac{1}{4}r^4\right]_0^2 = -3(2\pi)(4) = -24\pi\end{aligned}$$

10. $$\begin{aligned}\int_C (1-y^3)\,dx + (x^3 + e^{y^2})\,dy &= \iint_D \left[\frac{\partial}{\partial x}(x^3 + e^{y^2}) - \frac{\partial}{\partial y}(1-y^3)\right] dA = \iint_D (3x^2+3y^2)\,dA \\ &= \int_0^{2\pi}\int_2^3 (3r^2)\,r\,dr\,d\theta = 3\int_0^{2\pi} d\theta \int_2^3 r^3\,dr \\ &= 3\big[\theta\big]_0^{2\pi}\left[\tfrac{1}{4}r^4\right]_2^3 = 3(2\pi)\cdot\tfrac{1}{4}(81-16) = \tfrac{195}{2}\pi\end{aligned}$$

11. $\mathbf{F}(x,y) = \langle y\cos x - xy\sin x, xy + x\cos x\rangle$ and the region D enclosed by C is given by $\{(x,y) \mid 0 \le x \le 2,\ 0 \le y \le 4-2x\}$. C is traversed clockwise, so $-C$ gives the positive orientation.

$$\begin{aligned}\int_C \mathbf{F}\cdot d\mathbf{r} &= -\int_{-C} (y\cos x - xy\sin x)\,dx + (xy + x\cos x)\,dy = -\iint_D \left[\frac{\partial}{\partial x}(xy + x\cos x) - \frac{\partial}{\partial y}(y\cos x - xy\sin x)\right] dA \\ &= -\iint_D (y - x\sin x + \cos x - \cos x + x\sin x)\,dA = -\int_0^2 \int_0^{4-2x} y\,dy\,dx \\ &= -\int_0^2 \left[\tfrac{1}{2}y^2\right]_{y=0}^{y=4-2x} dx = -\int_0^2 \tfrac{1}{2}(4-2x)^2\,dx = -\int_0^2 (8 - 8x + 2x^2)\,dx = -\left[8x - 4x^2 + \tfrac{2}{3}x^3\right]_0^2 \\ &= -\left(16 - 16 + \tfrac{16}{3} - 0\right) = -\tfrac{16}{3}\end{aligned}$$

12. $\mathbf{F}(x,y) = \left\langle e^{-x} + y^2, e^{-y} + x^2\right\rangle$ and the region D enclosed by C is given by $\{(x,y) \mid -\pi/2 \le x \le \pi/2, 0 \le y \le \cos x\}$. C is traversed clockwise, so $-C$ gives the positive orientation.

$$\begin{aligned}\int_C \mathbf{F}\cdot d\mathbf{r} &= -\int_{-C} \left(e^{-x} + y^2\right) dx + \left(e^{-y} + x^2\right) dy = -\iint_D \left[\frac{\partial}{\partial x}\left(e^{-y} + x^2\right) - \frac{\partial}{\partial y}\left(e^{-x} + y^2\right)\right] dA \\ &= -\int_{-\pi/2}^{\pi/2}\int_0^{\cos x} (2x - 2y)\,dy\,dx = -\int_{-\pi/2}^{\pi/2} \left[2xy - y^2\right]_{y=0}^{y=\cos x} dx \\ &= -\int_{-\pi/2}^{\pi/2} (2x\cos x - \cos^2 x)\,dx = -\int_{-\pi/2}^{\pi/2} \left[2x\cos x - \tfrac{1}{2}(1 + \cos 2x)\right] dx \\ &= -\left[2x\sin x + 2\cos x - \tfrac{1}{2}\left(x + \tfrac{1}{2}\sin 2x\right)\right]_{-\pi/2}^{\pi/2} \qquad \text{[integrate by parts in the first term]} \\ &= -\left(\pi - \tfrac{1}{4}\pi - \pi - \tfrac{1}{4}\pi\right) = \tfrac{1}{2}\pi\end{aligned}$$

13. $\mathbf{F}(x,y) = \langle y - \cos y, x\sin y\rangle$ and the region D enclosed by C is the disk with radius 2 centered at $(3,-4)$.

C is traversed clockwise, so $-C$ gives the positive orientation.

$$\int_C \mathbf{F}\cdot d\mathbf{r} = -\int_{-C}(y-\cos y)\,dx + (x\sin y)\,dy = -\iint_D \left[\tfrac{\partial}{\partial x}(x\sin y) - \tfrac{\partial}{\partial y}(y-\cos y)\right]dA$$
$$= -\iint_D (\sin y - 1 - \sin y)\,dA = \iint_D dA = \text{area of } D = \pi(2)^2 = 4\pi$$

14. $\mathbf{F}(x,y) = \left\langle \sqrt{x^2+1}, \tan^{-1}x\right\rangle$ and the region D enclosed by C is given by $\{(x,y) \mid 0 \le x \le 1, x \le y \le 1\}$.

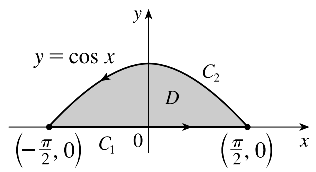
C is oriented positively, so

$$\int_C \mathbf{F}\cdot d\mathbf{r} = \int_C \sqrt{x^2+1}\,dx + \tan^{-1}x\,dy = \iint_D \left[\frac{\partial}{\partial x}\left(\tan^{-1}x\right) - \frac{\partial}{\partial y}\left(\sqrt{x^2+1}\right)\right]dA$$
$$= \int_0^1\int_x^1 \left(\frac{1}{1+x^2} - 0\right)dy\,dx = \int_0^1 \frac{1}{1+x^2}\,\left[\,y\,\right]_{y=x}^{y=1}\,dx = \int_0^1 \frac{1}{1+x^2}\,(1-x)\,dx$$
$$= \int_0^1 \left(\frac{1}{1+x^2} - \frac{x}{1+x^2}\right)dx = \left[\tan^{-1}x - \frac{1}{2}\ln(1+x^2)\right]_0^1 = \frac{\pi}{4} - \frac{1}{2}\ln 2$$

15. Here $C = C_1 + C_2$ where

C_1 can be parametrized as $x = t$, $y = 0$, $-\pi/2 \le t \le \pi/2$, and

C_2 is given by $x = -t$, $y = \cos t$, $-\pi/2 \le t \le \pi/2$.



Then the line integral is

$$\oint_{C_1+C_2} x^3y^4\,dx + x^5y^4\,dy = \int_{-\pi/2}^{\pi/2}(0+0)\,dt + \int_{-\pi/2}^{\pi/2}[(-t)^3(\cos t)^4(-1) + (-t)^5(\cos t)^4(-\sin t)]\,dt$$
$$= 0 + \int_{-\pi/2}^{\pi/2}(t^3\cos^4 t + t^5\cos^4 t\sin t)\,dt = \tfrac{1}{15}\pi^4 - \tfrac{4144}{1125}\pi^2 + \tfrac{7{,}578{,}368}{253{,}125} \approx 0.0779$$

according to a CAS. The double integral is

$$\iint_D \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y}\right)dA = \int_{-\pi/2}^{\pi/2}\int_0^{\cos x}(5x^4y^4 - 4x^3y^3)\,dy\,dx = \tfrac{1}{15}\pi^4 - \tfrac{4144}{1125}\pi^2 + \tfrac{7{,}578{,}368}{253{,}125} \approx 0.0779,$$ verifying Green's Theorem in this case.

16. We can parametrize C as $x = \cos\theta$, $y = 2\sin\theta$, $0 \le \theta \le 2\pi$. Then the line integral is

$$\oint_C P\,dx + Q\,dy = \int_0^{2\pi}\left[2\cos\theta - (\cos\theta)^3(2\sin\theta)^5\right](-\sin\theta)\,d\theta + \int_0^{2\pi}(\cos\theta)^3(2\sin\theta)^8\cdot 2\cos\theta\,d\theta$$
$$= \int_0^{2\pi}(-2\cos\theta\sin\theta + 32\cos^3\theta\sin^6\theta + 512\cos^4\theta\sin^8\theta)\,d\theta = 7\pi,$$

according to a CAS. The double integral is $\displaystyle\iint_D \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y}\right)dA = \int_{-1}^{1}\int_{-\sqrt{4-4x^2}}^{\sqrt{4-4x^2}}(3x^2y^8 + 5x^3y^4)\,dy\,dx = 7\pi.$

17. By Green's Theorem, $W = \int_C \mathbf{F}\cdot d\mathbf{r} = \int_C x(x+y)\,dx + xy^2\,dy = \iint_D (y^2 - x)\,dA$ where C is the path described in the question and D is the triangle bounded by C. So

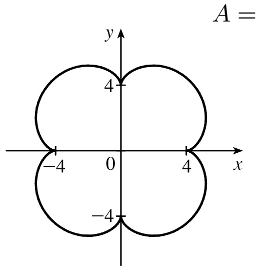
$$W = \int_0^1\int_0^{1-x}(y^2 - x)\,dy\,dx = \int_0^1 \left[\tfrac{1}{3}y^3 - xy\right]_{y=0}^{y=1-x}dx = \int_0^1 \left(\tfrac{1}{3}(1-x)^3 - x(1-x)\right)dx$$
$$= \left[-\tfrac{1}{12}(1-x)^4 - \tfrac{1}{2}x^2 + \tfrac{1}{3}x^3\right]_0^1 = \left(-\tfrac{1}{2} + \tfrac{1}{3}\right) - \left(-\tfrac{1}{12}\right) = -\tfrac{1}{12}$$

18. By Green's Theorem, $W = \int_C \mathbf{F} \cdot d\mathbf{r} = \int_C \sin x\,dx + \left(\sin y + xy^2 + \frac{1}{3}x^3\right) dy = \iint_D (y^2 + x^2 - 0)\,dA$, where D is the region (a quarter-disk) bounded by C. Converting to polar coordinates, we have $W = \int_0^{\pi/2}\int_0^5 r^2 \cdot r\,dr\,d\theta = \left[\theta\right]_0^{\pi/2}\left[\frac{1}{4}r^4\right]_0^5 = \frac{1}{2}\pi\left(\frac{625}{4}\right) = \frac{625}{8}\pi$.

19. Let C_1 be the arch of the cycloid from $(0,0)$ to $(2\pi,0)$, which corresponds to $0 \le t \le 2\pi$, and let C_2 be the segment from $(2\pi,0)$ to $(0,0)$, so C_2 is given by $x = 2\pi - t$, $y = 0$, $0 \le t \le 2\pi$. Then $C = C_1 \cup C_2$ is traversed clockwise, so $-C$ is oriented positively. Thus $-C$ encloses the area under one arch of the cycloid and from (5) we have

$$A = -\oint_{-C} y\,dx = \int_{C_1} y\,dx + \int_{C_2} y\,dx = \int_0^{2\pi}(1-\cos t)(1-\cos t)\,dt + \int_0^{2\pi} 0\,(-dt)$$
$$= \int_0^{2\pi}(1 - 2\cos t + \cos^2 t)\,dt + 0 = \left[t - 2\sin t + \tfrac{1}{2}t + \tfrac{1}{4}\sin 2t\right]_0^{2\pi} = 3\pi$$

20.



$$A = \oint_C x\,dy = \int_0^{2\pi}(5\cos t - \cos 5t)(5\cos t - 5\cos 5t)\,dt$$
$$= \int_0^{2\pi}(25\cos^2 t - 30\cos t\cos 5t + 5\cos^2 5t)\,dt$$
$$= \left[25\left(\tfrac{1}{2}t + \tfrac{1}{4}\sin 2t\right) - 30\left(\tfrac{1}{8}\sin 4t + \tfrac{1}{12}\sin 6t\right) + 5\left(\tfrac{1}{2}t + \tfrac{1}{20}\sin 10t\right)\right]_0^{2\pi}$$

[Use Formula 80 in the Table of Integrals]

$$= 30\pi$$

21. (a) Using Equation 16.2.8, we write parametric equations of the line segment as $x = (1-t)x_1 + tx_2$, $y = (1-t)y_1 + ty_2$, $0 \le t \le 1$. Then $dx = (x_2 - x_1)\,dt$ and $dy = (y_2 - y_1)\,dt$, so

$$\int_C x\,dy - y\,dx = \int_0^1 [(1-t)x_1 + tx_2](y_2 - y_1)\,dt + [(1-t)y_1 + ty_2](x_2 - x_1)\,dt$$
$$= \int_0^1 (x_1(y_2 - y_1) - y_1(x_2 - x_1) + t[(y_2 - y_1)(x_2 - x_1) - (x_2 - x_1)(y_2 - y_1)])\,dt$$
$$= \int_0^1 (x_1 y_2 - x_2 y_1)\,dt = x_1 y_2 - x_2 y_1$$

(b) We apply Green's Theorem to the path $C = C_1 \cup C_2 \cup \cdots \cup C_n$, where C_i is the line segment that joins (x_i, y_i) to (x_{i+1}, y_{i+1}) for $i = 1, 2, \ldots, n-1$, and C_n is the line segment that joins (x_n, y_n) to (x_1, y_1). From (5), $\frac{1}{2}\int_C x\,dy - y\,dx = \iint_D dA$, where D is the polygon bounded by C. Therefore

$$\text{area of polygon} = A(D) = \iint_D dA = \tfrac{1}{2}\int_C x\,dy - y\,dx$$
$$= \tfrac{1}{2}\left(\int_{C_1} x\,dy - y\,dx + \int_{C_2} x\,dy - y\,dx + \cdots + \int_{C_{n-1}} x\,dy - y\,dx + \int_{C_n} x\,dy - y\,dx\right)$$

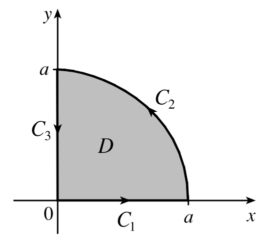
To evaluate these integrals we use the formula from (a) to get

$$A(D) = \tfrac{1}{2}[(x_1y_2 - x_2y_1) + (x_2y_3 - x_3y_2) + \cdots + (x_{n-1}y_n - x_ny_{n-1}) + (x_ny_1 - x_1y_n)].$$

(c) $A = \frac{1}{2}[(0\cdot 1 - 2\cdot 0) + (2\cdot 3 - 1\cdot 1) + (1\cdot 2 - 0\cdot 3) + (0\cdot 1 - (-1)\cdot 2) + (-1\cdot 0 - 0\cdot 1)]$
$= \frac{1}{2}(0 + 5 + 2 + 2) = \frac{9}{2}$

22. By Green's Theorem, $\frac{1}{2A}\oint_C x^2\,dy = \frac{1}{2A}\iint_D 2x\,dA = \frac{1}{A}\iint_D x\,dA = \overline{x}$ and $-\frac{1}{2A}\oint_C y^2\,dx = -\frac{1}{2A}\iint_D (-2y)\,dA = \frac{1}{A}\iint_D y\,dA = \overline{y}$.

23. We orient the quarter-circular region as shown in the figure.



$A = \frac{1}{4}\pi a^2$ so $\overline{x} = \dfrac{1}{\pi a^2/2}\displaystyle\oint_C x^2\,dy$ and $\overline{y} = -\dfrac{1}{\pi a^2/2}\displaystyle\oint_C y^2\,dx$.

Here $C = C_1 + C_2 + C_3$ where C_1: $x = t,\quad y = 0,\quad 0 \le t \le a$;

C_2: $x = a\cos t,\quad y = a\sin t,\quad 0 \le t \le \frac{\pi}{2}$; and

C_3: $x = 0, y = a - t, 0 \le t \le a$. Then

$$\begin{aligned}\oint_C x^2\,dy &= \int_{C_1} x^2\,dy + \int_{C_2} x^2\,dy + \int_{C_3} x^2\,dy = \int_0^a 0\,dt + \int_0^{\pi/2} (a\cos t)^2 (a\cos t)\,dt + \int_0^a 0\,dt \\ &= \int_0^{\pi/2} a^3\cos^3 t\,dt = a^3\int_0^{\pi/2} (1 - \sin^2 t)\cos t\,dt = a^3\left[\sin t - \tfrac{1}{3}\sin^3 t\right]_0^{\pi/2} = \tfrac{2}{3}a^3\end{aligned}$$

so $\overline{x} = \dfrac{1}{\pi a^2/2}\displaystyle\oint_C x^2\,dy = \dfrac{4a}{3\pi}$.

$$\begin{aligned}\oint_C y^2\,dx &= \int_{C_1} y^2\,dx + \int_{C_2} y^2\,dx + \int_{C_3} y^2\,dx = \int_0^a 0\,dt + \int_0^{\pi/2} (a\sin t)^2(-a\sin t)\,dt + \int_0^a 0\,dt \\ &= \int_0^{\pi/2} (-a^3\sin^3 t)\,dt = -a^3\int_0^{\pi/2} (1 - \cos^2 t)\sin t\,dt = -a^3\left[\tfrac{1}{3}\cos^3 t - \cos t\right]_0^{\pi/2} = -\tfrac{2}{3}a^3,\end{aligned}$$

so $\overline{y} = -\dfrac{1}{\pi a^2/2}\displaystyle\oint_C y^2\,dx = \dfrac{4a}{3\pi}$. Thus $(\overline{x}, \overline{y}) = \left(\dfrac{4a}{3\pi}, \dfrac{4a}{3\pi}\right)$.

24. Here $A = \frac{1}{2}ab$ and $C = C_1 + C_2 + C_3$, where C_1: $x = x, y = 0, 0 \le x \le a$;

C_2: $x = a, y = y, 0 \le y \le b$; and C_3: $x = x, y = \frac{b}{a}x, x = a$ to $x = 0$. Then

$$\begin{aligned}\oint_C x^2\,dy &= \int_{C_1} x^2\,dy + \int_{C_2} x^2\,dy + \int_{C_3} x^2\,dy = 0 + \int_0^b a^2\,dy + \int_a^0 (x^2)\left(\tfrac{b}{a}\,dx\right) \\ &= a^2 b + \tfrac{b}{a}\left[\tfrac{1}{3}x^3\right]_a^0 = a^2 b - \tfrac{1}{3}a^2 b = \tfrac{2}{3}a^2 b.\end{aligned}$$

Similarly, $\oint_C y^2\,dx = \int_{C_1} y^2\,dx + \int_{C_2} y^2\,dx + \int_{C_3} y^2\,dx = 0 + 0 + \int_a^0 \left(\frac{b}{a}x\right)^2\,dx = \frac{b^2}{a^2}\cdot\frac{1}{3}x^3\Big]_a^0 = -\frac{1}{3}ab^2$. Thus

$\overline{x} = \frac{1}{2A}\oint_C x^2\,dy = \frac{1}{ab}\cdot\frac{2}{3}a^2 b = \frac{2}{3}a$ and $\overline{y} = -\frac{1}{2A}\oint_C y^2\,dx = -\frac{1}{ab}\left(-\frac{1}{3}ab^2\right) = \frac{1}{3}b$, so $(\overline{x}, \overline{y}) = \left(\frac{2}{3}a, \frac{1}{3}b\right)$.

25. By Green's Theorem, $-\frac{1}{3}\rho\oint_C y^3\,dx = -\frac{1}{3}\rho\iint_D (-3y^2)\,dA = \iint_D y^2\rho\,dA = I_x$ and

$\frac{1}{3}\rho\oint_C x^3\,dy = \frac{1}{3}\rho\iint_D (3x^2)\,dA = \iint_D x^2\rho\,dA = I_y$.

26. By symmetry the moments of inertia about any two diameters are equal. Centering the disk at the origin, the moment of inertia about a diameter equals

$$I_y = \tfrac{1}{3}\rho\oint_C x^3\,dy = \tfrac{1}{3}\rho\int_0^{2\pi} (a^4\cos^4 t)\,dt = \tfrac{1}{3}a^4\rho\int_0^{2\pi} \left[\tfrac{3}{8} + \tfrac{1}{2}\cos 2t + \tfrac{1}{8}\cos 4t\right] dt = \tfrac{1}{3}a^4\rho\cdot\tfrac{3(2\pi)}{8} = \tfrac{1}{4}\pi a^4\rho$$

27. As in Example 5, let C' be a counterclockwise-oriented circle with center the origin and radius a, where a is chosen to be small enough so that C' lies inside C, and D the region bounded by C and C'. Here

$P = \dfrac{2xy}{(x^2 + y^2)^2} \quad\Rightarrow\quad \dfrac{\partial P}{\partial y} = \dfrac{2x(x^2 + y^2)^2 - 2xy\cdot 2(x^2 + y^2)\cdot 2y}{(x^2 + y^2)^4} = \dfrac{2x^3 - 6xy^2}{(x^2 + y^2)^3}$ and

$Q = \dfrac{y^2 - x^2}{(x^2 + y^2)^2} \quad\Rightarrow\quad \dfrac{\partial Q}{\partial x} = \dfrac{-2x(x^2 + y^2)^2 - (y^2 - x^2)\cdot 2(x^2 + y^2)\cdot 2x}{(x^2 + y^2)^4} = \dfrac{2x^3 - 6xy^2}{(x^2 + y^2)^3}$. Thus, as in the example,

$$\int_C P\,dx + Q\,dy + \int_{-C'} P\,dx + Q\,dy = \iint_D \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y}\right) dA = \iint_D 0\,dA = 0$$

and $\int_C \mathbf{F}\cdot d\mathbf{r} = \int_{C'} \mathbf{F}\cdot d\mathbf{r}$. We parametrize C' as $\mathbf{r}(t) = a\cos t\,\mathbf{i} + a\sin t\,\mathbf{j}$, $0 \le t \le 2\pi$. Then

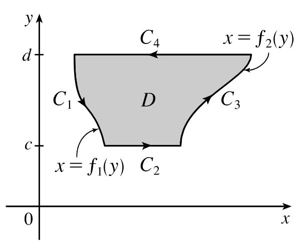
$$\begin{aligned}\int_C \mathbf{F}\cdot d\mathbf{r} = \int_{C'} \mathbf{F}\cdot d\mathbf{r} &= \int_0^{2\pi} \frac{2\,(a\cos t)\,(a\sin t)\,\mathbf{i} + \left(a^2\sin^2 t - a^2\cos^2 t\right)\mathbf{j}}{\left(a^2\cos^2 t + a^2\sin^2 t\right)^2} \cdot \Big(-a\sin t\,\mathbf{i} + a\cos t\,\mathbf{j}\Big)\,dt \\ &= \frac{1}{a}\int_0^{2\pi} \left(-\cos t\sin^2 t - \cos^3 t\right) dt = \frac{1}{a}\int_0^{2\pi} \left(-\cos t\sin^2 t - \cos t\left(1 - \sin^2 t\right)\right) dt \\ &= -\frac{1}{a}\int_0^{2\pi} \cos t\,dt = -\frac{1}{a}\sin t\Big]_0^{2\pi} = 0\end{aligned}$$

28. P and Q have continuous partial derivatives on $\mathbb{R}^2$, so by Green's Theorem we have

$$\int_C \mathbf{F}\cdot d\mathbf{r} = \iint_D \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y}\right) dA = \iint_D (3-1)\,dA = 2\iint_D dA = 2\cdot A(D) = 2\cdot 6 = 12$$

29. Since C is a simple closed path which doesn't pass through or enclose the origin, there exists an open region that doesn't contain the origin but does contain D. Thus $P = -y/(x^2+y^2)$ and $Q = x/(x^2+y^2)$ have continuous partial derivatives on this open region containing D and we can apply Green's Theorem. But by Exercise 16.3.35(a), $\partial P/\partial y = \partial Q/\partial x$, so $\oint_C \mathbf{F}\cdot d\mathbf{r} = \iint_D 0\,dA = 0$.

30. We express D as a type II region: $D = \{(x,y) \mid f_1(y) \le x \le f_2(y), c \le y \le d\}$ where f_1 and f_2 are continuous functions. Then $\displaystyle\iint_D \frac{\partial Q}{\partial x}\,dA = \int_c^d \int_{f_1(y)}^{f_2(y)} \frac{\partial Q}{\partial x}\,dx\,dy = \int_c^d [Q(f_2(y),y) - Q(f_1(y),y)]\,dy$ by the Fundamental Theorem of Calculus. But referring to the figure, $\oint_C Q\,dy = \oint_{C_1+C_2+C_3+C_4} Q\,dy$.



Then $\int_{C_1} Q\,dy = \int_d^c Q(f_1(y),y)\,dy$, $\int_{C_2} Q\,dy = \int_{C_4} Q\,dy = 0$, and $\int_{C_3} Q\,dy = \int_c^d Q(f_2(y),y)\,dy$. Hence $\oint_C Q\,dy = \int_c^d [Q(f_2(y),y) - Q(f_1(y),y)]\,dy = \iint_D (\partial Q/\partial x)\,dA$.

31. Using the first part of (5), we have that $\iint_R dx\,dy = A(R) = \int_{\partial R} x\,dy$. But $x = g(u,v)$, and $dy = \dfrac{\partial h}{\partial u}du + \dfrac{\partial h}{\partial v}dv$, and we orient ∂S by taking the positive direction to be that which corresponds, under the mapping, to the positive direction along ∂R, so

$$\begin{aligned}\int_{\partial R} x\,dy &= \int_{\partial S} g(u,v)\left(\frac{\partial h}{\partial u}du + \frac{\partial h}{\partial v}dv\right) = \int_{\partial S} g(u,v)\,\frac{\partial h}{\partial u}\,du + g(u,v)\,\frac{\partial h}{\partial v}\,dv \\ &= \pm\iint_S \left[\tfrac{\partial}{\partial u}\left(g(u,v)\,\tfrac{\partial h}{\partial v}\right) - \tfrac{\partial}{\partial v}\left(g(u,v)\,\tfrac{\partial h}{\partial u}\right)\right] dA \qquad \text{[using Green's Theorem in the } uv\text{-plane]} \\ &= \pm\iint_S \left(\tfrac{\partial g}{\partial u}\tfrac{\partial h}{\partial v} + g(u,v)\,\tfrac{\partial^2 h}{\partial u\,\partial v} - \tfrac{\partial g}{\partial v}\tfrac{\partial h}{\partial u} - g(u,v)\,\tfrac{\partial^2 h}{\partial v\,\partial u}\right) dA \qquad \text{[using the Chain Rule]} \\ &= \pm\iint_S \left(\tfrac{\partial x}{\partial u}\tfrac{\partial y}{\partial v} - \tfrac{\partial x}{\partial v}\tfrac{\partial y}{\partial u}\right) dA \quad \text{[by the equality of mixed partials]} \quad = \pm\iint_S \tfrac{\partial(x,y)}{\partial(u,v)}\,du\,dv\end{aligned}$$

The sign is chosen to be positive if the orientation that we gave to ∂S corresponds to the usual positive orientation, and it is negative otherwise. In either case, since $A(R)$ is positive, the sign chosen must be the same as the sign of $\dfrac{\partial(x,y)}{\partial(u,v)}$.

Therefore $A(R) = \iint_R dx\,dy = \iint_S \left|\dfrac{\partial(x,y)}{\partial(u,v)}\right| du\,dv$.

16.5 Curl and Divergence

1. (a) $\operatorname{curl}\mathbf{F} = \nabla\times\mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \partial/\partial x & \partial/\partial y & \partial/\partial z \\ xy^2z^2 & x^2yz^2 & x^2y^2z \end{vmatrix}$

$$= \left[\frac{\partial}{\partial y}(x^2y^2z) - \frac{\partial}{\partial z}(x^2yz^2)\right]\mathbf{i} - \left[\frac{\partial}{\partial x}(x^2y^2z) - \frac{\partial}{\partial z}(xy^2z^2)\right]\mathbf{j} + \left[\frac{\partial}{\partial x}(x^2yz^2) - \frac{\partial}{\partial y}(xy^2z^2)\right]\mathbf{k}$$

$$= (2x^2yz - 2x^2yz)\,\mathbf{i} - (2xy^2z - 2xy^2z)\,\mathbf{j} + (2xyz^2 - 2xyz^2)\,\mathbf{k} = \mathbf{0}$$

(b) $\operatorname{div}\mathbf{F} = \nabla\cdot\mathbf{F} = \dfrac{\partial}{\partial x}(xy^2z^2) + \dfrac{\partial}{\partial y}(x^2yz^2) + \dfrac{\partial}{\partial z}(x^2y^2z) = y^2z^2 + x^2z^2 + x^2y^2$

2. (a) $\operatorname{curl}\mathbf{F} = \nabla\times\mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \partial/\partial x & \partial/\partial y & \partial/\partial z \\ 0 & x^3yz^2 & y^4z^3 \end{vmatrix}$

$$= \left[\frac{\partial}{\partial y}(y^4z^3) - \frac{\partial}{\partial z}(x^3yz^2)\right]\mathbf{i} - \left[\frac{\partial}{\partial x}(y^4z^3) - \frac{\partial}{\partial z}(0)\right]\mathbf{j} + \left[\frac{\partial}{\partial x}(x^3yz^2) - \frac{\partial}{\partial y}(0)\right]\mathbf{k}$$

$$= (4y^3z^3 - 2x^3yz)\,\mathbf{i} - (0-0)\,\mathbf{j} + (3x^2yz^2 - 0)\,\mathbf{k} = (4y^3z^3 - 2x^3yz)\,\mathbf{i} + 3x^2yz^2\,\mathbf{k}$$

(b) $\operatorname{div}\mathbf{F} = \nabla\cdot\mathbf{F} = \dfrac{\partial}{\partial x}(0) + \dfrac{\partial}{\partial y}(x^3yz^2) + \dfrac{\partial}{\partial z}(y^4z^3) = 0 + x^3z^2 + 3y^4z^2 = x^3z^2 + 3y^4z^2$

3. (a) $\operatorname{curl}\mathbf{F} = \nabla\times\mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \partial/\partial x & \partial/\partial y & \partial/\partial z \\ xye^z & 0 & yze^x \end{vmatrix} = (ze^x - 0)\,\mathbf{i} - (yze^x - xye^z)\,\mathbf{j} + (0 - xe^z)\,\mathbf{k}$

$$= ze^x\,\mathbf{i} + (xye^z - yze^x)\,\mathbf{j} - xe^z\,\mathbf{k}$$

(b) $\operatorname{div}\mathbf{F} = \nabla\cdot\mathbf{F} = \dfrac{\partial}{\partial x}(xye^z) + \dfrac{\partial}{\partial y}(0) + \dfrac{\partial}{\partial z}(yze^x) = ye^z + 0 + ye^x = y(e^z + e^x)$

4. (a) $\operatorname{curl}\mathbf{F} = \nabla\times\mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \partial/\partial x & \partial/\partial y & \partial/\partial z \\ \sin yz & \sin zx & \sin xy \end{vmatrix}$

$$= (x\cos xy - x\cos zx)\,\mathbf{i} - (y\cos xy - y\cos yz)\,\mathbf{j} + (z\cos zx - z\cos yz)\,\mathbf{k}$$

$$= x(\cos xy - \cos zx)\,\mathbf{i} + y(\cos yz - \cos xy)\,\mathbf{j} + z(\cos zx - \cos yz)\,\mathbf{k}$$

(b) $\operatorname{div}\mathbf{F} = \nabla\cdot\mathbf{F} = \dfrac{\partial}{\partial x}(\sin yz) + \dfrac{\partial}{\partial y}(\sin zx) + \dfrac{\partial}{\partial z}(\sin xy) = 0 + 0 + 0 = 0$

5. (a) $\operatorname{curl}\mathbf{F} = \nabla \times \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \partial/\partial x & \partial/\partial y & \partial/\partial z \\ \dfrac{\sqrt{x}}{1+z} & \dfrac{\sqrt{y}}{1+x} & \dfrac{\sqrt{z}}{1+y} \end{vmatrix}$

$$= \left[\sqrt{z}\,(-1)(1+y)^{-2} - 0\right]\mathbf{i} - \left[0 - \sqrt{x}(-1)(1+z)^{-2}\right]\mathbf{j} + \left[\sqrt{y}\,(-1)(1+x)^{-2} - 0\right]\mathbf{k}$$

$$= -\frac{\sqrt{z}}{(1+y)^2}\,\mathbf{i} - \frac{\sqrt{x}}{(1+z)^2}\,\mathbf{j} - \frac{\sqrt{y}}{(1+x)^2}\,\mathbf{k}$$

(b) $\operatorname{div}\mathbf{F} = \nabla \cdot \mathbf{F} = \dfrac{\partial}{\partial x}\left(\dfrac{\sqrt{x}}{1+z}\right) + \dfrac{\partial}{\partial y}\left(\dfrac{\sqrt{y}}{1+x}\right) + \dfrac{\partial}{\partial z}\left(\dfrac{\sqrt{z}}{1+y}\right)$

$$= \frac{1}{2\sqrt{x}\,(1+z)} + \frac{1}{2\sqrt{y}\,(1+x)} + \frac{1}{2\sqrt{z}\,(1+y)}$$

6. (a) $\operatorname{curl}\mathbf{F} = \nabla \times \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \partial/\partial x & \partial/\partial y & \partial/\partial z \\ \ln(2y+3z) & \ln(x+3z) & \ln(x+2y) \end{vmatrix}$

$$= \left(\frac{2}{x+2y} - \frac{3}{x+3z}\right)\mathbf{i} - \left(\frac{1}{x+2y} - \frac{3}{2y+3z}\right)\mathbf{j} + \left(\frac{1}{x+3z} - \frac{2}{2y+3z}\right)\mathbf{k}$$

$$= \left(\frac{2}{x+2y} - \frac{3}{x+3z}\right)\mathbf{i} + \left(\frac{3}{2y+3z} - \frac{1}{x+2y}\right)\mathbf{j} + \left(\frac{1}{x+3z} - \frac{2}{2y+3z}\right)\mathbf{k}$$

(b) $\operatorname{div}\mathbf{F} = \nabla \cdot \mathbf{F} = \dfrac{\partial}{\partial x}\left[\ln(2y+3z)\right] + \dfrac{\partial}{\partial y}\left[\ln(x+3z)\right] + \dfrac{\partial}{\partial z}\left[\ln(x+2y)\right] = 0 + 0 + 0 = 0$

7. (a) $\operatorname{curl}\mathbf{F} = \nabla \times \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \partial/\partial x & \partial/\partial y & \partial/\partial z \\ e^x \sin y & e^y \sin z & e^z \sin x \end{vmatrix} = (0 - e^y \cos z)\,\mathbf{i} - (e^z \cos x - 0)\,\mathbf{j} + (0 - e^x \cos y)\,\mathbf{k}$

$$= \langle -e^y \cos z, -e^z \cos x, -e^x \cos y \rangle$$

(b) $\operatorname{div}\mathbf{F} = \nabla \cdot \mathbf{F} = \dfrac{\partial}{\partial x}\,(e^x \sin y) + \dfrac{\partial}{\partial y}\,(e^y \sin z) + \dfrac{\partial}{\partial z}\,(e^z \sin x) = e^x \sin y + e^y \sin z + e^z \sin x$

8. (a) $\operatorname{curl}\mathbf{F} = \nabla \times \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \partial/\partial x & \partial/\partial y & \partial/\partial z \\ \arctan(xy) & \arctan(yz) & \arctan(zx) \end{vmatrix}$

$$= \left(0 - \frac{y}{1+(yz)^2}\right)\mathbf{i} - \left(\frac{z}{1+(zx)^2} - 0\right)\mathbf{j} + \left(0 - \frac{x}{1+(xy)^2}\right)\mathbf{k}$$

$$= \left\langle -\frac{y}{1+y^2z^2}, -\frac{z}{1+x^2z^2}, -\frac{x}{1+x^2y^2} \right\rangle$$

(b) $\operatorname{div}\mathbf{F} = \nabla \cdot \mathbf{F} = \dfrac{\partial}{\partial x}\left[\arctan(xy)\right] + \dfrac{\partial}{\partial y}\left[\arctan(yz)\right] + \dfrac{\partial}{\partial z}\left[\arctan(zx)\right] = \dfrac{y}{1+x^2y^2} + \dfrac{z}{1+y^2z^2} + \dfrac{x}{1+x^2z^2}$

9. If the vector field is $\mathbf{F} = P\,\mathbf{i} + Q\,\mathbf{j} + R\,\mathbf{k}$, then we know $R = 0$. In addition, the x-component of each vector of $\mathbf{F}$ is 0, so $P = 0$, hence $\dfrac{\partial P}{\partial x} = \dfrac{\partial P}{\partial y} = \dfrac{\partial P}{\partial z} = \dfrac{\partial R}{\partial x} = \dfrac{\partial R}{\partial y} = \dfrac{\partial R}{\partial z} = 0$. Q decreases as y increases, so $\dfrac{\partial Q}{\partial y} < 0$, but Q doesn't change in the x- or z-directions, so $\dfrac{\partial Q}{\partial x} = \dfrac{\partial Q}{\partial z} = 0$.

(a) $\operatorname{div} \mathbf{F} = \dfrac{\partial P}{\partial x} + \dfrac{\partial Q}{\partial y} + \dfrac{\partial R}{\partial z} = 0 + \dfrac{\partial Q}{\partial y} + 0 < 0$

(b) $\operatorname{curl} \mathbf{F} = \left(\dfrac{\partial R}{\partial y} - \dfrac{\partial Q}{\partial z}\right)\mathbf{i} + \left(\dfrac{\partial P}{\partial z} - \dfrac{\partial R}{\partial x}\right)\mathbf{j} + \left(\dfrac{\partial Q}{\partial x} - \dfrac{\partial P}{\partial y}\right)\mathbf{k} = (0-0)\,\mathbf{i} + (0-0)\,\mathbf{j} + (0-0)\,\mathbf{k} = \mathbf{0}$

10. If the vector field is $\mathbf{F} = P\,\mathbf{i} + Q\,\mathbf{j} + R\,\mathbf{k}$, then we know $R = 0$. In addition, P and Q don't vary in the z-direction, so $\dfrac{\partial R}{\partial x} = \dfrac{\partial R}{\partial y} = \dfrac{\partial R}{\partial z} = \dfrac{\partial P}{\partial z} = \dfrac{\partial Q}{\partial z} = 0$. As x increases, the x-component of each vector of $\mathbf{F}$ increases while the y-component remains constant, so $\dfrac{\partial P}{\partial x} > 0$ and $\dfrac{\partial Q}{\partial x} = 0$. Similarly, as y increases, the y-component of each vector increases while the x-component remains constant, so $\dfrac{\partial Q}{\partial y} > 0$ and $\dfrac{\partial P}{\partial y} = 0$.

(a) $\operatorname{div} \mathbf{F} = \dfrac{\partial P}{\partial x} + \dfrac{\partial Q}{\partial y} + \dfrac{\partial R}{\partial z} = \dfrac{\partial P}{\partial x} + \dfrac{\partial Q}{\partial y} + 0 > 0$

(b) $\operatorname{curl} \mathbf{F} = \left(\dfrac{\partial R}{\partial y} - \dfrac{\partial Q}{\partial z}\right)\mathbf{i} + \left(\dfrac{\partial P}{\partial z} - \dfrac{\partial R}{\partial x}\right)\mathbf{j} + \left(\dfrac{\partial Q}{\partial x} - \dfrac{\partial P}{\partial y}\right)\mathbf{k} = (0-0)\,\mathbf{i} + (0-0)\,\mathbf{j} + (0-0)\,\mathbf{k} = \mathbf{0}$

11. If the vector field is $\mathbf{F} = P\,\mathbf{i} + Q\,\mathbf{j} + R\,\mathbf{k}$, then we know $R = 0$. In addition, the y-component of each vector of $\mathbf{F}$ is 0, so $Q = 0$, hence $\dfrac{\partial Q}{\partial x} = \dfrac{\partial Q}{\partial y} = \dfrac{\partial Q}{\partial z} = \dfrac{\partial R}{\partial x} = \dfrac{\partial R}{\partial y} = \dfrac{\partial R}{\partial z} = 0$. P increases as y increases, so $\dfrac{\partial P}{\partial y} > 0$, but P doesn't change in the x- or z-directions, so $\dfrac{\partial P}{\partial x} = \dfrac{\partial P}{\partial z} = 0$.

(a) $\operatorname{div} \mathbf{F} = \dfrac{\partial P}{\partial x} + \dfrac{\partial Q}{\partial y} + \dfrac{\partial R}{\partial z} = 0 + 0 + 0 = 0$

(b) $\operatorname{curl} \mathbf{F} = \left(\dfrac{\partial R}{\partial y} - \dfrac{\partial Q}{\partial z}\right)\mathbf{i} + \left(\dfrac{\partial P}{\partial z} - \dfrac{\partial R}{\partial x}\right)\mathbf{j} + \left(\dfrac{\partial Q}{\partial x} - \dfrac{\partial P}{\partial y}\right)\mathbf{k} = (0-0)\,\mathbf{i} + (0-0)\,\mathbf{j} + \left(0 - \dfrac{\partial P}{\partial y}\right)\mathbf{k} = -\dfrac{\partial P}{\partial y}\mathbf{k}$

Since $\dfrac{\partial P}{\partial y} > 0$, $-\dfrac{\partial P}{\partial y}\mathbf{k}$ is a vector pointing in the negative z-direction.

12. (a) $\operatorname{curl} f = \nabla \times f$ is meaningless because f is a scalar field.

(b) $\operatorname{grad} f$ is a vector field.

(c) $\operatorname{div} \mathbf{F}$ is a scalar field.

(d) $\operatorname{curl}(\operatorname{grad} f)$ is a vector field.

(e) $\operatorname{grad} \mathbf{F}$ is meaningless because $\mathbf{F}$ is not a scalar field.

(f) $\operatorname{grad}(\operatorname{div} \mathbf{F})$ is a vector field.

(g) $\operatorname{div}(\operatorname{grad} f)$ is a scalar field.

(h) $\operatorname{grad}(\operatorname{div} f)$ is meaningless because f is a scalar field.

(i) $\operatorname{curl}(\operatorname{curl} \mathbf{F})$ is a vector field.

(j) $\operatorname{div}(\operatorname{div} \mathbf{F})$ is meaningless because $\operatorname{div} \mathbf{F}$ is a scalar field.

(k) $(\text{grad } f) \times (\text{div } \mathbf{F})$ is meaningless because $\text{div } \mathbf{F}$ is a scalar field.

(l) $\text{div}(\text{curl}(\text{grad } f))$ is a scalar field.

13. $\text{curl } \mathbf{F} = \nabla \times \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \partial/\partial x & \partial/\partial y & \partial/\partial z \\ y^2z^3 & 2xyz^3 & 3xy^2z^2 \end{vmatrix} = (6xyz^2 - 6xyz^2)\,\mathbf{i} - (3y^2z^2 - 3y^2z^2)\,\mathbf{j} + (2yz^3 - 2yz^3)\,\mathbf{k} = \mathbf{0}$

and $\mathbf{F}$ is defined on all of $\mathbb{R}^3$ with component functions which have continuous partial derivatives, so by Theorem 4, $\mathbf{F}$ is conservative. Thus, there exists a function f such that $\mathbf{F} = \nabla f$. Then $f_x(x, y, z) = y^2z^3$ implies $f(x, y, z) = xy^2z^3 + g(y, z)$ and $f_y(x, y, z) = 2xyz^3 + g_y(y, z)$. But $f_y(x, y, z) = 2xyz^3$, so $g(y, z) = h(z)$ and $f(x, y, z) = xy^2z^3 + h(z)$. Thus $f_z(x, y, z) = 3xy^2z^2 + h'(z)$ but $f_z(x, y, z) = 3xy^2z^2$ so $h(z) = K$, a constant. Hence a potential function for $\mathbf{F}$ is $f(x, y, z) = xy^2z^3 + K$.

14. $\text{curl } \mathbf{F} = \nabla \times \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \partial/\partial x & \partial/\partial y & \partial/\partial z \\ xyz^4 & x^2z^4 & 4x^2yz^3 \end{vmatrix} = (4x^2z^3 - 4x^2z^3)\,\mathbf{i} - (8xyz^3 - 4xyz^3)\,\mathbf{j} + (2xz^4 - xz^4)\,\mathbf{k} \neq \mathbf{0}$,

so $\mathbf{F}$ is not conservative.

15. $\text{curl } \mathbf{F} = \nabla \times \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \partial/\partial x & \partial/\partial y & \partial/\partial z \\ z\cos y & xz\sin y & x\cos y \end{vmatrix}$

$$= (-x\sin y - x\sin y)\,\mathbf{i} - (\cos y - \cos y)\,\mathbf{j} + [z\sin y - (-z\sin y)]\,\mathbf{k} = -2x\sin y\,\mathbf{i} + 2z\sin y\,\mathbf{k} \neq \mathbf{0},$$

so $\mathbf{F}$ is not conservative.

16. $\text{curl } \mathbf{F} = \nabla \times \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \partial/\partial x & \partial/\partial y & \partial/\partial z \\ 1 & \sin z & y\cos z \end{vmatrix} = (\cos z - \cos z)\,\mathbf{i} - (0 - 0)\,\mathbf{j} + (0 - 0)\,\mathbf{k} = \mathbf{0}$, $\mathbf{F}$ is defined on all of $\mathbb{R}^3$,

and the partial derivatives of the component functions are continuous, so $\mathbf{F}$ is conservative. Thus there exists a function f such that $\nabla f = \mathbf{F}$. Then $f_x(x, y, z) = 1$ implies $f(x, y, z) = x + g(y, z)$ and $f_y(x, y, z) = g_y(y, z)$. But $f_y(x, y, z) = \sin z$, so $g(y, z) = y\sin z + h(z)$ and $f(x, y, z) = x + y\sin z + h(z)$. Thus $f_z(x, y, z) = y\cos z + h'(z)$ but $f_z(x, y, z) = y\cos z$ so $h(z) = K$ and $f(x, y, z) = x + y\sin z + K$.

17. $\text{curl } \mathbf{F} = \nabla \times \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \partial/\partial x & \partial/\partial y & \partial/\partial z \\ e^{yz} & xze^{yz} & xye^{yz} \end{vmatrix}$

$$= [xyze^{yz} + xe^{yz} - (xyze^{yz} + xe^{yz})]\,\mathbf{i} - (ye^{yz} - ye^{yz})\,\mathbf{j} + (ze^{yz} - ze^{yz})\,\mathbf{k} = \mathbf{0}$$

$\mathbf{F}$ is defined on all of $\mathbb{R}^3$, and the partial derivatives of the component functions are continuous, so $\mathbf{F}$ is conservative. Thus there exists a function f such that $\nabla f = \mathbf{F}$. Then $f_x(x, y, z) = e^{yz}$ implies $f(x, y, z) = xe^{yz} + g(y, z) \quad \Rightarrow$ $f_y(x, y, z) = xze^{yz} + g_y(y, z)$. But $f_y(x, y, z) = xze^{yz}$, so $g(y, z) = h(z)$ and $f(x, y, z) = xe^{yz} + h(z)$. Thus $f_z(x, y, z) = xye^{yz} + h'(z)$ but $f_z(x, y, z) = xye^{yz}$ so $h(z) = K$ and a potential function for $\mathbf{F}$ is $f(x, y, z) = xe^{yz} + K$.

18. $\operatorname{curl}\mathbf{F} = \nabla\times\mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \partial/\partial x & \partial/\partial y & \partial/\partial z \\ e^x \sin yz & ze^x \cos yz & ye^x \cos yz \end{vmatrix}$

$$= [-yze^x \sin yz + e^x \cos yz - (-yze^x \sin yz + e^x \cos yz)]\,\mathbf{i} - (ye^x \cos yz - ye^x \cos yz)\,\mathbf{j} + (ze^x \cos yz - ze^x \cos yz)\,\mathbf{k} = \mathbf{0}$$

$\mathbf{F}$ is defined on all of $\mathbb{R}^3$, and the partial derivatives of the component functions are continuous, so $\mathbf{F}$ is conservative. Thus there exists a function f such that $\nabla f = \mathbf{F}$. Then $f_x(x,y,z) = e^x \sin yz$ implies $f(x,y,z) = e^x \sin yz + g(y,z) \quad\Rightarrow$ $f_y(x,y,z) = ze^x \cos yz + g_y(y,z)$. But $f_y(x,y,z) = ze^x \cos yz$, so $g(y,z) = h(z)$ and $f(x,y,z) = e^x \sin yz + h(z)$. Thus $f_z(x,y,z) = ye^x \cos yz + h'(z)$ but $f_z(x,y,z) = ye^x \cos yz$ so $h(z) = K$ and a potential function for $\mathbf{F}$ is $f(x,y,z) = e^x \sin yz + K$.

19. No. Assume there is such a $\mathbf{G}$. Then $\operatorname{div}(\operatorname{curl}\mathbf{G}) = \dfrac{\partial}{\partial x}(x\sin y) + \dfrac{\partial}{\partial y}(\cos y) + \dfrac{\partial}{\partial z}(z - xy) = \sin y - \sin y + 1 \neq 0$, which contradicts Theorem 11.

20. No. Assume there is such a $\mathbf{G}$. Then $\operatorname{div}(\operatorname{curl}\mathbf{G}) = \dfrac{\partial}{\partial x}(x) + \dfrac{\partial}{\partial y}(y) + \dfrac{\partial}{\partial z}(z) = 1 + 1 + 1 \neq 0$ which contradicts Theorem 11.

21. $\operatorname{curl}\mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \partial/\partial x & \partial/\partial y & \partial/\partial z \\ f(x) & g(y) & h(z) \end{vmatrix} = (0-0)\,\mathbf{i} + (0-0)\,\mathbf{j} + (0-0)\,\mathbf{k} = \mathbf{0}$. Hence $\mathbf{F} = f(x)\,\mathbf{i} + g(y)\,\mathbf{j} + h(z)\,\mathbf{k}$ is irrotational.

22. $\operatorname{div}\mathbf{F} = \dfrac{\partial}{\partial x}(f(y,z)) + \dfrac{\partial}{\partial y}(g(x,z)) + \dfrac{\partial}{\partial z}(h(x,y)) = 0$ so $\mathbf{F}$ is incompressible.

For Exercises 23–29, let $\mathbf{F}(x,y,z) = P_1\,\mathbf{i} + Q_1\,\mathbf{j} + R_1\,\mathbf{k}$ and $\mathbf{G}(x,y,z) = P_2\,\mathbf{i} + Q_2\,\mathbf{j} + R_2\,\mathbf{k}$.

23. $\operatorname{div}(\mathbf{F}+\mathbf{G}) = \operatorname{div}\langle P_1 + P_2, Q_1 + Q_2, R_1 + R_2\rangle = \dfrac{\partial(P_1+P_2)}{\partial x} + \dfrac{\partial(Q_1+Q_2)}{\partial y} + \dfrac{\partial(R_1+R_2)}{\partial z}$

$$= \frac{\partial P_1}{\partial x} + \frac{\partial P_2}{\partial x} + \frac{\partial Q_1}{\partial y} + \frac{\partial Q_2}{\partial y} + \frac{\partial R_1}{\partial z} + \frac{\partial R_2}{\partial z} = \left(\frac{\partial P_1}{\partial x} + \frac{\partial Q_1}{\partial y} + \frac{\partial R_1}{\partial z}\right) + \left(\frac{\partial P_2}{\partial x} + \frac{\partial Q_2}{\partial y} + \frac{\partial R_2}{\partial z}\right)$$

$$= \operatorname{div}\langle P_1, Q_1, R_1\rangle + \operatorname{div}\langle P_2, Q_2, R_2\rangle = \operatorname{div}\mathbf{F} + \operatorname{div}\mathbf{G}$$

24. $\operatorname{curl}\mathbf{F} + \operatorname{curl}\mathbf{G} = \left[\left(\dfrac{\partial R_1}{\partial y} - \dfrac{\partial Q_1}{\partial z}\right)\mathbf{i} + \left(\dfrac{\partial P_1}{\partial z} - \dfrac{\partial R_1}{\partial x}\right)\mathbf{j} + \left(\dfrac{\partial Q_1}{\partial x} - \dfrac{\partial P_1}{\partial y}\right)\mathbf{k}\right]$

$$+ \left[\left(\frac{\partial R_2}{\partial y} - \frac{\partial Q_2}{\partial z}\right)\mathbf{i} + \left(\frac{\partial P_2}{\partial z} - \frac{\partial R_2}{\partial x}\right)\mathbf{j} + \left(\frac{\partial Q_2}{\partial x} - \frac{\partial P_2}{\partial y}\right)\mathbf{k}\right]$$

$$= \left[\frac{\partial(R_1+R_2)}{\partial y} - \frac{\partial(Q_1+Q_2)}{\partial z}\right]\mathbf{i} + \left[\frac{\partial(P_1+P_2)}{\partial z} - \frac{\partial(R_1+R_2)}{\partial x}\right]\mathbf{j}$$

$$+ \left[\frac{\partial(Q_1+Q_2)}{\partial x} - \frac{\partial(P_1+P_2)}{\partial y}\right]\mathbf{k} = \operatorname{curl}(\mathbf{F}+\mathbf{G})$$

25. $\operatorname{div}(f\mathbf{F}) = \operatorname{div}(f\langle P_1, Q_1, R_1\rangle) = \operatorname{div}\langle fP_1, fQ_1, fR_1\rangle = \dfrac{\partial(fP_1)}{\partial x} + \dfrac{\partial(fQ_1)}{\partial y} + \dfrac{\partial(fR_1)}{\partial z}$

$$= \left(f\,\frac{\partial P_1}{\partial x} + P_1\,\frac{\partial f}{\partial x}\right) + \left(f\,\frac{\partial Q_1}{\partial y} + Q_1\,\frac{\partial f}{\partial y}\right) + \left(f\,\frac{\partial R_1}{\partial z} + R_1\,\frac{\partial f}{\partial z}\right)$$

$$= f\left(\frac{\partial P_1}{\partial x} + \frac{\partial Q_1}{\partial y} + \frac{\partial R_1}{\partial z}\right) + \langle P_1, Q_1, R_1\rangle \cdot \left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}, \frac{\partial f}{\partial z}\right\rangle = f\operatorname{div}\mathbf{F} + \mathbf{F}\cdot\nabla f$$

26. $\operatorname{curl}(f\mathbf{F}) = \left[\dfrac{\partial(fR_1)}{\partial y} - \dfrac{\partial(fQ_1)}{\partial z}\right]\mathbf{i} + \left[\dfrac{\partial(fP_1)}{\partial z} - \dfrac{\partial(fR_1)}{\partial x}\right]\mathbf{j} + \left[\dfrac{\partial(fQ_1)}{\partial x} - \dfrac{\partial(fP_1)}{\partial y}\right]\mathbf{k}$

$$= \left[f\,\frac{\partial R_1}{\partial y} + R_1\,\frac{\partial f}{\partial y} - f\,\frac{\partial Q_1}{\partial z} - Q_1\,\frac{\partial f}{\partial z}\right]\mathbf{i} + \left[f\,\frac{\partial P_1}{\partial z} + P_1\,\frac{\partial f}{\partial z} - f\,\frac{\partial R_1}{\partial x} - R_1\,\frac{\partial f}{\partial x}\right]\mathbf{j}$$

$$+ \left[f\,\frac{\partial Q_1}{\partial x} + Q_1\,\frac{\partial f}{\partial x} - f\,\frac{\partial P_1}{\partial y} - P_1\,\frac{\partial f}{\partial y}\right]\mathbf{k}$$

$$= f\left[\frac{\partial R_1}{\partial y} - \frac{\partial Q_1}{\partial z}\right]\mathbf{i} + f\left[\frac{\partial P_1}{\partial z} - \frac{\partial R_1}{\partial x}\right]\mathbf{j} + f\left[\frac{\partial Q_1}{\partial x} - \frac{\partial P_1}{\partial y}\right]\mathbf{k}$$

$$+ \left[R_1\frac{\partial f}{\partial y} - Q_1\frac{\partial f}{\partial z}\right]\mathbf{i} + \left[P_1\frac{\partial f}{\partial z} - R_1\frac{\partial f}{\partial x}\right]\mathbf{j} + \left[Q_1\frac{\partial f}{\partial x} - P_1\frac{\partial f}{\partial y}\right]\mathbf{k}$$

$$= f\operatorname{curl}\mathbf{F} + (\nabla f)\times\mathbf{F}$$

27. $\operatorname{div}(\mathbf{F}\times\mathbf{G}) = \nabla\cdot(\mathbf{F}\times\mathbf{G}) = \begin{vmatrix} \partial/\partial x & \partial/\partial y & \partial/\partial z \\ P_1 & Q_1 & R_1 \\ P_2 & Q_2 & R_2 \end{vmatrix} = \dfrac{\partial}{\partial x}\begin{vmatrix} Q_1 & R_1 \\ Q_2 & R_2 \end{vmatrix} - \dfrac{\partial}{\partial y}\begin{vmatrix} P_1 & R_1 \\ P_2 & R_2 \end{vmatrix} + \dfrac{\partial}{\partial z}\begin{vmatrix} P_1 & Q_1 \\ P_2 & Q_2 \end{vmatrix}$

$$= \left[Q_1\,\frac{\partial R_2}{\partial x} + R_2\,\frac{\partial Q_1}{\partial x} - Q_2\,\frac{\partial R_1}{\partial x} - R_1\,\frac{\partial Q_2}{\partial x}\right] - \left[P_1\,\frac{\partial R_2}{\partial y} + R_2\,\frac{\partial P_1}{\partial y} - P_2\,\frac{\partial R_1}{\partial y} - R_1\,\frac{\partial P_2}{\partial y}\right]$$

$$+ \left[P_1\,\frac{\partial Q_2}{\partial z} + Q_2\,\frac{\partial P_1}{\partial z} - P_2\,\frac{\partial Q_1}{\partial z} - Q_1\,\frac{\partial P_2}{\partial z}\right]$$

$$= \left[P_2\left(\frac{\partial R_1}{\partial y} - \frac{\partial Q_1}{\partial z}\right) + Q_2\left(\frac{\partial P_1}{\partial z} - \frac{\partial R_1}{\partial x}\right) + R_2\left(\frac{\partial Q_1}{\partial x} - \frac{\partial P_1}{\partial y}\right)\right]$$

$$- \left[P_1\left(\frac{\partial R_2}{\partial y} - \frac{\partial Q_2}{\partial z}\right) + Q_1\left(\frac{\partial P_2}{\partial z} - \frac{\partial R_2}{\partial x}\right) + R_1\left(\frac{\partial Q_2}{\partial x} - \frac{\partial P_2}{\partial y}\right)\right]$$

$$= \mathbf{G}\cdot\operatorname{curl}\mathbf{F} - \mathbf{F}\cdot\operatorname{curl}\mathbf{G}$$

28. $\operatorname{div}(\nabla f\times\nabla g) = \nabla g\cdot\operatorname{curl}(\nabla f) - \nabla f\cdot\operatorname{curl}(\nabla g)$ [by Exercise 27] $= 0$ [by Theorem 3]

29. $\operatorname{curl}(\operatorname{curl}\mathbf{F}) = \nabla\times(\nabla\times\mathbf{F}) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \partial/\partial x & \partial/\partial y & \partial/\partial z \\ \partial R_1/\partial y - \partial Q_1/\partial z & \partial P_1/\partial z - \partial R_1/\partial x & \partial Q_1/\partial x - \partial P_1/\partial y \end{vmatrix}$

$$= \left(\frac{\partial^2 Q_1}{\partial y\partial x} - \frac{\partial^2 P_1}{\partial y^2} - \frac{\partial^2 P_1}{\partial z^2} + \frac{\partial^2 R_1}{\partial z\partial x}\right)\mathbf{i} + \left(\frac{\partial^2 R_1}{\partial z\partial y} - \frac{\partial^2 Q_1}{\partial z^2} - \frac{\partial^2 Q_1}{\partial x^2} + \frac{\partial^2 P_1}{\partial x\partial y}\right)\mathbf{j}$$

$$+ \left(\frac{\partial^2 P_1}{\partial x\partial z} - \frac{\partial^2 R_1}{\partial x^2} - \frac{\partial^2 R_1}{\partial y^2} + \frac{\partial^2 Q_1}{\partial y\partial z}\right)\mathbf{k}$$

Now let's consider $\operatorname{grad}(\operatorname{div}\mathbf{F}) - \nabla^2\mathbf{F}$ and compare with the above.

(Note that $\nabla^2\mathbf{F}$ is defined on page 1147 [ET 1107].)

$$\operatorname{grad}(\operatorname{div}\mathbf{F}) - \nabla^2\mathbf{F} = \left[\left(\frac{\partial^2 P_1}{\partial x^2} + \frac{\partial^2 Q_1}{\partial x\partial y} + \frac{\partial^2 R_1}{\partial x\partial z}\right)\mathbf{i} + \left(\frac{\partial^2 P_1}{\partial y\partial x} + \frac{\partial^2 Q_1}{\partial y^2} + \frac{\partial^2 R_1}{\partial y\partial z}\right)\mathbf{j} + \left(\frac{\partial^2 P_1}{\partial z\partial x} + \frac{\partial^2 Q_1}{\partial z\partial y} + \frac{\partial^2 R_1}{\partial z^2}\right)\mathbf{k}\right]$$

$$- \left[\left(\frac{\partial^2 P_1}{\partial x^2} + \frac{\partial^2 P_1}{\partial y^2} + \frac{\partial^2 P_1}{\partial z^2}\right)\mathbf{i} + \left(\frac{\partial^2 Q_1}{\partial x^2} + \frac{\partial^2 Q_1}{\partial y^2} + \frac{\partial^2 Q_1}{\partial z^2}\right)\mathbf{j}\right.$$

$$\left. + \left(\frac{\partial^2 R_1}{\partial x^2} + \frac{\partial^2 R_1}{\partial y^2} + \frac{\partial^2 R_1}{\partial z^2}\right)\mathbf{k}\right]$$

$$= \left(\frac{\partial^2 Q_1}{\partial x\partial y} + \frac{\partial^2 R_1}{\partial x\partial z} - \frac{\partial^2 P_1}{\partial y^2} - \frac{\partial^2 P_1}{\partial z^2}\right)\mathbf{i} + \left(\frac{\partial^2 P_1}{\partial y\partial x} + \frac{\partial^2 R_1}{\partial y\partial z} - \frac{\partial^2 Q_1}{\partial x^2} - \frac{\partial^2 Q_1}{\partial z^2}\right)\mathbf{j}$$

$$+ \left(\frac{\partial^2 P_1}{\partial z\partial x} + \frac{\partial^2 Q_1}{\partial z\partial y} - \frac{\partial^2 R_1}{\partial x^2} - \frac{\partial^2 R_2}{\partial y^2}\right)\mathbf{k}$$

Then applying Clairaut's Theorem to reverse the order of differentiation in the second partial derivatives as needed and comparing, we have $\operatorname{curl}\operatorname{curl}\mathbf{F} = \operatorname{grad}\operatorname{div}\mathbf{F} - \nabla^2\mathbf{F}$ as desired.

30. (a) $\nabla\cdot\mathbf{r} = \left(\frac{\partial}{\partial x}\,\mathbf{i} + \frac{\partial}{\partial y}\,\mathbf{j} + \frac{\partial}{\partial z}\,\mathbf{k}\right)\cdot(x\,\mathbf{i} + y\,\mathbf{j} + z\,\mathbf{k}) = 1 + 1 + 1 = 3$

(b) $\nabla\cdot(r\mathbf{r}) = \nabla\cdot\sqrt{x^2+y^2+z^2}\,(x\,\mathbf{i} + y\,\mathbf{j} + z\,\mathbf{k})$

$$= \left(\frac{x^2}{\sqrt{x^2+y^2+z^2}} + \sqrt{x^2+y^2+z^2}\right) + \left(\frac{y^2}{\sqrt{x^2+y^2+z^2}} + \sqrt{x^2+y^2+z^2}\right) + \left(\frac{z^2}{\sqrt{x^2+y^2+z^2}} + \sqrt{x^2+y^2+z^2}\right)$$

$$= \frac{1}{\sqrt{x^2+y^2+z^2}}\,(4x^2+4y^2+4z^2) = 4\sqrt{x^2+y^2+z^2} = 4r$$

Another method:

By Exercise 25, $\nabla\cdot(r\mathbf{r}) = \operatorname{div}(r\mathbf{r}) = r\operatorname{div}\mathbf{r} + \mathbf{r}\cdot\nabla r = 3r + \mathbf{r}\cdot\dfrac{\mathbf{r}}{r}$ [see Exercise 31(a) below] $= 4r$.

(c) $\nabla^2 r^3 = \nabla^2\left(x^2+y^2+z^2\right)^{3/2}$

$$= \tfrac{\partial}{\partial x}\left[\tfrac{3}{2}(x^2+y^2+z^2)^{1/2}(2x)\right] + \tfrac{\partial}{\partial y}\left[\tfrac{3}{2}(x^2+y^2+z^2)^{1/2}(2y)\right] + \tfrac{\partial}{\partial z}\left[\tfrac{3}{2}(x^2+y^2+z^2)^{1/2}(2z)\right]$$

$$= 3\left[\tfrac{1}{2}(x^2+y^2+z^2)^{-1/2}(2x)(x) + (x^2+y^2+z^2)^{1/2}\right]$$

$$+ 3\left[\tfrac{1}{2}(x^2+y^2+z^2)^{-1/2}(2y)(y) + (x^2+y^2+z^2)^{1/2}\right]$$

$$+ 3\left[\tfrac{1}{2}(x^2+y^2+z^2)^{-1/2}(2z)(z) + (x^2+y^2+z^2)^{1/2}\right]$$

$$= 3(x^2+y^2+z^2)^{-1/2}(4x^2+4y^2+4z^2) = 12(x^2+y^2+z^2)^{1/2} = 12r$$

Another method: $\frac{\partial}{\partial x}\,(x^2+y^2+z^2)^{3/2} = 3x\sqrt{x^2+y^2+z^2} \;\Rightarrow\; \nabla r^3 = 3r(x\,\mathbf{i} + y\,\mathbf{j} + z\,\mathbf{k}) = 3r\,\mathbf{r}$,

so $\nabla^2 r^3 = \nabla\cdot\nabla r^3 = \nabla\cdot(3r\,\mathbf{r}) = 3(4r) = 12r$ by part (b).

31. (a) $\nabla r = \nabla\sqrt{x^2+y^2+z^2} = \dfrac{x}{\sqrt{x^2+y^2+z^2}}\,\mathbf{i} + \dfrac{y}{\sqrt{x^2+y^2+z^2}}\,\mathbf{j} + \dfrac{z}{\sqrt{x^2+y^2+z^2}}\,\mathbf{k} = \dfrac{x\,\mathbf{i}+y\,\mathbf{j}+z\,\mathbf{k}}{\sqrt{x^2+y^2+z^2}} = \dfrac{\mathbf{r}}{r}$

(b) $\nabla\times\mathbf{r} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \dfrac{\partial}{\partial x} & \dfrac{\partial}{\partial y} & \dfrac{\partial}{\partial z} \\ x & y & z \end{vmatrix} = \left[\dfrac{\partial}{\partial y}(z) - \dfrac{\partial}{\partial z}(y)\right]\mathbf{i} + \left[\dfrac{\partial}{\partial z}(x) - \dfrac{\partial}{\partial x}(z)\right]\mathbf{j} + \left[\dfrac{\partial}{\partial x}(y) - \dfrac{\partial}{\partial y}(x)\right]\mathbf{k} = \mathbf{0}$

(c)
$$\nabla\left(\frac{1}{r}\right) = \nabla\left(\frac{1}{\sqrt{x^2+y^2+z^2}}\right)$$
$$= \frac{-\dfrac{1}{2\sqrt{x^2+y^2+z^2}}(2x)}{x^2+y^2+z^2}\,\mathbf{i} - \frac{\dfrac{1}{2\sqrt{x^2+y^2+z^2}}(2y)}{x^2+y^2+z^2}\,\mathbf{j} - \frac{\dfrac{1}{2\sqrt{x^2+y^2+z^2}}(2z)}{x^2+y^2+z^2}\,\mathbf{k}$$
$$= -\frac{x\,\mathbf{i}+y\,\mathbf{j}+z\,\mathbf{k}}{(x^2+y^2+z^2)^{3/2}} = -\frac{\mathbf{r}}{r^3}$$

(d)
$$\nabla\ln r = \nabla\ln(x^2+y^2+z^2)^{1/2} = \tfrac{1}{2}\nabla\ln(x^2+y^2+z^2)$$
$$= \frac{x}{x^2+y^2+z^2}\,\mathbf{i} + \frac{y}{x^2+y^2+z^2}\,\mathbf{j} + \frac{z}{x^2+y^2+z^2}\,\mathbf{k} = \frac{x\,\mathbf{i}+y\,\mathbf{j}+z\,\mathbf{k}}{x^2+y^2+z^2} = \frac{\mathbf{r}}{r^2}$$

32. $\mathbf{r} = x\,\mathbf{i}+y\,\mathbf{j}+z\,\mathbf{k} \;\Rightarrow\; r = |\mathbf{r}| = \sqrt{x^2+y^2+z^2}$, so

$$\mathbf{F} = \frac{\mathbf{r}}{r^p} = \frac{x}{(x^2+y^2+z^2)^{p/2}}\,\mathbf{i} + \frac{y}{(x^2+y^2+z^2)^{p/2}}\,\mathbf{j} + \frac{z}{(x^2+y^2+z^2)^{p/2}}\,\mathbf{k}$$

Then $\dfrac{\partial}{\partial x}\dfrac{x}{(x^2+y^2+z^2)^{p/2}} = \dfrac{(x^2+y^2+z^2)-px^2}{(x^2+y^2+z^2)^{1+p/2}} = \dfrac{r^2-px^2}{r^{p+2}}$. Similarly,

$\dfrac{\partial}{\partial y}\dfrac{y}{(x^2+y^2+z^2)^{p/2}} = \dfrac{r^2-py^2}{r^{p+2}}$ and $\dfrac{\partial}{\partial z}\dfrac{z}{(x^2+y^2+z^2)^{p/2}} = \dfrac{r^2-pz^2}{r^{p+2}}$. Thus

$$\operatorname{div}\mathbf{F} = \nabla\cdot\mathbf{F} = \frac{r^2-px^2}{r^{p+2}} + \frac{r^2-py^2}{r^{p+2}} + \frac{r^2-pz^2}{r^{p+2}} = \frac{3r^2-px^2-py^2-pz^2}{r^{p+2}}$$
$$= \frac{3r^2-p(x^2+y^2+z^2)}{r^{p+2}} = \frac{3r^2-pr^2}{r^{p+2}} = \frac{3-p}{r^p}$$

Consequently, if $p=3$ we have $\operatorname{div}\mathbf{F}=0$.

33. By (13), $\oint_C f(\nabla g)\cdot\mathbf{n}\,ds = \iint_D \operatorname{div}(f\nabla g)\,dA = \iint_D [f\operatorname{div}(\nabla g) + \nabla g\cdot\nabla f]\,dA$ by Exercise 25. But $\operatorname{div}(\nabla g) = \nabla^2 g$.

Hence $\iint_D f\nabla^2 g\,dA = \oint_C f(\nabla g)\cdot\mathbf{n}\,ds - \iint_D \nabla g\cdot\nabla f\,dA$.

34. By Exercise 33, $\iint_D f\nabla^2 g\,dA = \oint_C f(\nabla g)\cdot\mathbf{n}\,ds - \iint_D \nabla g\cdot\nabla f\,dA$ and

$\iint_D g\nabla^2 f\,dA = \oint_C g(\nabla f)\cdot\mathbf{n}\,ds - \iint_D \nabla f\cdot\nabla g\,dA$. Hence

$\iint_D \left(f\nabla^2 g - g\nabla^2 f\right)dA = \oint_C [f(\nabla g)\cdot\mathbf{n} - g(\nabla f)\cdot\mathbf{n}]\,ds + \iint_D (\nabla f\cdot\nabla g - \nabla g\cdot\nabla f)\,dA = \oint_C [f\nabla g - g\nabla f]\cdot\mathbf{n}\,ds$.

35. Let $f(x,y)=1$. Then $\nabla f = \mathbf{0}$ and Green's first identity (see Exercise 33) says

$\iint_D \nabla^2 g\,dA = \oint_C (\nabla g)\cdot\mathbf{n}\,ds - \iint_D \mathbf{0}\cdot\nabla g\,dA \;\Rightarrow\; \iint_D \nabla^2 g\,dA = \oint_C \nabla g\cdot\mathbf{n}\,ds$. But g is harmonic on D, so

$\nabla^2 g = 0 \;\Rightarrow\; \oint_C \nabla g\cdot\mathbf{n}\,ds = 0$ and $\oint_C D_{\mathbf{n}} g\,ds = \oint_C (\nabla g\cdot\mathbf{n})\,ds = 0$.

36. Let $g = f$. Then Green's first identity (see Exercise 33) says $\iint_D f\,\nabla^2 f\,dA = \oint_C (f)(\nabla f)\cdot\mathbf{n}\,ds - \iint_D \nabla f\cdot\nabla f\,dA$. But f is harmonic, so $\nabla^2 f = 0$, and $\nabla f\cdot\nabla f = |\nabla f|^2$, so we have $0 = \oint_C (f)(\nabla f)\cdot\mathbf{n}\,ds - \iint_D |\nabla f|^2\,dA \;\Rightarrow$ $\iint_D |\nabla f|^2\,dA = \oint_C (f)(\nabla f)\cdot\mathbf{n}\,ds = 0$ since $f(x,y) = 0$ on C.

37. (a) We know that $\omega = v/d$, and from the diagram $\sin\theta = d/r \;\Rightarrow\; v = d\omega = (\sin\theta)r\omega = |\mathbf{w}\times\mathbf{r}|$. But $\mathbf{v}$ is perpendicular to both $\mathbf{w}$ and $\mathbf{r}$, so that $\mathbf{v} = \mathbf{w}\times\mathbf{r}$.

(b) From (a), $\mathbf{v} = \mathbf{w}\times\mathbf{r} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 0 & 0 & \omega \\ x & y & z \end{vmatrix} = (0\cdot z - \omega y)\,\mathbf{i} + (\omega x - 0\cdot z)\,\mathbf{j} + (0\cdot y - x\cdot 0)\,\mathbf{k} = -\omega y\,\mathbf{i} + \omega x\,\mathbf{j}$

(c)
$$\operatorname{curl}\mathbf{v} = \nabla\times\mathbf{v} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \partial/\partial x & \partial/\partial y & \partial/\partial z \\ -\omega y & \omega x & 0 \end{vmatrix}$$
$$= \left[\frac{\partial}{\partial y}(0) - \frac{\partial}{\partial z}(\omega x)\right]\mathbf{i} + \left[\frac{\partial}{\partial z}(-\omega y) - \frac{\partial}{\partial x}(0)\right]\mathbf{j} + \left[\frac{\partial}{\partial x}(\omega x) - \frac{\partial}{\partial y}(-\omega y)\right]\mathbf{k}$$
$$= [\omega - (-\omega)]\,\mathbf{k} = 2\omega\,\mathbf{k} = 2\mathbf{w}$$

38. Let $\mathbf{H} = \langle h_1, h_2, h_3\rangle$ and $\mathbf{E} = \langle E_1, E_2, E_3\rangle$.

(a)
$$\nabla\times(\nabla\times\mathbf{E}) = \nabla\times(\operatorname{curl}\mathbf{E}) = \nabla\times\left(-\frac{1}{c}\frac{\partial\mathbf{H}}{\partial t}\right) = -\frac{1}{c}\begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \partial/\partial x & \partial/\partial y & \partial/\partial z \\ \partial h_1/\partial t & \partial h_2/\partial t & \partial h_3/\partial t \end{vmatrix}$$
$$= -\frac{1}{c}\left[\left(\frac{\partial^2 h_3}{\partial y\,\partial t} - \frac{\partial^2 h_2}{\partial z\,\partial t}\right)\mathbf{i} + \left(\frac{\partial^2 h_1}{\partial z\,\partial t} - \frac{\partial^2 h_3}{\partial x\,\partial t}\right)\mathbf{j} + \left(\frac{\partial^2 h_2}{\partial x\,\partial t} - \frac{\partial^2 h_1}{\partial y\,\partial t}\right)\mathbf{k}\right]$$
$$= -\frac{1}{c}\frac{\partial}{\partial t}\left[\left(\frac{\partial h_3}{\partial y} - \frac{\partial h_2}{\partial z}\right)\mathbf{i} + \left(\frac{\partial h_1}{\partial z} - \frac{\partial h_3}{\partial x}\right)\mathbf{j} + \left(\frac{\partial h_2}{\partial x} - \frac{\partial h_1}{\partial y}\right)\mathbf{k}\right]$$
[assuming that the partial derivatives are continuous so that the order of differentiation does not matter]
$$= -\frac{1}{c}\frac{\partial}{\partial t}\operatorname{curl}\mathbf{H} = -\frac{1}{c}\frac{\partial}{\partial t}\left(\frac{1}{c}\frac{\partial\mathbf{E}}{\partial t}\right) = -\frac{1}{c^2}\frac{\partial^2\mathbf{E}}{\partial t^2}$$

(b)
$$\nabla\times(\nabla\times\mathbf{H}) = \nabla\times(\operatorname{curl}\mathbf{H}) = \nabla\times\left(\frac{1}{c}\frac{\partial\mathbf{E}}{\partial t}\right) = \frac{1}{c}\begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \partial/\partial x & \partial/\partial y & \partial/\partial z \\ \partial E_1/\partial t & \partial E_2/\partial t & \partial E_3/\partial t \end{vmatrix}$$
$$= \frac{1}{c}\left[\left(\frac{\partial^2 E_3}{\partial y\,\partial t} - \frac{\partial^2 E_2}{\partial z\,\partial t}\right)\mathbf{i} + \left(\frac{\partial^2 E_1}{\partial z\,\partial t} - \frac{\partial^2 E_3}{\partial x\,\partial t}\right)\mathbf{j} + \left(\frac{\partial^2 E_2}{\partial x\,\partial t} - \frac{\partial^2 E_1}{\partial y\,\partial t}\right)\mathbf{k}\right]$$
$$= \frac{1}{c}\frac{\partial}{\partial t}\left[\left(\frac{\partial E_3}{\partial y} - \frac{\partial E_2}{\partial z}\right)\mathbf{i} + \left(\frac{\partial E_1}{\partial z} - \frac{\partial E_3}{\partial x}\right)\mathbf{j} + \left(\frac{\partial E_2}{\partial x} - \frac{\partial E_1}{\partial y}\right)\mathbf{k}\right]$$
[assuming that the partial derivatives are continuous so that the order of differentiation does not matter]
$$= \frac{1}{c}\frac{\partial}{\partial t}\operatorname{curl}\mathbf{E} = \frac{1}{c}\frac{\partial}{\partial t}\left(-\frac{1}{c}\frac{\partial\mathbf{H}}{\partial t}\right) = -\frac{1}{c^2}\frac{\partial^2\mathbf{H}}{\partial t^2}$$

(c) Using Exercise 29, we have that $\operatorname{curl}\operatorname{curl}\mathbf{E} = \operatorname{grad}\operatorname{div}\mathbf{E} - \nabla^2\mathbf{E} \Rightarrow$

$$\nabla^2\mathbf{E} = \operatorname{grad}\operatorname{div}\mathbf{E} - \operatorname{curl}\operatorname{curl}\mathbf{E} = \operatorname{grad} 0 + \frac{1}{c^2}\frac{\partial^2\mathbf{E}}{\partial t^2} \quad \text{[from part (a)]} \quad = \frac{1}{c^2}\frac{\partial^2\mathbf{E}}{\partial t^2}.$$

(d) As in part (c), $\nabla^2\mathbf{H} = \operatorname{grad}\operatorname{div}\mathbf{H} - \operatorname{curl}\operatorname{curl}\mathbf{H} = \operatorname{grad} 0 + \dfrac{1}{c^2}\dfrac{\partial^2\mathbf{H}}{\partial t^2}$ [using part (b)] $= \dfrac{1}{c^2}\dfrac{\partial^2\mathbf{H}}{\partial t^2}$.

39. For any continuous function f on $\mathbb{R}^3$, define a vector field $\mathbf{G}(x,y,z) = \langle g(x,y,z), 0, 0\rangle$ where $g(x,y,z) = \int_0^x f(t,y,z)\,dt$.
Then $\operatorname{div}\mathbf{G} = \dfrac{\partial}{\partial x}(g(x,y,z)) + \dfrac{\partial}{\partial y}(0) + \dfrac{\partial}{\partial z}(0) = \dfrac{\partial}{\partial x}\int_0^x f(t,y,z)\,dt = f(x,y,z)$ by the Fundamental Theorem of Calculus. Thus every continuous function f on $\mathbb{R}^3$ is the divergence of some vector field.

16.6 Parametric Surfaces and Their Areas

1. $P(4,-5,1)$ lies on the parametric surface $\mathbf{r}(u,v) = \langle u+v, u-2v, 3+u-v\rangle$ if and only if there are values for u and v where $u+v=4$, $u-2v=-5$, and $3+u-v=1$. From the first equation we have $u = 4-v$ and substituting into the second equation gives $4-v-2v=-5 \Leftrightarrow v=3$. Then $u=1$, and these values satisfy the third equation, so P does lie on the surface.

$Q(0,4,6)$ lies on $\mathbf{r}(u,v)$ if and only if $u+v=0$, $u-2v=4$, and $3+u-v=6$, but solving the first two equations simultaneoulsy gives $u=\frac{4}{3}$, $v=-\frac{4}{3}$ and these values do not satisfy the third equation, so Q does not lie on the surface.

2. $P(1,2,1)$ lies on the parametric surface $\mathbf{r}(u,v) = \left\langle 1+u-v, u+v^2, u^2-v^2\right\rangle$ if and only if there are values for u and v where $1+u-v=1$, $u+v^2=2$, and $u^2-v^2=1$. From the first equation we have $u=v$ and substituting into the third equation gives $0=1$, an impossibility, so P does not lie on the surface.

$Q(2,3,3)$ lies on $\mathbf{r}(u,v)$ if and only if $1+u-v=2$, $u+v^2=3$, and $u^2-v^2=3$. From the first equation we have $u=v+1$ and substituting into the second equation gives $v+1+v^2=3 \Leftrightarrow v^2+v-2=0 \Leftrightarrow (v+2)(v-1)=0$, so $v=-2 \Rightarrow u=-1$ or $v=1 \Rightarrow u=2$. The third equation is satisfied by $u=2$, $v=1$ so Q does lie on the surface.

3. $\mathbf{r}(u,v) = (u+v)\,\mathbf{i} + (3-v)\,\mathbf{j} + (1+4u+5v)\,\mathbf{k} = \langle 0,3,1\rangle + u\,\langle 1,0,4\rangle + v\,\langle 1,-1,5\rangle$. From Example 3, we recognize this as a vector equation of a plane through the point $(0,3,1)$ and containing vectors $\mathbf{a} = \langle 1,0,4\rangle$ and $\mathbf{b} = \langle 1,-1,5\rangle$. If we wish to find a more conventional equation for the plane, a normal vector to the plane is $\mathbf{a}\times\mathbf{b} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 0 & 4 \\ 1 & -1 & 5 \end{vmatrix} = 4\,\mathbf{i} - \mathbf{j} - \mathbf{k}$

and an equation of the plane is $4(x-0)-(y-3)-(z-1)=0$ or $4x-y-z=-4$.

4. $\mathbf{r}(u,v) = u^2\,\mathbf{i} + u\cos v\,\mathbf{j} + u\sin v\,\mathbf{k}$, so the corresponding parametric equations for the surface are $x=u^2$, $y=u\cos v$, $z=u\sin v$. For any point (x,y,z) on the surface, we have $y^2+z^2 = u^2\cos^2 v + u^2\sin^2 v = u^2 = x$. Since no restrictions are placed on the parameters, the surface is $x = y^2+z^2$, which we recognize as a circular paraboloid whose axis is the x-axis.

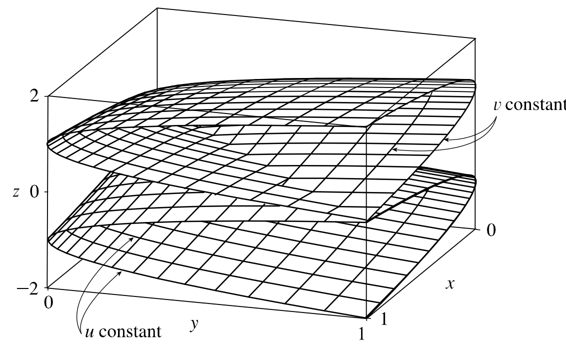
5. $\mathbf{r}(s,t) = \langle s\cos t, s\sin t, s\rangle$, so the corresponding parametric equations for the surface are $x = s\cos t,\ \ y = s\sin t,\ \ z = s$. For any point (x,y,z) on the surface, we have $x^2 + y^2 = s^2\cos^2 t + s^2\sin^2 t = s^2 = z^2$. Since no restrictions are placed on the parameters, the surface is $z^2 = x^2 + y^2$, which we recognize as a circular cone with axis the z-axis.

6. $\mathbf{r}(s,t) = \langle 3\cos t, s, \sin t\rangle$, so the corresponding parametric equations for the surface are $x = 3\cos t,\ \ y = s,\ \ z = \sin t$. For any point (x,y,z) on the surface, we have $(x/3)^2 + z^2 = \cos^2 t + \sin^2 t = 1$, so vertical cross-sections parallel to the xz-plane are all identical ellipses. Since $y = s$ and $-1 \le s \le 1$, the surface is the portion of the elliptic cylinder $\frac{1}{9}x^2 + z^2 = 1$ corresponding to $-1 \le y \le 1$.

7. $\mathbf{r}(u,v) = \langle u^2, v^2, u+v\rangle,\ \ -1 \le u \le 1,\ \ -1 \le v \le 1.$

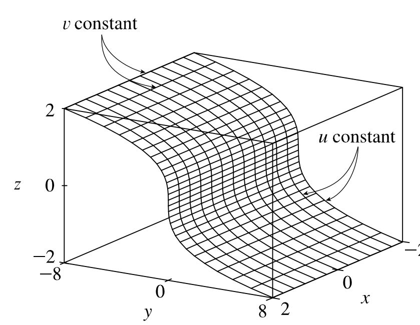
The surface has parametric equations $x = u^2$, $y = v^2$, $z = u + v$, $-1 \le u \le 1$, $-1 \le v \le 1$.

In Maple, the surface can be graphed by entering `plot3d([u^2,v^2,u+v],u=-1..1,v=-1..1);`. In Mathematica we use the `ParametricPlot3D` command. If we keep u constant at u_0, $x = u_0^2$, a constant, so the corresponding grid curves must be the curves parallel to the yz-plane. If v is constant, we have $y = v_0^2$, a constant, so these grid curves are the curves parallel to the xz-plane.



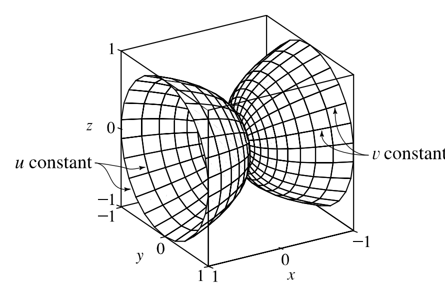
8. $\mathbf{r}(u,v) = \langle u, v^3, -v\rangle,\ \ -2 \le u \le 2,\ \ -2 \le v \le 2.$

The surface has parametric equations $x = u$, $y = v^3$, $z = -v$, $-2 \le u \le 2$, $-2 \le v \le 2$. If $u = u_0$ is constant, $x = u_0 =$ constant, so the corresponding grid curves are the curves parallel to the yz-plane. If $v = v_0$ is constant, $y = v_0^3 =$ constant, so the corresponding grid curves are the curves parallel to the xz-plane.



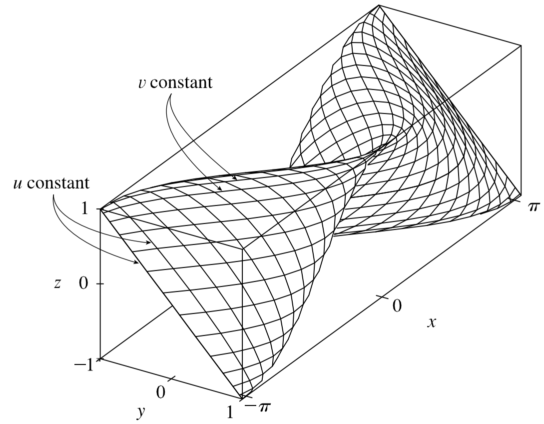
9. $\mathbf{r}(u,v) = \langle u^3, u\sin v, u\cos v\rangle,\ -1 \le u \le 1,\ 0 \le v \le 2\pi$

The surface has parametric equations $x = u^3,\ y = u\sin v,\ z = u\cos v,\ -1 \le u \le 1,\ 0 \le v \le 2\pi$. Note that if $u = u_0$ is constant then $x = u_0^3$ is constant and $y = u_0\sin v$, $z = u_0\cos v$ describe a circle in y, z of radius $|u_0|$, so the corresponding grid curves are circles parallel to the yz-plane. If $v = v_0$, a constant, the parametric equations become $x = u^3$, $y = u\sin v_0$, $z = u\cos v_0$. Then $y = (\tan v_0)z$, so these are the grid curves we see that lie in planes $y = kz$ that pass through the x-axis.



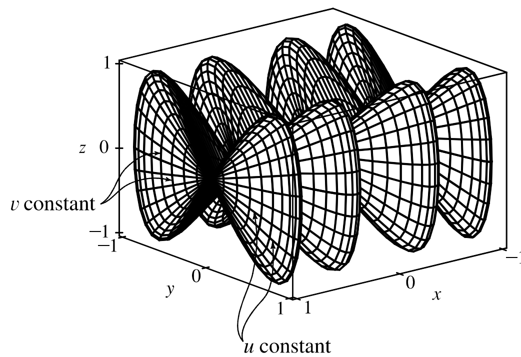
10. $\mathbf{r}(u,v) = \langle u, \sin(u+v), \sin v\rangle,\ -\pi \le u \le \pi,\ -\pi \le v \le \pi.$

The surface has parametric equations $x = u$, $y = \sin(u+v)$, $z = \sin v$, $-\pi \le u \le \pi$, $-\pi \le v \le \pi$. If $u = u_0$ is constant, $x = u_0 =$ constant, so the corresponding grid curves are the curves parallel to the yz-plane. If $v = v_0$ is constant, $z = \sin v_0 =$ constant, so the corresponding grid curves are the curves parallel to the xy-plane.



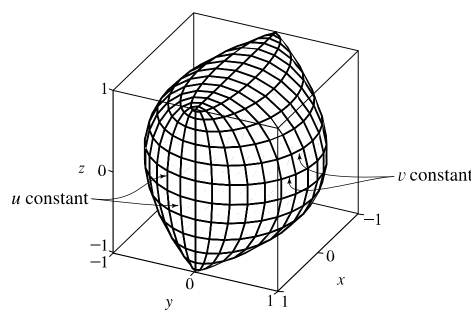
11. $x = \sin v,\ \ y = \cos u \sin 4v,\ \ z = \sin 2u \sin 4v,\ \ 0 \le u \le 2\pi,\ \ -\frac{\pi}{2} \le v \le \frac{\pi}{2}.$

Note that if $v = v_0$ is constant, then $x = \sin v_0$ is constant, so the corresponding grid curves must be parallel to the yz-plane. These are the vertically oriented grid curves we see, each shaped like a "figure-eight." When $u = u_0$ is held constant, the parametric equations become $x = \sin v$, $y = \cos u_0 \sin 4v$, $z = \sin 2u_0 \sin 4v$. Since z is a constant multiple of y, the corresponding grid curves are the curves contained in planes $z = ky$ that pass through the x-axis.



12. $x = \cos u,\ y = \sin u\ \sin v,\ z = \cos v,\ 0 \le u \le 2\pi,\ \ 0 \le v \le 2\pi.$

If $u = u_0$ is constant, then $x = \cos u_0 =$ constant, so the corresponding grid curves are the curves parallel to the yz-plane. If $v = v_0$ is constant, then $z = \cos v_0 =$ constant, so the corresponding grid curves are the curves parallel to the xy-plane.



13. $\mathbf{r}(u,v) = u\cos v\,\mathbf{i} + u \sin v\,\mathbf{j} + v\,\mathbf{k}$. The parametric equations for the surface are $x = u\cos v$, $y = u \sin v$, $z = v$. We look at the grid curves first; if we fix v, then x and y parametrize a straight line in the plane $z = v$ which intersects the z-axis. If u is held constant, the projection onto the xy-plane is circular; with $z = v$, each grid curve is a helix. The surface is a spiraling ramp, graph IV.

14. $\mathbf{r}(u,v) = uv^2\,\mathbf{i} + u^2 v\,\mathbf{j} + (u^2 - v^2)\,\mathbf{k}$. The parametric equations for the surface are $x = uv^2,\ y = u^2 v,\ z = u^2 - v^2$. If $u = u_0$ is held constant, then $x = u_0 v^2$, $y = u_0^2 v$ so $x = u_0(y/u_0^2)^2 = (1/u_0^3)y^2$, and $z = u_0^2 - v^2 = u_0^2 - (1/u_0)x$. Thus each grid curve corresponding to $u = u_0$ lies in the plane $z = u_0^2 - (1/u_0)x$ and its projection onto the xy-plane is a parabola $x = ky^2$ with axis the x-axis. Similarly, if $v = v_0$ is held constant, then $x = uv_0^2$, $y = u^2 v_0 \quad \Rightarrow$

$y = (x/v_0^2)^2 v_0 = (1/v_0^3)x^2$, and $z = u^2 - v_0^2 = (1/v_0)y - v_0^2$. Each grid curve lies in the plane $z = (1/v_0)y - v_0^2$ and its projection onto the xy-plane is a parabola $y = kx^2$ with axis the y-axis. The surface is graph VI.

15. $\mathbf{r}(u,v) = (u^3 - u)\,\mathbf{i} + v^2\,\mathbf{j} + u^2\,\mathbf{k}$. The parametric equations for the surface are $x = u^3 - u,\ y = v^2,\ z = u^2$. If we fix u then x and z are constant so each corresponding grid curve is contained in a line parallel to the y-axis. (Since $y = v^2 \geq 0$, the grid curves are half-lines.) If v is held constant, then $y = v^2 =$ constant, so each grid curve is contained in a plane parallel to the xz-plane. Since x and z are functions of u only, the grid curves all have the same shape. The surface is the cylinder shown in graph I.

16. $x = (1-u)(3+\cos v)\cos 4\pi u$, $y = (1-u)(3+\cos v)\sin 4\pi u$, $z = 3u + (1-u)\sin v$. These equations correspond to graph V: when $u = 0$, then $x = 3 + \cos v$, $y = 0$, and $z = \sin v$, which are equations of a circle with radius 1 in the xz-plane centered at $(3,0,0)$. When $u = \frac{1}{2}$, then $x = \frac{3}{2} + \frac{1}{2}\cos v$, $y = 0$, and $z = \frac{3}{2} + \frac{1}{2}\sin v$, which are equations of a circle with radius $\frac{1}{2}$ in the xz-plane centered at $\left(\frac{3}{2}, 0, \frac{3}{2}\right)$. When $u = 1$, then $x = y = 0$ and $z = 3$, giving the topmost point shown in the graph. This suggests that the grid curves with u constant are the vertically oriented circles visible on the surface. The spiralling grid curves correspond to keeping v constant.

17. $x = \cos^3 u\,\cos^3 v$, $y = \sin^3 u\,\cos^3 v$, $z = \sin^3 v$. If $v = v_0$ is held constant then $z = \sin^3 v_0$ is constant, so the corresponding grid curve lies in a horizontal plane. Several of the graphs exhibit horizontal grid curves, but the curves for this surface are neither ellipses nor straight lines, so graph III is the only possibility. (In fact, the horizontal grid curves here are members of the family $x = a\cos^3 u$, $y = a\sin^3 u$ and are called astroids.) The vertical grid curves we see on the surface correspond to $u = u_0$ held constant, as then we have $x = \cos^3 u_0\,\cos^3 v$, $y = \sin^3 u_0\,\cos^3 v$ so the corresponding grid curve lies in the vertical plane $y = (\tan^3 u_0)x$ through the z-axis.

18. $x = \sin u,\ y = \cos u\,\sin v,\ z = \sin v$. If $v = v_0$ is fixed, then $z = \sin v_0$ is constant, and $x = \sin u$, $y = (\sin v_0)\cos u$ describe an ellipse that is contained in the horizontal plane $z = \sin v_0$. If $u = u_0$ is fixed, then $x = \sin u_0$ is constant, and $y = (\cos u_0)\sin v$, $z = \sin v \quad \Rightarrow \quad y = (\cos u_0)z$, so the grid curves are portions of lines through the x-axis contained in the plane $x = \sin u_0$ (parallel to the yz-plane). The surface is graph II.

19. From Example 3, parametric equations for the plane through the point $(0,0,0)$ that contains the vectors $\mathbf{a} = \langle 1,-1,0\rangle$ and $\mathbf{b} = \langle 0,1,-1\rangle$ are $x = 0 + u(1) + v(0) = u,\ y = 0 + u(-1) + v(1) = v - u,\ z = 0 + u(0) + v(-1) = -v$.

20. From Example 3, parametric equations for the plane through the point $(0,-1,5)$ that contains the vectors $\mathbf{a} = \langle 2,1,4\rangle$ and $\mathbf{b} = \langle -3,2,5\rangle$ are $x = 0 + u(2) + v(-3) = 2u - 3v,\ y = -1 + u(1) + v(2) = -1 + u + 2v$, $z = 5 + u(4) + v(5) = 5 + 4u + 5v$.

21. Solving the equation for x gives $x^2 = 1 + y^2 + \frac{1}{4}z^2 \quad \Rightarrow \quad x = \sqrt{1 + y^2 + \frac{1}{4}z^2}$. (We choose the positive root since we want the part of the hyperboloid that corresponds to $x \geq 0$.) If we let y and z be the parameters, parametric equations are $y = y$, $z = z,\ x = \sqrt{1 + y^2 + \frac{1}{4}z^2}$.

22. Solving the equation for y gives $y^2 = \frac{1}{2}(1 - x^2 - 3z^2) \Rightarrow y = -\sqrt{\frac{1}{2}(1 - x^2 - 3z^2)}$ (since we want the part of the ellipsoid that corresponds to $y \le 0$). If we let x and z be the parameters, parametric equations are $x = x,\ z = z$, $y = -\sqrt{\frac{1}{2}(1 - x^2 - 3z^2)}$.

Alternate solution: The equation can be rewritten as $x^2 + \dfrac{y^2}{\left(1/\sqrt{2}\right)^2} + \dfrac{z^2}{(1/\sqrt{3})^2} = 1$, and if we let $x = u\cos v$ and $z = \dfrac{1}{\sqrt{3}}\,u\sin v$, then $y = -\sqrt{\frac{1}{2}(1 - x^2 - 3z^2)} = -\sqrt{\frac{1}{2}(1 - u^2\cos^2 v - u^2\sin^2 v)} = -\sqrt{\frac{1}{2}(1 - u^2)}$, where $0 \le u \le 1$ and $0 \le v \le 2\pi$.

Second alternate solution: We can adapt the formulas for converting from spherical to rectangular coordinates as follows. We let $x = \sin\phi\cos\theta,\ y = \dfrac{1}{\sqrt{2}}\sin\phi\sin\theta,\ z = \dfrac{1}{\sqrt{3}}\cos\phi$; the surface is generated for $0 \le \phi \le \pi,\ \pi \le \theta \le 2\pi$.

23. Since the cone intersects the sphere in the circle $x^2 + y^2 = 2$, $z = \sqrt{2}$ and we want the portion of the sphere above this, we can parametrize the surface as $x = x$, $y = y$, $z = \sqrt{4 - x^2 - y^2}$ where $x^2 + y^2 \le 2$.

Alternate solution: Using spherical coordinates, $x = 2\sin\phi\cos\theta$, $y = 2\sin\phi\sin\theta$, $z = 2\cos\phi$ where $0 \le \phi \le \frac{\pi}{4}$ and $0 \le \theta \le 2\pi$.

24. We can parametrize the cylinder as $x = 3\cos\theta,\ y = y,\ z = 3\sin\theta$. To restrict the surface to that portion above the xy-plane and between the planes $y = -4$ and $y = 4$ we require $0 \le \theta \le \pi$, $-4 \le y \le 4$.

25. In spherical coordinates, parametric equations are $x = 6\sin\phi\cos\theta$, $y = 6\sin\phi\sin\theta$, $z = 6\cos\phi$. The intersection of the sphere with the plane $z = 3\sqrt{3}$ corresponds to $z = 6\cos\phi = 3\sqrt{3} \Rightarrow \cos\phi = \frac{\sqrt{3}}{2} \Rightarrow \phi = \frac{\pi}{6}$, and the plane $z = 0$ (the xy-plane) corresponds to $\phi = \frac{\pi}{2}$. Thus the surface is described by $\frac{\pi}{6} \le \phi \le \frac{\pi}{2},\ 0 \le \theta \le 2\pi$.

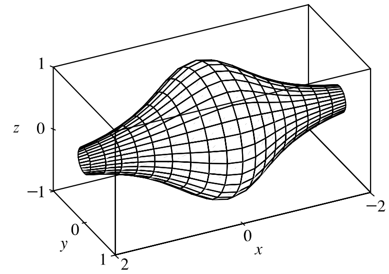
26. Using x and y as the parameters, $x = x$, $y = y$, $z = x + 3$ where $0 \le x^2 + y^2 \le 1$. Also, since the plane intersects the cylinder in an ellipse, the surface is a planar ellipse in the plane $z = x + 3$. Thus, parametrizing with respect to s and θ, we have $x = s\cos\theta$, $y = s\sin\theta$, $z = 3 + s\cos\theta$ where $0 \le s \le 1$ and $0 \le \theta \le 2\pi$.

27. The surface appears to be a portion of a circular cylinder of radius 3 with axis the x-axis. An equation of the cylinder is $y^2 + z^2 = 9$, and we can impose the restrictions $0 \le x \le 5$, $y \le 0$ to obtain the portion shown. To graph the surface on a CAS, we can use parametric equations $x = u$, $y = 3\cos v$, $z = 3\sin v$ with the parameter domain $0 \le u \le 5$, $\frac{\pi}{2} \le v \le \frac{3\pi}{2}$. Alternatively, we can regard x and z as parameters. Then parametric equations are $x = x$, $z = z$, $y = -\sqrt{9 - z^2}$, where $0 \le x \le 5$ and $-3 \le z \le 3$.

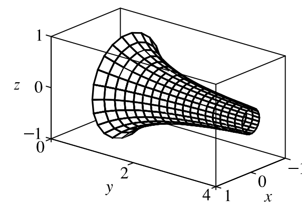
28. The surface appears to be a portion of a sphere of radius 1 centered at the origin. In spherical coordinates, the sphere has equation $\rho = 1$, and imposing the restrictions $\frac{\pi}{2} \le \theta \le 2\pi$, $\frac{\pi}{4} \le \phi \le \pi$ will give only the portion of the sphere shown. Thus, to graph the surface on a CAS we can either use spherical coordinates with the stated restrictions, or we can use parametric equations: $x = \sin\phi\cos\theta$, $y = \sin\phi\sin\theta$, $z = \cos\phi$, $\frac{\pi}{2} \le \theta \le 2\pi$, $\frac{\pi}{4} \le \phi \le \pi$.

29. Using Equations 3, we have the parametrization $x = x$,

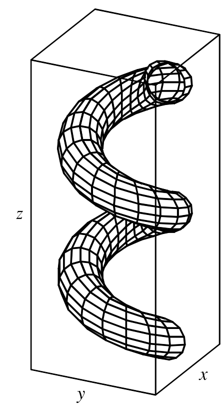
$y = \dfrac{1}{1+x^2}\cos\theta,\ \ z = \dfrac{1}{1+x^2}\sin\theta,\ \ -2 \le x \le 2,\ \ 0 \le \theta \le 2\pi$.



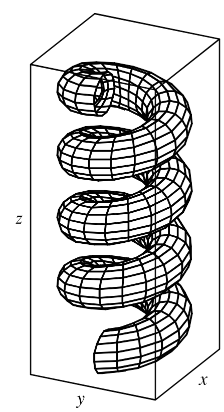
30. Letting θ be the angle of rotation about the y-axis (adapting Equations 3), we have the parametrization $x = (1/y)\cos\theta,\ \ y = y$, $z = (1/y)\sin\theta,\ \ y \ge 1,\ \ 0 \le \theta \le 2\pi$.



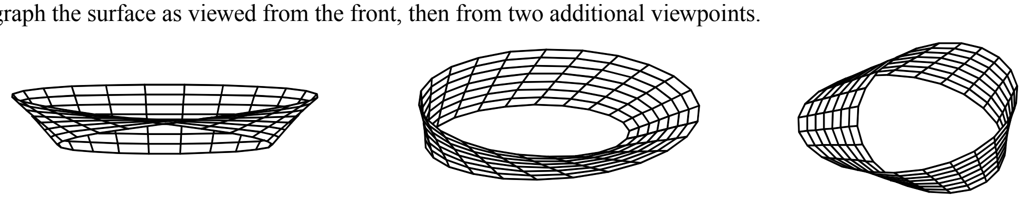
31. (a) Replacing $\cos u$ by $\sin u$ and $\sin u$ by $\cos u$ gives parametric equations $x = (2+\sin v)\sin u$, $y = (2+\sin v)\cos u$, $z = u + \cos v$. From the graph, it appears that the direction of the spiral is reversed. We can verify this observation by noting that the projection of the spiral grid curves onto the xy-plane, given by $x = (2+\sin v)\sin u$, $y = (2+\sin v)\cos u$, $z = 0$, draws a circle in the clockwise direction for each value of v. The original equations, on the other hand, give circular projections drawn in the counterclockwise direction. The equation for z is identical in both surfaces, so as z increases, these grid curves spiral up in opposite directions for the two surfaces.



(b) Replacing $\cos u$ by $\cos 2u$ and $\sin u$ by $\sin 2u$ gives parametric equations $x = (2+\sin v)\cos 2u$, $y = (2+\sin v)\sin 2u$, $z = u + \cos v$. From the graph, it appears that the number of coils in the surface doubles within the same parametric domain. We can verify this observation by noting that the projection of the spiral grid curves onto the xy-plane, given by $x = (2+\sin v)\cos 2u$, $y = (2+\sin v)\sin 2u$, $z = 0$ (where v is constant), complete circular revolutions for $0 \le u \le \pi$ while the original surface requires $0 \le u \le 2\pi$ for a complete revolution. Thus, the new surface winds around twice as fast as the original surface, and since the equation for z is identical in both surfaces, we observe twice as many circular coils in the same z-interval.



32. First we graph the surface as viewed from the front, then from two additional viewpoints.



The surface appears as a twisted sheet, and is unusual because it has only one side. (The Möbius strip is discussed in more detail in Section 16.7.)

33. $\mathbf{r}(u,v) = (u+v)\,\mathbf{i} + 3u^2\,\mathbf{j} + (u-v)\,\mathbf{k}$.

$\mathbf{r}_u = \mathbf{i} + 6u\,\mathbf{j} + \mathbf{k}$ and $\mathbf{r}_v = \mathbf{i} - \mathbf{k}$, so $\mathbf{r}_u \times \mathbf{r}_v = -6u\,\mathbf{i} + 2\,\mathbf{j} - 6u\,\mathbf{k}$. Since the point $(2,3,0)$ corresponds to $u=1$, $v=1$, a normal vector to the surface at $(2,3,0)$ is $-6\,\mathbf{i} + 2\,\mathbf{j} - 6\,\mathbf{k}$, and an equation of the tangent plane is $-6x + 2y - 6z = -6$ or $3x - y + 3z = 3$.

34. $\mathbf{r}(u,v) = (u^2+1)\,\mathbf{i} + (v^3+1)\,\mathbf{j} + (u+v)\,\mathbf{k}$.

$\mathbf{r}_u = 2u\,\mathbf{i} + \mathbf{k}$ and $\mathbf{r}_v = 3v^2\,\mathbf{j} + \mathbf{k}$, so $\mathbf{r}_u \times \mathbf{r}_v = -3v^2\,\mathbf{i} - 2u\,\mathbf{j} + 6uv^2\,\mathbf{k}$. Since the point $(5,2,3)$ corresponds to $u=2$, $v=1$, a normal vector to the surface at $(5,2,3)$ is $-3\,\mathbf{i} - 4\,\mathbf{j} + 12\,\mathbf{k}$, and an equation of the tangent plane is $-3(x-5) - 4(y-2) + 12(z-3) = 0$ or $3x + 4y - 12z = -13$.

35. $\mathbf{r}(u,v) = u\cos v\,\mathbf{i} + u\sin v\,\mathbf{j} + v\,\mathbf{k} \quad\Rightarrow\quad \mathbf{r}\left(1, \frac{\pi}{3}\right) = \left(\frac{1}{2}, \frac{\sqrt{3}}{2}, \frac{\pi}{3}\right)$.

$\mathbf{r}_u = \cos v\,\mathbf{i} + \sin v\,\mathbf{j}$ and $\mathbf{r}_v = -u\sin v\,\mathbf{i} + u\cos v\,\mathbf{j} + \mathbf{k}$, so a normal vector to the surface at the point $\left(\frac{1}{2}, \frac{\sqrt{3}}{2}, \frac{\pi}{3}\right)$ is $\mathbf{r}_u\left(1, \frac{\pi}{3}\right) \times \mathbf{r}_v\left(1, \frac{\pi}{3}\right) = \left(\frac{1}{2}\,\mathbf{i} + \frac{\sqrt{3}}{2}\,\mathbf{j}\right) \times \left(-\frac{\sqrt{3}}{2}\,\mathbf{i} + \frac{1}{2}\,\mathbf{j} + \mathbf{k}\right) = \frac{\sqrt{3}}{2}\,\mathbf{i} - \frac{1}{2}\,\mathbf{j} + \mathbf{k}$. Thus an equation of the tangent plane at $\left(\frac{1}{2}, \frac{\sqrt{3}}{2}, \frac{\pi}{3}\right)$ is $\frac{\sqrt{3}}{2}\left(x - \frac{1}{2}\right) - \frac{1}{2}\left(y - \frac{\sqrt{3}}{2}\right) + 1\left(z - \frac{\pi}{3}\right) = 0$ or $\frac{\sqrt{3}}{2}x - \frac{1}{2}y + z = \frac{\pi}{3}$.

36. $\mathbf{r}(u,v) = \sin u\,\mathbf{i} + \cos u\,\sin v\,\mathbf{j} + \sin v\,\mathbf{k} \quad\Rightarrow\quad \mathbf{r}\left(\frac{\pi}{6}, \frac{\pi}{6}\right) = \left(\frac{1}{2}, \frac{\sqrt{3}}{4}, \frac{1}{2}\right)$.

$\mathbf{r}_u = \cos u\,\mathbf{i} - \sin u\sin v\,\mathbf{j}$ and $\mathbf{r}_v = \cos u\cos v\,\mathbf{j} + \cos v\,\mathbf{k}$, so a normal vector to the surface at the point $\left(\frac{1}{2}, \frac{\sqrt{3}}{4}, \frac{1}{2}\right)$ is

$\mathbf{r}_u\left(\frac{\pi}{6}, \frac{\pi}{6}\right) \times \mathbf{r}_v\left(\frac{\pi}{6}, \frac{\pi}{6}\right) = \left(\frac{\sqrt{3}}{2}\,\mathbf{i} - \frac{1}{4}\,\mathbf{j}\right) \times \left(\frac{3}{4}\,\mathbf{j} + \frac{\sqrt{3}}{2}\,\mathbf{k}\right) = -\frac{\sqrt{3}}{8}\,\mathbf{i} - \frac{3}{4}\,\mathbf{j} + \frac{3\sqrt{3}}{8}\,\mathbf{k}$.

Thus an equation of the tangent plane at $\left(\frac{1}{2}, \frac{\sqrt{3}}{4}, \frac{1}{2}\right)$ is $-\frac{\sqrt{3}}{8}\left(x - \frac{1}{2}\right) - \frac{3}{4}\left(y - \frac{\sqrt{3}}{4}\right) + \frac{3\sqrt{3}}{8}\left(z - \frac{1}{2}\right) = 0$ or $\sqrt{3}\,x + 6y - 3\sqrt{3}\,z = \frac{\sqrt{3}}{2}$ or $2x + 4\sqrt{3}\,y - 6z = 1$.

37. $\mathbf{r}(u,v) = u^2\,\mathbf{i} + 2u\sin v\,\mathbf{j} + u\cos v\,\mathbf{k} \quad\Rightarrow\quad \mathbf{r}(1,0) = (1,0,1)$.

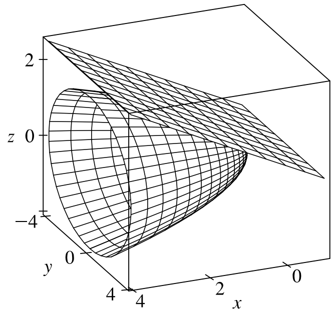
$\mathbf{r}_u = 2u\,\mathbf{i} + 2\sin v\,\mathbf{j} + \cos v\,\mathbf{k}$ and $\mathbf{r}_v = 2u\cos v\,\mathbf{j} - u\sin v\,\mathbf{k}$,

so a normal vector to the surface at the point $(1,0,1)$ is

$\mathbf{r}_u(1,0) \times \mathbf{r}_v(1,0) = (2\,\mathbf{i} + \mathbf{k}) \times (2\,\mathbf{j}) = -2\,\mathbf{i} + 4\,\mathbf{k}$.

Thus an equation of the tangent plane at $(1,0,1)$ is

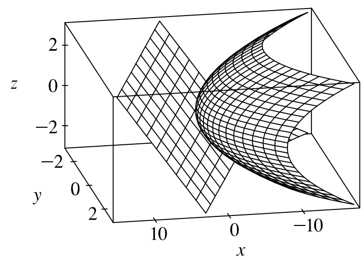
$-2(x-1) + 0(y-0) + 4(z-1) = 0$ or $-x + 2z = 1$.



38. $\mathbf{r}(u,v) = (1 - u^2 - v^2)\,\mathbf{i} - v\,\mathbf{j} - u\,\mathbf{k}$.

$\mathbf{r}_u = -2u\,\mathbf{i} - \mathbf{k}$ and $\mathbf{r}_v = -2v\,\mathbf{i} - \mathbf{j}$. Since the point $(-1,-1,-1)$ corresponds to $u=1$, $v=1$, a normal vector to the surface at $(-1,-1,-1)$ is

$\mathbf{r}_u(1,1) \times \mathbf{r}_v(1,1) = (-2\,\mathbf{i} - \mathbf{k}) \times (-2\,\mathbf{i} - \mathbf{j}) = -\mathbf{i} + 2\,\mathbf{j} + 2\,\mathbf{k}$.



Thus an equation of the tangent plane is $-1(x+1) + 2(y+1) + 2(z+1) = 0$ or $-x + 2y + 2z = -3$.

39. The surface S is given by $z = f(x,y) = 6 - 3x - 2y$ which intersects the xy-plane in the line $3x + 2y = 6$, so D is the triangular region given by $\left\{(x,y) \mid 0 \le x \le 2,\ 0 \le y \le 3 - \frac{3}{2}x\right\}$. By Formula 9, the surface area of S is

$$\begin{aligned} A(S) &= \iint_D \sqrt{1 + \left(\frac{\partial z}{\partial x}\right)^2 + \left(\frac{\partial z}{\partial y}\right)^2}\,dA \\ &= \iint_D \sqrt{1 + (-3)^2 + (-2)^2}\,dA = \sqrt{14}\iint_D dA = \sqrt{14}\,A(D) = \sqrt{14}\left(\tfrac{1}{2}\cdot 2\cdot 3\right) = 3\sqrt{14}. \end{aligned}$$

40. $\mathbf{r}(u,v) = \langle u+v, 2-3u, 1+u-v\rangle \quad\Rightarrow\quad \mathbf{r}_u = \langle 1,-3,1\rangle$, $\mathbf{r}_v = \langle 1,0,-1\rangle$, and $\mathbf{r}_u \times \mathbf{r}_v = \langle 3,2,3\rangle$. Then by Definition 6,

$$A(S) = \iint_D |\,\mathbf{r}_u \times \mathbf{r}_v\,|\,dA = \int_0^2\int_{-1}^1 |\,\langle 3,2,3\rangle\,|\,dv\,du = \sqrt{22}\int_0^2 du\int_{-1}^1 dv = \sqrt{22}\,(2)(2) = 4\sqrt{22}$$

41. Here we can write $z = f(x,y) = \frac{1}{3} - \frac{1}{3}x - \frac{2}{3}y$ and D is the disk $x^2 + y^2 \le 3$, so by Formula 9 the area of the surface is

$$\begin{aligned} A(S) &= \iint_D \sqrt{1 + \left(\frac{\partial z}{\partial x}\right)^2 + \left(\frac{\partial z}{\partial y}\right)^2}\,dA = \iint_D \sqrt{1 + \left(-\tfrac{1}{3}\right)^2 + \left(-\tfrac{2}{3}\right)^2}\,dA = \tfrac{\sqrt{14}}{3}\iint_D dA \\ &= \tfrac{\sqrt{14}}{3}\,A(D) = \tfrac{\sqrt{14}}{3}\cdot\pi\left(\sqrt{3}\right)^2 = \sqrt{14}\,\pi \end{aligned}$$

42. $z = f(x,y) = \sqrt{x^2+y^2} \quad\Rightarrow\quad \dfrac{\partial z}{\partial x} = \dfrac{1}{2}\left(x^2+y^2\right)^{-1/2}\cdot 2x = \dfrac{x}{\sqrt{x^2+y^2}}$, $\dfrac{\partial z}{\partial y} = \dfrac{y}{\sqrt{x^2+y^2}}$, and

$$\sqrt{1 + \left(\frac{\partial z}{\partial x}\right)^2 + \left(\frac{\partial z}{\partial y}\right)^2} = \sqrt{1 + \frac{x^2}{x^2+y^2} + \frac{y^2}{x^2+y^2}} = \sqrt{1 + \frac{x^2+y^2}{x^2+y^2}} = \sqrt{2}$$

Here D is given by $\left\{(x,y) \mid 0 \le x \le 1,\ x^2 \le y \le x\right\}$, so by Formula 9, the surface area of S is

$$A(S) = \iint_D \sqrt{2}\,dA = \int_0^1\int_{x^2}^x \sqrt{2}\,dy\,dx = \sqrt{2}\int_0^1 \left(x - x^2\right)dx = \sqrt{2}\,\left[\tfrac{1}{2}x^2 - \tfrac{1}{3}x^3\right]_0^1 = \sqrt{2}\left(\tfrac{1}{2} - \tfrac{1}{3}\right) = \tfrac{\sqrt{2}}{6}$$

43. $z = f(x,y) = \frac{2}{3}(x^{3/2} + y^{3/2})$ and $D = \{(x,y) \mid 0 \le x \le 1,\ 0 \le y \le 1\}$. Then $f_x = x^{1/2}$, $f_y = y^{1/2}$ and

$$\begin{aligned} A(S) &= \iint_D \sqrt{1 + \left(\sqrt{x}\right)^2 + \left(\sqrt{y}\right)^2}\,dA = \int_0^1\int_0^1 \sqrt{1+x+y}\,dy\,dx \\ &= \int_0^1 \left[\tfrac{2}{3}(x+y+1)^{3/2}\right]_{y=0}^{y=1} dx = \tfrac{2}{3}\int_0^1 \left[(x+2)^{3/2} - (x+1)^{3/2}\right]dx \\ &= \tfrac{2}{3}\left[\tfrac{2}{5}(x+2)^{5/2} - \tfrac{2}{5}(x+1)^{5/2}\right]_0^1 = \tfrac{4}{15}(3^{5/2} - 2^{5/2} - 2^{5/2} + 1) = \tfrac{4}{15}(3^{5/2} - 2^{7/2} + 1) \end{aligned}$$

44. $z = f(x,y) = 4 - 2x^2 + y$ and $D = \{(x,y) \mid 0 \le x \le 1,\ 0 \le y \le x\}$. Thus, by Formula 9,

$$\begin{aligned} A(S) &= \iint_D \sqrt{1 + (-4x)^2 + (1)^2}\,dA = \int_0^1\int_0^x \sqrt{16x^2+2}\,dy\,dx = \int_0^1 x\sqrt{16x^2+2}\,dx \\ &= \tfrac{1}{32}\cdot\tfrac{2}{3}(16x^2+2)^{3/2}\Big]_0^1 = \tfrac{1}{48}(18^{3/2} - 2^{3/2}) = \tfrac{1}{48}(54\sqrt{2} - 2\sqrt{2}) = \tfrac{13}{12}\sqrt{2} \end{aligned}$$

45. $z = f(x,y) = xy$ with $x^2 + y^2 \le 1$, so $f_x = y$, $f_y = x \quad\Rightarrow$

$$\begin{aligned} A(S) &= \iint_D \sqrt{1 + y^2 + x^2}\,dA = \int_0^{2\pi}\int_0^1 \sqrt{r^2+1}\,r\,dr\,d\theta = \int_0^{2\pi}\left[\tfrac{1}{3}\left(r^2+1\right)^{3/2}\right]_{r=0}^{r=1} d\theta \\ &= \int_0^{2\pi} \tfrac{1}{3}\left(2\sqrt{2} - 1\right)d\theta = \tfrac{2\pi}{3}\left(2\sqrt{2} - 1\right) \end{aligned}$$

46. A parametric representation of the surface is $x = z^2 + y$, $y = y$, $z = z$ with $0 \le y \le 2$, $0 \le z \le 2$.

Hence $\mathbf{r}_y \times \mathbf{r}_z = (\mathbf{i} + \mathbf{j}) \times (2z\,\mathbf{i} + \mathbf{k}) = \mathbf{i} - \mathbf{j} - 2z\,\mathbf{k}$.

Then

$$A(S) = \iint_D |\mathbf{r}_y \times \mathbf{r}_z|\,dA = \int_0^2\int_0^2 \sqrt{1+1+4z^2}\,dy\,dz = \int_0^2 2\sqrt{2+4z^2}\,dz$$

$$= \left[2 \cdot \tfrac{1}{2}\left(z\sqrt{2+4z^2} + \ln\left(2z + \sqrt{2+4z^2}\right)\right)\right]_0^2 \quad \left[\begin{array}{c}\text{Use trigonometric substitution}\\ \text{or Formula 21 in the Table of Integrals}\end{array}\right]$$

$$= 6\sqrt{2} + \ln\left(4 + 3\sqrt{2}\right) - \ln\sqrt{2} \text{ or } 6\sqrt{2} + \ln\frac{4+3\sqrt{2}}{\sqrt{2}} = 6\sqrt{2} + \ln\left(2\sqrt{2}+3\right)$$

Note: In general, if $x = f(y,z)$ then $\mathbf{r}_y \times \mathbf{r}_z = \mathbf{i} - \dfrac{\partial f}{\partial y}\mathbf{j} - \dfrac{\partial f}{\partial z}\mathbf{k}$ and $A(S) = \iint_D \sqrt{1 + \left(\dfrac{\partial f}{\partial y}\right)^2 + \left(\dfrac{\partial f}{\partial z}\right)^2}\,dA$.

47. A parametric representation of the surface is $x = x$, $y = x^2 + z^2$, $z = z$ with $0 \le x^2 + z^2 \le 16$.

Hence $\mathbf{r}_x \times \mathbf{r}_z = (\mathbf{i} + 2x\,\mathbf{j}) \times (2z\,\mathbf{j} + \mathbf{k}) = 2x\,\mathbf{i} - \mathbf{j} + 2z\,\mathbf{k}$.

Note: In general, if $y = f(x,z)$ then $\mathbf{r}_x \times \mathbf{r}_z = \dfrac{\partial f}{\partial x}\mathbf{i} - \mathbf{j} + \dfrac{\partial f}{\partial z}\mathbf{k}$, and $A(S) = \iint_D \sqrt{1 + \left(\dfrac{\partial f}{\partial x}\right)^2 + \left(\dfrac{\partial f}{\partial z}\right)^2}\,dA$. Then

$$A(S) = \iint_{0 \le x^2+z^2 \le 16} \sqrt{1 + 4x^2 + 4z^2}\,dA = \int_0^{2\pi}\int_0^4 \sqrt{1+4r^2}\,r\,dr\,d\theta$$

$$= \int_0^{2\pi} d\theta \int_0^4 r\sqrt{1+4r^2}\,dr = 2\pi\left[\tfrac{1}{12}(1+4r^2)^{3/2}\right]_0^4 = \tfrac{\pi}{6}\left(65^{3/2} - 1\right)$$

48. $\mathbf{r}_u = \langle \cos v, \sin v, 0\rangle$, $\mathbf{r}_v = \langle -u\sin v, u\cos v, 1\rangle$, and $\mathbf{r}_u \times \mathbf{r}_v = \langle \sin v, -\cos v, u\rangle$. Then

$$A(S) = \int_0^{\pi}\int_0^1 \sqrt{1+u^2}\,du\,dv = \int_0^{\pi} dv \int_0^1 \sqrt{1+u^2}\,du$$

$$= \pi\left[\tfrac{u}{2}\sqrt{u^2+1} + \tfrac{1}{2}\ln\left|u + \sqrt{u^2+1}\right|\right]_0^1 = \tfrac{\pi}{2}\left[\sqrt{2} + \ln\left(1+\sqrt{2}\right)\right]$$

49. $\mathbf{r}_u = \langle 2u, v, 0\rangle$, $\mathbf{r}_v = \langle 0, u, v\rangle$, and $\mathbf{r}_u \times \mathbf{r}_v = \left\langle v^2, -2uv, 2u^2\right\rangle$. Then

$$A(S) = \iint_D |\mathbf{r}_u \times \mathbf{r}_v|\,dA = \int_0^1\int_0^2 \sqrt{v^4 + 4u^2v^2 + 4u^4}\,dv\,du = \int_0^1\int_0^2 \sqrt{(v^2+2u^2)^2}\,dv\,du$$

$$= \int_0^1\int_0^2 (v^2 + 2u^2)\,dv\,du = \int_0^1 \left[\tfrac{1}{3}v^3 + 2u^2v\right]_{v=0}^{v=2} du = \int_0^1 \left(\tfrac{8}{3} + 4u^2\right) du = \left[\tfrac{8}{3}u + \tfrac{4}{3}u^3\right]_0^1 = 4$$

50. The cylinder encloses separate portions of the sphere in the upper and lower halves. The top half of the sphere is $z = f(x,y) = \sqrt{b^2 - x^2 - y^2}$ and D is given by $\left\{(x,y) \mid x^2 + y^2 \le a^2\right\}$. By Formula 9, the surface area of the upper enclosed portion is

$$A = \iint_D \sqrt{1 + \left(\frac{-x}{\sqrt{b^2-x^2-y^2}}\right)^2 + \left(\frac{-y}{\sqrt{b^2-x^2-y^2}}\right)^2}\,dA = \iint_D \sqrt{1 + \frac{x^2+y^2}{b^2-x^2-y^2}}\,dA$$

$$= \iint_D \sqrt{\frac{b^2}{b^2-x^2-y^2}}\,dA = \int_0^{2\pi}\int_0^a \frac{b}{\sqrt{b^2-r^2}}\,r\,dr\,d\theta = b\int_0^{2\pi} d\theta \int_0^a \frac{r}{\sqrt{b^2-r^2}}\,dr$$

$$= b\left[\theta\right]_0^{2\pi}\left[-\sqrt{b^2-r^2}\right]_0^a = 2\pi b\left(-\sqrt{b^2-a^2} + \sqrt{b^2-0}\right) = 2\pi b\left(b - \sqrt{b^2-a^2}\right)$$

The lower portion of the sphere enclosed by the cylinder has identical shape, so the total area is $2A = 4\pi b\left(b - \sqrt{b^2-a^2}\right)$.

51. From Equation 9 we have $A(S) = \iint_D \sqrt{1 + (f_x)^2 + (f_y)^2}\, dA$. But if $|f_x| \le 1$ and $|f_y| \le 1$ then $0 \le (f_x)^2 \le 1$, $0 \le (f_y)^2 \le 1 \quad \Rightarrow \quad 1 \le 1 + (f_x)^2 + (f_y)^2 \le 3 \quad \Rightarrow \quad 1 \le \sqrt{1 + (f_x)^2 + (f_y)^2} \le \sqrt{3}$. By Property 15.2.11, $\iint_D 1\, dA \le \iint_D \sqrt{1 + (f_x)^2 + (f_y)^2}\, dA \le \iint_D \sqrt{3}\, dA \quad \Rightarrow \quad A(D) \le A(S) \le \sqrt{3}\, A(D) \quad \Rightarrow$ $\pi R^2 \le A(S) \le \sqrt{3}\pi R^2$.

52. $z = f(x, y) = \cos(x^2 + y^2)$ with $x^2 + y^2 \le 1$.

$$\begin{aligned} A(S) &= \iint_D \sqrt{1 + (-2x\sin(x^2+y^2))^2 + (-2y\sin(x^2+y^2))^2}\, dA \\ &= \iint_D \sqrt{1 + 4x^2\sin^2(x^2+y^2) + 4y^2\sin^2(x^2+y^2)}\, dA = \iint_D \sqrt{1 + 4(x^2+y^2)\sin^2(x^2+y^2)}\, dA \\ &= \int_0^{2\pi}\int_0^1 \sqrt{1 + 4r^2\sin^2(r^2)}\, r\, dr\, d\theta = \int_0^{2\pi} d\theta \int_0^1 r\sqrt{1 + 4r^2\sin^2(r^2)}\, dr \\ &= 2\pi \int_0^1 r\sqrt{1 + 4r^2\sin^2(r^2)}\, dr \approx 4.1073 \end{aligned}$$

53. $z = f(x, y) = \ln(x^2 + y^2 + 2)$ with $x^2 + y^2 \le 1$.

$$\begin{aligned} A(S) &= \iint_D \sqrt{1 + \left(\frac{2x}{x^2+y^2+2}\right)^2 + \left(\frac{2y}{x^2+y^2+2}\right)^2}\, dA = \iint_D \sqrt{1 + \frac{4x^2+4y^2}{(x^2+y^2+2)^2}}\, dA \\ &= \int_0^{2\pi}\int_0^1 \sqrt{1 + \frac{4r^2}{(r^2+2)^2}}\, r\, dr\, d\theta = \int_0^{2\pi} d\theta \int_0^1 r\sqrt{\frac{(r^2+2)^2 + 4r^2}{(r^2+2)^2}}\, dr = 2\pi \int_0^1 \frac{r\sqrt{r^4+8r^2+4}}{r^2+2}\, dr \approx 3.5618 \end{aligned}$$

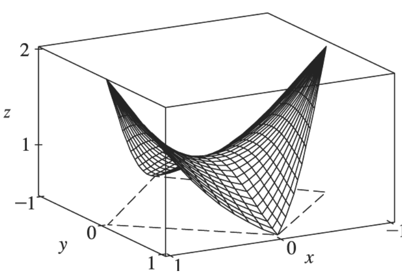
54. Let $f(x, y) = \dfrac{1 + x^2}{1 + y^2}$. Then $f_x = \dfrac{2x}{1 + y^2}$,

$f_y = (1 + x^2)\left[-\dfrac{2y}{(1 + y^2)^2}\right] = -\dfrac{2y(1 + x^2)}{(1 + y^2)^2}$.

We use a CAS to estimate

$\int_{-1}^1 \int_{-(1-|x|)}^{1-|x|} \sqrt{1 + f_x^2 + f_y^2}\, dy\, dx \approx 2.6959$.

In order to graph only the part of the surface above the square, we use $-(1 - |x|) \le y \le 1 - |x|$ as the y-range in our plot command.



55. (a) $A(S) = \iint_D \sqrt{1 + \left(\dfrac{\partial z}{\partial x}\right)^2 + \left(\dfrac{\partial z}{\partial y}\right)^2}\, dA = \int_0^6 \int_0^4 \sqrt{1 + \dfrac{4x^2 + 4y^2}{(1 + x^2 + y^2)^4}}\, dy\, dx$.

Using the Midpoint Rule with $f(x, y) = \sqrt{1 + \dfrac{4x^2 + 4y^2}{(1 + x^2 + y^2)^4}}$, $m = 3$, $n = 2$ we have

$$A(S) \approx \sum_{i=1}^{3}\sum_{j=1}^{2} f(\overline{x}_i, \overline{y}_j)\, \Delta A = 4\,[f(1,1) + f(1,3) + f(3,1) + f(3,3) + f(5,1) + f(5,3)] \approx 24.2055$$

(b) Using a CAS we have $A(S) = \int_0^6 \int_0^4 \sqrt{1 + \dfrac{4x^2 + 4y^2}{(1 + x^2 + y^2)^4}}\, dy\, dx \approx 24.2476$. This agrees with the estimate in part (a) to the first decimal place.

56. $\mathbf{r}(u,v) = \langle \cos^3 u \cos^3 v, \sin^3 u \cos^3 v, \sin^3 v \rangle$, so $\mathbf{r}_u = \langle -3\cos^2 u \sin u \cos^3 v, 3\sin^2 u \cos u \cos^3 v, 0 \rangle$,

$\mathbf{r}_v = \langle -3\cos^3 u \cos^2 v \sin v, -3\sin^3 u \cos^2 v \sin v, 3\sin^2 v \cos v \rangle$, and

$\mathbf{r}_u \times \mathbf{r}_v = \langle 9\cos u \sin^2 u \cos^4 v \sin^2 v, 9\cos^2 u \sin u \cos^4 v \sin^2 v, 9\cos^2 u \sin^2 u \cos^5 v \sin v \rangle$. Then

$$\begin{aligned} |\mathbf{r}_u \times \mathbf{r}_v| &= 9\sqrt{\cos^2 u \sin^4 u \cos^8 v \sin^4 v + \cos^4 u \sin^2 u \cos^8 v \sin^4 v + \cos^4 u \sin^4 u \cos^{10} v \sin^2 v} \\ &= 9\sqrt{\cos^2 u \sin^2 u \cos^8 v \sin^2 v\,(\sin^2 v + \cos^2 u \sin^2 u \cos^2 v)} \\ &= 9\cos^4 v\,|\cos u \sin u \sin v|\,\sqrt{\sin^2 v + \cos^2 u \sin^2 u \cos^2 v} \end{aligned}$$

Using a CAS, we have $A(S) = \int_0^{\pi}\int_0^{2\pi} 9\cos^4 v\,|\cos u \sin u \sin v|\,\sqrt{\sin^2 v + \cos^2 u \sin^2 u \cos^2 v}\,dv\,du \approx 4.4506$.

57. $z = 1 + 2x + 3y + 4y^2$, so

$$A(S) = \iint_D \sqrt{1 + \left(\frac{\partial z}{\partial x}\right)^2 + \left(\frac{\partial z}{\partial y}\right)^2}\,dA = \int_1^4 \int_0^1 \sqrt{1 + 4 + (3+8y)^2}\,dy\,dx = \int_1^4 \int_0^1 \sqrt{14 + 48y + 64y^2}\,dy\,dx.$$

Using a CAS, we have

$\int_1^4 \int_0^1 \sqrt{14 + 48y + 64y^2}\,dy\,dx = \frac{45}{8}\sqrt{14} + \frac{15}{16}\ln\!\left(11\sqrt{5} + 3\sqrt{14}\sqrt{5}\right) - \frac{15}{16}\ln\!\left(3\sqrt{5} + \sqrt{14}\sqrt{5}\right)$

or $\frac{45}{8}\sqrt{14} + \frac{15}{16}\ln\frac{11\sqrt{5} + 3\sqrt{70}}{3\sqrt{5} + \sqrt{70}}$.

58. (a) $\mathbf{r}_u = a\cos v\,\mathbf{i} + b\sin v\,\mathbf{j} + 2u\,\mathbf{k}$, $\mathbf{r}_v = -au\sin v\,\mathbf{i} + bu\cos v\,\mathbf{j} + 0\,\mathbf{k}$, and

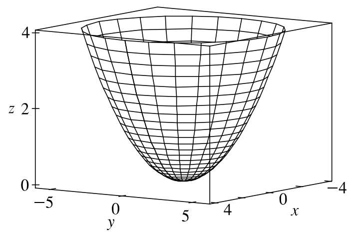
$\mathbf{r}_u \times \mathbf{r}_v = -2bu^2\cos v\,\mathbf{i} - 2au^2\sin v\,\mathbf{j} + abu\,\mathbf{k}$.

$A(S) = \int_0^{2\pi}\int_0^2 |\mathbf{r}_u \times \mathbf{r}_v|\,du\,dv = \int_0^{2\pi}\int_0^2 \sqrt{4b^2u^4\cos^2 v + 4a^2u^4\sin^2 v + a^2b^2u^2}\,du\,dv$

(b) $x^2 = a^2u^2\cos^2 v$, $y^2 = b^2u^2\sin^2 v$, $z = u^2 \;\Rightarrow\; x^2/a^2 + y^2/b^2 = u^2 = z$ which is an elliptic paraboloid. To find D, notice that $0 \le u \le 2 \;\Rightarrow\; 0 \le z \le 4 \;\Rightarrow\; 0 \le x^2/a^2 + y^2/b^2 \le 4$. Therefore, using Formula 9, we have

$$A(S) = \int_{-2a}^{2a}\int_{-b\sqrt{4-(x^2/a^2)}}^{b\sqrt{4-(x^2/a^2)}} \sqrt{1 + (2x/a^2)^2 + (2y/b^2)^2}\,dy\,dx.$$

(c)



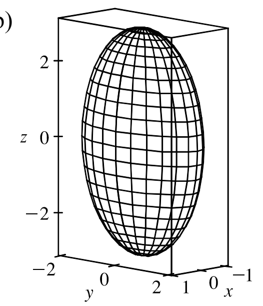
(d) We substitute $a = 2$, $b = 3$ in the integral in part (a) to get $A(S) = \int_0^{2\pi}\int_0^2 2u\sqrt{9u^2\cos^2 v + 4u^2\sin^2 v + 9}\,du\,dv$. We use a CAS to estimate the integral accurate to four decimal places. To speed up the calculation, we can set `Digits:=7;` (in Maple) or use the approximation command `N` (in Mathematica). We find that $A(S) \approx 115.6596$.

59. (a) $x = a\sin u\cos v$, $y = b\sin u\sin v$, $z = c\cos u \;\Rightarrow$

$$\begin{aligned} \frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} &= (\sin u\cos v)^2 + (\sin u\sin v)^2 + (\cos u)^2 \\ &= \sin^2 u + \cos^2 u = 1 \end{aligned}$$

and since the ranges of u and v are sufficient to generate the entire graph, the parametric equations represent an ellipsoid.

(b)



(c) From the parametric equations (with $a = 1$, $b = 2$, and $c = 3$),

we calculate $\mathbf{r}_u = \cos u \cos v\,\mathbf{i} + 2\cos u \sin v\,\mathbf{j} - 3\sin u\,\mathbf{k}$ and

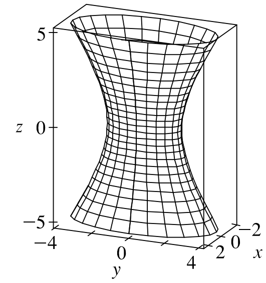
$\mathbf{r}_v = -\sin u \sin v\,\mathbf{i} + 2\sin u \cos v\,\mathbf{j}$. So $\mathbf{r}_u \times \mathbf{r}_v = 6\sin^2 u \cos v\,\mathbf{i} + 3\sin^2 u \sin v\,\mathbf{j} + 2\sin u \cos u\,\mathbf{k}$, and the surface area is given by $A(S) = \int_0^{2\pi}\int_0^{\pi} |\mathbf{r}_u \times \mathbf{r}_v|\,du\,dv = \int_0^{2\pi}\int_0^{\pi} \sqrt{36\sin^4 u\cos^2 v + 9\sin^4 u \sin^2 v + 4\cos^2 u \sin^2 u}\,du\,dv$

60. (a) $x = a\cosh u\,\cos v, \quad y = b\cosh u\,\sin v, \quad z = c\sinh u \quad \Rightarrow$

$$\begin{aligned}\frac{x^2}{a^2} + \frac{y^2}{b^2} - \frac{z^2}{c^2} &= \cosh^2 u\,\cos^2 v + \cosh^2 u\,\sin^2 v - \sinh^2 u\\ &= \cosh^2 u - \sinh^2 u = 1\end{aligned}$$

and the parametric equations represent a hyperboloid of one sheet.

(b)



(c) $\mathbf{r}_u = \sinh u\,\cos v\,\mathbf{i} + 2\sinh u\,\sin v\,\mathbf{j} + 3\cosh u\,\mathbf{k}$ and

$\mathbf{r}_v = -\cosh u\,\sin v\,\mathbf{i} + 2\cosh u\,\cos v\,\mathbf{j}$, so $\mathbf{r}_u \times \mathbf{r}_v = -6\cosh^2 u\,\cos v\,\mathbf{i} - 3\cosh^2 u\,\sin v\,\mathbf{j} + 2\cosh u\,\sinh u\,\mathbf{k}$.

We integrate between $u = \sinh^{-1}(-1) = -\ln\left(1+\sqrt{2}\right)$ and $u = \sinh^{-1} 1 = \ln\left(1+\sqrt{2}\right)$, since then z varies between -3 and 3, as desired. So the surface area is

$$\begin{aligned}A(S) &= \int_0^{2\pi}\int_{-\ln\left(1+\sqrt{2}\right)}^{\ln\left(1+\sqrt{2}\right)} |\mathbf{r}_u \times \mathbf{r}_v|\,du\,dv\\ &= \int_0^{2\pi}\int_{-\ln\left(1+\sqrt{2}\right)}^{\ln\left(1+\sqrt{2}\right)} \sqrt{36\cosh^4 u\,\cos^2 v + 9\cosh^4 u\,\sin^2 v + 4\cosh^2 u\,\sinh^2 u}\,du\,dv\end{aligned}$$

61. To find the region D: $z = x^2 + y^2$ implies $z + z^2 = 4z$ or $z^2 - 3z = 0$. Thus $z = 0$ or $z = 3$ are the planes where the surfaces intersect. But $x^2 + y^2 + z^2 = 4z$ implies $x^2 + y^2 + (z-2)^2 = 4$, so $z = 3$ intersects the upper hemisphere. Thus $(z-2)^2 = 4 - x^2 - y^2$ or $z = 2 + \sqrt{4 - x^2 - y^2}$. Therefore D is the region inside the circle $x^2 + y^2 + (3-2)^2 = 4$, that is, $D = \left\{(x,y) \mid x^2 + y^2 \le 3\right\}$.

$$\begin{aligned}A(S) &= \iint_D \sqrt{1 + [(-x)(4 - x^2 - y^2)^{-1/2}]^2 + [(-y)(4 - x^2 - y^2)^{-1/2}]^2}\,dA\\ &= \int_0^{2\pi}\int_0^{\sqrt{3}} \sqrt{1 + \frac{r^2}{4 - r^2}}\,r\,dr\,d\theta = \int_0^{2\pi}\int_0^{\sqrt{3}} \frac{2r\,dr}{\sqrt{4 - r^2}}\,d\theta = \int_0^{2\pi}\left[-2(4 - r^2)^{1/2}\right]_{r=0}^{r=\sqrt{3}}\,d\theta\\ &= \int_0^{2\pi}(-2+4)\,d\theta = 2\theta\Big]_0^{2\pi} = 4\pi\end{aligned}$$

62. We first find the area of the face of the surface that intersects the positive y-axis. A parametric representation of the surface is $x = x, \;\; y = \sqrt{1 - z^2}, \;\; z = z$ with $x^2 + z^2 \le 1$. Then $\mathbf{r}(x,z) = \left\langle x, \sqrt{1 - z^2}, z\right\rangle \;\; \Rightarrow \;\; \mathbf{r}_x = \langle 1, 0, 0\rangle$,

$\mathbf{r}_z = \left\langle 0, -z/\sqrt{1 - z^2}, 1\right\rangle$ and $\mathbf{r}_x \times \mathbf{r}_z = \left\langle 0, -1, -z/\sqrt{1 - z^2}\,\right\rangle \;\; \Rightarrow \;\; |\,\mathbf{r}_x \times \mathbf{r}_z\,| = \sqrt{1 + \dfrac{z^2}{1 - z^2}} = \dfrac{1}{\sqrt{1 - z^2}}$.

$$A(S) = \iint\limits_{x^2 + z^2 \le 1} |\,\mathbf{r}_x \times \mathbf{r}_z\,|\,dA = \int_{-1}^{1}\int_{-\sqrt{1-z^2}}^{\sqrt{1-z^2}} \frac{1}{\sqrt{1 - z^2}}\,dx\,dz = 4\int_0^1\int_0^{\sqrt{1-z^2}} \frac{1}{\sqrt{1 - z^2}}\,dx\,dz \quad \left[\begin{array}{c}\text{by the symmetry}\\ \text{of the surface}\end{array}\right]$$

This integral is improper [when $z = 1$], so

$$A(S) = \lim_{t\to 1^-} 4\int_0^t \int_0^{\sqrt{1-z^2}} \frac{1}{\sqrt{1-z^2}}\,dx\,dz = \lim_{t\to 1^-} 4\int_0^t \frac{\sqrt{1-z^2}}{\sqrt{1-z^2}}\,dz = \lim_{t\to 1^-} 4\int_0^t dz = \lim_{t\to 1^-} 4t = 4$$

Since the complete surface consists of four congruent faces, the total surface area is $4(4) = 16$.

Alternate solution: The face of the surface that intersects the positive y-axis can also be parametrized as $\mathbf{r}(x,\theta) = \langle x, \cos\theta, \sin\theta\rangle$ for $-\frac{\pi}{2} \le \theta \le \frac{\pi}{2}$ and $x^2 + z^2 \le 1 \quad\Leftrightarrow\quad x^2 + \sin^2\theta \le 1 \quad\Leftrightarrow$ $-\sqrt{1-\sin^2\theta} \le x \le \sqrt{1-\sin^2\theta} \quad\Leftrightarrow\quad -\cos\theta \le x \le \cos\theta$. Then $\mathbf{r}_x = \langle 1,0,0\rangle$, $\mathbf{r}_\theta = \langle 0, -\sin\theta, \cos\theta\rangle$ and $\mathbf{r}_x \times \mathbf{r}_\theta = \langle 0, -\cos\theta, -\sin\theta\rangle \quad\Rightarrow\quad |\,\mathbf{r}_x \times \mathbf{r}_\theta\,| = 1$, so $A(S) = \int_{-\pi/2}^{\pi/2}\int_{-\cos\theta}^{\cos\theta} 1\,dx\,d\theta = \int_{-\pi/2}^{\pi/2} 2\cos\theta\,d\theta = \left.2\sin\theta\right]_{-\pi/2}^{\pi/2} = 4$. Again, the area of the complete surface is $4(4) = 16$.

63. Let $A(S_1)$ be the surface area of that portion of the surface which lies above the plane $z = 0$. Then $A(S) = 2A(S_1)$. Following Example 10, a parametric representation of S_1 is $x = a\sin\phi\cos\theta$, $y = a\sin\phi\sin\theta$, $z = a\cos\phi$ and $|\mathbf{r}_\phi \times \mathbf{r}_\theta| = a^2\sin\phi$. For D, $0 \le \phi \le \frac{\pi}{2}$ and for each fixed ϕ, $\left(x - \frac{1}{2}a\right)^2 + y^2 \le \left(\frac{1}{2}a\right)^2$ or $\left[a\sin\phi\cos\theta - \frac{1}{2}a\right]^2 + a^2\sin^2\phi\sin^2\theta \le (a/2)^2$ implies $a^2\sin^2\phi - a^2\sin\phi\cos\theta \le 0$ or $\sin\phi\,(\sin\phi - \cos\theta) \le 0$. But $0 \le \phi \le \frac{\pi}{2}$, so $\cos\theta \ge \sin\phi$ or $\sin\left(\frac{\pi}{2} + \theta\right) \ge \sin\phi$ or $\phi - \frac{\pi}{2} \le \theta \le \frac{\pi}{2} - \phi$. Hence $D = \left\{(\phi,\theta) \mid 0 \le \phi \le \frac{\pi}{2}, \phi - \frac{\pi}{2} \le \theta \le \frac{\pi}{2} - \phi\right\}$. Then

$$\begin{aligned} A(S_1) &= \int_0^{\pi/2}\int_{\phi - (\pi/2)}^{(\pi/2) - \phi} a^2\sin\phi\,d\theta\,d\phi = a^2\int_0^{\pi/2}(\pi - 2\phi)\sin\phi\,d\phi \\ &= a^2\left[(-\pi\cos\phi) - 2(-\phi\cos\phi + \sin\phi)\right]_0^{\pi/2} = a^2(\pi - 2) \end{aligned}$$

Thus $A(S) = 2a^2(\pi - 2)$.

Alternate solution: Working on S_1 we could parametrize the portion of the sphere by $x = x$, $y = y$, $z = \sqrt{a^2 - x^2 - y^2}$.

Then $|\mathbf{r}_x \times \mathbf{r}_y| = \sqrt{1 + \dfrac{x^2}{a^2 - x^2 - y^2} + \dfrac{y^2}{a^2 - x^2 - y^2}} = \dfrac{a}{\sqrt{a^2 - x^2 - y^2}}$ and

$$\begin{aligned} A(S_1) &= \iint\limits_{0 \le (x - (a/2))^2 + y^2 \le (a/2)^2} \frac{a}{\sqrt{a^2 - x^2 - y^2}}\,dA = \int_{-\pi/2}^{\pi/2}\int_0^{a\cos\theta} \frac{a}{\sqrt{a^2 - r^2}}\,r\,dr\,d\theta \\ &= \int_{-\pi/2}^{\pi/2} \left.-a(a^2 - r^2)^{1/2}\right]_{r=0}^{r = a\cos\theta} d\theta = \int_{-\pi/2}^{\pi/2} a^2\left[1 - (1 - \cos^2\theta)^{1/2}\right] d\theta \\ &= \int_{-\pi/2}^{\pi/2} a^2(1 - |\sin\theta|)\,d\theta = 2a^2\int_0^{\pi/2}(1 - \sin\theta)\,d\theta = 2a^2\left(\tfrac{\pi}{2} - 1\right) \end{aligned}$$

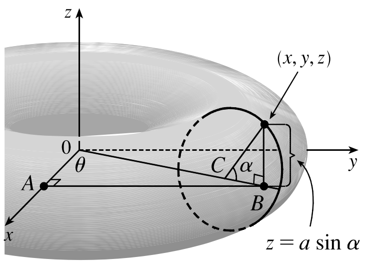
Thus $A(S) = 4a^2\left(\frac{\pi}{2} - 1\right) = 2a^2(\pi - 2)$.

Notes:

(1) Perhaps working in spherical coordinates is the most obvious approach here. However, you must be careful in setting up D.

(2) In the alternate solution, you can avoid having to use $|\sin\theta|$ by working in the first octant and then multiplying by 4. However, if you set up S_1 as above and arrived at $A(S_1) = a^2\pi$, you now see your error.

64. (a) Here $z = a\sin\alpha$, $y = |AB|$, and $x = |OA|$. But

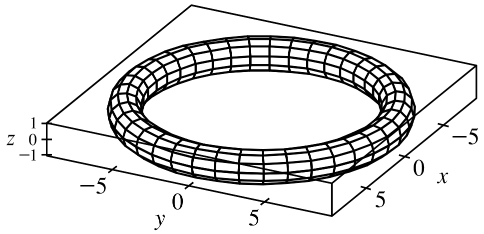


$|OB| = |OC| + |CB| = b + a\cos\alpha$ and $\sin\theta = \dfrac{|AB|}{|OB|}$ so that

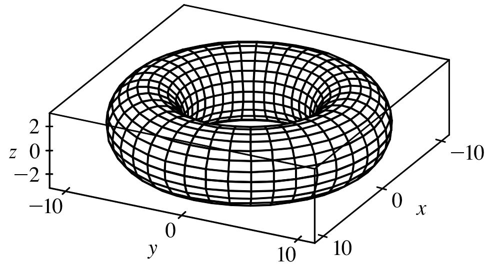
$y = |OB|\sin\theta = (b + a\cos\alpha)\sin\theta$. Similarly $\cos\theta = \dfrac{|OA|}{|OB|}$ so

$x = (b + a\cos\alpha)\cos\theta$. Hence a parametric representation for the torus is $x = b\cos\theta + a\cos\alpha\,\cos\theta$, $y = b\sin\theta + a\cos\alpha\,\sin\theta$, $z = a\sin\alpha$, where $0 \le \alpha \le 2\pi$, $0 \le \theta \le 2\pi$.

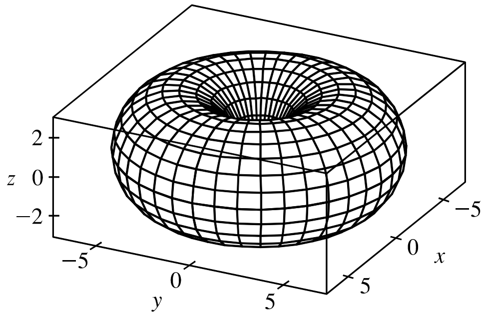
(b)



$a = 1, b = 8$



$a = 3, b = 8$



$a = 3, b = 4$

(c) $x = b\cos\theta + a\cos\alpha\,\cos\theta$, $y = b\sin\theta + a\cos\alpha\,\sin\theta$, $z = a\sin\alpha$, so $\mathbf{r}_\alpha = \langle -a\sin\alpha\,\cos\theta, -a\sin\alpha\,\sin\theta, a\cos\alpha\rangle$,

$\mathbf{r}_\theta = \langle -(b + a\cos\alpha)\sin\theta, (b + a\cos\alpha)\cos\theta, 0\rangle$ and

$$\begin{aligned}\mathbf{r}_\alpha \times \mathbf{r}_\theta &= \left(-ab\cos\alpha\,\cos\theta - a^2\cos\alpha\,\cos^2\theta\right)\mathbf{i} + \left(-ab\sin\alpha\,\cos\theta - a^2\sin\alpha\,\cos^2\theta\right)\mathbf{j} \\ &\quad + \left(-ab\cos^2\alpha\,\sin\theta - a^2\cos^2\alpha\,\sin\theta\,\cos\theta - ab\sin^2\alpha\,\sin\theta - a^2\sin^2\alpha\,\sin\theta\,\cos\theta\right)\mathbf{k} \\ &= -a\,(b + a\cos\alpha)\,[(\cos\theta\,\cos\alpha)\,\mathbf{i} + (\sin\theta\,\cos\alpha)\,\mathbf{j} + (\sin\alpha)\,\mathbf{k}]\end{aligned}$$

Then $|\mathbf{r}_\alpha \times \mathbf{r}_\theta| = a(b + a\cos\alpha)\sqrt{\cos^2\theta\,\cos^2\alpha + \sin^2\theta\,\cos^2\alpha + \sin^2\alpha} = a(b + a\cos\alpha)$.

Note: $b > a$, $-1 \le \cos\alpha \le 1$ so $|b + a\cos\alpha| = b + a\cos\alpha$. Hence

$A\,(S) = \int_0^{2\pi}\int_0^{2\pi} a(b + a\cos\alpha)\,d\alpha\,d\theta = 2\pi\left[ab\alpha + a^2\sin\alpha\right]_0^{2\pi} = 4\pi^2 ab$.

16.7 Surface Integrals

1. The box is a cube where each face has surface area 4. The centers of the faces are $(\pm1,0,0)$, $(0,\pm1,0)$, $(0,0,\pm1)$. For each face we take the point P_{ij}^* to be the center of the face and $f(x,y,z)=\cos(x+2y+3z)$, so by Definition 1,

$$\begin{aligned}\iint_S f(x,y,z)\,dS &\approx [f(1,0,0)](4)+[f(-1,0,0)](4)+[f(0,1,0)](4)\\&\qquad+[f(0,-1,0)](4)+[f(0,0,1)](4)+[f(0,0,-1)](4)\\&=4\,[\cos1+\cos(-1)+\cos2+\cos(-2)+\cos3+\cos(-3)]\approx-6.93\end{aligned}$$

2. Each quarter-cylinder has surface area $\frac{1}{4}[2\pi(1)(2)]=\pi$, and the top and bottom disks have surface area $\pi(1)^2=\pi$. We can take $(0,0,1)$ as a sample point in the top disk, $(0,0,-1)$ in the bottom disk, and $(\pm1,0,0)$, $(0,\pm1,0)$ in the four quarter-cylinders. Then $\iint_S f(x,y,z)\,dS$ can be approximated by the Riemann sum

$$\begin{aligned}&f(1,0,0)(\pi)+f(-1,0,0)(\pi)+f(0,1,0)\,(\pi)+f(0,-1,0)(\pi)+f(0,0,1)(\pi)+f(0,0,-1)(\pi)\\&\qquad=(2+2+3+3+4+4)\pi=18\pi\approx56.5.\end{aligned}$$

3. We can use the xz- and yz-planes to divide H into four patches of equal size, each with surface area equal to $\frac{1}{8}$ the surface area of a sphere with radius $\sqrt{50}$, so $\Delta S=\frac{1}{8}(4)\pi\big(\sqrt{50}\big)^2=25\pi$. Then $(\pm3,\pm4,5)$ are sample points in the four patches, and using a Riemann sum as in Definition 1, we have

$$\begin{aligned}\iint_H f(x,y,z)\,dS&\approx f(3,4,5)\,\Delta S+f(3,-4,5)\,\Delta S+f(-3,4,5)\,\Delta S+f(-3,-4,5)\,\Delta S\\&=(7+8+9+12)(25\pi)=900\pi\approx2827\end{aligned}$$

4. On the surface, $f(x,y,z)=g\Big(\sqrt{x^2+y^2+z^2}\Big)=g(2)=-5$. So since the area of a sphere is $4\pi r^2$,

$\iint_S f(x,y,z)\,dS=\iint_S g(2)\,dS=-5\iint_S dS=-5[4\pi(2)^2]=-80\pi$.

5. $\mathbf{r}(u,v)=(u+v)\,\mathbf{i}+(u-v)\,\mathbf{j}+(1+2u+v)\,\mathbf{k}$, $0\le u\le2$, $0\le v\le1$ and

$\mathbf{r}_u\times\mathbf{r}_v=(\mathbf{i}+\mathbf{j}+2\,\mathbf{k})\times(\mathbf{i}-\mathbf{j}+\mathbf{k})=3\,\mathbf{i}+\mathbf{j}-2\,\mathbf{k}\quad\Rightarrow\quad|\mathbf{r}_u\times\mathbf{r}_v|=\sqrt{3^2+1^2+(-2)^2}=\sqrt{14}$. Then by Formula 2,

$$\begin{aligned}\iint_S(x+y+z)\,dS&=\iint_D(u+v+u-v+1+2u+v)\;|\mathbf{r}_u\times\mathbf{r}_v|\;dA=\int_0^1\int_0^2(4u+v+1)\cdot\sqrt{14}\,du\,dv\\&=\sqrt{14}\int_0^1\big[2u^2+uv+u\big]_{u=0}^{u=2}\,dv=\sqrt{14}\int_0^1(2v+10)\,dv=\sqrt{14}\,\big[v^2+10v\big]_0^1=11\sqrt{14}\end{aligned}$$

6. $\mathbf{r}(u,v)=u\cos v\,\mathbf{i}+u\sin v\,\mathbf{j}+u\,\mathbf{k}$, $0\le u\le1$, $0\le v\le\pi/2$ and

$\mathbf{r}_u\times\mathbf{r}_v=(\cos v\,\mathbf{i}+\sin v\,\mathbf{j}+\mathbf{k})\times(-u\sin v\,\mathbf{i}+u\cos v\,\mathbf{j})=-u\cos v\,\mathbf{i}-u\sin v\,\mathbf{j}+u\,\mathbf{k}\quad\Rightarrow$

$|\mathbf{r}_u\times\mathbf{r}_v|=\sqrt{u^2\cos^2v+u^2\sin^2v+u^2}=\sqrt{2u^2}=\sqrt{2}\,u$ [since $u\ge0$]. Then by Formula 2,

$$\begin{aligned}\iint_S xyz\,dS&=\iint_D(u\cos v)(u\sin v)(u)\;|\mathbf{r}_u\times\mathbf{r}_v|\;dA=\int_0^1\int_0^{\pi/2}(u^3\sin v\cos v)\cdot\sqrt{2}\,u\,dv\,du\\&=\sqrt{2}\int_0^1u^4\,du\int_0^{\pi/2}\sin v\cos v\,dv=\sqrt{2}\left[\tfrac{1}{5}u^5\right]_0^1\;\left[\tfrac{1}{2}\sin^2v\right]_0^{\pi/2}=\sqrt{2}\cdot\tfrac{1}{5}\cdot\tfrac{1}{2}=\tfrac{1}{10}\sqrt{2}\end{aligned}$$

7. $\mathbf{r}(u,v)=\langle u\cos v,u\sin v,v\rangle,\;0\le u\le1,\;0\le v\le\pi$ and

$\mathbf{r}_u\times\mathbf{r}_v=\langle\cos v,\sin v,0\rangle\times\langle-u\sin v,u\cos v,1\rangle=\langle\sin v,-\cos v,u\rangle\quad\Rightarrow$

$|\mathbf{r}_u \times \mathbf{r}_v| = \sqrt{\sin^2 v + \cos^2 v + u^2} = \sqrt{u^2 + 1}$. Then

$$\iint_S y\,dS = \iint_D (u \sin v)\ |\mathbf{r}_u \times \mathbf{r}_v|\ dA = \int_0^1 \int_0^\pi (u \sin v) \cdot \sqrt{u^2+1}\,dv\,du = \int_0^1 u\sqrt{u^2+1}\,du\ \int_0^\pi \sin v\,dv$$

$$= \left[\tfrac{1}{3}(u^2+1)^{3/2}\right]_0^1\ [-\cos v]_0^\pi = \tfrac{1}{3}(2^{3/2}-1) \cdot 2 = \tfrac{2}{3}(2\sqrt{2}-1)$$

8. $\mathbf{r}(u,v) = \langle 2uv, u^2 - v^2, u^2 + v^2 \rangle$, $u^2 + v^2 \le 1$ and

$\mathbf{r}_u \times \mathbf{r}_v = \langle 2v, 2u, 2u \rangle \times \langle 2u, -2v, 2v \rangle = \langle 8uv, 4u^2 - 4v^2, -4u^2 - 4v^2 \rangle$, so

$$|\mathbf{r}_u \times \mathbf{r}_v| = \sqrt{(8uv)^2 + (4u^2-4v^2)^2 + (-4u^2-4v^2)^2} = \sqrt{64u^2v^2 + 32u^4 + 32v^4}$$

$$= \sqrt{32(u^2+v^2)^2} = 4\sqrt{2}\,(u^2+v^2)$$

Then

$$\iint_S (x^2+y^2)\,dS = \iint_D \left[(2uv)^2 + (u^2-v^2)^2\right]\ |\mathbf{r}_u \times \mathbf{r}_v|\ dA = \iint_D (4u^2v^2 + u^4 - 2u^2v^2 + v^4) \cdot 4\sqrt{2}\,(u^2+v^2)\,dA$$

$$= 4\sqrt{2} \iint_D (u^4 + 2u^2v^2 + v^4)\,(u^2+v^2)\,dA = 4\sqrt{2} \iint_D (u^2+v^2)^3\,dA = 4\sqrt{2} \int_0^{2\pi} \int_0^1 (r^2)^3\,r\,dr\,d\theta$$

$$= 4\sqrt{2} \int_0^{2\pi} d\theta \int_0^1 r^7\,dr = 4\sqrt{2}\ \left[\,\theta\,\right]_0^{2\pi}\ \left[\tfrac{1}{8}r^8\right]_0^1 = 4\sqrt{2} \cdot 2\pi \cdot \tfrac{1}{8} = \sqrt{2}\,\pi$$

9. $z = 1 + 2x + 3y$ so $\dfrac{\partial z}{\partial x} = 2$ and $\dfrac{\partial z}{\partial y} = 3$. Then by Formula 4,

$$\iint_S x^2yz\,dS = \iint_D x^2yz\sqrt{\left(\frac{\partial z}{\partial x}\right)^2 + \left(\frac{\partial z}{\partial y}\right)^2 + 1}\,dA = \int_0^3 \int_0^2 x^2y(1+2x+3y)\,\sqrt{4+9+1}\ dy\,dx$$

$$= \sqrt{14} \int_0^3 \int_0^2 (x^2y + 2x^3y + 3x^2y^2)\,dy\,dx = \sqrt{14} \int_0^3 \left[\tfrac{1}{2}x^2y^2 + x^3y^2 + x^2y^3\right]_{y=0}^{y=2} dx$$

$$= \sqrt{14} \int_0^3 (10x^2 + 4x^3)\,dx = \sqrt{14}\left[\tfrac{10}{3}x^3 + x^4\right]_0^3 = 171\sqrt{14}$$

10. S is the part of the plane $z = 4 - 2x - 2y$ over the region $D = \{(x,y) \mid 0 \le x \le 2,\ 0 \le y \le 2 - x\}$. Thus

$$\iint_S xz\,dS = \iint_D x(4-2x-2y)\,\sqrt{(-2)^2 + (-2)^2 + 1}\ dA = 3\int_0^2 \int_0^{2-x} \left(4x - 2x^2 - 2xy\right) dy\,dx$$

$$= 3\int_0^2 \left[4xy - 2x^2y - xy^2\right]_{y=0}^{y=2-x} dx = 3\int_0^2 \left[4x(2-x) - 2x^2(2-x) - x(2-x)^2\right] dx$$

$$= 3\int_0^2 \left(x^3 - 4x^2 + 4x\right) dx = 3\left[\tfrac{1}{4}x^4 - \tfrac{4}{3}x^3 + 2x^2\right]_0^2 = 3\left(4 - \tfrac{32}{3} + 8\right) = 4$$

11. An equation of the plane through the points $(1,0,0)$, $(0,-2,0)$, and $(0,0,4)$ is $4x - 2y + z = 4$, so S is the region in the plane $z = 4 - 4x + 2y$ over $D = \{(x,y) \mid 0 \le x \le 1,\ 2x - 2 \le y \le 0\}$. Thus by Formula 4,

$$\iint_S x\,dS = \iint_D x\,\sqrt{(-4)^2 + (2)^2 + 1}\,dA = \sqrt{21}\ \int_0^1 \int_{2x-2}^0 x\,dy\,dx = \sqrt{21}\ \int_0^1 [xy]_{y=2x-2}^{y=0}\ dx$$

$$= \sqrt{21}\ \int_0^1 (-2x^2 + 2x)\,dx = \sqrt{21}\left[-\tfrac{2}{3}x^3 + x^2\right]_0^1 = \sqrt{21}\left(-\tfrac{2}{3} + 1\right) = \tfrac{\sqrt{21}}{3}$$

12. $z = \tfrac{2}{3}(x^{3/2} + y^{3/2})$ and

$$\iint_S y\,dS = \iint_D y\sqrt{\left(\sqrt{x}\,\right)^2 + \left(\sqrt{y}\,\right)^2 + 1}\ dA = \int_0^1 \int_0^1 y\sqrt{x+y+1}\ dx\,dy$$

$$= \int_0^1 y\left[\tfrac{2}{3}(x+y+1)^{3/2}\right]_{x=0}^{x=1} dy = \int_0^1 \tfrac{2}{3}y\left[(y+2)^{3/2} - (y+1)^{3/2}\right] dy$$

[continued]

Substituting $u = y + 2$ in the first term and $t = y + 1$ in the second, we have

$$\iint_S y\,dS = \tfrac{2}{3}\int_2^3 (u-2)u^{3/2}\,du - \tfrac{2}{3}\int_1^2 (t-1)t^{3/2}\,dt = \tfrac{2}{3}\left[\tfrac{2}{7}u^{7/2} - \tfrac{4}{5}u^{5/2}\right]_2^3 - \tfrac{2}{3}\left[\tfrac{2}{7}t^{7/2} - \tfrac{2}{5}t^{5/2}\right]_1^2$$
$$= \tfrac{2}{3}\left[\tfrac{2}{7}(3^{7/2} - 2^{7/2}) - \tfrac{4}{5}(3^{5/2} - 2^{5/2}) - \tfrac{2}{7}(2^{7/2} - 1) + \tfrac{2}{5}(2^{5/2} - 1)\right]$$
$$= \tfrac{2}{3}\left(\tfrac{18}{35}\sqrt{3} + \tfrac{8}{35}\sqrt{2} - \tfrac{4}{35}\right) = \tfrac{4}{105}\left(9\sqrt{3} + 4\sqrt{2} - 2\right)$$

13. Using y and z as parameters, we have $\mathbf{r}(y,z) = (y^2 + z^2)\,\mathbf{i} + y\,\mathbf{j} + z\,\mathbf{k},\ y^2 + z^2 \le 1$. Then

$\mathbf{r}_y \times \mathbf{r}_z = (2y\,\mathbf{i} + \mathbf{j}) \times (2z\,\mathbf{i} + \mathbf{k}) = \mathbf{i} - 2y\,\mathbf{j} - 2z\,\mathbf{k}$ and $|\mathbf{r}_y \times \mathbf{r}_z| = \sqrt{1 + 4y^2 + 4z^2} = \sqrt{1 + 4(y^2 + z^2)}$. Thus

$$\iint_S z^2\,dS = \iint_{y^2+z^2\le 1} z^2\sqrt{1 + 4(y^2+z^2)}\,dA = \int_0^{2\pi}\int_0^1 (r\sin\theta)^2\sqrt{1+4r^2}\,r\,dr\,d\theta$$
$$= \int_0^{2\pi}\sin^2\theta\,d\theta\int_0^1 r^3\sqrt{1+4r^2}\,dr \qquad \left[\text{let } u = 1 + 4r^2 \;\Rightarrow\; r^2 = \tfrac{1}{4}(u-1) \text{ and } r\,dr = \tfrac{1}{8}du\right]$$
$$= \left[\tfrac{1}{2}\theta - \tfrac{1}{4}\sin 2\theta\right]_0^{2\pi}\int_1^5 \tfrac{1}{4}(u-1)\sqrt{u}\cdot\tfrac{1}{8}du = \pi\cdot\tfrac{1}{32}\int_1^5 (u^{3/2} - u^{1/2})\,du = \tfrac{1}{32}\pi\left[\tfrac{2}{5}u^{5/2} - \tfrac{2}{3}u^{3/2}\right]_1^5$$
$$= \tfrac{1}{32}\pi\left[\tfrac{2}{5}(5)^{5/2} - \tfrac{2}{3}(5)^{3/2} - \tfrac{2}{5} + \tfrac{2}{3}\right] = \tfrac{1}{32}\pi\left(\tfrac{20}{3}\sqrt{5} + \tfrac{4}{15}\right) = \tfrac{1}{120}\pi\left(25\sqrt{5} + 1\right)$$

14. Using x and z as parameters, we have $\mathbf{r}(x,z) = x\,\mathbf{i} + \sqrt{x^2+z^2}\,\mathbf{j} + z\,\mathbf{k},\ x^2 + z^2 \le 25$. Then

$$\mathbf{r}_x \times \mathbf{r}_z = \left(\mathbf{i} + \frac{x}{\sqrt{x^2+z^2}}\,\mathbf{j}\right) \times \left(\frac{z}{\sqrt{x^2+z^2}}\,\mathbf{j} + \mathbf{k}\right) = \frac{x}{\sqrt{x^2+z^2}}\,\mathbf{i} - \mathbf{j} + \frac{z}{\sqrt{x^2+z^2}}\,\mathbf{k} \text{ and}$$

$$|\mathbf{r}_x \times \mathbf{r}_z| = \sqrt{\frac{x^2}{x^2+z^2} + 1 + \frac{z^2}{x^2+z^2}} = \sqrt{\frac{x^2+z^2}{x^2+z^2} + 1} = \sqrt{2}. \text{ Thus}$$

$$\iint_S y^2z^2\,dS = \iint_{x^2+z^2\le 25} (x^2+z^2)z^2\sqrt{2}\,dA = \sqrt{2}\int_0^{2\pi}\int_0^5 r^2(r\sin\theta)^2\,r\,dr\,d\theta$$
$$= \sqrt{2}\int_0^{2\pi}\sin^2\theta\,d\theta\int_0^5 r^5\,dr = \sqrt{2}\left[\tfrac{1}{2}\theta - \tfrac{1}{4}\sin 2\theta\right]_0^{2\pi}\left[\tfrac{1}{6}r^6\right]_0^5$$
$$= \sqrt{2}\,(\pi)\cdot\tfrac{1}{6}(15{,}625 - 0) = \frac{15{,}625\sqrt{2}}{6}\pi$$

15. Using x and z as parameters, we have $\mathbf{r}(x,z) = x\,\mathbf{i} + (x^2 + 4z)\,\mathbf{j} + z\,\mathbf{k},\ 0 \le x \le 1, 0 \le z \le 1$. Then

$\mathbf{r}_x \times \mathbf{r}_z = (\mathbf{i} + 2x\,\mathbf{j}) \times (4\,\mathbf{j} + \mathbf{k}) = 2x\,\mathbf{i} - \mathbf{j} + 4\,\mathbf{k}$ and $|\mathbf{r}_x \times \mathbf{r}_z| = \sqrt{4x^2 + 1 + 16} = \sqrt{4x^2 + 17}$. Thus

$$\iint_S x\,dS = \int_0^1\int_0^1 x\sqrt{4x^2+17}\,dz\,dx = \int_0^1 x\sqrt{4x^2+17}\,dx = \left[\tfrac{1}{8}\cdot\tfrac{2}{3}(4x^2+17)^{3/2}\right]_0^1$$
$$= \tfrac{1}{12}(21^{3/2} - 17^{3/2}) = \tfrac{1}{12}\left(21\sqrt{21} - 17\sqrt{17}\right) = \tfrac{7}{4}\sqrt{21} - \tfrac{17}{12}\sqrt{17}$$

16. The sphere intersects the cone in the circle $x^2 + y^2 = \frac{1}{2}$, $z = \frac{1}{\sqrt{2}}$, so S is the portion of the sphere where $z \ge \frac{1}{\sqrt{2}}$.

Using spherical coordinates to parametrize the sphere we have $\mathbf{r}(\phi,\theta) = \sin\phi\,\cos\theta\,\mathbf{i} + \sin\phi\,\sin\theta\,\mathbf{j} + \cos\phi\,\mathbf{k}$, and

$|\mathbf{r}_\phi \times \mathbf{r}_\theta| = \sin\phi$ (as in Example 1). The portion where $z \ge \frac{1}{\sqrt{2}}$ corresponds to $0 \le \phi \le \frac{\pi}{4}$, $0 \le \theta \le 2\pi$ so

$$\iint_S y^2\,dS = \int_0^{2\pi}\int_0^{\pi/4}(\sin\phi\sin\theta)^2(\sin\phi)\,d\phi\,d\theta = \int_0^{2\pi}\sin^2\theta\,d\theta\int_0^{\pi/4}\sin^3\phi\,d\phi = \int_0^{2\pi}\sin^2\theta\,d\theta\int_0^{\pi/4}(1 - \cos^2\phi)\sin\phi\,d\phi$$
$$= \left[\tfrac{1}{2}\theta - \tfrac{1}{4}\sin 2\theta\right]_0^{2\pi}\left[\tfrac{1}{3}\cos^3\phi - \cos\phi\right]_0^{\pi/4} = \pi\left(\tfrac{\sqrt{2}}{12} - \tfrac{\sqrt{2}}{2} - \tfrac{1}{3} + 1\right) = \left(\tfrac{2}{3} - \tfrac{5\sqrt{2}}{12}\right)\pi$$

17. Using spherical coordinates to parametrize the sphere we have $\mathbf{r}(\phi,\theta) = 2\sin\phi\cos\theta\,\mathbf{i} + 2\sin\phi\sin\theta\,\mathbf{j} + 2\cos\phi\,\mathbf{k}$ and $|\mathbf{r}_\phi \times \mathbf{r}_\theta| = 4\sin\phi$ (see Example 16.6.10). Here S is the portion of the sphere corresponding to $0 \le \phi \le \pi/2$, so

$$\iint_S (x^2z + y^2z)\,dS = \iint_S (x^2+y^2)z\,dS = \int_0^{2\pi}\int_0^{\pi/2} (4\sin^2\phi)(2\cos\phi)(4\sin\phi)\,d\phi\,d\theta$$
$$= 32\int_0^{2\pi} d\theta \int_0^{\pi/2} \sin^3\phi\cos\phi\,d\phi = 32\,(2\pi)\,\left[\tfrac14\sin^4\phi\right]_0^{\pi/2} = 16\pi(1-0) = 16\pi$$

18. S is given by $\mathbf{r}(u,v) = \cos v\,\mathbf{i} + u\,\mathbf{j} + \sin v\,\mathbf{k}$, $0 \le u \le 2$, $0 \le v \le \pi$. Then

$\mathbf{r}_u \times \mathbf{r}_v = \mathbf{j} \times (-\sin v\,\mathbf{i} + \cos v\,\mathbf{k}) = \cos v\,\mathbf{i} + \sin v\,\mathbf{k}$ and $|\mathbf{r}_u \times \mathbf{r}_v| = \sqrt{\cos^2 v + \sin^2 v} = 1$, so

$$\iint_S (x+y+z)\,dS = \int_0^\pi \int_0^2 (\cos v + u + \sin v)(1)\,du\,dv = \int_0^\pi \left[u(\cos v + \sin v) + \tfrac12 u^2\right]_{u=0}^{u=2} dv$$
$$= \int_0^\pi (2\cos v + 2\sin v + 2)\,dv = [2\sin v - 2\cos v + 2v]_0^\pi = 2 + 2\pi + 2 = 4 + 2\pi$$

19. Here S consists of three surfaces: S_1, the lateral surface of the cylinder; S_2, the front formed by the plane $x+y=5$; and the back, S_3, in the plane $x=0$.

On S_1: the surface is given by $\mathbf{r}(u,v) = u\,\mathbf{i} + 3\cos v\,\mathbf{j} + 3\sin v\,\mathbf{k}$, $0 \le v \le 2\pi$, and $0 \le x \le 5-y \quad\Rightarrow$

$0 \le u \le 5 - 3\cos v$. Then $\mathbf{r}_u \times \mathbf{r}_v = -3\cos v\,\mathbf{j} - 3\sin v\,\mathbf{k}$ and $|\mathbf{r}_u \times \mathbf{r}_v| = \sqrt{9\cos^2 v + 9\sin^2 v} = 3$, so

$$\iint_{S_1} xz\,dS = \int_0^{2\pi}\int_0^{5-3\cos v} u(3\sin v)(3)\,du\,dv = 9\int_0^{2\pi} \left[\tfrac12 u^2\right]_{u=0}^{u=5-3\cos v} \sin v\,dv$$
$$= \tfrac92 \int_0^{2\pi} (5-3\cos v)^2 \sin v\,dv = \tfrac92\left[\tfrac19(5-3\cos v)^3\right]_0^{2\pi} = 0.$$

On S_2: $\mathbf{r}(y,z) = (5-y)\,\mathbf{i} + y\,\mathbf{j} + z\,\mathbf{k}$ and $|\mathbf{r}_y \times \mathbf{r}_z| = |\mathbf{i} + \mathbf{j}| = \sqrt2$, where $y^2 + z^2 \le 9$ and

$$\iint_{S_2} xz\,dS = \iint_{y^2+z^2\le 9} (5-y)z\sqrt2\,dA = \sqrt2\int_0^{2\pi}\int_0^3 (5 - r\cos\theta)(r\sin\theta)\,r\,dr\,d\theta$$
$$= \sqrt2\int_0^{2\pi}\int_0^3 (5r^2 - r^3\cos\theta)(\sin\theta)\,dr\,d\theta = \sqrt2\int_0^{2\pi} \left[\tfrac53 r^3 - \tfrac14 r^4\cos\theta\right]_{r=0}^{r=3} \sin\theta\,d\theta$$
$$= \sqrt2\int_0^{2\pi} \left(45 - \tfrac{81}{4}\cos\theta\right)\sin\theta\,d\theta = \sqrt2\left(\tfrac{4}{81}\right)\cdot\tfrac12\left(45 - \tfrac{81}{4}\cos\theta\right)^2\Big]_0^{2\pi} = 0$$

On S_3: $x = 0$ so $\iint_{S_3} xz\,dS = 0$. Hence $\iint_S xz\,dS = 0 + 0 + 0 = 0$.

20. Let S_1 be the lateral surface, S_2 the top disk, and S_3 the bottom disk.

On S_1: $\mathbf{r}(\theta,z) = 3\cos\theta\,\mathbf{i} + 3\sin\theta\,\mathbf{j} + z\,\mathbf{k}$, $0 \le \theta \le 2\pi$, $0 \le z \le 2$, $|\mathbf{r}_\theta \times \mathbf{r}_z| = 3$,

$\iint_{S_1} (x^2+y^2+z^2)\,dS = \int_0^{2\pi}\int_0^2 (9+z^2)\,3\,dz\,d\theta = 2\pi(54+8) = 124\pi$.

On S_2: $\mathbf{r}(\theta,r) = r\cos\theta\,\mathbf{i} + r\sin\theta\,\mathbf{j} + 2\,\mathbf{k}$, $0 \le r \le 3$, $0 \le \theta \le 2\pi$, $|\mathbf{r}_\theta \times \mathbf{r}_r| = r$,

$\iint_{S_2} (x^2+y^2+z^2)\,dS = \int_0^{2\pi}\int_0^3 (r^2+4)\,r\,dr\,d\theta = 2\pi\left(\frac{81}{4} + 18\right) = \frac{153}{2}\pi$.

On S_3: $\mathbf{r}(\theta,r) = r\cos\theta\,\mathbf{i} + r\sin\theta\,\mathbf{j}$, $0 \le r \le 3$, $0 \le \theta \le 2\pi$, $|\mathbf{r}_\theta \times \mathbf{r}_r| = r$,

$\iint_{S_3} (x^2+y^2+z^2)\,dS = \int_0^{2\pi}\int_0^3 (r^2+0)\,r\,dr\,d\theta = 2\pi\left(\frac{81}{4}\right) = \frac{81}{2}\pi$.

Hence $\iint_S \left(x^2+y^2+z^2\right) dS = 124\pi + \frac{153}{2}\pi + \frac{81}{2}\pi = 241\pi$.

21. From Exercise 5, $\mathbf{r}(u,v) = (u+v)\,\mathbf{i} + (u-v)\,\mathbf{j} + (1+2u+v)\,\mathbf{k}$, $0 \le u \le 2$, $0 \le v \le 1$, and $\mathbf{r}_u \times \mathbf{r}_v = 3\,\mathbf{i} + \mathbf{j} - 2\,\mathbf{k}$. Then

$$\begin{aligned}\mathbf{F}(\mathbf{r}(u,v)) &= (1+2u+v)e^{(u+v)(u-v)}\,\mathbf{i} - 3(1+2u+v)e^{(u+v)(u-v)}\,\mathbf{j} + (u+v)(u-v)\,\mathbf{k} \\ &= (1+2u+v)e^{u^2-v^2}\,\mathbf{i} - 3(1+2u+v)e^{u^2-v^2}\,\mathbf{j} + (u^2-v^2)\,\mathbf{k}\end{aligned}$$

Because the z-component of $\mathbf{r}_u \times \mathbf{r}_v$ is negative we use $-(\mathbf{r}_u \times \mathbf{r}_v)$ in Formula 9 for the upward orientation:

$$\begin{aligned}\iint_S \mathbf{F}\cdot d\mathbf{S} &= \iint_D \mathbf{F}\cdot(-(\mathbf{r}_u \times \mathbf{r}_v))\,dA = \int_0^1\int_0^2 \left[-3(1+2u+v)e^{u^2-v^2} + 3(1+2u+v)e^{u^2-v^2} + 2(u^2-v^2)\right] du\,dv \\ &= \int_0^1\int_0^2 2(u^2-v^2)\,du\,dv = 2\int_0^1 \left[\tfrac{1}{3}u^3 - uv^2\right]_{u=0}^{u=2} dv = 2\int_0^1 \left(\tfrac{8}{3} - 2v^2\right) dv \\ &= 2\left[\tfrac{8}{3}v - \tfrac{2}{3}v^3\right]_0^1 = 2\left(\tfrac{8}{3} - \tfrac{2}{3}\right) = 4\end{aligned}$$

22. $\mathbf{r}(u,v) = \langle u\cos v, u\sin v, v\rangle$, $0 \le u \le 1$, $0 \le v \le \pi$ and

$\mathbf{r}_u \times \mathbf{r}_v = \langle \cos v, \sin v, 0\rangle \times \langle -u\sin v, u\cos v, 1\rangle = \langle \sin v, -\cos v, u\rangle$. Here $\mathbf{F}(\mathbf{r}(u,v)) = v\,\mathbf{i} + u\sin v\,\mathbf{j} + u\cos v\,\mathbf{k}$ and, by Formula 9,

$$\begin{aligned}\iint_S \mathbf{F}\cdot d\mathbf{S} &= \iint_D \mathbf{F}\cdot(\mathbf{r}_u \times \mathbf{r}_v)\,dA = \int_0^1\int_0^\pi (v\sin v - u\sin v\cos v + u^2\cos v)\,dv\,du \\ &= \int_0^1 \left[\sin v - v\cos v - \tfrac{1}{2}u\sin^2 v + u^2\sin v\right]_{v=0}^{v=\pi} du = \int_0^1 \pi\,du = \pi u\big]_0^1 = \pi\end{aligned}$$

23. $\mathbf{F}(x,y,z) = xy\,\mathbf{i} + yz\,\mathbf{j} + zx\,\mathbf{k}$, $z = g(x,y) = 4 - x^2 - y^2$, and D is the square $[0,1]\times[0,1]$, so by Equation 10

$$\begin{aligned}\iint_S \mathbf{F}\cdot d\mathbf{S} &= \iint_D [-xy(-2x) - yz(-2y) + zx]\,dA = \int_0^1\int_0^1 [2x^2y + 2y^2(4-x^2-y^2) + x(4-x^2-y^2)]\,dy\,dx \\ &= \int_0^1 \left[x^2y^2 + \tfrac{8}{3}y^3 - \tfrac{2}{3}x^2y^3 - \tfrac{2}{5}y^5 + 4xy - x^3y - \tfrac{1}{3}xy^3\right]_{y=0}^{y=1} dx \\ &= \int_0^1 \left(\tfrac{1}{3}x^2 + \tfrac{11}{3}x - x^3 + \tfrac{34}{15}\right) dx = \left[\tfrac{1}{9}x^3 + \tfrac{11}{6}x^2 - \tfrac{1}{4}x^4 + \tfrac{34}{15}x\right]_0^1 = \tfrac{713}{180}\end{aligned}$$

24. $\mathbf{F}(x,y,z) = -x\,\mathbf{i} - y\,\mathbf{j} + z^3\,\mathbf{k}$, $z = g(x,y) = \sqrt{x^2+y^2}$, and D is the annular region $\{(x,y) \mid 1 \le x^2+y^2 \le 9\}$. Since S has downward orientation, we have

$$\begin{aligned}\iint_S \mathbf{F}\cdot d\mathbf{S} &= -\iint_D \left[-(-x)\left(\frac{x}{\sqrt{x^2+y^2}}\right) - (-y)\left(\frac{y}{\sqrt{x^2+y^2}}\right) + z^3\right] dA \\ &= -\iint_D \left[\frac{x^2+y^2}{\sqrt{x^2+y^2}} + \left(\sqrt{x^2+y^2}\right)^3\right] dA = -\int_0^{2\pi}\int_1^3 \left(\frac{r^2}{r} + r^3\right) r\,dr\,d\theta \\ &= -\int_0^{2\pi} d\theta \int_1^3 (r^2 + r^4)\,dr = -\big[\,\theta\,\big]_0^{2\pi} \left[\tfrac{1}{3}r^3 + \tfrac{1}{5}r^5\right]_1^3 \\ &= -2\pi\left(9 + \tfrac{243}{5} - \tfrac{1}{3} - \tfrac{1}{5}\right) = -\tfrac{1712}{15}\pi\end{aligned}$$

25. $\mathbf{F}(x,y,z) = x\,\mathbf{i} + y\,\mathbf{j} + z^2\,\mathbf{k}$, and using spherical coordinates, S is given by $x = \sin\phi\cos\theta$, $y = \sin\phi\sin\theta$, $z = \cos\phi$, $0 \le \theta \le 2\pi$, $0 \le \phi \le \pi$. $\mathbf{F}(\mathbf{r}(\phi,\theta)) = (\sin\phi\cos\theta)\,\mathbf{i} + (\sin\phi\sin\theta)\,\mathbf{j} + (\cos^2\phi)\,\mathbf{k}$ and, from Example 4, $\mathbf{r}_\phi \times \mathbf{r}_\theta = \sin^2\phi\cos\theta\,\mathbf{i} + \sin^2\phi\sin\theta\,\mathbf{j} + \sin\phi\cos\phi\,\mathbf{k}$. Thus

$$\mathbf{F}(\mathbf{r}(\phi,\theta))\cdot(\mathbf{r}_\phi \times \mathbf{r}_\theta) = \sin^3\phi\cos^2\theta + \sin^3\phi\sin^2\theta + \sin\phi\cos^3\phi = \sin^3\phi + \sin\phi\cos^3\phi$$

and

$$\iint_S \mathbf{F}\cdot d\mathbf{S} = \iint_D [\mathbf{F}(\mathbf{r}(\phi,\theta))\cdot(\mathbf{r}_\phi\times\mathbf{r}_\theta)]\,dA = \int_0^{2\pi}\int_0^{\pi}(\sin^3\phi + \sin\phi\cos^3\phi)\,d\phi\,d\theta$$
$$= \int_0^{2\pi}d\theta\int_0^{\pi}(1-\cos^2\phi+\cos^3\phi)\sin\phi\,d\phi = (2\pi)\left[-\cos\phi+\tfrac{1}{3}\cos^3\phi-\tfrac{1}{4}\cos^4\phi\right]_0^{\pi}$$
$$= 2\pi\left(1-\tfrac{1}{3}-\tfrac{1}{4}+1-\tfrac{1}{3}+\tfrac{1}{4}\right) = \tfrac{8}{3}\pi$$

26. $\mathbf{F}(x,y,z) = y\,\mathbf{i} - x\,\mathbf{j} + 2z\,\mathbf{k}$, $z = g(x,y) = \sqrt{4-x^2-y^2}$ and D is the disk $\{(x,y)\mid x^2+y^2\le 4\}$. S has downward orientation, so by Equation 10,

$$\iint_S \mathbf{F}\cdot d\mathbf{S} = -\iint_D[-y\cdot\tfrac{1}{2}(4-x^2-y^2)^{-1/2}(-2x)-(-x)\cdot\tfrac{1}{2}(4-x^2-y^2)^{-1/2}(-2y)+2z]\,dA$$
$$= -\iint_D\left(\frac{xy}{\sqrt{4-x^2-y^2}}-\frac{xy}{\sqrt{4-x^2-y^2}}+2\sqrt{4-x^2-y^2}\right)dA$$
$$= -\iint_D 2\sqrt{4-x^2-y^2}\,dA = -2\int_0^{2\pi}\int_0^2\sqrt{4-r^2}\,r\,dr\,d\theta = -2\int_0^{2\pi}d\theta\int_0^2 r\sqrt{4-r^2}\,dr$$
$$= -2(2\pi)\left[-\tfrac{1}{2}\cdot\tfrac{2}{3}(4-r^2)^{3/2}\right]_0^2 = -4\pi\left[0+\tfrac{1}{3}(4)^{3/2}\right] = -4\pi\cdot\tfrac{8}{3} = -\tfrac{32}{3}\pi$$

27. Let S_1 be the paraboloid $y = x^2+z^2$, $0\le y\le 1$ and S_2 the disk $x^2+z^2\le 1$, $y=1$. Since S is a closed surface, we use the outward orientation.

On S_1: $\mathbf{F}(\mathbf{r}(x,z)) = (x^2+z^2)\,\mathbf{j} - z\,\mathbf{k}$ and $\mathbf{r}_x\times\mathbf{r}_z = 2x\,\mathbf{i}-\mathbf{j}+2z\,\mathbf{k}$ (since the $\mathbf{j}$-component must be negative on S_1). Then

$$\iint_{S_1}\mathbf{F}\cdot d\mathbf{S} = \iint_{x^2+z^2\le 1}[-(x^2+z^2)-2z^2]\,dA = -\int_0^{2\pi}\int_0^1(r^2+2r^2\sin^2\theta)\,r\,dr\,d\theta$$
$$= -\int_0^{2\pi}\int_0^1 r^3(1+2\sin^2\theta)\,dr\,d\theta = -\int_0^{2\pi}(1+1-\cos 2\theta)\,d\theta\int_0^1 r^3\,dr$$
$$= -\left[2\theta-\tfrac{1}{2}\sin 2\theta\right]_0^{2\pi}\left[\tfrac{1}{4}r^4\right]_0^1 = -4\pi\cdot\tfrac{1}{4} = -\pi$$

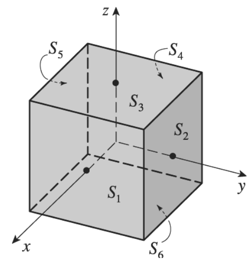
On S_2: $\mathbf{F}(\mathbf{r}(x,z)) = \mathbf{j} - z\,\mathbf{k}$ and $\mathbf{r}_z\times\mathbf{r}_x = \mathbf{j}$. Then $\iint_{S_2}\mathbf{F}\cdot d\mathbf{S} = \iint_{x^2+z^2\le 1}(1)\,dA = \pi$.

Hence $\iint_S\mathbf{F}\cdot d\mathbf{S} = -\pi+\pi = 0$.

28. $\mathbf{F}(x,y,z) = yz\,\mathbf{i}+zx\,\mathbf{j}+xy\,\mathbf{k}$, $z = g(x,y) = x\sin y$, and D is the rectangle $[0,2]\times[0,\pi]$, so by Equation 10

$$\iint_S\mathbf{F}\cdot d\mathbf{S} = \iint_D[-yz(\sin y)-zx(x\cos y)+xy]\,dA = \int_0^{\pi}\int_0^2(-xy\sin^2 y - x^3\sin y\cos y + xy)\,dx\,dy$$
$$= \int_0^{\pi}\left[-\tfrac{1}{2}x^2y\sin^2 y-\tfrac{1}{4}x^4\sin y\cos y+\tfrac{1}{2}x^2y\right]_{x=0}^{x=2}dy$$
$$= \int_0^{\pi}\left(-2y\sin^2 y-4\sin y\cos y+2y\right)dy \qquad \text{[integrate by parts in the first term]}$$
$$= \left[\left(-\tfrac{1}{2}y^2+\tfrac{1}{2}y\sin 2y+\tfrac{1}{4}\cos 2y\right)-2\sin^2 y+y^2\right]_0^{\pi} = -\tfrac{1}{2}\pi^2+\tfrac{1}{4}+\pi^2-\tfrac{1}{4} = \tfrac{1}{2}\pi^2$$

29. Here S consists of the six faces of the cube as labeled in the figure. On S_1:



$\mathbf{F} = \mathbf{i}+2y\,\mathbf{j}+3z\,\mathbf{k}$, $\mathbf{r}_y\times\mathbf{r}_z = \mathbf{i}$ and $\iint_{S_1}\mathbf{F}\cdot d\mathbf{S} = \int_{-1}^1\int_{-1}^1 dy\,dz = 4$;

S_2: $\mathbf{F} = x\,\mathbf{i}+2\,\mathbf{j}+3z\,\mathbf{k}$, $\mathbf{r}_z\times\mathbf{r}_x = \mathbf{j}$ and $\iint_{S_2}\mathbf{F}\cdot d\mathbf{S} = \int_{-1}^1\int_{-1}^1 2\,dx\,dz = 8$;

S_3: $\mathbf{F} = x\,\mathbf{i}+2y\,\mathbf{j}+3\,\mathbf{k}$, $\mathbf{r}_x\times\mathbf{r}_y = \mathbf{k}$ and $\iint_{S_3}\mathbf{F}\cdot d\mathbf{S} = \int_{-1}^1\int_{-1}^1 3\,dx\,dy = 12$;

S_4: $\mathbf{F} = -\mathbf{i}+2y\,\mathbf{j}+3z\,\mathbf{k}$, $\mathbf{r}_z\times\mathbf{r}_y = -\mathbf{i}$ and $\iint_{S_4}\mathbf{F}\cdot d\mathbf{S} = 4$;

S_5: $\mathbf{F} = x\,\mathbf{i}-2\,\mathbf{j}+3z\,\mathbf{k}$, $\mathbf{r}_x\times\mathbf{r}_z = -\mathbf{j}$ and $\iint_{S_5}\mathbf{F}\cdot d\mathbf{S} = 8$;

S_6: $\mathbf{F} = x\,\mathbf{i} + 2y\,\mathbf{j} - 3\,\mathbf{k}$, $\mathbf{r}_y \times \mathbf{r}_x = -\mathbf{k}$ and $\iint_{S_6} \mathbf{F} \cdot d\mathbf{S} = \int_{-1}^{1} \int_{-1}^{1} 3\,dx\,dy = 12$.

Hence $\iint_S \mathbf{F} \cdot d\mathbf{S} = \sum\limits_{i=1}^{6} \iint_{S_i} \mathbf{F} \cdot d\mathbf{S} = 48$.

30. Here S consists of three surfaces: S_1, the lateral surface of the cylinder; S_2, the front formed by the plane $x + y = 2$; and the back, S_3, in the plane $y = 0$.

On S_1: $\mathbf{F}(\mathbf{r}(\theta, y)) = \sin\theta\,\mathbf{i} + y\,\mathbf{j} + 5\,\mathbf{k}$ and $\mathbf{r}_\theta \times \mathbf{r}_y = \sin\theta\,\mathbf{i} + \cos\theta\,\mathbf{k} \quad \Rightarrow$

$$\begin{aligned} \iint_{S_1} \mathbf{F} \cdot d\mathbf{S} &= \int_0^{2\pi} \int_0^{2 - \sin\theta} (\sin^2\theta + 5\cos\theta)\,dy\,d\theta \\ &= \int_0^{2\pi} (2\sin^2\theta + 10\cos\theta - \sin^3\theta - 5\sin\theta\,\cos\theta)\,d\theta = 2\pi \end{aligned}$$

On S_2: $\mathbf{F}(\mathbf{r}(x, z)) = x\,\mathbf{i} + (2 - x)\,\mathbf{j} + 5\,\mathbf{k}$ and $\mathbf{r}_z \times \mathbf{r}_x = \mathbf{i} + \mathbf{j}$.

$$\iint_{S_2} \mathbf{F} \cdot d\mathbf{S} = \iint\limits_{x^2 + z^2 \le 1} [x + (2 - x)]\,dA = 2\pi$$

On S_3: $\mathbf{F}(\mathbf{r}(x, z)) = x\,\mathbf{i} + 5\,\mathbf{k}$ and $\mathbf{r}_x \times \mathbf{r}_z = -\mathbf{j}$ so $\iint_{S_3} \mathbf{F} \cdot d\mathbf{S} = 0$. Hence $\iint_S \mathbf{F} \cdot d\mathbf{S} = 4\pi$.

31. Here S consists of four surfaces: S_1, the top surface (a portion of the circular cylinder $y^2 + z^2 = 1$); S_2, the bottom surface (a portion of the xy-plane); S_3, the front half-disk in the plane $x = 2$, and S_4, the back half-disk in the plane $x = 0$.

On S_1: The surface is $z = \sqrt{1 - y^2}$ for $0 \le x \le 2$, $-1 \le y \le 1$ with upward orientation, so

$$\begin{aligned} \iint_{S_1} \mathbf{F} \cdot d\mathbf{S} &= \int_0^2 \int_{-1}^1 \left[-x^2\,(0) - y^2\left(-\frac{y}{\sqrt{1 - y^2}}\right) + z^2\right] dy\,dx = \int_0^2 \int_{-1}^1 \left(\frac{y^3}{\sqrt{1 - y^2}} + 1 - y^2\right) dy\,dx \\ &= \int_0^2 \left[-\sqrt{1 - y^2} + \tfrac{1}{3}(1 - y^2)^{3/2} + y - \tfrac{1}{3}y^3\right]_{y=-1}^{y=1} dx = \int_0^2 \tfrac{4}{3}\,dx = \tfrac{8}{3} \end{aligned}$$

On S_2: The surface is $z = 0$ with downward orientation, so

$$\iint_{S_2} \mathbf{F} \cdot d\mathbf{S} = \int_0^2 \int_{-1}^1 \left(-z^2\right) dy\,dx = \int_0^2 \int_{-1}^1 (0)\,dy\,dx = 0$$

On S_3: The surface is $x = 2$ for $-1 \le y \le 1$, $0 \le z \le \sqrt{1 - y^2}$, oriented in the positive x-direction. Regarding y and z as parameters, we have $\mathbf{r}_y \times \mathbf{r}_z = \mathbf{i}$ and

$$\iint_{S_3} \mathbf{F} \cdot d\mathbf{S} = \int_{-1}^1 \int_0^{\sqrt{1 - y^2}} x^2\,dz\,dy = \int_{-1}^1 \int_0^{\sqrt{1 - y^2}} 4\,dz\,dy = 4A\,(S_3) = 2\pi$$

On S_4: The surface is $x = 0$ for $-1 \le y \le 1$, $0 \le z \le \sqrt{1 - y^2}$, oriented in the negative x-direction. Regarding y and z as parameters, we use $-\left(\mathbf{r}_y \times \mathbf{r}_z\right) = -\mathbf{i}$ and

$$\iint_{S_4} \mathbf{F} \cdot d\mathbf{S} = \int_{-1}^1 \int_0^{\sqrt{1 - y^2}} x^2\,dz\,dy = \int_{-1}^1 \int_0^{\sqrt{1 - y^2}} (0)\;dz\,dy = 0$$

Thus $\iint_S \mathbf{F} \cdot d\mathbf{S} = \frac{8}{3} + 0 + 2\pi + 0 = 2\pi + \frac{8}{3}$.

32. Here S consists of four surfaces: S_1, the triangular face with vertices $(1, 0, 0)$, $(0, 1, 0)$, and $(0, 0, 1)$; S_2, the face of the tetrahedron in the xy-plane; S_3, the face in the xz-plane; and S_4, the face in the yz-plane.

On S_1: The face is the portion of the plane $z = 1 - x - y$ for $0 \le x \le 1$, $0 \le y \le 1 - x$ with upward orientation, so

$$\begin{aligned} \iint_{S_1} \mathbf{F} \cdot d\mathbf{S} &= \int_0^1 \int_0^{1-x} [-y\,(-1) - (z - y)\,(-1) + x]\,dy\,dx = \int_0^1 \int_0^{1-x} (z + x)\,dy\,dx = \int_0^1 \int_0^{1-x} (1 - y)\,dy\,dx \\ &= \int_0^1 \left[y - \tfrac{1}{2}y^2\right]_{y=0}^{y=1-x} dx = \tfrac{1}{2} \int_0^1 \left(1 - x^2\right) dx = \tfrac{1}{2}\left[x - \tfrac{1}{3}x^3\right]_0^1 = \tfrac{1}{3} \end{aligned}$$

On S_2: The surface is $z = 0$ with downward orientation, so

$$\iint_{S_2} \mathbf{F} \cdot d\mathbf{S} = \int_0^1 \int_0^{1-x} (-x)\, dy\, dx = -\int_0^1 x\,(1-x)\, dx = -\left[\tfrac{1}{2}x^2 - \tfrac{1}{3}x^3\right]_0^1 = -\tfrac{1}{6}$$

On S_3: The surface is $y = 0$ for $0 \le x \le 1$, $0 \le z \le 1 - x$, oriented in the negative y-direction. Regarding x and z as parameters, we have $\mathbf{r}_x \times \mathbf{r}_z = -\mathbf{j}$ and

$$\begin{aligned}\iint_{S_3} \mathbf{F} \cdot d\mathbf{S} &= \int_0^1 \int_0^{1-x} -(z-y)\, dz\, dx = -\int_0^1 \int_0^{1-x} z\, dz\, dx = -\int_0^1 \left[\tfrac{1}{2}z^2\right]_{z=0}^{z=1-x} dx \\ &= -\tfrac{1}{2}\int_0^1 (1-x)^2\, dx = \tfrac{1}{6}\left[(1-x)^3\right]_0^1 = -\tfrac{1}{6}\end{aligned}$$

On S_4: The surface is $x = 0$ for $0 \le y \le 1$, $0 \le z \le 1 - y$, oriented in the negative x-direction. Regarding y and z as parameters, we have $\mathbf{r}_y \times \mathbf{r}_z = \mathbf{i}$ so we use $-(\mathbf{r}_y \times \mathbf{r}_z) = -\mathbf{i}$ and

$$\iint_{S_4} \mathbf{F} \cdot d\mathbf{S} = \int_0^1 \int_0^{1-y} (-y)\, dz\, dy = -\int_0^1 y\,(1-y)\, dy = -\left[\tfrac{1}{2}y^2 - \tfrac{1}{3}y^3\right]_0^1 = -\tfrac{1}{6}$$

Thus $\iint_S \mathbf{F} \cdot d\mathbf{S} = \frac{1}{3} - \frac{1}{6} - \frac{1}{6} - \frac{1}{6} = -\frac{1}{6}$.

33. $z = xe^y \;\;\Rightarrow\;\; \partial z/\partial x = e^y$, $\partial z/\partial y = xe^y$, so by Formula 4, a CAS gives

$\iint_S (x^2 + y^2 + z^2)\, dS = \int_0^1 \int_0^1 (x^2 + y^2 + x^2 e^{2y})\sqrt{e^{2y} + x^2 e^{2y} + 1}\, dx\, dy \approx 4.5822.$

34. $z = x^2y^2 \;\;\Rightarrow\;\; \partial z/\partial x = 2xy^2,\; \partial z/\partial y = 2x^2y$, so by Formula 4, a CAS gives

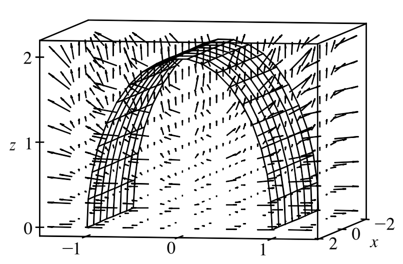
$$\begin{aligned}\iint_S xyz\, dS &= \int_0^2 \int_0^1 xy(x^2y^2)\sqrt{(2xy^2)^2 + (2x^2y)^2 + 1}\, dx\, dy \\ &= \int_0^2 \int_0^1 x^3y^3 \sqrt{4x^2y^4 + 4x^4y^2 + 1}\, dx\, dy = -\tfrac{151}{33} - \tfrac{1}{220}\sqrt{3}\,\pi + \tfrac{1977}{176}\ln 7 - \tfrac{9891}{880}\ln 3 + \tfrac{3}{440}\sqrt{3}\tan^{-1}\tfrac{5}{\sqrt{3}}\end{aligned}$$

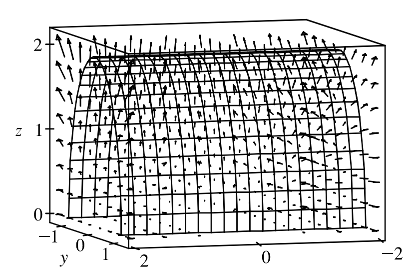
35. We use Formula 4 with $z = 3 - 2x^2 - y^2 \;\;\Rightarrow\;\; \partial z/\partial x = -4x$, $\partial z/\partial y = -2y$. The boundaries of the region $3 - 2x^2 - y^2 \ge 0$ are $-\sqrt{\frac{3}{2}} \le x \le \sqrt{\frac{3}{2}}$ and $-\sqrt{3 - 2x^2} \le y \le \sqrt{3 - 2x^2}$, so we use a CAS (with precision reduced to seven or fewer digits; otherwise the calculation may take a long time) to calculate

$$\iint_S x^2y^2z^2\, dS = \int_{-\sqrt{3/2}}^{\sqrt{3/2}} \int_{-\sqrt{3-2x^2}}^{\sqrt{3-2x^2}} x^2y^2(3 - 2x^2 - y^2)^2 \sqrt{16x^2 + 4y^2 + 1}\, dy\, dx \approx 3.4895$$

36. The flux of $\mathbf{F}$ across S is given by $\iint_S \mathbf{F} \cdot d\mathbf{S} = \iint_S \mathbf{F} \cdot \mathbf{n}\, dS$. Now on S, $z = g(x, y) = 2\sqrt{1 - y^2}$, so $\partial g/\partial x = 0$ and $\partial g/\partial y = -2y(1 - y^2)^{-1/2}$. Therefore, by (10),

$$\iint_S \mathbf{F} \cdot d\mathbf{S} = \int_{-2}^2 \int_{-1}^1 \left(-x^2y\left[-2y(1-y^2)^{-1/2}\right] + \left[2\sqrt{1-y^2}\right]^2 e^{x/5}\right) dy\, dx = \tfrac{1}{3}(16\pi + 80e^{2/5} - 80e^{-2/5})$$





37. If S is given by $y = h(x,z)$, then S is also the level surface $f(x,y,z) = y - h(x,z) = 0$.

$\mathbf{n} = \dfrac{\nabla f(x,y,z)}{|\nabla f(x,y,z)|} = \dfrac{-h_x\,\mathbf{i} + \mathbf{j} - h_z\,\mathbf{k}}{\sqrt{h_x^2 + 1 + h_z^2}}$, and $-\mathbf{n}$ is the unit normal that points to the left. Now we proceed as in the derivation of (10), using Formula 4 to evaluate

$$\iint_S \mathbf{F}\cdot d\mathbf{S} = \iint_S \mathbf{F}\cdot\mathbf{n}\,dS = \iint_D (P\,\mathbf{i} + Q\,\mathbf{j} + R\,\mathbf{k})\,\frac{\dfrac{\partial h}{\partial x}\,\mathbf{i} - \mathbf{j} + \dfrac{\partial h}{\partial z}\,\mathbf{k}}{\sqrt{\left(\dfrac{\partial h}{\partial x}\right)^2 + 1 + \left(\dfrac{\partial h}{\partial z}\right)^2}}\sqrt{\left(\frac{\partial h}{\partial x}\right)^2 + 1 + \left(\frac{\partial h}{\partial z}\right)^2}\,dA$$

where D is the projection of S onto the xz-plane. Therefore $\displaystyle\iint_S \mathbf{F}\cdot d\mathbf{S} = \iint_D \left(P\,\frac{\partial h}{\partial x} - Q + R\,\frac{\partial h}{\partial z}\right)dA$.

38. If S is given by $x = k(y,z)$, then S is also the level surface $f(x,y,z) = x - k(y,z) = 0$.

$\mathbf{n} = \dfrac{\nabla f(x,y,z)}{|\nabla f(x,y,z)|} = \dfrac{\mathbf{i} - k_y\,\mathbf{j} - k_z\,\mathbf{k}}{\sqrt{1 + k_y^2 + k_z^2}}$, and since the x-component is positive this is the unit normal that points forward.

Now we proceed as in the derivation of (10), using Formula 4 for

$$\iint_S \mathbf{F}\cdot d\mathbf{S} = \iint_S \mathbf{F}\cdot\mathbf{n}\,dS = \iint_D (P\,\mathbf{i} + Q\,\mathbf{j} + R\,\mathbf{k})\,\frac{\mathbf{i} - \dfrac{\partial k}{\partial y}\,\mathbf{j} - \dfrac{\partial k}{\partial z}\,\mathbf{k}}{\sqrt{1 + \left(\dfrac{\partial k}{\partial y}\right)^2 + \left(\dfrac{\partial k}{\partial z}\right)^2}}\sqrt{1 + \left(\frac{\partial k}{\partial y}\right)^2 + \left(\frac{\partial k}{\partial z}\right)^2}\,dA$$

where D is the projection of S onto the yz-plane. Therefore $\displaystyle\iint_S \mathbf{F}\cdot d\mathbf{S} = \iint_D \left(P - Q\,\frac{\partial k}{\partial y} - R\,\frac{\partial k}{\partial z}\right)dA$.

39. $m = \iint_S K\,dS = K\cdot 4\pi\left(\frac{1}{2}a^2\right) = 2\pi a^2 K$; by symmetry $M_{xz} = M_{yz} = 0$, and

$M_{xy} = \iint_S zK\,dS = K\int_0^{2\pi}\int_0^{\pi/2}(a\cos\phi)(a^2\sin\phi)\,d\phi\,d\theta = 2\pi K a^3\left[-\frac{1}{4}\cos 2\phi\right]_0^{\pi/2} = \pi K a^3$.

Hence $(\overline{x}, \overline{y}, \overline{z}) = \left(0, 0, \frac{1}{2}a\right)$.

40. S is given by $\mathbf{r}(x,y) = x\,\mathbf{i} + y\,\mathbf{j} + \sqrt{x^2+y^2}\,\mathbf{k}$, $|\mathbf{r}_x \times \mathbf{r}_y| = \sqrt{1 + \dfrac{x^2+y^2}{x^2+y^2}} = \sqrt{2}$ so

$$m = \iint_S\left(10 - \sqrt{x^2+y^2}\right)dS = \iint_{1\,\le\, x^2+y^2\,\le\,16}\left(10 - \sqrt{x^2+y^2}\right)\sqrt{2}\,dA$$
$$= \int_0^{2\pi}\int_1^4 \sqrt{2}\,(10-r)\,r\,dr\,d\theta = 2\pi\sqrt{2}\left[5r^2 - \tfrac{1}{3}r^3\right]_1^4 = 108\sqrt{2}\,\pi$$

41. (a) $I_z = \iint_S (x^2+y^2)\rho(x,y,z)\,dS$

(b) $I_z = \iint_S (x^2+y^2)\left(10 - \sqrt{x^2+y^2}\right)dS = \displaystyle\iint_{1\,\le\, x^2+y^2\,\le\,16}(x^2+y^2)\left(10 - \sqrt{x^2+y^2}\right)\sqrt{2}\,dA$

$= \int_0^{2\pi}\int_1^4 \sqrt{2}\,(10r^3 - r^4)\,dr\,d\theta = 2\sqrt{2}\,\pi\left(\frac{4329}{10}\right) = \frac{4329}{5}\sqrt{2}\,\pi$

42. Using spherical coordinates to parametrize the sphere we have $\mathbf{r}(\phi,\theta) = 5\sin\phi\cos\theta\,\mathbf{i} + 5\sin\phi\sin\theta\,\mathbf{j} + 5\cos\phi\,\mathbf{k}$, and $|\mathbf{r}_\phi \times \mathbf{r}_\theta| = 25\sin\phi$ (see Example 16.6.10). S is the portion of the sphere where $z \ge 4$, so $0 \le \phi \le \tan^{-1}(3/4)$ and $0 \le \theta \le 2\pi$.

(a) $m = \iint_S \rho(x,y,z)\,dS = \int_0^{2\pi}\int_0^{\tan^{-1}(3/4)} k(25\sin\phi)\,d\phi\,d\theta = 25k\int_0^{2\pi} d\theta\,\int_0^{\tan^{-1}(3/4)}\sin\phi\,d\phi$

$= 25k(2\pi)\left[-\cos\left(\tan^{-1}\frac{3}{4}\right)+1\right] = 50\pi k\left(-\frac{4}{5}+1\right) = 10\pi k.$

Because S has constant density, $\overline{x} = \overline{y} = 0$ by symmetry, and

$\overline{z} = \frac{1}{m}\iint_S z\rho(x,y,z)\,dS = \frac{1}{10\pi k}\int_0^{2\pi}\int_0^{\tan^{-1}(3/4)} k(5\cos\phi)(25\sin\phi)\,d\phi\,d\theta$

$= \frac{1}{10\pi k}\,(125k)\int_0^{2\pi} d\theta\,\int_0^{\tan^{-1}(3/4)}\sin\phi\cos\phi\,d\phi = \frac{1}{10\pi k}\,(125k)\,(2\pi)\left[\frac{1}{2}\sin^2\phi\right]_0^{\tan^{-1}(3/4)} = 25\cdot\frac{1}{2}\left(\frac{3}{5}\right)^2 = \frac{9}{2},$

so the center of mass is $(\overline{x},\overline{y},\overline{z}) = \left(0,0,\frac{9}{2}\right)$.

(b) $I_z = \iint_S (x^2+y^2)\rho(x,y,z)\,dS = \int_0^{2\pi}\int_0^{\tan^{-1}(3/4)} k(25\sin^2\phi)(25\sin\phi)\,d\phi\,d\theta$

$= 625k\int_0^{2\pi} d\theta\,\int_0^{\tan^{-1}(3/4)}\sin^3\phi\,d\phi = 625k(2\pi)\left[\frac{1}{3}\cos^3\phi - \cos\phi\right]_0^{\tan^{-1}(3/4)}$

$= 1250\pi k\left[\frac{1}{3}\left(\frac{4}{5}\right)^3 - \frac{4}{5} - \frac{1}{3} + 1\right] = 1250\pi k\left(\frac{14}{375}\right) = \frac{140}{3}\pi k$

43. The rate of flow through the cylinder is the flux $\iint_S \rho\mathbf{v}\cdot\mathbf{n}\,dS = \iint_S \rho\mathbf{v}\cdot d\mathbf{S}$. We use the parametric representation $\mathbf{r}(u,v) = 2\cos u\,\mathbf{i} + 2\sin u\,\mathbf{j} + v\,\mathbf{k}$ for S, where $0 \le u \le 2\pi$, $0 \le v \le 1$, so $\mathbf{r}_u = -2\sin u\,\mathbf{i} + 2\cos u\,\mathbf{j}$, $\mathbf{r}_v = \mathbf{k}$, and the outward orientation is given by $\mathbf{r}_u \times \mathbf{r}_v = 2\cos u\,\mathbf{i} + 2\sin u\,\mathbf{j}$. Then

$$\begin{aligned}\iint_S \rho\mathbf{v}\cdot d\mathbf{S} &= \rho\int_0^{2\pi}\int_0^1 \left(v\,\mathbf{i} + 4\sin^2 u\,\mathbf{j} + 4\cos^2 u\,\mathbf{k}\right)\cdot(2\cos u\,\mathbf{i} + 2\sin u\,\mathbf{j})\,dv\,du\\ &= \rho\int_0^{2\pi}\int_0^1 \left(2v\cos u + 8\sin^3 u\right)dv\,du = \rho\int_0^{2\pi}\left(\cos u + 8\sin^3 u\right)du\\ &= \rho\left[\sin u + 8\left(-\tfrac{1}{3}\right)(2+\sin^2 u)\cos u\right]_0^{2\pi} = 0\text{ kg/s}\end{aligned}$$

44. A parametric representation for the hemisphere S is $\mathbf{r}(\phi,\theta) = 3\sin\phi\,\cos\theta\,\mathbf{i} + 3\sin\phi\,\sin\theta\,\mathbf{j} + 3\cos\phi\,\mathbf{k}$, $0 \le \phi \le \pi/2$, $0 \le \theta \le 2\pi$. Then $\mathbf{r}_\phi = 3\cos\phi\,\cos\theta\,\mathbf{i} + 3\cos\phi\,\sin\theta\,\mathbf{j} - 3\sin\phi\,\mathbf{k}$, $\mathbf{r}_\theta = -3\sin\phi\sin\theta\,\mathbf{i} + 3\sin\phi\cos\theta\,\mathbf{j}$, and the outward orientation is given by $\mathbf{r}_\phi \times \mathbf{r}_\theta = 9\sin^2\phi\,\cos\theta\,\mathbf{i} + 9\sin^2\phi\,\sin\theta\,\mathbf{j} + 9\sin\phi\,\cos\phi\,\mathbf{k}$. The rate of flow through S is

$$\begin{aligned}\iint_S \rho\mathbf{v}\cdot d\mathbf{S} &= \rho\int_0^{\pi/2}\int_0^{2\pi}(3\sin\phi\,\sin\theta\,\mathbf{i} + 3\sin\phi\,\cos\theta\,\mathbf{j})\cdot\left(9\sin^2\phi\,\cos\theta\,\mathbf{i} + 9\sin^2\phi\sin\theta\,\mathbf{j} + 9\sin\phi\,\cos\phi\,\mathbf{k}\right)d\theta\,d\phi\\ &= 27\rho\int_0^{\pi/2}\int_0^{2\pi}\left(\sin^3\phi\,\sin\theta\,\cos\theta + \sin^3\phi\,\sin\theta\,\cos\theta\right)d\theta\,d\phi = 54\rho\int_0^{\pi/2}\sin^3\phi\,d\phi\,\int_0^{2\pi}\sin\theta\,\cos\theta\,d\theta\\ &= 54\rho\left[-\tfrac{1}{3}(2+\sin^2\phi)\cos\phi\right]_0^{\pi/2}\,\left[\tfrac{1}{2}\sin^2\theta\right]_0^{2\pi} = 0\text{ kg/s}\end{aligned}$$

45. S consists of the hemisphere S_1 given by $z = \sqrt{a^2-x^2-y^2}$ and the disk S_2 given by $0 \le x^2+y^2 \le a^2$, $z = 0$.

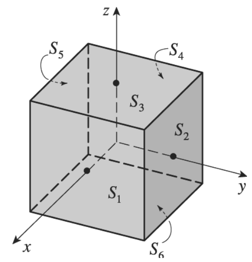
On S_1: $\mathbf{E} = a\sin\phi\,\cos\theta\,\mathbf{i} + a\sin\phi\,\sin\theta\,\mathbf{j} + 2a\cos\phi\,\mathbf{k}$,

$\mathbf{T}_\phi \times \mathbf{T}_\theta = a^2\sin^2\phi\,\cos\theta\,\mathbf{i} + a^2\sin^2\phi\,\sin\theta\,\mathbf{j} + a^2\sin\phi\,\cos\phi\,\mathbf{k}$. Thus

$$\begin{aligned}\iint_{S_1}\mathbf{E}\cdot d\mathbf{S} &= \int_0^{2\pi}\int_0^{\pi/2}(a^3\sin^3\phi + 2a^3\sin\phi\,\cos^2\phi)\,d\phi\,d\theta\\ &= \int_0^{2\pi}\int_0^{\pi/2}(a^3\sin\phi + a^3\sin\phi\,\cos^2\phi)\,d\phi\,d\theta = (2\pi)a^3\left(1+\tfrac{1}{3}\right) = \tfrac{8}{3}\pi a^3\end{aligned}$$

On S_2: $\mathbf{E} = x\,\mathbf{i} + y\,\mathbf{j}$, and $\mathbf{r}_y \times \mathbf{r}_x = -\mathbf{k}$ so $\iint_{S_2}\mathbf{E}\cdot d\mathbf{S} = 0$. Hence the total charge is $q = \varepsilon_0\iint_S \mathbf{E}\cdot d\mathbf{S} = \frac{8}{3}\pi a^3\varepsilon_0$.

46. Referring to the figure, on



S_1: $\mathbf{E} = \mathbf{i} + y\,\mathbf{j} + z\,\mathbf{k}$, $\mathbf{r}_y \times \mathbf{r}_z = \mathbf{i}$ and $\iint_{S_1} \mathbf{E} \cdot d\mathbf{S} = \int_{-1}^{1}\int_{-1}^{1} dy\,dz = 4$;

S_2: $\mathbf{E} = x\,\mathbf{i} + \mathbf{j} + z\,\mathbf{k}$, $\mathbf{r}_z \times \mathbf{r}_x = \mathbf{j}$ and $\iint_{S_2} \mathbf{E} \cdot d\mathbf{S} = \int_{-1}^{1}\int_{-1}^{1} dx\,dz = 4$;

S_3: $\mathbf{E} = x\,\mathbf{i} + y\,\mathbf{j} + \mathbf{k}$, $\mathbf{r}_x \times \mathbf{r}_y = \mathbf{k}$ and $\iint_{S_3} \mathbf{E} \cdot d\mathbf{S} = \int_{-1}^{1}\int_{-1}^{1} dx\,dy = 4$;

S_4: $\mathbf{E} = -\mathbf{i} + y\,\mathbf{j} + z\,\mathbf{k}$, $\mathbf{r}_z \times \mathbf{r}_y = -\mathbf{i}$ and $\iint_{S_4} \mathbf{E} \cdot d\mathbf{S} = 4$.

Similarly $\iint_{S_5} \mathbf{E} \cdot d\mathbf{S} = \iint_{S_6} \mathbf{E} \cdot d\mathbf{S} = 4$. Hence $q = \varepsilon_0 \iint_S \mathbf{E} \cdot d\mathbf{S} = \varepsilon_0 \sum\limits_{i=1}^{6} \iint_{S_i} \mathbf{E} \cdot d\mathbf{S} = 24\varepsilon_0$.

47. $K\nabla u = 6.5(4y\,\mathbf{j} + 4z\,\mathbf{k})$. S is given by $\mathbf{r}(x,\theta) = x\,\mathbf{i} + \sqrt{6}\,\cos\theta\,\mathbf{j} + \sqrt{6}\,\sin\theta\,\mathbf{k}$ and since we want the inward heat flow, we use $\mathbf{r}_x \times \mathbf{r}_\theta = -\sqrt{6}\,\cos\theta\,\mathbf{j} - \sqrt{6}\,\sin\theta\,\mathbf{k}$. Then the rate of heat flow inward is given by

$\iint_S (-K\,\nabla u) \cdot d\mathbf{S} = \int_0^{2\pi}\int_0^4 -(6.5)(-24)\,dx\,d\theta = (2\pi)(156)(4) = 1248\pi$.

48. $u(x,y,z) = c/\sqrt{x^2+y^2+z^2}$,

$$\mathbf{F} = -K\,\nabla u = -K\left[-\frac{cx}{(x^2+y^2+z^2)^{3/2}}\,\mathbf{i} - \frac{cy}{(x^2+y^2+z^2)^{3/2}}\,\mathbf{j} - \frac{cz}{(x^2+y^2+z^2)^{3/2}}\,\mathbf{k}\right]$$
$$= \frac{cK}{(x^2+y^2+z^2)^{3/2}}\,(x\,\mathbf{i} + y\,\mathbf{j} + z\,\mathbf{k})$$

and the outward unit normal is $\mathbf{n} = \dfrac{1}{a}\,(x\,\mathbf{i} + y\,\mathbf{j} + z\,\mathbf{k})$.

Thus $\mathbf{F} \cdot \mathbf{n} = \dfrac{cK}{a(x^2+y^2+z^2)^{3/2}}\,(x^2+y^2+z^2)$, but on S, $x^2+y^2+z^2 = a^2$ so $\mathbf{F} \cdot \mathbf{n} = \dfrac{cK}{a^2}$. Hence the rate of heat flow across S is $\displaystyle\iint_S \mathbf{F} \cdot d\mathbf{S} = \frac{cK}{a^2}\iint_S dS = \frac{cK}{a^2}\,(4\pi a^2) = 4\pi Kc$.

49. Let S be a sphere of radius a centered at the origin. Then $|\mathbf{r}| = a$ and $\mathbf{F}(\mathbf{r}) = c\mathbf{r}/|\mathbf{r}|^3 = \left(c/a^3\right)(x\,\mathbf{i} + y\,\mathbf{j} + z\,\mathbf{k})$. A parametric representation for S is $\mathbf{r}(\phi,\theta) = a\sin\phi\,\cos\theta\,\mathbf{i} + a\sin\phi\,\sin\theta\,\mathbf{j} + a\cos\phi\,\mathbf{k}$, $0 \le \phi \le \pi$, $0 \le \theta \le 2\pi$. Then $\mathbf{r}_\phi = a\cos\phi\,\cos\theta\,\mathbf{i} + a\cos\phi\,\sin\theta\,\mathbf{j} - a\sin\phi\,\mathbf{k}$, $\mathbf{r}_\theta = -a\sin\phi\,\sin\theta\,\mathbf{i} + a\sin\phi\,\cos\theta\,\mathbf{j}$, and the outward orientation is given by $\mathbf{r}_\phi \times \mathbf{r}_\theta = a^2\sin^2\phi\,\cos\theta\,\mathbf{i} + a^2\sin^2\phi\,\sin\theta\,\mathbf{j} + a^2\sin\phi\,\cos\phi\,\mathbf{k}$. The flux of $\mathbf{F}$ across S is

$$\iint_S \mathbf{F} \cdot\, d\mathbf{S} = \int_0^\pi\int_0^{2\pi} \frac{c}{a^3}\,(a\sin\phi\,\cos\theta\,\mathbf{i} + a\sin\phi\,\sin\theta\,\mathbf{j} + a\cos\phi\,\mathbf{k})$$
$$\cdot\left(a^2\sin^2\phi\,\cos\theta\,\mathbf{i} + a^2\sin^2\phi\,\sin\theta\,\mathbf{j} + a^2\sin\phi\,\cos\phi\,\mathbf{k}\right) d\theta\,d\phi$$
$$= \frac{c}{a^3}\int_0^\pi\int_0^{2\pi} a^3\left(\sin^3\phi + \sin\phi\,\cos^2\phi\right) d\theta\,d\phi = c\int_0^\pi\int_0^{2\pi} \sin\phi\,d\theta\,d\phi = 4\pi c$$

Thus the flux does not depend on the radius a.

16.8 Stokes' Theorem

1. Both H and P are oriented piecewise-smooth surfaces that are bounded by the simple, closed, smooth curve $x^2 + y^2 = 4$, $z = 0$ (which we can take to be oriented positively for both surfaces). Then H and P satisfy the hypotheses of Stokes' Theorem, so by (3) we know $\iint_H \operatorname{curl} \mathbf{F} \cdot d\mathbf{S} = \int_C \mathbf{F} \cdot d\mathbf{r} = \iint_P \operatorname{curl} \mathbf{F} \cdot d\mathbf{S}$ (where C is the boundary curve).

2. The paraboloid $z = 1 - x^2 - y^2$ intersects the xy-plane in the circle $x^2 + y^2 = 1$, $z = 0$. This boundary curve C should be oriented in the counterclockwise direction when viewed from above, so a vector equation of C is $\mathbf{r}(t) = \cos t\,\mathbf{i} + \sin t\,\mathbf{j}$, $0 \le t \le 2\pi$. Then $\mathbf{r}'(t) = -\sin t\,\mathbf{i} + \cos t\,\mathbf{j}$,

$$\mathbf{F}(\mathbf{r}(t)) = (\cos t)^2(\sin 0)\,\mathbf{i} + (\sin t)^2\,\mathbf{j} + (\cos t)(\sin t)\,\mathbf{k} = \sin^2 t\,\mathbf{j} + \sin t\,\cos t\,\mathbf{k},$$

and by Stokes' Theorem,

$$\begin{aligned}\iint_S \operatorname{curl} \mathbf{F} \cdot d\mathbf{S} &= \int_C \mathbf{F} \cdot d\mathbf{r} = \int_0^{2\pi} \mathbf{F}(\mathbf{r}(t)) \cdot \mathbf{r}'(t)\,dt = \int_0^{2\pi} (\sin^2 t\,\mathbf{j} + \sin t\,\cos t\,\mathbf{k}) \cdot (-\sin t\,\mathbf{i} + \cos t\,\mathbf{j})\,dt \\ &= \int_0^{2\pi} (0 + \sin^2 t \cos t + 0)\,dt = \left[\tfrac{1}{3}\sin^3 t\right]_0^{2\pi} = 0\end{aligned}$$

3. The boundary curve C is the circle $x^2 + z^2 = 16$, $y = 0$ where the hemisphere intersects the xz-plane. The curve should be oriented in the counterclockwise direction when viewed from the right (from the positive y-axis), so a vector equation of C is $\mathbf{r}(t) = 4\cos(-t)\,\mathbf{i} + 4\sin(-t)\,\mathbf{k} = 4\cos t\,\mathbf{i} - 4\sin t\,\mathbf{k}$, $0 \le t \le 2\pi$. Then $\mathbf{r}'(t) = -4\sin t\,\mathbf{i} - 4\cos t\,\mathbf{k}$ and $\mathbf{F}(\mathbf{r}(t)) = (-4\sin t)e^0\,\mathbf{i} + (4\cos t)(\cos 0)\,\mathbf{j} + (4\cos t)(-4\sin t)(\sin 0)\,\mathbf{k} = -4\sin t\,\mathbf{i} + 4\cos t\,\mathbf{j}$, and by Stokes' Theorem,

$$\begin{aligned}\iint_S \operatorname{curl} \mathbf{F} \cdot d\mathbf{S} &= \int_C \mathbf{F} \cdot d\mathbf{r} = \int_0^{2\pi} \mathbf{F}(\mathbf{r}(t)) \cdot \mathbf{r}'(t)\,dt = \int_0^{2\pi} (-4\sin t\,\mathbf{i} + 4\cos t\,\mathbf{j}) \cdot (-4\sin t\,\mathbf{i} - 4\cos t\,\mathbf{k})\,dt \\ &= \int_0^{2\pi} (16\sin^2 t + 0 + 0)\,dt = 16\left[\tfrac{1}{2}t - \tfrac{1}{4}\sin 2t\right]_0^{2\pi} = 16\pi\end{aligned}$$

4. The boundary curve C is the circle $y^2 + z^2 = 4$, $x = 2$ which should be oriented in the counterclockwise direction when viewed from the front, so a vector equation of C is $\mathbf{r}(t) = 2\,\mathbf{i} + 2\cos t\,\mathbf{j} + 2\sin t\,\mathbf{k}$, $0 \le t \le 2\pi$. Then $\mathbf{F}(\mathbf{r}(t)) = \tan^{-1}(32\cos t\sin^2 t)\,\mathbf{i} + 8\cos t\,\mathbf{j} + 16\sin^2 t\,\mathbf{k}$, $\mathbf{r}'(t) = -2\sin t\,\mathbf{j} + 2\cos t\,\mathbf{k}$, and $\mathbf{F}(\mathbf{r}(t)) \cdot \mathbf{r}'(t) = -16\sin t\cos t + 32\sin^2 t\cos t$. Thus

$$\begin{aligned}\iint_S \operatorname{curl} \mathbf{F} \cdot d\mathbf{S} &= \oint_C \mathbf{F} \cdot d\mathbf{r} = \int_0^{2\pi} \mathbf{F}(\mathbf{r}(t)) \cdot \mathbf{r}'(t)\,dt = \int_0^{2\pi} (-16\sin t\cos t + 32\sin^2 t\cos t)\,dt \\ &= \left[-8\sin^2 t + \tfrac{32}{3}\sin^3 t\right]_0^{2\pi} = 0\end{aligned}$$

5. C is the square in the plane $z = -1$. Rather than evaluating a line integral around C we can use Equation 3: $\iint_{S_1} \operatorname{curl} \mathbf{F} \cdot d\mathbf{S} = \oint_C \mathbf{F} \cdot d\mathbf{r} = \iint_{S_2} \operatorname{curl} \mathbf{F} \cdot d\mathbf{S}$ where S_1 is the original cube without the bottom and S_2 is the bottom face of the cube. $\operatorname{curl} \mathbf{F} = x^2 z\,\mathbf{i} + (xy - 2xyz)\,\mathbf{j} + (y - xz)\,\mathbf{k}$. For S_2, we choose $\mathbf{n} = \mathbf{k}$ so that C has the same orientation for both surfaces. Then $\operatorname{curl} \mathbf{F} \cdot \mathbf{n} = y - xz = x + y$ on S_2, where $z = -1$. Thus $\iint_{S_2} \operatorname{curl} \mathbf{F} \cdot d\mathbf{S} = \int_{-1}^{1}\int_{-1}^{1} (x + y)\,dx\,dy = 0$ so $\iint_{S_1} \operatorname{curl} \mathbf{F} \cdot d\mathbf{S} = 0$.

6. The boundary curve C is the circle $x^2+z^2=1$, $y=0$ which should be oriented in the counterclockwise direction when viewed from the right, so a vector equation of C is $\mathbf{r}(t)=\cos(-t)\,\mathbf{i}+\sin(-t)\,\mathbf{k}=\cos t\,\mathbf{i}-\sin t\,\mathbf{k}$, $0\le t\le 2\pi$. Then $\mathbf{F}(\mathbf{r}(t))=\mathbf{i}+e^{-\cos t\sin t}\,\mathbf{j}-\cos^2 t\,\sin t\,\mathbf{k}$, $\mathbf{r}'(t)=-\sin t\,\mathbf{i}-\cos t\,\mathbf{k}$, and $\mathbf{F}(\mathbf{r}(t))\cdot\mathbf{r}'(t)=-\sin t+\cos^3 t\,\sin t$. Thus

$$\begin{aligned}\iint_S \operatorname{curl}\mathbf{F}\cdot d\mathbf{S}&=\oint_C \mathbf{F}\cdot d\mathbf{r}=\int_0^{2\pi}\mathbf{F}(\mathbf{r}(t))\cdot\mathbf{r}'(t)\,dt=\int_0^{2\pi}(-\sin t+\cos^3 t\,\sin t)\,dt\\&=\left[\cos t-\tfrac{1}{4}\cos^4 t\right]_0^{2\pi}=0\end{aligned}$$

7. $\operatorname{curl}\mathbf{F}=-2z\,\mathbf{i}-2x\,\mathbf{j}-2y\,\mathbf{k}$ and we take the surface S to be the planar region enclosed by C, so S is the portion of the plane $x+y+z=1$ over $D=\{(x,y)\mid 0\le x\le 1, 0\le y\le 1-x\}$. Since C is oriented counterclockwise, we orient S upward. Using Equation 16.7.10, we have $z=g(x,y)=1-x-y$, $P=-2z$, $Q=-2x$, $R=-2y$, and

$$\begin{aligned}\int_C \mathbf{F}\cdot d\mathbf{r}&=\iint_S \operatorname{curl}\mathbf{F}\cdot d\mathbf{S}=\iint_D[-(-2z)(-1)-(-2x)(-1)+(-2y)]\,dA\\&=\int_0^1\int_0^{1-x}(-2)\,dy\,dx=-2\int_0^1(1-x)\,dx=-1\end{aligned}$$

8. $\operatorname{curl}\mathbf{F}=(x-y)\,\mathbf{i}-y\,\mathbf{j}+\mathbf{k}$ and S is the portion of the plane $3x+2y+z=1$ over $D=\left\{(x,y)\mid 0\le x\le\frac{1}{3}, 0\le y\le\frac{1}{2}(1-3x)\right\}$. We orient S upward and use Equation 16.7.10 with $z=g(x,y)=1-3x-2y$:

$$\begin{aligned}\int_C \mathbf{F}\cdot d\mathbf{r}&=\iint_S \operatorname{curl}\mathbf{F}\cdot d\mathbf{S}=\iint_D[-(x-y)(-3)-(-y)(-2)+1]\,dA=\int_0^{1/3}\int_0^{(1-3x)/2}(1+3x-5y)\,dy\,dx\\&=\int_0^{1/3}\left[(1+3x)y-\tfrac{5}{2}y^2\right]_{y=0}^{y=(1-3x)/2}dx=\int_0^{1/3}\left[\tfrac{1}{2}(1+3x)(1-3x)-\tfrac{5}{2}\cdot\tfrac{1}{4}(1-3x)^2\right]dx\\&=\int_0^{1/3}\left(-\tfrac{81}{8}x^2+\tfrac{15}{4}x-\tfrac{1}{8}\right)dx=\left[-\tfrac{27}{8}x^3+\tfrac{15}{8}x^2-\tfrac{1}{8}x\right]_0^{1/3}=-\tfrac{1}{8}+\tfrac{5}{24}-\tfrac{1}{24}=\tfrac{1}{24}\end{aligned}$$

9. $\operatorname{curl}\mathbf{F}=-y\,\mathbf{i}-z\,\mathbf{j}-x\,\mathbf{k}$ and we take S to be the part of the paraboloid $z=1-x^2-y^2$ in the first octant. Since C is oriented counterclockwise (from above), we orient S upward. Then using Equation 16.7.10 with $z=g(x,y)=1-x^2-y^2$ we have

$$\begin{aligned}\int_C \mathbf{F}\cdot d\mathbf{r}&=\iint_S \operatorname{curl}\mathbf{F}\cdot d\mathbf{S}=\iint_D[-(-y)(-2x)-(-z)(-2y)+(-x)]\,dA=\iint_D\left[-2xy-2y(1-x^2-y^2)-x\right]dA\\&=\int_0^{\pi/2}\int_0^1\left[-2(r\cos\theta)(r\sin\theta)-2(r\sin\theta)(1-r^2)-r\cos\theta\right]r\,dr\,d\theta\\&=\int_0^{\pi/2}\int_0^1\left[-2r^3\sin\theta\cos\theta-2(r^2-r^4)\sin\theta-r^2\cos\theta\right]dr\,d\theta\\&=\int_0^{\pi/2}\left[-\tfrac{1}{2}r^4\sin\theta\cos\theta-2\left(\tfrac{1}{3}r^3-\tfrac{1}{5}r^5\right)\sin\theta-\tfrac{1}{3}r^3\cos\theta\right]_{r=0}^{r=1}d\theta\\&=\int_0^{\pi/2}\left(-\tfrac{1}{2}\sin\theta\cos\theta-\tfrac{4}{15}\sin\theta-\tfrac{1}{3}\cos\theta\right)d\theta=\left[-\tfrac{1}{4}\sin^2\theta+\tfrac{4}{15}\cos\theta-\tfrac{1}{3}\sin\theta\right]_0^{\pi/2}\\&=-\tfrac{1}{4}-\tfrac{4}{15}-\tfrac{1}{3}=-\tfrac{17}{20}\end{aligned}$$

10. The curve of intersection is an ellipse in the plane $z=y+2$. $\operatorname{curl}\mathbf{F}=(1-x)\,\mathbf{i}-\mathbf{j}+(z-2)\,\mathbf{k}$ and we take the surface S to be the planar region enclosed by C with upward orientation. From Equation 16.7.10 with $z=g(x,y)=y+2$ we have

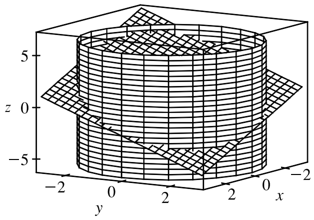
$$\begin{aligned}\oint_C \mathbf{F}\cdot d\mathbf{r}&=\iint_S \operatorname{curl}\mathbf{F}\cdot d\mathbf{S}=\iint_{x^2+y^2\le 1}[-(1-x)\,(0)-(-1)(1)+(y+2-2)]\,dA\\&=\iint_{x^2+y^2\le 1}(y+1)\,dA=\int_0^{2\pi}\int_0^1(r\sin\theta+1)\,r\,dr\,d\theta=\int_0^{2\pi}\left[\tfrac{1}{3}r^3\sin\theta+\tfrac{1}{2}r^2\right]_{r=0}^{r=1}d\theta\\&=\int_0^{2\pi}\left(\tfrac{1}{3}\sin\theta+\tfrac{1}{2}\right)d\theta=\left[-\tfrac{1}{3}\cos\theta+\tfrac{1}{2}\theta\right]_0^{2\pi}=\pi\end{aligned}$$

11. (a) The curve of intersection is an ellipse in the plane $x + y + z = 1$ with unit normal $\mathbf{n} = \frac{1}{\sqrt{3}}\,(\mathbf{i} + \mathbf{j} + \mathbf{k})$,

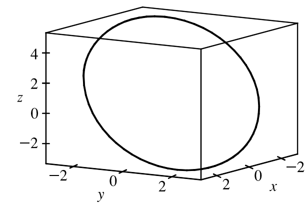
curl $\mathbf{F} = x^2\,\mathbf{j} + y^2\,\mathbf{k}$, and curl $\mathbf{F} \cdot \mathbf{n} = \frac{1}{\sqrt{3}}(x^2 + y^2)$. Then

$$\oint_C \mathbf{F} \cdot d\mathbf{r} = \iint_S \tfrac{1}{\sqrt{3}}\left(x^2 + y^2\right) dS = \iint_{x^2 + y^2 \leq 9} \left(x^2 + y^2\right) dx\,dy = \int_0^{2\pi}\!\int_0^3 r^3\,dr\,d\theta = 2\pi\left(\tfrac{81}{4}\right) = \tfrac{81\pi}{2}$$

(b)



(c) One possible parametrization is $x = 3\cos t$, $y = 3\sin t$, $z = 1 - 3\cos t - 3\sin t$, $0 \leq t \leq 2\pi$.



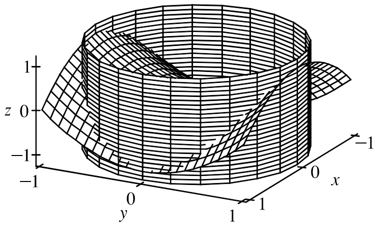
12. (a) S is the part of the surface $z = y^2 - x^2$ that lies above the unit disk D. curl $\mathbf{F} = x\,\mathbf{i} - y\,\mathbf{j} + (x^2 - x^2)\,\mathbf{k} = x\,\mathbf{i} - y\,\mathbf{j}$.

Using Equation 16.7.10 with $g(x, y) = y^2 - x^2$, $P = x$, $Q = -y$, we have

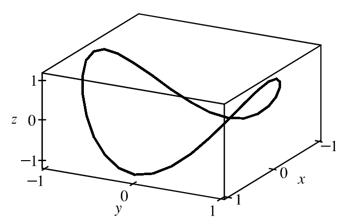
$$\int_C \mathbf{F} \cdot d\mathbf{r} = \iint_S \operatorname{curl} \mathbf{F} \cdot d\mathbf{S} = \iint_D [-x(-2x) - (-y)(2y)]\,dA = 2\iint_D (x^2 + y^2)\,dA$$

$$= 2\int_0^{2\pi}\!\int_0^1 r^2 r\,dr\,d\theta = 2(2\pi)\left[\tfrac{1}{4}r^4\right]_0^1 = \pi$$

(b)



(c) One possible set of parametric equations is $x = \cos t$, $y = \sin t$, $z = \sin^2 t - \cos^2 t$, $0 \leq t \leq 2\pi$.



13. The boundary curve C is the circle $x^2 + y^2 = 16$, $z = 4$ oriented in the clockwise direction as viewed from above (since S is oriented downward). We can parametrize C by $\mathbf{r}(t) = 4\cos t\,\mathbf{i} - 4\sin t\,\mathbf{j} + 4\,\mathbf{k}$, $0 \leq t \leq 2\pi$, and then $\mathbf{r}'(t) = -4\sin t\,\mathbf{i} - 4\cos t\,\mathbf{j}$. Thus $\mathbf{F}(\mathbf{r}(t)) = 4\sin t\,\mathbf{i} + 4\cos t\,\mathbf{j} - 2\,\mathbf{k}$, $\mathbf{F}(\mathbf{r}(t)) \cdot \mathbf{r}'(t) = -16\sin^2 t - 16\cos^2 t = -16$, and

$$\oint_C \mathbf{F} \cdot d\mathbf{r} = \int_0^{2\pi} \mathbf{F}(\mathbf{r}(t)) \cdot \mathbf{r}'(t)\,dt = \int_0^{2\pi} (-16)\,dt = -16\,(2\pi) = -32\pi$$

Now curl $\mathbf{F} = 2\,\mathbf{k}$, and the projection D of S on the xy-plane is the disk $x^2 + y^2 \leq 16$, so by Equation 16.7.10 with $z = g(x, y) = \sqrt{x^2 + y^2}$ [and multiplying by -1 for the downward orientation] we have

$$\iint_S \operatorname{curl} \mathbf{F} \cdot d\mathbf{S} = -\iint_D (-0 - 0 + 2)\,dA = -2 \cdot A(D) = -2 \cdot \pi(4^2) = -32\pi$$

14. The paraboloid intersects the plane $z = 1$ when $1 = 5 - x^2 - y^2 \quad \Leftrightarrow \quad x^2 + y^2 = 4$, so the boundary curve C is the circle $x^2 + y^2 = 4$, $z = 1$ oriented in the counterclockwise direction as viewed from above. We can parametrize C by $\mathbf{r}(t) = 2\cos t\,\mathbf{i} + 2\sin t\,\mathbf{j} + \mathbf{k}$, $0 \leq t \leq 2\pi$, and then $\mathbf{r}'(t) = -2\sin t\,\mathbf{i} + 2\cos t\,\mathbf{j}$. Thus $\mathbf{F}(\mathbf{r}(t)) = -4\sin t\,\mathbf{i} + 2\sin t\,\mathbf{j} + 6\cos t\,\mathbf{k}$, $\mathbf{F}(\mathbf{r}(t)) \cdot \mathbf{r}'(t) = 8\sin^2 t + 4\sin t\cos t$, and

$$\oint_C \mathbf{F} \cdot d\mathbf{r} = \int_0^{2\pi} (8\sin^2 t + 4\sin t\cos t)\,dt = 8\left(\tfrac{1}{2}t - \tfrac{1}{4}\sin 2t\right) + 2\sin^2 t\Big]_0^{2\pi} = 8\pi$$

Now curl $\mathbf{F} = (-3-2y)\,\mathbf{j} + 2z\,\mathbf{k}$, and the projection D of S on the xy-plane is the disk $x^2+y^2 \le 4$, so by Equation 16.7.10 with $z = g(x,y) = 5 - x^2 - y^2$ we have

$$\begin{aligned}\iint_S \operatorname{curl}\mathbf{F}\cdot d\mathbf{S} &= \iint_D [-0-(-3-2y)(-2y)+2z]\,dA = \iint_D [-6y-4y^2+2(5-x^2-y^2)]\,dA\\ &= \int_0^{2\pi}\int_0^2 \left[-6r\sin\theta - 4r^2\sin^2\theta + 2(5-r^2)\right] r\,dr\,d\theta = \int_0^{2\pi}\left[-2r^3\sin\theta - r^4\sin^2\theta + 5r^2 - \tfrac{1}{2}r^4\right]_{r=0}^{r=2} d\theta\\ &= \int_0^{2\pi}\left(-16\sin\theta - 16\sin^2\theta + 20 - 8\right) d\theta = 16\cos\theta - 16\left(\tfrac{1}{2}\theta - \tfrac{1}{4}\sin 2\theta\right) + 12\theta\Big]_0^{2\pi} = 8\pi\end{aligned}$$

15. The boundary curve C is the circle $x^2+z^2=1$, $y=0$ oriented in the counterclockwise direction as viewed from the positive y-axis. Then C can be described by $\mathbf{r}(t) = \cos t\,\mathbf{i} - \sin t\,\mathbf{k}$, $0 \le t \le 2\pi$, and $\mathbf{r}'(t) = -\sin t\,\mathbf{i} - \cos t\,\mathbf{k}$. Thus $\mathbf{F}(\mathbf{r}(t)) = -\sin t\,\mathbf{j} + \cos t\,\mathbf{k}$, $\mathbf{F}(\mathbf{r}(t))\cdot\mathbf{r}'(t) = -\cos^2 t$, and $\oint_C \mathbf{F}\cdot d\mathbf{r} = \int_0^{2\pi}(-\cos^2 t)\,dt = -\frac{1}{2}t - \frac{1}{4}\sin 2t\Big]_0^{2\pi} = -\pi$.
Now curl $\mathbf{F} = -\mathbf{i} - \mathbf{j} - \mathbf{k}$, and S can be parametrized (see Example 16.6.10) by
$\mathbf{r}(\phi,\theta) = \sin\phi\,\cos\theta\,\mathbf{i} + \sin\phi\,\sin\theta\,\mathbf{j} + \cos\phi\,\mathbf{k}$, $0 \le \theta \le \pi$, $0 \le \phi \le \pi$. Then
$\mathbf{r}_\phi \times \mathbf{r}_\theta = \sin^2\phi\,\cos\theta\,\mathbf{i} + \sin^2\phi\,\sin\theta\,\mathbf{j} + \sin\phi\,\cos\phi\,\mathbf{k}$ and

$$\begin{aligned}\iint_S \operatorname{curl}\mathbf{F}\cdot d\mathbf{S} &= \iint\limits_{x^2+z^2\le 1} \operatorname{curl}\mathbf{F}\cdot(\mathbf{r}_\phi\times\mathbf{r}_\theta)\,dA = \int_0^\pi\int_0^\pi(-\sin^2\phi\,\cos\theta - \sin^2\phi\,\sin\theta - \sin\phi\,\cos\phi)\,d\theta\,d\phi\\ &= \int_0^\pi(-2\sin^2\phi - \pi\sin\phi\,\cos\phi)\,d\phi = \left[\tfrac{1}{2}\sin 2\phi - \phi - \tfrac{\pi}{2}\sin^2\phi\right]_0^\pi = -\pi\end{aligned}$$

16. Let S be the surface in the plane $x+y+z=1$ with upward orientation enclosed by C. Then an upward unit normal vector for S is $\mathbf{n} = \frac{1}{\sqrt{3}}(\mathbf{i}+\mathbf{j}+\mathbf{k})$. Orient C in the counterclockwise direction, as viewed from above. $\int_C z\,dx - 2x\,dy + 3y\,dz$ is equivalent to $\int_C \mathbf{F}\cdot d\mathbf{r}$ for $\mathbf{F}(x,y,z) = z\,\mathbf{i} - 2x\,\mathbf{j} + 3y\,\mathbf{k}$, and the components of $\mathbf{F}$ are polynomials, which have continuous partial derivatives throughout $\mathbb{R}^3$. We have curl $\mathbf{F} = 3\,\mathbf{i} + \mathbf{j} - 2\,\mathbf{k}$, so by Stokes' Theorem,

$$\begin{aligned}\int_C z\,dx - 2x\,dy + 3y\,dz &= \int_C \mathbf{F}\cdot d\mathbf{r} = \iint_S \operatorname{curl}\mathbf{F}\cdot\mathbf{n}\,dS = \iint_S (3\,\mathbf{i}+\mathbf{j}-2\,\mathbf{k})\cdot\tfrac{1}{\sqrt{3}}(\mathbf{i}+\mathbf{j}+\mathbf{k})\;dS\\ &= \tfrac{2}{\sqrt{3}}\iint_S dS = \tfrac{2}{\sqrt{3}}\,(\text{surface area of } S)\end{aligned}$$

Thus the value of $\int_C z\,dx - 2x\,dy + 3y\,dz$ is always $\frac{2}{\sqrt{3}}$ times the area of the region enclosed by C, regardless of its shape or location. [Notice that because $\mathbf{n}$ is normal to a plane, it is constant. But curl $\mathbf{F}$ is also constant, so the dot product curl $\mathbf{F}\cdot\mathbf{n}$ is constant and we could have simply argued that $\iint_S \operatorname{curl}\mathbf{F}\cdot\mathbf{n}\,dS$ is a constant multple of $\iint_S dS$, the surface area of S.]

17. It is easier to use Stokes' Theorem than to compute the work directly. Let S be the planar region enclosed by the path of the particle, so S is the portion of the plane $z = \frac{1}{2}y$ for $0 \le x \le 1$, $0 \le y \le 2$, with upward orientation.
curl $\mathbf{F} = 8y\,\mathbf{i} + 2z\,\mathbf{j} + 2y\,\mathbf{k}$ and

$$\begin{aligned}\oint_C \mathbf{F}\cdot d\mathbf{r} &= \iint_S \operatorname{curl}\mathbf{F}\cdot d\mathbf{S} = \iint_D \left[-8y\,(0) - 2z\left(\tfrac{1}{2}\right) + 2y\right] dA = \int_0^1\int_0^2 \left(2y - \tfrac{1}{2}y\right) dy\,dx\\ &= \int_0^1\int_0^2 \tfrac{3}{2}y\,dy\,dx = \int_0^1 \left[\tfrac{3}{4}y^2\right]_{y=0}^{y=2} dx = \int_0^1 3\,dx = 3\end{aligned}$$

18. $\int_C (y+\sin x)\,dx + (z^2+\cos y)\,dy + x^3\,dz = \int_C \mathbf{F}\cdot d\mathbf{r}$, where $\mathbf{F}(x,y,z) = (y+\sin x)\,\mathbf{i} + (z^2+\cos y)\,\mathbf{j} + x^3\,\mathbf{k}$ $\Rightarrow$ curl $\mathbf{F} = -2z\,\mathbf{i} - 3x^2\,\mathbf{j} - \mathbf{k}$. Since $\sin 2t = 2\sin t\,\cos t$, C lies on the surface $z = 2xy$. Let S be the part of this surface that is bounded by C. Then the projection of S onto the xy-plane is the unit disk D $[x^2+y^2 \le 1]$. C is traversed clockwise (when viewed from above) so S is oriented downward. Using Equation 16.7.10 with $g(x,y) = 2xy$,

$P = -2z = -2(2xy) = -4xy$, $Q = -3x^2$, $R = -1$ and multiplying by -1 for the downward orientation, we have

$$\int_C \mathbf{F} \cdot d\mathbf{r} = -\iint_S \operatorname{curl} \mathbf{F} \cdot d\mathbf{S} = -\iint_D \left[-(-4xy)(2y) - (-3x^2)(2x) - 1\right] dA$$
$$= -\iint_D (8xy^2 + 6x^3 - 1)\,dA = -\int_0^{2\pi}\int_0^1 (8r^3\cos\theta\sin^2\theta + 6r^3\cos^3\theta - 1)\,r\,dr\,d\theta$$
$$= -\int_0^{2\pi}\left(\tfrac{8}{5}\cos\theta\sin^2\theta + \tfrac{6}{5}\cos^3\theta - \tfrac{1}{2}\right)d\theta = -\left[\tfrac{8}{15}\sin^3\theta + \tfrac{6}{5}\left(\sin\theta - \tfrac{1}{3}\sin^3\theta\right) - \tfrac{1}{2}\theta\right]_0^{2\pi} = \pi$$

19. Assume S is centered at the origin with radius a and let H_1 and H_2 be the upper and lower hemispheres, respectively, of S. Then $\iint_S \operatorname{curl}\mathbf{F}\cdot d\mathbf{S} = \iint_{H_1}\operatorname{curl}\mathbf{F}\cdot d\mathbf{S} + \iint_{H_2}\operatorname{curl}\mathbf{F}\cdot d\mathbf{S} = \oint_{C_1}\mathbf{F}\cdot d\mathbf{r} + \oint_{C_2}\mathbf{F}\cdot d\mathbf{r}$ by Stokes' Theorem. But C_1 is the circle $x^2+y^2=a^2$ oriented in the counterclockwise direction while C_2 is the same circle oriented in the clockwise direction. Hence $\oint_{C_2}\mathbf{F}\cdot d\mathbf{r} = -\oint_{C_1}\mathbf{F}\cdot d\mathbf{r}$ so $\iint_S \operatorname{curl}\mathbf{F}\cdot d\mathbf{S} = 0$ as desired.

20. (a) By Exercise 16.5.26, $\operatorname{curl}(f\nabla g) = f\operatorname{curl}(\nabla g) + \nabla f \times \nabla g = \nabla f \times \nabla g$ since $\operatorname{curl}(\nabla g) = \mathbf{0}$. Hence by Stokes' Theorem $\int_C (f\nabla g)\cdot d\mathbf{r} = \iint_S (\nabla f \times \nabla g)\cdot d\mathbf{S}$.

(b) As in (a), $\operatorname{curl}(f\nabla f) = \nabla f \times \nabla f = \mathbf{0}$, so by Stokes' Theorem, $\int_C (f\nabla f)\cdot d\mathbf{r} = \iint_S [\operatorname{curl}(f\nabla f)]\cdot d\mathbf{S} = 0$.

(c) As in part (a),

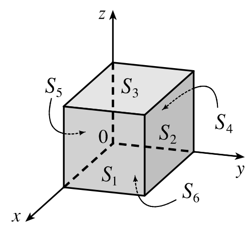
$$\operatorname{curl}(f\nabla g + g\nabla f) = \operatorname{curl}(f\nabla g) + \operatorname{curl}(g\nabla f) \qquad \text{[by Exercise 16.5.24]}$$
$$= (\nabla f \times \nabla g) + (\nabla g \times \nabla f) = \mathbf{0} \qquad [\text{since } \mathbf{u}\times\mathbf{v} = -(\mathbf{v}\times\mathbf{u})]$$

Hence by Stokes' Theorem, $\int_C (f\nabla g + g\nabla f)\cdot d\mathbf{r} = \iint_S \operatorname{curl}(f\nabla g + g\nabla f)\cdot d\mathbf{S} = 0$.

16.9 The Divergence Theorem

1. $\operatorname{div}\mathbf{F} = 3 + x + 2x = 3 + 3x$, so

$\iiint_E \operatorname{div}\mathbf{F}\,dV = \int_0^1\int_0^1\int_0^1 (3x+3)\,dx\,dy\,dz = \frac{9}{2}$ (notice the triple integral is three times the volume of the cube plus three times $\overline{x}$).



To compute $\iint_S \mathbf{F}\cdot d\mathbf{S}$, on

S_1: $\mathbf{n} = \mathbf{i}$, $\mathbf{F} = 3\,\mathbf{i} + y\,\mathbf{j} + 2z\,\mathbf{k}$, and $\iint_{S_1}\mathbf{F}\cdot d\mathbf{S} = \iint_{S_1} 3\,dS = 3$;

S_2: $\mathbf{F} = 3x\,\mathbf{i} + x\,\mathbf{j} + 2xz\,\mathbf{k}$, $\mathbf{n} = \mathbf{j}$ and $\iint_{S_2}\mathbf{F}\cdot d\mathbf{S} = \iint_{S_2} x\,dS = \frac{1}{2}$;

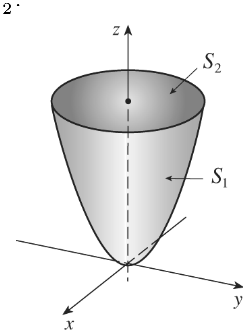
S_3: $\mathbf{F} = 3x\,\mathbf{i} + xy\,\mathbf{j} + 2x\,\mathbf{k}$, $\mathbf{n} = \mathbf{k}$ and $\iint_{S_3}\mathbf{F}\cdot d\mathbf{S} = \iint_{S_3} 2x\,dS = 1$;

S_4: $\mathbf{F} = \mathbf{0}$, $\iint_{S_4}\mathbf{F}\cdot d\mathbf{S} = 0$; S_5: $\mathbf{F} = 3x\,\mathbf{i} + 2x\,\mathbf{k}$, $\mathbf{n} = -\mathbf{j}$ and $\iint_{S_5}\mathbf{F}\cdot d\mathbf{S} = \iint_{S_5} 0\,dS = 0$;

S_6: $\mathbf{F} = 3x\,\mathbf{i} + xy\,\mathbf{j}$, $\mathbf{n} = -\mathbf{k}$ and $\iint_{S_6}\mathbf{F}\cdot d\mathbf{S} = \iint_{S_6} 0\,dS = 0$. Thus $\iint_S \mathbf{F}\cdot d\mathbf{S} = \frac{9}{2}$.

2. $\operatorname{div}\mathbf{F} = 0 + 2z + 8z = 10z$ so, using cylindrical coordinates,

$$\iiint_E \operatorname{div}\mathbf{F}\,dV = \iiint_E 10z\,dV = \int_0^{2\pi}\int_0^3\int_{r^2}^9 (10z)\,r\,dz\,dr\,d\theta$$
$$= \int_0^{2\pi}\int_0^3 \left[5rz^2\right]_{z=r^2}^{z=9} dr\,d\theta = \int_0^{2\pi}\int_0^3 (405r - 5r^5)\,dr\,d\theta$$
$$= \int_0^{2\pi} d\theta \int_0^3 (405r - 5r^5)\,dr = \left[\theta\right]_0^{2\pi}\left[\tfrac{405}{2}r^2 - \tfrac{5}{6}r^6\right]_0^3$$
$$= 2\pi\left(\tfrac{3645}{2} - \tfrac{1215}{2}\right) = 2430\pi$$



[continued]

On S_1: The surface is $z = x^2 + y^2$, $x^2 + y^2 \le 9$, with downward orientation, and $\mathbf{F}(x,y,z) = y^2z^3\,\mathbf{i} + 2yz\,\mathbf{j} + 4z^2\,\mathbf{k}$.

Then

$$\begin{aligned}
\iint_{S_1} \mathbf{F}\cdot d\mathbf{S} &= -\iint_D [-(y^2z^3)(2x) - (2yz)(2y) + (4z^2)]\,dA \\
&= \iint_D \left[2xy^2(x^2+y^2)^3 + 4y^2(x^2+y^2) - 4(x^2+y^2)^2\right] dA \\
&= \int_0^{2\pi}\int_0^3 (2r^3\cos\theta\sin^2\theta\cdot r^6 + 4r^2\sin^2\theta\cdot r^2 - 4r^4)\,r\,dr\,d\theta \\
&= \int_0^{2\pi}\int_0^3 (2r^{10}\sin^2\theta\cos\theta + 4r^5\sin^2\theta - 4r^5)\,dr\,d\theta \\
&= \int_0^{2\pi} \left[\tfrac{2}{11}r^{11}\sin^2\theta\cos\theta + \tfrac{2}{3}r^6\sin^2\theta - \tfrac{2}{3}r^6\right]_{r=0}^{r=3} d\theta \\
&= \int_0^{2\pi} \left(\tfrac{354{,}294}{11}\sin^2\theta\cos\theta + 486\sin^2\theta - 486\right) d\theta \\
&= \left[\tfrac{354{,}294}{11}\cdot\tfrac{1}{3}\sin^3\theta + 486\left(\tfrac{1}{2}\theta - \tfrac{1}{4}\sin 2\theta\right) - 486\theta\right]_0^{2\pi} \\
&= 0 + 486(\pi - 0) - 486(2\pi) = -486\pi
\end{aligned}$$

On S_2: The surface is $z = 9$, $x^2 + y^2 \le 9$, with upward orientation, so $\mathbf{F}(x,y,z) = y^2z^3\,\mathbf{i} + 2yz\,\mathbf{j} + 4z^2\,\mathbf{k}$ and

$$\begin{aligned}
\iint_{S_2} \mathbf{F}\cdot d\mathbf{S} &= \iint_D [-(y^2z^3)(0) - (2yz)(0) + (4z^2)]\,dA = \iint_D 4(9)^2\,dA \\
&= 324\,A(D) = 324\cdot\pi(3)^2 = 2916\pi
\end{aligned}$$

Thus $\iint_S \mathbf{F}\cdot d\mathbf{S} = \iint_{S_1}\mathbf{F}\cdot d\mathbf{S} + \iint_{S_2}\mathbf{F}\cdot d\mathbf{S} = -486\pi + 2916\pi = 2430\pi$.

3. $\operatorname{div}\mathbf{F} = 0 + 1 + 0 = 1$, so $\iiint_E \operatorname{div}\mathbf{F}\,dV = \iiint_E 1\,dV = V(E) = \frac{4}{3}\pi\cdot 4^3 = \frac{256}{3}\pi$.

S is a sphere of radius 4 centered at the origin which can be parametrized by $\mathbf{r}(\phi,\theta) = \langle 4\sin\phi\cos\theta, 4\sin\phi\sin\theta, 4\cos\phi\rangle$, $0 \le \phi \le \pi$, $0 \le \theta \le 2\pi$ (similar to Example 16.6.10). Then

$$\begin{aligned}
\mathbf{r}_\phi \times \mathbf{r}_\theta &= \langle 4\cos\phi\cos\theta, 4\cos\phi\sin\theta, -4\sin\phi\rangle \times \langle -4\sin\phi\sin\theta, 4\sin\phi\cos\theta, 0\rangle \\
&= \left\langle 16\sin^2\phi\cos\theta, 16\sin^2\phi\sin\theta, 16\cos\phi\sin\phi\right\rangle
\end{aligned}$$

and $\mathbf{F}(\mathbf{r}(\phi,\theta)) = \langle 4\cos\phi, 4\sin\phi\sin\theta, 4\sin\phi\cos\theta\rangle$. Thus

$\mathbf{F}\cdot(\mathbf{r}_\phi\times\mathbf{r}_\theta) = 64\cos\phi\sin^2\phi\cos\theta + 64\sin^3\phi\sin^2\theta + 64\cos\phi\sin^2\phi\cos\theta = 128\cos\phi\sin^2\phi\cos\theta + 64\sin^3\phi\sin^2\theta$

and

$$\begin{aligned}
\iint_S \mathbf{F}\cdot d\mathbf{S} &= \iint_D \mathbf{F}\cdot(\mathbf{r}_\phi\times\mathbf{r}_\theta)\,dA = \int_0^{2\pi}\int_0^{\pi} (128\cos\phi\sin^2\phi\cos\theta + 64\sin^3\phi\sin^2\theta)\,d\phi\,d\theta \\
&= \int_0^{2\pi} \left[\tfrac{128}{3}\sin^3\phi\cos\theta + 64\left(\tfrac{1}{3}\cos^3\phi - \cos\phi\right)\sin^2\theta\right]_{\phi=0}^{\phi=\pi} d\theta \\
&= \int_0^{2\pi} \tfrac{256}{3}\sin^2\theta\,d\theta = \tfrac{256}{3}\left[\tfrac{1}{2}\theta - \tfrac{1}{4}\sin 2\theta\right]_0^{2\pi} = \tfrac{256}{3}\pi
\end{aligned}$$

4. $\operatorname{div}\mathbf{F} = 2x - 1 + 1 = 2x$, so

$$\iiint_E \operatorname{div}\mathbf{F}\,dV = \iint_{y^2+z^2\le 9}\left[\int_0^2 2x\,dx\right] dA = \iint_{y^2+z^2\le 9} 4\,dA = 4(\text{area of circle}) = 4(\pi\cdot 3^2) = 36\pi$$

Let S_1 be the front of the cylinder (in the plane $x = 2$), S_2 the back (in the yz-plane), and S_3 the lateral surface of the cylinder.

S_1 is the disk $x = 2$, $y^2 + z^2 \le 9$. A unit normal vector is $\mathbf{n} = \langle 1, 0, 0\rangle$ and $\mathbf{F} = \langle 4, -y, z\rangle$ on S_1, so

$\iint_{S_1}\mathbf{F}\cdot d\mathbf{S} = \iint_{S_1}\mathbf{F}\cdot\mathbf{n}\,dS = \iint_{S_1} 4\,dS = 4(\text{surface area of } S_1) = 4(\pi\cdot 3^2) = 36\pi$. S_2 is the disk $x = 0$, $y^2 + z^2 \le 9$.

Here $\mathbf{n} = \langle -1, 0, 0 \rangle$ and $\mathbf{F} = \langle 0, -y, z \rangle$, so $\iint_{S_2} \mathbf{F} \cdot d\mathbf{S} = \iint_{S_2} \mathbf{F} \cdot \mathbf{n}\, dS = \iint_{S_2} 0\, dS = 0$.

S_3 can be parametrized by $\mathbf{r}(x, \theta) = \langle x, 3\cos\theta, 3\sin\theta \rangle$, $0 \le x \le 2$, $0 \le \theta \le 2\pi$. Then

$\mathbf{r}_x \times \mathbf{r}_\theta = \langle 1, 0, 0 \rangle \times \langle 0, -3\sin\theta, 3\cos\theta \rangle = \langle 0, -3\cos\theta, -3\sin\theta \rangle$. For the outward (positive) orientation we use

$-(\mathbf{r}_x \times \mathbf{r}_\theta)$ and $\mathbf{F}(\mathbf{r}(x, \theta)) = \left\langle x^2, -3\cos\theta, 3\sin\theta \right\rangle$, so

$$\begin{aligned}\iint_{S_3} \mathbf{F} \cdot d\mathbf{S} &= \iint_D \mathbf{F} \cdot (-(\mathbf{r}_x \times \mathbf{r}_\theta))\ dA = \int_0^2 \int_0^{2\pi} (0 - 9\cos^2\theta + 9\sin^2\theta)\, d\theta\, dx \\ &= -9\int_0^2 dx \int_0^{2\pi} \cos 2\theta\, d\theta = -9\,(2)\left[\tfrac{1}{2}\sin 2\theta\right]_0^{2\pi} = 0\end{aligned}$$

Thus $\iint_S \mathbf{F} \cdot d\mathbf{S} = 36\pi + 0 + 0 = 36\pi$.

5. $\operatorname{div} \mathbf{F} = \frac{\partial}{\partial x}(xye^z) + \frac{\partial}{\partial y}(xy^2z^3) + \frac{\partial}{\partial z}(-ye^z) = ye^z + 2xyz^3 - ye^z = 2xyz^3$, so by the Divergence Theorem,

$$\begin{aligned}\iint_S \mathbf{F} \cdot d\mathbf{S} &= \iiint_E \operatorname{div} \mathbf{F}\, dV = \int_0^3 \int_0^2 \int_0^1 2xyz^3\, dz\, dy\, dx = 2\int_0^3 x\, dx \int_0^2 y\, dy \int_0^1 z^3\, dz \\ &= 2\left[\tfrac{1}{2}x^2\right]_0^3 \left[\tfrac{1}{2}y^2\right]_0^2 \left[\tfrac{1}{4}z^4\right]_0^1 = 2\left(\tfrac{9}{2}\right)(2)\left(\tfrac{1}{4}\right) = \tfrac{9}{2}\end{aligned}$$

6. $\operatorname{div} \mathbf{F} = \frac{\partial}{\partial x}(x^2yz) + \frac{\partial}{\partial y}(xy^2z) + \frac{\partial}{\partial z}(xyz^2) = 2xyz + 2xyz + 2xyz = 6xyz$, so by the Divergence Theorem,

$$\begin{aligned}\iint_S \mathbf{F} \cdot d\mathbf{S} &= \iiint_E \operatorname{div} \mathbf{F}\, dV = \int_0^a \int_0^b \int_0^c 6xyz\, dz\, dy\, dx = 6\int_0^a x\, dx \int_0^b y\, dy \int_0^c z\, dz \\ &= 6\left[\tfrac{1}{2}x^2\right]_0^a \left[\tfrac{1}{2}y^2\right]_0^b \left[\tfrac{1}{2}z^2\right]_0^c = 6\left(\tfrac{1}{2}a^2\right)\left(\tfrac{1}{2}b^2\right)\left(\tfrac{1}{2}c^2\right) = \tfrac{3}{4}a^2b^2c^2\end{aligned}$$

7. $\operatorname{div} \mathbf{F} = 3y^2 + 0 + 3z^2$, so using cylindrical coordinates with $y = r\cos\theta$, $z = r\sin\theta$, $x = x$ we have

$$\begin{aligned}\iint_S \mathbf{F} \cdot d\mathbf{S} &= \iiint_E (3y^2 + 3z^2)\, dV = \int_0^{2\pi} \int_0^1 \int_{-1}^2 (3r^2\cos^2\theta + 3r^2\sin^2\theta)\, r\, dx\, dr\, d\theta \\ &= 3\int_0^{2\pi} d\theta \int_0^1 r^3\, dr \int_{-1}^2 dx = 3\left[\,\theta\,\right]_0^{2\pi} \left[\tfrac{1}{4}r^4\right]_0^1 \left[\,x\,\right]_{-1}^2 = 3(2\pi)\left(\tfrac{1}{4}\right)(3) = \tfrac{9\pi}{2}\end{aligned}$$

8. $\operatorname{div} \mathbf{F} = 3x^2 + 3y^2 + 3z^2$, so by the Divergence Theorem,

$$\begin{aligned}\iint_S \mathbf{F} \cdot d\mathbf{S} &= \iiint_E 3(x^2 + y^2 + z^2)\, dV = \int_0^\pi \int_0^{2\pi} \int_0^2 3\rho^2 \cdot \rho^2 \sin\phi\, d\rho\, d\theta\, d\phi = 3\int_0^\pi \sin\phi\, d\phi \int_0^{2\pi} d\theta \int_0^2 \rho^4\, d\rho \\ &= 3\left[-\cos\phi\right]_0^\pi \left[\,\theta\,\right]_0^{2\pi} \left[\tfrac{1}{5}\rho^5\right]_0^2 = 3\,(2)\,(2\pi)\left(\tfrac{32}{5}\right) = \tfrac{384}{5}\pi\end{aligned}$$

9. $\operatorname{div} \mathbf{F} = e^y + (-e^y) + 0 = 0$, so by the Divergence Theorem, $\iint_S \mathbf{F} \cdot d\mathbf{S} = \iiint_E 0\, dV = 0$.

10. The tetrahedron has vertices $(0, 0, 0)$, $(a, 0, 0)$, $(0, b, 0)$, $(0, 0, c)$ and is described by

$E = \left\{(x, y, z) \mid 0 \le x \le a, 0 \le y \le b\left(1 - \frac{x}{a}\right), 0 \le z \le c\left(1 - \frac{x}{a} - \frac{y}{b}\right)\right\}$. Here we have $\operatorname{div} \mathbf{F} = 0 + 1 + x = x + 1$, so

$$\begin{aligned}\iint_S \mathbf{F} \cdot d\mathbf{S} &= \iiint_E (x + 1)\, dV = \int_0^a \int_0^{b\left(1 - \frac{x}{a}\right)} \int_0^{c\left(1 - \frac{x}{a} - \frac{y}{b}\right)} (x + 1)\, dz\, dy\, dx \\ &= \int_0^a \int_0^{b\left(1 - \frac{x}{a}\right)} (x + 1)\left[c\left(1 - \tfrac{x}{a} - \tfrac{y}{b}\right)\right] dy\, dx = c\int_0^a (x + 1)\left[\left(1 - \tfrac{x}{a}\right)y - \tfrac{1}{2b}y^2\right]_{y=0}^{y=b\left(1 - \frac{x}{a}\right)} dx \\ &= c\int_0^a (x + 1)\left[\left(1 - \tfrac{x}{a}\right) \cdot b\left(1 - \tfrac{x}{a}\right) - \tfrac{1}{2b} \cdot b^2\left(1 - \tfrac{x}{a}\right)^2\right] dx = \tfrac{1}{2}bc\int_0^a (x + 1)\left(1 - \tfrac{x}{a}\right)^2 dx \\ &= \tfrac{1}{2}bc\int_0^a \left(\tfrac{1}{a^2}x^3 + \tfrac{1}{a^2}x^2 - \tfrac{2}{a}x^2 + x - \tfrac{2}{a}x + 1\right) dx \\ &= \tfrac{1}{2}bc\left[\tfrac{1}{4a^2}x^4 + \tfrac{1}{3a^2}x^3 - \tfrac{2}{3a}x^3 + \tfrac{1}{2}x^2 - \tfrac{1}{a}x^2 + x\right]_0^a \\ &= \tfrac{1}{2}bc\left(\tfrac{1}{4}a^2 + \tfrac{1}{3}a - \tfrac{2}{3}a^2 + \tfrac{1}{2}a^2 - a + a\right) = \tfrac{1}{2}bc\left(\tfrac{1}{12}a^2 + \tfrac{1}{3}a\right) = \tfrac{1}{24}abc(a + 4)\end{aligned}$$

11. div $\mathbf{F} = 6x^2 + 3y^2 + 3y^2 = 6x^2 + 6y^2$ so

$$\iint_S \mathbf{F}\cdot d\mathbf{S} = \iiint_E 6(x^2+y^2)\,dV = \int_0^{2\pi}\int_0^1\int_0^{1-r^2} 6r^2\cdot r\,dz\,dr\,d\theta = \int_0^{2\pi}\int_0^1 6r^3(1-r^2)\,dr\,d\theta$$
$$= \int_0^{2\pi} d\theta \int_0^1 (6r^3 - 6r^5)\,dr = \big[\,\theta\,\big]_0^{2\pi}\,\big[\tfrac{3}{2}r^4 - r^6\big]_0^1 = 2\pi\left(\tfrac{3}{2}-1\right) = \pi$$

12. For $x^2+y^2 \le 4$ the plane $z = y-2$ is below the xy-plane, so the solid E bounded by S is $E = \{(x,y,z) \mid x^2+y^2\le 4,\ y-2\le z\le 0\}$. Here div $\mathbf{F} = y + 2z + 2y - 2z = 3y$ so

$$\iint_S \mathbf{F}\cdot d\mathbf{S} = \iiint_E 3y\,dV = \int_0^{2\pi}\int_0^2\int_{r\sin\theta-2}^0 (3r\sin\theta)\,r\,dz\,dr\,d\theta$$
$$= \int_0^{2\pi}\int_0^2 (3r^2\sin\theta)(0 - r\sin\theta + 2)\,dr\,d\theta = \int_0^{2\pi}\int_0^2\left(-3r^3\sin^2\theta + 6r^2\sin\theta\right)dr\,d\theta$$
$$= \int_0^{2\pi}\left[-\tfrac{3}{4}r^4\sin^2\theta + 2r^3\sin\theta\right]_{r=0}^{r=2} d\theta = \int_0^{2\pi}\left(-12\sin^2\theta + 16\sin\theta\right)d\theta$$
$$= \left[-12\left(\tfrac{1}{2}\theta - \tfrac{1}{4}\sin 2\theta\right) - 16\cos\theta\right]_0^{2\pi} = -12\pi - 16 + 16 = -12\pi$$

13. $\mathbf{F}(x,y,z) = x\sqrt{x^2+y^2+z^2}\,\mathbf{i} + y\sqrt{x^2+y^2+z^2}\,\mathbf{j} + z\sqrt{x^2+y^2+z^2}\,\mathbf{k}$, so

$$\text{div}\,\mathbf{F} = x\cdot\tfrac{1}{2}(x^2+y^2+z^2)^{-1/2}(2x) + (x^2+y^2+z^2)^{1/2} + y\cdot\tfrac{1}{2}(x^2+y^2+z^2)^{-1/2}(2y) + (x^2+y^2+z^2)^{1/2}$$
$$+\ z\cdot\tfrac{1}{2}(x^2+y^2+z^2)^{-1/2}(2z) + (x^2+y^2+z^2)^{1/2}$$
$$= (x^2+y^2+z^2)^{-1/2}\left[x^2 + (x^2+y^2+z^2) + y^2 + (x^2+y^2+z^2) + z^2 + (x^2+y^2+z^2)\right]$$
$$= \frac{4(x^2+y^2+z^2)}{\sqrt{x^2+y^2+z^2}} = 4\sqrt{x^2+y^2+z^2}.$$

Then
$$\iint_S \mathbf{F}\cdot d\mathbf{S} = \iiint_E 4\sqrt{x^2+y^2+z^2}\,dV = \int_0^{\pi/2}\int_0^{2\pi}\int_0^1 4\sqrt{\rho^2}\cdot\rho^2\sin\phi\,d\rho\,d\theta\,d\phi$$
$$= \int_0^{\pi/2}\sin\phi\,d\phi\int_0^{2\pi}d\theta\int_0^1 4\rho^3\,d\rho = \left[-\cos\phi\right]_0^{\pi/2}\left[\theta\right]_0^{2\pi}\left[\rho^4\right]_0^1 = (1)\,(2\pi)\,(1) = 2\pi$$

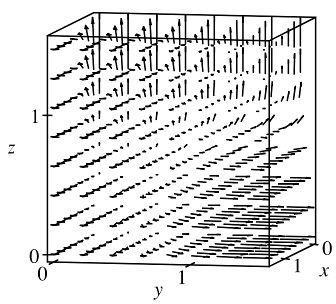
14. $\mathbf{F}(x,y,z) = x(x^2+y^2+z^2)\,\mathbf{i} + y(x^2+y^2+z^2)\,\mathbf{j} + z(x^2+y^2+z^2)\,\mathbf{k}$, so

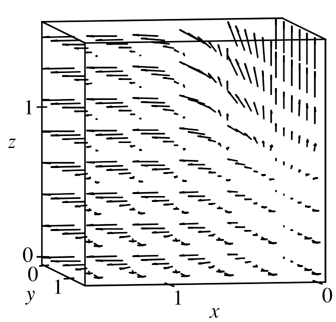
div $\mathbf{F} = x\cdot 2x + (x^2+y^2+z^2) + y\cdot 2y + (x^2+y^2+z^2) + z\cdot 2z + (x^2+y^2+z^2) = 5(x^2+y^2+z^2)$. Then

$$\iint_S \mathbf{F}\cdot d\mathbf{S} = \iiint_E 5(x^2+y^2+z^2)\,dV = \int_0^{\pi}\int_0^{2\pi}\int_0^R 5\rho^2\cdot\rho^2\sin\phi\,d\rho\,d\theta\,d\phi$$
$$= 5\int_0^{\pi}\sin\phi\,d\phi\int_0^{2\pi}d\theta\int_0^R\rho^4\,d\rho = 5\left[-\cos\phi\right]_0^{\pi}\left[\theta\right]_0^{2\pi}\left[\tfrac{1}{5}\rho^5\right]_0^R = 5\,(2)\,(2\pi)\left(\tfrac{1}{5}R^5\right) = 4\pi R^5$$

15. $\iint_S \mathbf{F}\cdot d\mathbf{S} = \iiint_E \sqrt{3-x^2}\,dV = \int_{-1}^1\int_{-1}^1\int_0^{2-x^4-y^4}\sqrt{3-x^2}\,dz\,dy\,dx = \frac{341}{60}\sqrt{2} + \frac{81}{20}\sin^{-1}\left(\frac{\sqrt{3}}{3}\right)$

16.





By the Divergence Theorem, the flux of $\mathbf{F}$ across the surface of the cube is

$$\iint_S \mathbf{F}\cdot d\mathbf{S} = \int_0^{\pi/2}\int_0^{\pi/2}\int_0^{\pi/2}\left[\cos x\,\cos^2 y + 3\sin^2 y\,\cos y\,\cos^4 z + 5\sin^4 z\,\cos z\,\cos^6 x\right]dz\,dy\,dx = \tfrac{19}{64}\pi^2.$$

17. For S_1 we have $\mathbf{n} = -\mathbf{k}$, so $\mathbf{F} \cdot \mathbf{n} = \mathbf{F} \cdot (-\mathbf{k}) = -x^2 z - y^2 = -y^2$ (since $z = 0$ on S_1). So if D is the unit disk, we get $\iint_{S_1} \mathbf{F} \cdot d\mathbf{S} = \iint_{S_1} \mathbf{F} \cdot \mathbf{n}\, dS = \iint_D (-y^2)\, dA = -\int_0^{2\pi} \int_0^1 r^2 (\sin^2\theta)\, r\, dr\, d\theta = -\frac{1}{4}\pi$. Now since S_2 is closed, we can use the Divergence Theorem. Since $\operatorname{div} \mathbf{F} = \frac{\partial}{\partial x}(z^2 x) + \frac{\partial}{\partial y}\left(\frac{1}{3}y^3 + \tan z\right) + \frac{\partial}{\partial z}(x^2 z + y^2) = z^2 + y^2 + x^2$, we use spherical coordinates to get $\iint_{S_2} \mathbf{F} \cdot d\mathbf{S} = \iiint_E \operatorname{div} \mathbf{F}\, dV = \int_0^{2\pi} \int_0^{\pi/2} \int_0^1 \rho^2 \cdot \rho^2 \sin\phi\, d\rho\, d\phi\, d\theta = \frac{2}{5}\pi$. Finally $\iint_S \mathbf{F} \cdot d\mathbf{S} = \iint_{S_2} \mathbf{F} \cdot d\mathbf{S} - \iint_{S_1} \mathbf{F} \cdot d\mathbf{S} = \frac{2}{5}\pi - \left(-\frac{1}{4}\pi\right) = \frac{13}{20}\pi$.

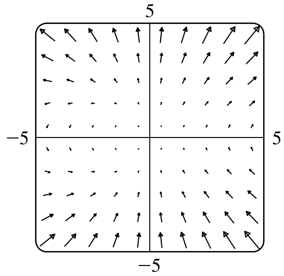
18. As in the hint to Exercise 17, we create a closed surface $S_2 = S \cup S_1$, where S is the part of the paraboloid $x^2 + y^2 + z = 2$ that lies above the plane $z = 1$, and S_1 is the disk $x^2 + y^2 = 1$ on the plane $z = 1$ oriented downward, and we then apply the Divergence Theorem. Since the disk S_1 is oriented downward, its unit normal vector is $\mathbf{n} = -\mathbf{k}$ and $\mathbf{F} \cdot (-\mathbf{k}) = -z = -1$ on S_1. So $\iint_{S_1} \mathbf{F} \cdot d\mathbf{S} = \iint_{S_1} \mathbf{F} \cdot \mathbf{n}\, dS = \iint_{S_1} (-1)\, dS = -A(S_1) = -\pi$. Let E be the region bounded by S_2. Then $\iint_{S_2} \mathbf{F} \cdot d\mathbf{S} = \iiint_E \operatorname{div} \mathbf{F}\, dV = \iiint_E 1\, dV = \int_0^1 \int_0^{2\pi} \int_1^{2-r^2} r\, dz\, d\theta\, dr = \int_0^1 \int_0^{2\pi} (r - r^3)\, d\theta\, dr = (2\pi)\frac{1}{4} = \frac{\pi}{2}$. Thus the flux of $\mathbf{F}$ across S is $\iint_S \mathbf{F} \cdot d\mathbf{S} = \iint_{S_2} \mathbf{F} \cdot d\mathbf{S} - \iint_{S_1} \mathbf{F} \cdot d\mathbf{S} = \frac{\pi}{2} - (-\pi) = \frac{3\pi}{2}$.

19. The vectors that end near P_1 are longer than the vectors that start near P_1, so the net flow is inward near P_1 and $\operatorname{div} \mathbf{F}(P_1)$ is negative. The vectors that end near P_2 are shorter than the vectors that start near P_2, so the net flow is outward near P_2 and $\operatorname{div} \mathbf{F}(P_2)$ is positive.

20. (a) The vectors that end near P_1 are shorter than the vectors that start near P_1, so the net flow is outward and P_1 is a source. The vectors that end near P_2 are longer than the vectors that start near P_2, so the net flow is inward and P_2 is a sink.

(b) $\mathbf{F}(x, y) = \langle x, y^2 \rangle \Rightarrow \operatorname{div} \mathbf{F} = \nabla \cdot \mathbf{F} = 1 + 2y$. The y-value at P_1 is positive, so $\operatorname{div} \mathbf{F} = 1 + 2y$ is positive, thus P_1 is a source. At P_2, $y < -1$, so $\operatorname{div} \mathbf{F} = 1 + 2y$ is negative, and P_2 is a sink.

21.

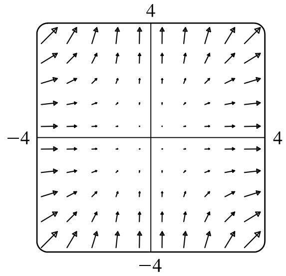


From the graph it appears that for points above the x-axis, vectors starting near a particular point are longer than vectors ending there, so divergence is positive. The opposite is true at points below the x-axis, where divergence is negative.

$\mathbf{F}(x, y) = \langle xy, x + y^2 \rangle \Rightarrow \operatorname{div} \mathbf{F} = \frac{\partial}{\partial x}(xy) + \frac{\partial}{\partial y}\left(x + y^2\right) = y + 2y = 3y$.

Thus $\operatorname{div} \mathbf{F} > 0$ for $y > 0$, and $\operatorname{div} \mathbf{F} < 0$ for $y < 0$.

22.



From the graph it appears that for points above the line $y = -x$, vectors starting near a particular point are longer than vectors ending there, so divergence is positive. The opposite is true at points below the line $y = -x$, where divergence is negative.

$\mathbf{F}(x, y) = \langle x^2, y^2 \rangle \Rightarrow \operatorname{div} \mathbf{F} = \frac{\partial}{\partial x}(x^2) + \frac{\partial}{\partial y}(y^2) = 2x + 2y$. Then $\operatorname{div} \mathbf{F} > 0$ for $2x + 2y > 0 \Rightarrow y > -x$, and $\operatorname{div} \mathbf{F} < 0$ for $y < -x$.

23. Since $\dfrac{\mathbf{x}}{|\mathbf{x}|^3} = \dfrac{x\,\mathbf{i} + y\,\mathbf{j} + z\,\mathbf{k}}{(x^2+y^2+z^2)^{3/2}}$ and $\dfrac{\partial}{\partial x}\left(\dfrac{x}{(x^2+y^2+z^2)^{3/2}}\right) = \dfrac{(x^2+y^2+z^2) - 3x^2}{(x^2+y^2+z^2)^{5/2}}$ with similar expressions for $\dfrac{\partial}{\partial y}\left(\dfrac{y}{(x^2+y^2+z^2)^{3/2}}\right)$ and $\dfrac{\partial}{\partial z}\left(\dfrac{z}{(x^2+y^2+z^2)^{3/2}}\right)$, we have

$\operatorname{div}\left(\dfrac{\mathbf{x}}{|\mathbf{x}|^3}\right) = \dfrac{3(x^2+y^2+z^2) - 3(x^2+y^2+z^2)}{(x^2+y^2+z^2)^{5/2}} = 0$, except at $(0,0,0)$ where it is undefined.

24. We first need to find $\mathbf{F}$ so that $\iint_S \mathbf{F}\cdot\mathbf{n}\,dS = \iint_S (2x+2y+z^2)\,dS$, so $\mathbf{F}\cdot\mathbf{n} = 2x+2y+z^2$. But for S,

$\mathbf{n} = \dfrac{x\,\mathbf{i} + y\,\mathbf{j} + z\,\mathbf{k}}{\sqrt{x^2+y^2+z^2}} = x\,\mathbf{i} + y\,\mathbf{j} + z\,\mathbf{k}$. Thus $\mathbf{F} = 2\,\mathbf{i} + 2\,\mathbf{j} + z\,\mathbf{k}$ and $\operatorname{div}\mathbf{F} = 1$.

If $B = \{(x,y,z) \mid x^2+y^2+z^2 \le 1\}$, then $\iint_S (2x+2y+z^2)\,dS = \iiint_B dV = V(B) = \frac{4}{3}\pi(1)^3 = \frac{4}{3}\pi$.

25. $\iint_S \mathbf{a}\cdot\mathbf{n}\,dS = \iiint_E \operatorname{div}\mathbf{a}\,dV = 0$ since $\operatorname{div}\mathbf{a} = 0$.

26. $\frac{1}{3}\iint_S \mathbf{F}\cdot d\mathbf{S} = \frac{1}{3}\iiint_E \operatorname{div}\mathbf{F}\,dV = \frac{1}{3}\iiint_E 3\,dV = V(E)$

27. $\iint_S \operatorname{curl}\mathbf{F}\cdot d\mathbf{S} = \iiint_E \operatorname{div}(\operatorname{curl}\mathbf{F})\,dV = 0$ by Theorem 16.5.11.

28. $\iint_S D_{\mathbf{n}} f\,dS = \iint_S (\nabla f\cdot\mathbf{n})\,dS = \iiint_E \operatorname{div}(\nabla f)\,dV = \iiint_E \nabla^2 f\,dV$

29. $\iint_S (f\nabla g)\cdot\mathbf{n}\,dS = \iiint_E \operatorname{div}(f\nabla g)\,dV = \iiint_E (f\nabla^2 g + \nabla g\cdot\nabla f)\,dV$ by Exercise 16.5.25.

30. $\iint_S (f\nabla g - g\nabla f)\cdot\mathbf{n}\,dS = \iiint_E \left[(f\nabla^2 g + \nabla g\cdot\nabla f) - (g\nabla^2 f + \nabla g\cdot\nabla f)\right] dV$ [by Exercise 29].

But $\nabla g\cdot\nabla f = \nabla f\cdot\nabla g$, so that $\iint_S (f\nabla g - g\nabla f)\cdot\mathbf{n}\,dS = \iiint_E (f\nabla^2 g - g\nabla^2 f)\,dV$.

31. If $\mathbf{c} = c_1\,\mathbf{i} + c_2\,\mathbf{j} + c_3\,\mathbf{k}$ is an arbitrary constant vector, we define $\mathbf{F} = f\mathbf{c} = fc_1\,\mathbf{i} + fc_2\,\mathbf{j} + fc_3\,\mathbf{k}$. Then

$\operatorname{div}\mathbf{F} = \operatorname{div} f\mathbf{c} = \dfrac{\partial f}{\partial x}c_1 + \dfrac{\partial f}{\partial y}c_2 + \dfrac{\partial f}{\partial z}c_3 = \nabla f\cdot\mathbf{c}$ and the Divergence Theorem says $\iint_S \mathbf{F}\cdot d\mathbf{S} = \iiint_E \operatorname{div}\mathbf{F}\,dV \Rightarrow$

$\iint_S \mathbf{F}\cdot\mathbf{n}\,dS = \iiint_E \nabla f\cdot\mathbf{c}\,dV$. In particular, if $\mathbf{c} = \mathbf{i}$ then $\iint_S f\mathbf{i}\cdot\mathbf{n}\,dS = \iiint_E \nabla f\cdot\mathbf{i}\,dV \Rightarrow$

$\displaystyle\iint_S fn_1\,dS = \iiint_E \frac{\partial f}{\partial x}\,dV$ (where $\mathbf{n} = n_1\,\mathbf{i} + n_2\,\mathbf{j} + n_3\,\mathbf{k}$). Similarly, if $\mathbf{c} = \mathbf{j}$ we have $\displaystyle\iint_S fn_2\,dS = \iiint_E \frac{\partial f}{\partial y}\,dV$,

and $\mathbf{c} = \mathbf{k}$ gives $\displaystyle\iint_S fn_3\,dS = \iiint_E \frac{\partial f}{\partial z}\,dV$. Then

$$\begin{aligned}\iint_S f\mathbf{n}\,dS &= \left(\iint_S fn_1\,dS\right)\mathbf{i} + \left(\iint_S fn_2\,dS\right)\mathbf{j} + \left(\iint_S fn_3\,dS\right)\mathbf{k} \\ &= \left(\iiint_E \frac{\partial f}{\partial x}\,dV\right)\mathbf{i} + \left(\iiint_E \frac{\partial f}{\partial y}\,dV\right)\mathbf{j} + \left(\iiint_E \frac{\partial f}{\partial z}\,dV\right)\mathbf{k} = \iiint_E \left(\frac{\partial f}{\partial x}\mathbf{i} + \frac{\partial f}{\partial y}\mathbf{j} + \frac{\partial f}{\partial z}\mathbf{k}\right) dV \\ &= \iiint_E \nabla f\,dV \quad \text{as desired.}\end{aligned}$$

32. By Exercise 31, $\iint_S p\mathbf{n}\,dS = \iiint_E \nabla p\,dV$, so

$$\mathbf{F} = -\iint_S p\mathbf{n}\,dS = -\iiint_E \nabla p\,dV = -\iiint_E \nabla(\rho g z)\,dV = -\iiint_E (\rho g\,\mathbf{k})\,dV = -\rho g\big(\iiint_E dV\big)\,\mathbf{k} = -\rho g V(E)\,\mathbf{k}.$$

But the weight of the displaced liquid is volume $\times$ density $\times$ $g = \rho g V(E)$, thus $\mathbf{F} = -W\mathbf{k}$ as desired.

16 Review

TRUE-FALSE QUIZ

1. False; div $\mathbf{F}$ is a scalar field.

2. True. (See Definition 16.5.1.)

3. True, by Theorem 16.5.3 and the fact that div $\mathbf{0} = 0$.

4. True, by Theorem 16.3.2.

5. False. See Exercise 16.3.35. (But the assertion is true if D is simply-connected; see Theorem 16.3.6.)

6. False. See the discussion accompanying Figure 8 on page 1120 [ET 1080].

7. False. For example, $\operatorname{div}(y\,\mathbf{i}) = 0 = \operatorname{div}(x\,\mathbf{j})$ but $y\,\mathbf{i} \neq x\,\mathbf{j}$.

8. True. Line integrals of conservative vector fields are independent of path, and by Theorem 16.3.3, work $= \int_C \mathbf{F}\cdot d\mathbf{r} = 0$ for any closed path C.

9. True. See Exercise 16.5.24.

10. False. $\mathbf{F}\cdot\mathbf{G}$ is a scalar field, so $\operatorname{curl}(\mathbf{F}\cdot\mathbf{G})$ has no meaning.

11. True. Apply the Divergence Theorem and use the fact that div $\mathbf{F} = 0$.

12. False by Theorem 16.5.11, because if it were true, then div curl $\mathbf{F} = 3 \neq 0$.

13. False. By Equations 16.4.5, the area is given by $-\oint_C y\,dx$ or $\oint_C x\,dy$.

EXERCISES

1. (a) Vectors starting on C point in roughly the direction opposite to C, so the tangential component $\mathbf{F}\cdot\mathbf{T}$ is negative. Thus $\int_C \mathbf{F}\cdot d\mathbf{r} = \int_C \mathbf{F}\cdot\mathbf{T}\,ds$ is negative.

(b) The vectors that end near P are shorter than the vectors that start near P, so the net flow is outward near P and div $\mathbf{F}(P)$ is positive.

2. We can parametrize C by $x = x$, $y = x^2$, $0 \le x \le 1$ so

$$\int_C x\,ds = \int_0^1 x\,\sqrt{1+(2x)^2}\,dx = \tfrac{1}{12}(1+4x^2)^{3/2}\Big]_0^1 = \tfrac{1}{12}\big(5\sqrt{5}-1\big).$$

3. $$\int_C yz\cos x\,ds = \int_0^\pi (3\cos t)\,(3\sin t)\cos t\,\sqrt{(1)^2+(-3\sin t)^2+(3\cos t)^2}\,dt = \int_0^\pi (9\cos^2 t\,\sin t)\sqrt{10}\,dt$$
$$= 9\sqrt{10}\left(-\tfrac{1}{3}\cos^3 t\right)\Big]_0^\pi = -3\sqrt{10}\,(-2) = 6\sqrt{10}$$

4. $x = 3\cos t \quad \Rightarrow \quad dx = -3\sin t\,dt$, $y = 2\sin t \quad \Rightarrow \quad dy = 2\cos t\,dt$, $0 \le t \le 2\pi$, so

$$\begin{aligned}\int_C y\,dx + \left(x + y^2\right) dy &= \int_0^{2\pi} \left[(2\sin t)(-3\sin t) + (3\cos t + 4\sin^2 t)(2\cos t)\right] dt \\ &= \int_0^{2\pi} (-6\sin^2 t + 6\cos^2 t + 8\sin^2 t\,\cos t)\,dt = \int_0^{2\pi} \left[6(\cos^2 t - \sin^2 t) + 8\sin^2 t\,\cos t\right] dt \\ &= \int_0^{2\pi} (6\cos 2t + 8\sin^2 t\,\cos t)\,dt = \left. 3\sin 2t + \tfrac{8}{3}\sin^3 t\right]_0^{2\pi} = 0\end{aligned}$$

Or: Notice that $\frac{\partial}{\partial y}(y) = 1 = \frac{\partial}{\partial x}\left(x + y^2\right)$, so $\mathbf{F}(x,y) = \left\langle y, x + y^2\right\rangle$ is a conservative vector field. Since C is a closed curve, $\int_C \mathbf{F} \cdot d\mathbf{r} = \int_C y\,dx + (x + y^2)\,dy = 0$.

5. $$\begin{aligned}\int_C y^3\,dx + x^2\,dy &= \int_{-1}^{1} \left[y^3(-2y) + (1 - y^2)^2\right] dy = \int_{-1}^{1} (-y^4 - 2y^2 + 1)\,dy \\ &= \left[-\tfrac{1}{5}y^5 - \tfrac{2}{3}y^3 + y\right]_{-1}^{1} = -\tfrac{1}{5} - \tfrac{2}{3} + 1 - \tfrac{1}{5} - \tfrac{2}{3} + 1 = \tfrac{4}{15}\end{aligned}$$

6. $$\begin{aligned}\int_C \sqrt{xy}\,dx + e^y\,dy + xz\,dz &= \int_0^1 \left(\sqrt{t^4 \cdot t^2} \cdot 4t^3 + e^{t^2} \cdot 2t + t^4 \cdot t^3 \cdot 3t^2\right) dt = \int_0^1 (4t^6 + 2te^{t^2} + 3t^9)\,dt \\ &= \left[\tfrac{4}{7}t^7 + e^{t^2} + \tfrac{3}{10}t^{10}\right]_0^1 = e - \tfrac{9}{70}\end{aligned}$$

7. C: $x = 1 + 2t \quad \Rightarrow \quad dx = 2\,dt$, $y = 4t \quad \Rightarrow \quad dy = 4\,dt$, $z = -1 + 3t \quad \Rightarrow \quad dz = 3\,dt$, $0 \le t \le 1$.

$$\begin{aligned}\int_C xy\,dx + y^2\,dy + yz\,dz &= \int_0^1 [(1 + 2t)(4t)(2) + (4t)^2(4) + (4t)(-1 + 3t)(3)]\,dt \\ &= \int_0^1 (116t^2 - 4t)\,dt = \left[\tfrac{116}{3}t^3 - 2t^2\right]_0^1 = \tfrac{116}{3} - 2 = \tfrac{110}{3}\end{aligned}$$

8. $\mathbf{F}(\mathbf{r}(t)) = (\sin t)(1 + t)\,\mathbf{i} + (\sin^2 t)\,\mathbf{j}$, $\mathbf{r}'(t) = \cos t\,\mathbf{i} + \mathbf{j}$ and

$$\begin{aligned}\int_C \mathbf{F} \cdot d\mathbf{r} &= \int_0^{\pi} ((1 + t)\sin t\cos t + \sin^2 t)\,dt = \int_0^{\pi} \left(\tfrac{1}{2}(1 + t)\sin 2t + \sin^2 t\right) dt \\ &= \left[\tfrac{1}{2}\left((1 + t)\left(-\tfrac{1}{2}\cos 2t\right) + \tfrac{1}{4}\sin 2t\right) + \tfrac{1}{2}t - \tfrac{1}{4}\sin 2t\right]_0^{\pi} = \tfrac{\pi}{4}\end{aligned}$$

9. $\mathbf{F}(\mathbf{r}(t)) = e^{-t}\,\mathbf{i} + t^2(-t)\,\mathbf{j} + (t^2 + t^3)\,\mathbf{k}$, $\mathbf{r}'(t) = 2t\,\mathbf{i} + 3t^2\,\mathbf{j} - \mathbf{k}$ and

$\int_C \mathbf{F} \cdot d\mathbf{r} = \int_0^1 (2te^{-t} - 3t^5 - (t^2 + t^3))\,dt = \left[-2te^{-t} - 2e^{-t} - \tfrac{1}{2}t^6 - \tfrac{1}{3}t^3 - \tfrac{1}{4}t^4\right]_0^1 = \tfrac{11}{12} - \tfrac{4}{e}$.

10. (a) C: $x = 3 - 3t$, $y = \frac{\pi}{2}t$, $z = 3t$, $0 \le t \le 1$. Then

$W = \int_C \mathbf{F} \cdot d\mathbf{r} = \int_0^1 \left[3t\,\mathbf{i} + (3 - 3t)\,\mathbf{j} + \tfrac{\pi}{2}t\,\mathbf{k}\right] \cdot \left[-3\,\mathbf{i} + \tfrac{\pi}{2}\,\mathbf{j} + 3\,\mathbf{k}\right] dt = \int_0^1 \left[-9t + \tfrac{3\pi}{2}\right] dt = \tfrac{1}{2}(3\pi - 9)$.

(b) $$\begin{aligned}W &= \int_C \mathbf{F} \cdot d\mathbf{r} = \int_0^{\pi/2} (3\sin t\,\mathbf{i} + 3\cos t\,\mathbf{j} + t\,\mathbf{k}) \cdot (-3\sin t\,\mathbf{i} + \mathbf{j} + 3\cos t\,\mathbf{k})\,dt \\ &= \int_0^{\pi/2} (-9\sin^2 t + 3\cos t + 3t\cos t)\,dt = \left[-9\left(\tfrac{1}{2}t - \tfrac{1}{4}\sin 2t\right) + 3\sin t + 3(t\sin t + \cos t)\right]_0^{\pi/2} \\ &= -\tfrac{9\pi}{4} + 3 + \tfrac{3\pi}{2} - 3 = -\tfrac{3\pi}{4}\end{aligned}$$

11. $\frac{\partial}{\partial y}\left[(1 + xy)e^{xy}\right] = 2xe^{xy} + x^2ye^{xy} = \frac{\partial}{\partial x}\left[e^y + x^2e^{xy}\right]$ and the domain of $\mathbf{F}$ is $\mathbb{R}^2$, so $\mathbf{F}$ is conservative. Thus there exists a function f such that $\mathbf{F} = \nabla f$. Then $f_y(x,y) = e^y + x^2e^{xy}$ implies $f(x,y) = e^y + xe^{xy} + g(x)$ and then

$f_x(x,y) = xye^{xy} + e^{xy} + g'(x) = (1+xy)e^{xy} + g'(x)$. But $f_x(x,y) = (1+xy)e^{xy}$, so $g'(x) = 0 \;\Rightarrow\; g(x) = K$. Thus $f(x,y) = e^y + xe^{xy} + K$ is a potential function for $\mathbf{F}$.

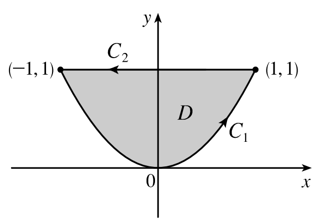
12. $\mathbf{F}$ is defined on all of $\mathbb{R}^3$, its components have continuous partial derivatives, and curl $\mathbf{F} = (0-0)\,\mathbf{i} - (0-0)\,\mathbf{j} + (\cos y - \cos y)\,\mathbf{k} = \mathbf{0}$, so $\mathbf{F}$ is conservative by Theorem 16.5.4. Thus there exists a function f such that $\nabla f = \mathbf{F}$. Then $f_x(x,y,z) = \sin y$ implies $f(x,y,z) = x\sin y + g(y,z)$ and then $f_y(x,y,z) = x\cos y + g_y(y,z)$. But $f_y(x,y,z) = x\cos y$, so $g_y(y,z) = 0 \;\Rightarrow\; g(y,z) = h(z)$. Then $f(x,y,z) = x\sin y + h(z)$ implies $f_z(x,y,z) = h'(z)$. But $f_z(x,y,z) = -\sin z$, so $h(z) = \cos z + K$. Thus a potential function for $\mathbf{F}$ is $f(x,y,z) = x\sin y + \cos z + K$.

13. Since $\frac{\partial}{\partial y}\left(4x^3y^2 - 2xy^3\right) = 8x^3y - 6xy^2 = \frac{\partial}{\partial x}\left(2x^4y - 3x^2y^2 + 4y^3\right)$ and the domain of $\mathbf{F}$ is $\mathbb{R}^2$, $\mathbf{F}$ is conservative. Furthermore $f(x,y) = x^4y^2 - x^2y^3 + y^4$ is a potential function for $\mathbf{F}$. $t = 0$ corresponds to the point $(0,1)$ and $t = 1$ corresponds to $(1,1)$, so $\int_C \mathbf{F}\cdot d\mathbf{r} = f(1,1) - f(0,1) = 1 - 1 = 0$.

14. Here curl $\mathbf{F} = \mathbf{0}$, the domain of $\mathbf{F}$ is $\mathbb{R}^3$, and the components of $\mathbf{F}$ have continuous partial derivatives, so $\mathbf{F}$ is conservative. Furthermore $f(x,y,z) = xe^y + ye^z$ is a potential function for $\mathbf{F}$. Then $\int_C \mathbf{F}\cdot d\mathbf{r} = f(4,0,3) - f(0,2,0) = 4 - 2 = 2$.

15. C_1: $\mathbf{r}(t) = t\,\mathbf{i} + t^2\,\mathbf{j}$, $-1 \le t \le 1$;
C_2: $\mathbf{r}(t) = -t\,\mathbf{i} + \mathbf{j}$, $-1 \le t \le 1$.
Then

$$\int_C xy^2\,dx - x^2y\,dy = \int_{-1}^{1}(t^5 - 2t^5)\,dt + \int_{-1}^{1} t\,dt = \left[-\tfrac{1}{6}t^6\right]_{-1}^{1} + \left[\tfrac{1}{2}t^2\right]_{-1}^{1} = 0$$



Using Green's Theorem, we have

$$\int_C xy^2\,dx - x^2y\,dy = \iint_D \left[\frac{\partial}{\partial x}\left(-x^2y\right) - \frac{\partial}{\partial y}\left(xy^2\right)\right] dA = \iint_D (-2xy - 2xy)\,dA = \int_{-1}^{1}\int_{x^2}^{1} -4xy\,dy\,dx$$
$$= \int_{-1}^{1}\left[-2xy^2\right]_{y=x^2}^{y=1}\,dx = \int_{-1}^{1}\left(2x^5 - 2x\right)dx = \left[\tfrac{1}{3}x^6 - x^2\right]_{-1}^{1} = 0$$

16. $\int_C \sqrt{1+x^3}\,dx + 2xy\,dy = \iint_D \left[\frac{\partial}{\partial x}(2xy) - \frac{\partial}{\partial y}\left(\sqrt{1+x^3}\right)\right] dA = \int_0^1\int_0^{3x}(2y - 0)\,dy\,dx = \int_0^1 9x^2\,dx = 3x^3\Big]_0^1 = 3$

17. $\int_C x^2y\,dx - xy^2\,dy = \iint_{x^2+y^2\le 4}\left[\frac{\partial}{\partial x}\left(-xy^2\right) - \frac{\partial}{\partial y}\left(x^2y\right)\right] dA = \iint_{x^2+y^2\le 4}\left(-y^2 - x^2\right) dA = -\int_0^{2\pi}\int_0^2 r^3\,dr\,d\theta = -8\pi$

18. curl $\mathbf{F} = (0 - e^{-y}\cos z)\,\mathbf{i} - (e^{-z}\cos x - 0)\,\mathbf{j} + (0 - e^{-x}\cos y)\,\mathbf{k} = -e^{-y}\cos z\,\mathbf{i} - e^{-z}\cos x\,\mathbf{j} - e^{-x}\cos y\,\mathbf{k}$,
div $\mathbf{F} = -e^{-x}\sin y - e^{-y}\sin z - e^{-z}\sin x$

19. If we assume there is such a vector field $\mathbf{G}$, then $\operatorname{div}(\operatorname{curl}\mathbf{G}) = 2 + 3z - 2xz$. But $\operatorname{div}(\operatorname{curl}\mathbf{F}) = 0$ for all vector fields $\mathbf{F}$. Thus such a $\mathbf{G}$ cannot exist.

20. Let $\mathbf{F} = P_1\,\mathbf{i} + Q_1\,\mathbf{j} + R_1\,\mathbf{k}$ and $\mathbf{G} = P_2\,\mathbf{i} + Q_2\,\mathbf{j} + R_2\,\mathbf{k}$ be vector fields whose first partials exist and are continuous. Then

$$\begin{aligned}\mathbf{F}\operatorname{div}\mathbf{G} - \mathbf{G}\operatorname{div}\mathbf{F} = &\left[P_1\left(\frac{\partial P_2}{\partial x} + \frac{\partial Q_2}{\partial y} + \frac{\partial R_2}{\partial z}\right)\mathbf{i} + Q_1\left(\frac{\partial P_2}{\partial x} + \frac{\partial Q_2}{\partial y} + \frac{\partial R_2}{\partial z}\right)\mathbf{j} + R_1\left(\frac{\partial P_2}{\partial x} + \frac{\partial Q_2}{\partial y} + \frac{\partial R_2}{\partial z}\right)\mathbf{k}\right] \\ &- \left[P_2\left(\frac{\partial P_1}{\partial x} + \frac{\partial Q_1}{\partial y} + \frac{\partial R_1}{\partial z}\right)\mathbf{i} + Q_2\left(\frac{\partial P_1}{\partial x} + \frac{\partial Q_1}{\partial y} + \frac{\partial R_1}{\partial z}\right)\mathbf{j} \right.\\ &\left. + R_2\left(\frac{\partial P_1}{\partial x} + \frac{\partial Q}{\partial y} + \frac{\partial R_1}{\partial z}\right)\mathbf{k}\right]\end{aligned}$$

and

$$\begin{aligned}(\mathbf{G}\cdot\nabla)\,\mathbf{F} - (\mathbf{F}\cdot\nabla)\,\mathbf{G} = &\left[\left(P_2\,\frac{\partial P_1}{\partial x} + Q_2\,\frac{\partial P_1}{\partial y} + R_2\,\frac{\partial P_1}{\partial z}\right)\mathbf{i} + \left(P_2\,\frac{\partial Q_1}{\partial x} + Q_2\,\frac{\partial Q_1}{\partial y} + R_2\,\frac{\partial Q_1}{\partial z}\right)\mathbf{j}\right. \\ &\left. + \left(P_2\,\frac{\partial R_1}{\partial x} + Q_2\,\frac{\partial R_1}{\partial y} + R_2\,\frac{\partial R_1}{\partial z}\right)\mathbf{k}\right] \\ &- \left[\left(P_1\,\frac{\partial P_2}{\partial x} + Q_1\,\frac{\partial P_2}{\partial y} + R_1\,\frac{\partial P_2}{\partial z}\right)\mathbf{i} + \left(P_1\,\frac{\partial Q_2}{\partial x} + Q_1\,\frac{\partial Q_2}{\partial y} + R_1\,\frac{\partial Q_2}{\partial z}\right)\mathbf{j}\right. \\ &\left. + \left(P_1\,\frac{\partial R_2}{\partial x} + Q_1\,\frac{\partial R_2}{\partial y} + R_1\,\frac{\partial R_2}{\partial z}\right)\mathbf{k}\right]\end{aligned}$$

Hence

$$\begin{aligned}&\mathbf{F}\operatorname{div}\mathbf{G} - \mathbf{G}\operatorname{div}\mathbf{F} + (\mathbf{G}\cdot\nabla)\,\mathbf{F} - (\mathbf{F}\cdot\nabla)\,\mathbf{G} \\ &= \left[\left(P_1\,\frac{\partial Q_2}{\partial y} + Q_2\,\frac{\partial P_1}{\partial x}\right) - \left(P_2\,\frac{\partial Q_1}{\partial y} + Q_1\,\frac{\partial P_2}{\partial y}\right)\right. \\ &\qquad\left. - \left(P_2\,\frac{\partial R_1}{\partial z} + R_1\,\frac{\partial P_2}{\partial z}\right) + \left(P_1\,\frac{\partial R_2}{\partial z} + R_2\,\frac{\partial P_1}{\partial z}\right)\right]\mathbf{i} \\ &\quad + \left[\left(Q_1\,\frac{\partial R_2}{\partial z} + R_2\,\frac{\partial Q_1}{\partial z}\right) - \left(Q_2\,\frac{\partial R_1}{\partial z} + R_1\,\frac{\partial Q_2}{\partial z}\right)\right. \\ &\qquad\left. - \left(P_1\,\frac{\partial Q_2}{\partial x} + Q_2\,\frac{\partial P_1}{\partial x}\right) + \left(P_2\,\frac{\partial Q_1}{\partial x} + Q_1\,\frac{\partial P_2}{\partial x}\right)\right]\mathbf{j} \\ &\quad + \left[\left(P_2\,\frac{\partial R_1}{\partial x} + R_1\,\frac{\partial P_2}{\partial x}\right) - \left(P_1\,\frac{\partial R_2}{\partial x} + R_2\,\frac{\partial P_1}{\partial x}\right)\right. \\ &\qquad\left. - \left(Q_1\,\frac{\partial R_2}{\partial y} + R_2\,\frac{\partial Q_1}{\partial y}\right) + \left(Q_2\,\frac{\partial R_1}{\partial y} + R_1\,\frac{\partial Q_2}{\partial y}\right)\right]\mathbf{k} \\ &= \left[\frac{\partial}{\partial y}\,(P_1Q_2 - P_2Q_1) - \frac{\partial}{\partial z}\,(P_2R_1 - P_1R_2)\right]\mathbf{i} \\ &\quad + \left[\frac{\partial}{\partial z}\,(Q_1R_2 - Q_2R_1) - \frac{\partial}{\partial x}\,(P_1Q_2 - P_2Q_1)\right]\mathbf{j} \\ &\quad + \left[\frac{\partial}{\partial x}\,(P_2R_1 - P_1R_2) - \frac{\partial}{\partial y}\,(Q_1R_2 - Q_2R_1)\right]\mathbf{k} \\ &= \operatorname{curl}\,(\mathbf{F}\times\mathbf{G})\end{aligned}$$

21. For any piecewise-smooth simple closed plane curve C bounding a region D, we can apply Green's Theorem to

$\mathbf{F}(x,y) = f(x)\,\mathbf{i} + g(y)\,\mathbf{j}$ to get $\int_C f(x)\,dx + g(y)\,dy = \iint_D \left[\frac{\partial}{\partial x}\,g(y) - \frac{\partial}{\partial y}\,f(x)\right] dA = \iint_D 0\,dA = 0.$

22. $\nabla^2(fg) = \dfrac{\partial^2(fg)}{\partial x^2} + \dfrac{\partial^2(fg)}{\partial y^2} + \dfrac{\partial^2(fg)}{\partial z^2}$

$$= \frac{\partial}{\partial x}\left(\frac{\partial f}{\partial x}\,g + f\,\frac{\partial g}{\partial x}\right) + \frac{\partial}{\partial y}\left(\frac{\partial f}{\partial y}\,g + f\,\frac{\partial g}{\partial y}\right) + \frac{\partial}{\partial z}\left(\frac{\partial f}{\partial z}\,g + f\,\frac{\partial g}{\partial z}\right) \quad \text{[Product Rule]}$$

$$= \frac{\partial^2 f}{\partial x^2}\,g + 2\,\frac{\partial f}{\partial x}\frac{\partial g}{\partial x} + f\,\frac{\partial^2 g}{\partial x^2} + \frac{\partial^2 f}{\partial y^2}\,g + 2\,\frac{\partial f}{\partial y}\frac{\partial g}{\partial y}$$

$$+ f\,\frac{\partial^2 g}{\partial y^2} + \frac{\partial^2 f}{\partial z^2}\,g + 2\,\frac{\partial f}{\partial z}\frac{\partial g}{\partial z} + f\,\frac{\partial^2 g}{\partial z^2} \quad \text{[Product Rule]}$$

$$= f\left(\frac{\partial^2 g}{\partial x^2} + \frac{\partial^2 g}{\partial y^2} + \frac{\partial^2 g}{\partial z^2}\right) + g\left(\frac{\partial^2 f}{\partial x^2} + \frac{\partial^2 f}{\partial y^2} + \frac{\partial^2 f}{\partial z^2}\right) + 2\left\langle \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}, \frac{\partial f}{\partial z}\right\rangle \cdot \left\langle \frac{\partial g}{\partial x}, \frac{\partial g}{\partial y}, \frac{\partial g}{\partial z}\right\rangle$$

$$= f\nabla^2 g + g\nabla^2 f + 2\nabla f \cdot \nabla g$$

Another method: Using the rules in Exercises 14.6.37(b) and 16.5.25, we have

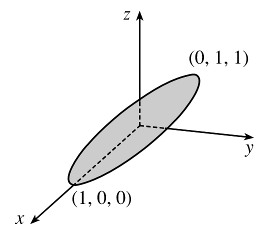
$$\nabla^2(fg) = \nabla \cdot \nabla(fg) = \nabla \cdot (g\,\nabla f + f\,\nabla g) = \nabla g \cdot \nabla f + g\nabla \cdot \nabla f + \nabla f \cdot \nabla g + f\nabla \cdot \nabla g$$
$$= g\,\nabla^2 f + f\,\nabla^2 g + 2\nabla f \cdot \nabla g$$

23. $\nabla^2 f = 0$ means that $\dfrac{\partial^2 f}{\partial x^2} + \dfrac{\partial^2 f}{\partial y^2} = 0$. Now if $\mathbf{F} = f_y\,\mathbf{i} - f_x\,\mathbf{j}$ and C is any closed path in D, then applying Green's Theorem, we get

$$\int_C \mathbf{F} \cdot d\mathbf{r} = \int_C f_y\,dx - f_x\,dy = \iint_D \left[\tfrac{\partial}{\partial x}(-f_x) - \tfrac{\partial}{\partial y}(f_y)\right] dA$$
$$= -\iint_D (f_{xx} + f_{yy})\,dA = -\iint_D 0\,dA = 0$$

Therefore the line integral is independent of path, by Theorem 16.3.3.

24. (a) $x^2 + y^2 = \cos^2 t + \sin^2 t = 1$, so C lies on the circular cylinder $x^2 + y^2 = 1$. But also $y = z$, so C lies on the plane $y = z$. Thus C is contained in the intersection of the plane $y = z$ and the cylinder $x^2 + y^2 = 1$; with $0 \le t \le 2\pi$ we get the entire intersection (an ellipse).



(b) Apply Stokes' Theorem, $\int_C \mathbf{F} \cdot d\mathbf{r} = \iint_S \operatorname{curl} \mathbf{F} \cdot d\mathbf{S}$:

$$\operatorname{curl} \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \partial/\partial x & \partial/\partial y & \partial/\partial z \\ 2xe^{2y} & 2x^2e^{2y} + 2y\cot z & -y^2\csc^2 z \end{vmatrix} = \left\langle -2y\csc^2 z - (-2y\csc^2 z), 0, 4xe^{2y} - 4xe^{2y} \right\rangle = \mathbf{0}$$

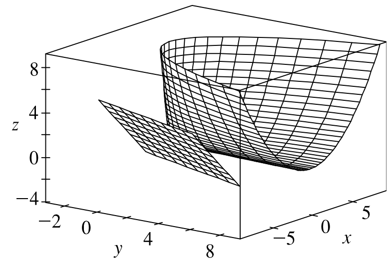
Therefore $\int_C \mathbf{F} \cdot d\mathbf{r} = \iint_S \mathbf{0} \cdot d\mathbf{S} = 0$.

25. $z = f(x, y) = x^2 + 2y$ with $0 \le x \le 1$, $0 \le y \le 2x$. Thus

$$A(S) = \iint_D \sqrt{1 + 4x^2 + 4}\,dA = \int_0^1 \int_0^{2x} \sqrt{5 + 4x^2}\,dy\,dx = \int_0^1 2x\,\sqrt{5 + 4x^2}\,dx = \tfrac{1}{6}(5 + 4x^2)^{3/2}\Big]_0^1 = \tfrac{1}{6}\left(27 - 5\sqrt{5}\right).$$

26. (a) $\mathbf{r}_u = -v\,\mathbf{j} + 2u\,\mathbf{k}$, $\mathbf{r}_v = 2v\,\mathbf{i} - u\,\mathbf{j}$ and $\mathbf{r}_u \times \mathbf{r}_v = 2u^2\,\mathbf{i} + 4uv\,\mathbf{j} + 2v^2\,\mathbf{k}$. Since the point $(4, -2, 1)$ corresponds to $u = 1$, $v = 2$ (or $u = -1$, $v = -2$ but $\mathbf{r}_u \times \mathbf{r}_v$ is the same for both), a normal vector to the surface at $(4, -2, 1)$ is $2\,\mathbf{i} + 8\,\mathbf{j} + 8\,\mathbf{k}$ and an equation of the tangent plane is $2x + 8y + 8z = 0$ or $x + 4y + 4z = 0$.

(b)



(c) By Definition 16.6.6, the area of S is given by

$$A(S) = \iint_D |\,\mathbf{r}_u \times \mathbf{r}_v\,|\,dA = \int_0^3\int_{-3}^3 \sqrt{(2u^2)^2 + (4uv)^2 + (2v^2)^2}\,dv\,du = 2\int_0^3\int_{-3}^3 \sqrt{u^4 + 4u^2v^2 + v^4}\,dv\,du.$$

(d) By Equation 16.7.9, the surface integral is

$$\iint_S \mathbf{F}\cdot d\mathbf{S} = \iint_D \mathbf{F}\cdot(\,\mathbf{r}_u \times \mathbf{r}_v\,)\,dA = \int_0^3\int_{-3}^3 \left\langle \frac{(u^2)^2}{1+(v^2)^2}, \frac{(v^2)^2}{1+(-uv)^2}, \frac{(-uv)^2}{1+(u^2)^2} \right\rangle \cdot \langle 2u^2, 4uv, 2v^2\rangle\,dv\,du$$

$$= \int_0^3\int_{-3}^3 \left(\frac{2u^6}{1+v^4} + \frac{4uv^5}{1+u^2v^2} + \frac{2u^2v^4}{1+u^4} \right) dv\,du \approx 1524.0190$$

27. $z = f(x, y) = x^2 + y^2$ with $0 \le x^2 + y^2 \le 4$ so $\mathbf{r}_x \times \mathbf{r}_y = -2x\,\mathbf{i} - 2y\,\mathbf{j} + \mathbf{k}$. Then

$$\iint_S z\,dS = \iint_{x^2+y^2\le 4} (x^2 + y^2)\sqrt{4x^2 + 4y^2 + 1}\,dA$$

$$= \int_0^{2\pi}\int_0^2 r^3\sqrt{1 + 4r^2}\,dr\,d\theta = \tfrac{1}{60}\pi\big(391\sqrt{17} + 1\big)$$

(Substitute $u = 1 + 4r^2$ and use tables.)

28. $z = f(x, y) = 4 + x + y$ with $0 \le x^2 + y^2 \le 4$ so $\mathbf{r}_x \times \mathbf{r}_y = -\mathbf{i} - \mathbf{j} + \mathbf{k}$. Then

$$\iint_S (x^2z + y^2z)\,dS = \iint_{x^2+y^2\le 4} (x^2 + y^2)(4 + x + y)\sqrt{3}\,dA$$

$$= \int_0^2\int_0^{2\pi} \sqrt{3}\,r^3(4 + r\cos\theta + r\sin\theta)\,d\theta\,dr = \int_0^2 8\pi\sqrt{3}\,r^3\,dr = 32\pi\sqrt{3}$$

29. Since the sphere bounds a simple solid region, the Divergence Theorem applies and

$$\iint_S \mathbf{F}\cdot d\mathbf{S} = \iiint_E \operatorname{div}\mathbf{F}\,dV = \iiint_E (z - 2)\,dV = \iiint_E z\,dV - 2\iiint_E dV$$

$$= 0\,\left[\begin{array}{c}\text{odd function in } z\\ \text{and } E \text{ is symmetric}\end{array}\right] - 2\cdot V(E) = -2\cdot\tfrac{4}{3}\pi(2)^3 = -\tfrac{64}{3}\pi$$

Alternate solution: $\mathbf{F}(\mathbf{r}(\phi, \theta)) = 4\sin\phi\,\cos\theta\,\cos\phi\,\mathbf{i} - 4\sin\phi\,\sin\theta\,\mathbf{j} + 6\sin\phi\,\cos\theta\,\mathbf{k}$,

$\mathbf{r}_\phi \times \mathbf{r}_\theta = 4\sin^2\phi\,\cos\theta\,\mathbf{i} + 4\sin^2\phi\,\sin\theta\,\mathbf{j} + 4\sin\phi\,\cos\phi\,\mathbf{k}$, and

$\mathbf{F}\cdot(\mathbf{r}_\phi \times \mathbf{r}_\theta) = 16\sin^3\phi\,\cos^2\theta\,\cos\phi - 16\sin^3\phi\,\sin^2\theta + 24\sin^2\phi\,\cos\phi\,\cos\theta$. Then

$$\iint_S \mathbf{F}\cdot d\mathbf{S} = \int_0^{2\pi}\int_0^{\pi} (16\sin^3\phi\,\cos\phi\,\cos^2\theta - 16\sin^3\phi\,\sin^2\theta + 24\sin^2\phi\,\cos\phi\,\cos\theta)\,d\phi\,d\theta$$

$$= \int_0^{2\pi} \tfrac{4}{3}(-16\sin^2\theta)\,d\theta = -\tfrac{64}{3}\pi$$

30. $z = f(x, y) = x^2 + y^2$, $\mathbf{r}_x \times \mathbf{r}_y = -2x\,\mathbf{i} - 2y\,\mathbf{j} + \mathbf{k}$ (because of upward orientation) and

$\mathbf{F}(\mathbf{r}(x, y)) \cdot (\mathbf{r}_x \times \mathbf{r}_y) = -2x^3 - 2xy^2 + x^2 + y^2$. Then

$$\iint_S \mathbf{F} \cdot d\mathbf{S} = \iint\limits_{x^2+y^2 \le 1} (-2x^3 - 2xy^2 + x^2 + y^2)\, dA$$
$$= \int_0^1 \int_0^{2\pi} (-2r^3 \cos^3\theta - 2r^3 \cos\theta\, \sin^2\theta + r^2)\, r\, dr\, d\theta = \int_0^1 r^3(2\pi)\, dr = \tfrac{\pi}{2}$$

31. Since $\operatorname{curl} \mathbf{F} = \mathbf{0}$, $\iint_S (\operatorname{curl} \mathbf{F}) \cdot d\mathbf{S} = 0$. We parametrize C: $\mathbf{r}(t) = \cos t\,\mathbf{i} + \sin t\,\mathbf{j}$, $0 \le t \le 2\pi$ and

$\oint_C \mathbf{F} \cdot d\mathbf{r} = \int_0^{2\pi} (-\cos^2 t\, \sin t + \sin^2 t\, \cos t)\, dt = \tfrac{1}{3}\cos^3 t + \tfrac{1}{3}\sin^3 t\Big]_0^{2\pi} = 0.$

32. $\iint_S \operatorname{curl} \mathbf{F} \cdot d\mathbf{S} = \oint_C \mathbf{F} \cdot d\mathbf{r}$ where C: $\mathbf{r}(t) = 2\cos t\,\mathbf{i} + 2\sin t\,\mathbf{j} + \mathbf{k}$, $0 \le t \le 2\pi$, so $\mathbf{r}'(t) = -2\sin t\,\mathbf{i} + 2\cos t\,\mathbf{j}$,

$\mathbf{F}(\mathbf{r}(t)) = 8\cos^2 t\, \sin t\,\mathbf{i} + 2\sin t\,\mathbf{j} + e^{4\cos t \sin t}\,\mathbf{k}$, and $\mathbf{F}(\mathbf{r}(t)) \cdot \mathbf{r}'(t) = -16\cos^2 t \sin^2 t + 4\sin t \cos t$. Thus

$\oint_C \mathbf{F} \cdot d\mathbf{r} = \int_0^{2\pi} (-16\cos^2 t\, \sin^2 t + 4\sin t\, \cos t)\, dt = \left[-16\left(-\tfrac{1}{4}\sin t\, \cos^3 t + \tfrac{1}{16}\sin 2t + \tfrac{1}{8}t\right) + 2\sin^2 t\right]_0^{2\pi} = -4\pi.$

33. The surface is given by $x + y + z = 1$ or $z = 1 - x - y$, $0 \le x \le 1$, $0 \le y \le 1 - x$ and $\mathbf{r}_x \times \mathbf{r}_y = \mathbf{i} + \mathbf{j} + \mathbf{k}$. Then

$\oint_C \mathbf{F} \cdot d\mathbf{r} = \iint_S \operatorname{curl} \mathbf{F} \cdot d\mathbf{S} = \iint_D (-y\,\mathbf{i} - z\,\mathbf{j} - x\,\mathbf{k}) \cdot (\mathbf{i} + \mathbf{j} + \mathbf{k})\, dA = \iint_D (-1)\, dA = -(\text{area of } D) = -\tfrac{1}{2}.$

34. $\iint_S \mathbf{F} \cdot d\mathbf{S} = \iiint_E 3(x^2 + y^2 + z^2)\, dV = \int_0^{2\pi} \int_0^1 \int_0^2 (3r^2 + 3z^2)\, r\, dz\, dr\, d\theta = 2\pi \int_0^1 (6r^3 + 8r)\, dr = 11\pi$

35. $\iiint_E \operatorname{div} \mathbf{F}\, dV = \iiint\limits_{x^2+y^2+z^2 \le 1} 3\, dV = 3(\text{volume of sphere}) = 4\pi$. Then

$\mathbf{F}(\mathbf{r}(\phi, \theta)) \cdot (\mathbf{r}_\phi \times \mathbf{r}_\theta) = \sin^3\phi\, \cos^2\theta + \sin^3\phi\, \sin^2\theta + \sin\phi\, \cos^2\phi = \sin\phi$ and

$\iint_S \mathbf{F} \cdot d\mathbf{S} = \int_0^{2\pi} \int_0^{\pi} \sin\phi\, d\phi\, d\theta = (2\pi)(2) = 4\pi.$

36. Here we must use Equation 16.9.7 since $\mathbf{F}$ is not defined at the origin. Let S_1 be the sphere of radius 1 with center at the origin and outer unit normal $\mathbf{n}_1$. Let S_2 be the surface of the ellipsoid with outer unit normal $\mathbf{n}_2$ and let E be the solid region between S_1 and S_2. Then the outward flux of $\mathbf{F}$ through the ellipsoid is given by

$\iint_{S_2} \mathbf{F} \cdot \mathbf{n}_2\, dS = -\iint_{S_1} \mathbf{F} \cdot (-\mathbf{n}_1)\, dS + \iiint_E \operatorname{div} \mathbf{F}\, dV$. But $\mathbf{F} = \mathbf{r}/|\mathbf{r}|^3$, so

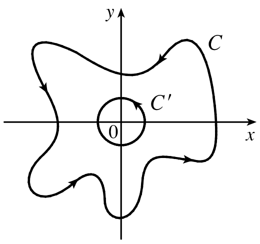
$\operatorname{div} \mathbf{F} = \nabla \cdot \left(|\mathbf{r}|^{-3}\,\mathbf{r}\right) = |\mathbf{r}|^{-3}(\nabla \cdot \mathbf{r}) + \mathbf{r} \cdot \left(\nabla\, |\mathbf{r}|^{-3}\right) = |\mathbf{r}|^{-3}\,(3) + \mathbf{r} \cdot \left(-3\,|\mathbf{r}|^{-4}\right)\left(\mathbf{r}\,|\mathbf{r}|^{-1}\right) = 0$. [Here we have used Exercises 16.5.30(a) and 16.5.31(a).] And $\mathbf{F} \cdot \mathbf{n}_1 = \dfrac{\mathbf{r}}{|\mathbf{r}|^3} \cdot \dfrac{\mathbf{r}}{|\mathbf{r}|} = |\mathbf{r}|^{-2} = 1$ on S_1.

Thus $\iint_{S_2} \mathbf{F} \cdot \mathbf{n}_2\, dS = \iint_{S_1} dS + \iiint_E 0\, dV = (\text{surface area of the unit sphere}) = 4\pi(1)^2 = 4\pi.$

37. Because $\operatorname{curl} \mathbf{F} = \mathbf{0}$, $\mathbf{F}$ is conservative, so there exists a function f such that $\nabla f = \mathbf{F}$. Then $f_x(x, y, z) = 3x^2yz - 3y$ implies $f(x, y, z) = x^3yz - 3xy + g(y, z) \quad \Rightarrow \quad f_y(x, y, z) = x^3z - 3x + g_y(y, z)$. But $f_y(x, y, z) = x^3z - 3x$, so $g(y, z) = h(z)$ and $f(x, y, z) = x^3yz - 3xy + h(z)$. Then $f_z(x, y, z) = x^3y + h'(z)$ but $f_z(x, y, z) = x^3y + 2z$, so $h(z) = z^2 + K$ and a potential function for $\mathbf{F}$ is $f(x, y, z) = x^3yz - 3xy + z^2$. Hence

$\int_C \mathbf{F} \cdot d\mathbf{r} = \int_C \nabla f \cdot d\mathbf{r} = f(0, 3, 0) - f(0, 0, 2) = 0 - 4 = -4.$

38. Let C' be the circle with center at the origin and radius a as in the figure. Let D be the region bounded by C and C'. Then D's positively oriented boundary is $C \cup (-C')$. Hence by Green's Theorem



$$\int_C \mathbf{F} \cdot d\mathbf{r} + \int_{-C'} \mathbf{F} \cdot d\mathbf{r} = \iint_D \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) dA = 0, \text{ so}$$

$$\int_C \mathbf{F} \cdot d\mathbf{r} = -\int_{-C'} \mathbf{F} \cdot d\mathbf{r} = \int_{C'} \mathbf{F} \cdot dr = \int_0^{2\pi} \mathbf{F}(\mathbf{r}(t)) \cdot \mathbf{r}'(t)\,dt$$

$$= \int_0^{2\pi} \left[\frac{2a^3 \cos^3 t + 2a^3 \cos t \, \sin^2 t - 2a \sin t}{a^2} (-a \sin t) + \frac{2a^3 \sin^3 t + 2a^3 \cos^2 t \, \sin t + 2a \cos t}{a^2} (a \cos t) \right] dt$$

$$= \int_0^{2\pi} \frac{2a^2}{a^2}\,dt = 4\pi$$

39. By the Divergence Theorem, $\iint_S \mathbf{F} \cdot \mathbf{n}\,dS = \iiint_E \operatorname{div} \mathbf{F}\,dV = 3(\text{volume of } E) = 3(8-1) = 21$.

40. The stated conditions allow us to use the Divergence Theorem. Hence $\iint_S \operatorname{curl} \mathbf{F} \cdot d\mathbf{S} = \iiint_E \operatorname{div}(\operatorname{curl} \mathbf{F})\,dV = 0$ since $\operatorname{div}(\operatorname{curl} \mathbf{F}) = 0$.

41. Let $\mathbf{F} = \mathbf{a} \times \mathbf{r} = \langle a_1, a_2, a_3 \rangle \times \langle x, y, z \rangle = \langle a_2 z - a_3 y, a_3 x - a_1 z, a_1 y - a_2 x \rangle$. Then $\operatorname{curl} \mathbf{F} = \langle 2a_1, 2a_2, 2a_3 \rangle = 2\mathbf{a}$, and $\iint_S 2\mathbf{a} \cdot d\mathbf{S} = \iint_S \operatorname{curl} \mathbf{F} \cdot d\mathbf{S} = \int_C \mathbf{F} \cdot d\mathbf{r} = \int_C (\mathbf{a} \times \mathbf{r}) \cdot d\mathbf{r}$ by Stokes' Theorem.

PROBLEMS PLUS

1. Let S_1 be the portion of $\Omega(S)$ between $S(a)$ and S, and let ∂S_1 be its boundary. Also let S_L be the lateral surface of S_1 [that is, the surface of S_1 except S and $S(a)$]. Applying the Divergence Theorem we have $\iint_{\partial S_1} \frac{\mathbf{r}\cdot\mathbf{n}}{r^3}\,dS = \iiint_{S_1} \nabla\cdot\frac{\mathbf{r}}{r^3}\,dV$.

But
$$\begin{aligned}\nabla\cdot\frac{\mathbf{r}}{r^3} &= \left\langle \frac{\partial}{\partial x},\frac{\partial}{\partial y},\frac{\partial}{\partial z}\right\rangle\cdot\left\langle \frac{x}{(x^2+y^2+z^2)^{3/2}},\frac{y}{(x^2+y^2+z^2)^{3/2}},\frac{z}{(x^2+y^2+z^2)^{3/2}}\right\rangle\\ &= \frac{(x^2+y^2+z^2-3x^2)+(x^2+y^2+z^2-3y^2)+(x^2+y^2+z^2-3z^2)}{(x^2+y^2+z^2)^{5/2}} = 0\end{aligned}$$

$\Rightarrow\quad \iint_{\partial S_1}\frac{\mathbf{r}\cdot\mathbf{n}}{r^3}\,dS = \iiint_{S_1} 0\,dV = 0$. On the other hand, notice that for the surfaces of ∂S_1 other than $S(a)$ and S,

$\mathbf{r}\cdot\mathbf{n} = 0 \quad\Rightarrow$

$0 = \iint_{\partial S_1}\frac{\mathbf{r}\cdot\mathbf{n}}{r^3}\,dS = \iint_S \frac{\mathbf{r}\cdot\mathbf{n}}{r^3}\,dS + \iint_{S(a)}\frac{\mathbf{r}\cdot\mathbf{n}}{r^3}\,dS + \iint_{S_L}\frac{\mathbf{r}\cdot\mathbf{n}}{r^3}\,dS = \iint_S \frac{\mathbf{r}\cdot\mathbf{n}}{r^3}\,dS + \iint_{S(a)}\frac{\mathbf{r}\cdot\mathbf{n}}{r^3}\,dS \quad\Rightarrow$

$\iint_S\frac{\mathbf{r}\cdot\mathbf{n}}{r^3}\,dS = -\iint_{S(a)}\frac{\mathbf{r}\cdot\mathbf{n}}{r^3}\,dS$. Notice that on $S(a)$, $r=a \quad\Rightarrow\quad \mathbf{n} = -\frac{\mathbf{r}}{r} = -\frac{\mathbf{r}}{a}$ and $\mathbf{r}\cdot\mathbf{r} = r^2 = a^2$, so

that $-\iint_{S(a)}\frac{\mathbf{r}\cdot\mathbf{n}}{r^3}\,dS = \iint_{S(a)}\frac{\mathbf{r}\cdot\mathbf{r}}{a^4}\,dS = \iint_{S(a)}\frac{a^2}{a^4}\,dS = \frac{1}{a^2}\iint_{S(a)}dS = \frac{\text{area of } S(a)}{a^2} = |\Omega(S)|$.

Therefore $|\Omega(S)| = \iint_S\frac{\mathbf{r}\cdot\mathbf{n}}{r^3}\,dS$.

2. By Green's Theorem

$$\int_C (y^3-y)\,dx - 2x^3\,dy = \iint_D\left[\frac{\partial(-2x^3)}{\partial x}-\frac{\partial(y^3-y)}{\partial y}\right]dA = \iint_D (1-6x^2-3y^2)\,dA$$

Notice that for $6x^2+3y^2>1$, the integrand is negative. The integral has maximum value if it is evaluated only in the region where the integrand is positive, which is within the ellipse $6x^2+3y^2=1$. So the simple closed curve that gives a maximum value for the line integral is the ellipse $6x^2+3y^2=1$.

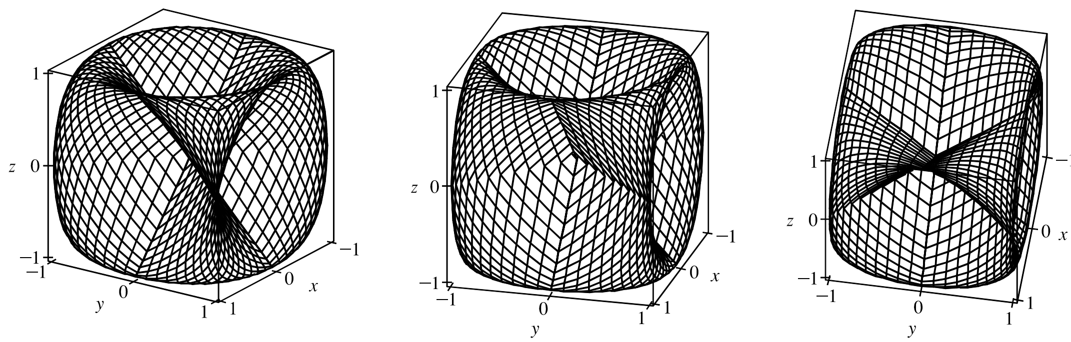
3. The given line integral $\frac{1}{2}\int_C (bz-cy)\,dx + (cx-az)\,dy + (ay-bx)\,dz$ can be expressed as $\int_C \mathbf{F}\cdot d\mathbf{r}$ if we define the vector field $\mathbf{F}$ by $\mathbf{F}(x,y,z) = P\,\mathbf{i}+Q\,\mathbf{j}+R\,\mathbf{k} = \frac{1}{2}(bz-cy)\,\mathbf{i}+\frac{1}{2}(cx-az)\,\mathbf{j}+\frac{1}{2}(ay-bx)\,\mathbf{k}$. Then define S to be the planar interior of C, so S is an oriented, smooth surface. Stokes' Theorem says $\int_C\mathbf{F}\cdot d\mathbf{r} = \iint_S \operatorname{curl}\mathbf{F}\cdot d\mathbf{S} = \iint_S \operatorname{curl}\mathbf{F}\cdot\mathbf{n}\,dS$.

Now

$$\begin{aligned}\operatorname{curl}\mathbf{F} &= \left(\frac{\partial R}{\partial y}-\frac{\partial Q}{\partial z}\right)\mathbf{i} + \left(\frac{\partial P}{\partial z}-\frac{\partial R}{\partial x}\right)\mathbf{j} + \left(\frac{\partial Q}{\partial x}-\frac{\partial P}{\partial y}\right)\mathbf{k}\\ &= \left(\tfrac{1}{2}a+\tfrac{1}{2}a\right)\mathbf{i} + \left(\tfrac{1}{2}b+\tfrac{1}{2}b\right)\mathbf{j} + \left(\tfrac{1}{2}c+\tfrac{1}{2}c\right)\mathbf{k} = a\,\mathbf{i}+b\,\mathbf{j}+c\,\mathbf{k} = \mathbf{n}\end{aligned}$$

so $\operatorname{curl}\mathbf{F}\cdot\mathbf{n} = \mathbf{n}\cdot\mathbf{n} = |\mathbf{n}|^2 = 1$, hence $\iint_S \operatorname{curl}\mathbf{F}\cdot\mathbf{n}\,dS = \iint_S dS$ which is simply the surface area of S. Thus, $\int_C \mathbf{F}\cdot d\mathbf{r} = \frac{1}{2}\int_C (bz-cy)\,dx + (cx-az)\,dy + (ay-bx)\,dz$ is the plane area enclosed by C.

4. The surface given by $x = \sin u$, $y = \sin v$, $z = \sin(u + v)$ is difficult to visualize, so we first graph the surface from three different points of view.

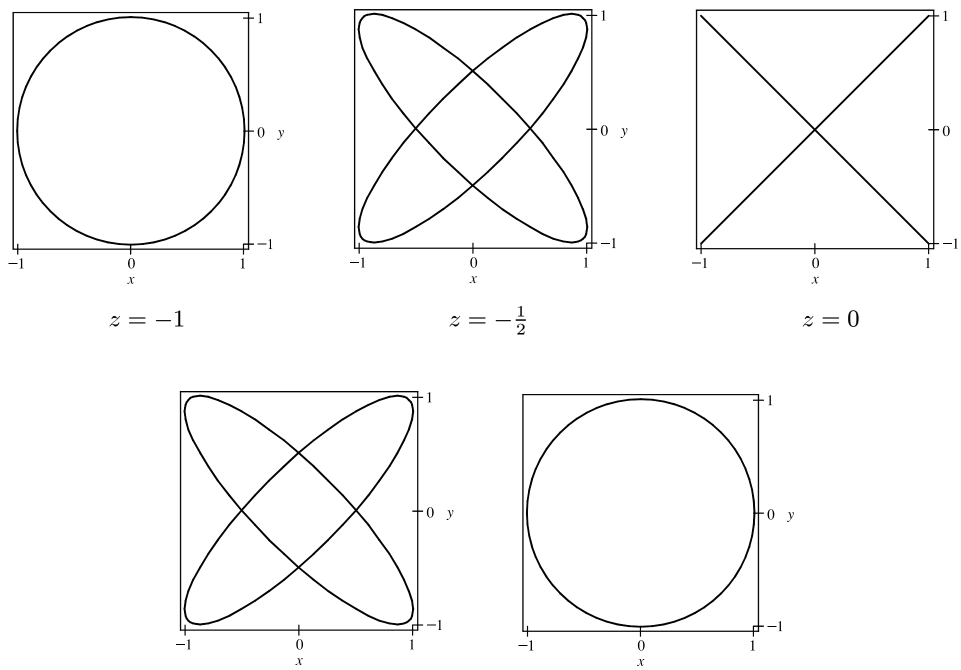


The trace in the horizontal plane $z = 0$ is given by $z = \sin(u + v) = 0 \quad \Rightarrow \quad u + v = k\pi$ $[k$ an integer$]$. Then we can write $v = k\pi - u$, and the trace is given by the parametric equations $x = \sin u$, $y = \sin v = \sin(k\pi - u) = \sin k\pi\ \cos u - \cos k\pi\ \sin u = \pm\sin u$, and since $\sin u = x$, the trace consists of the two lines $y = \pm x$.

If $z = 1$, $z = \sin(u + v) = 1 \quad \Rightarrow \quad u + v = \frac{\pi}{2} + 2k\pi$. So $v = \left(\frac{\pi}{2} + 2k\pi\right) - u$ and the trace in $z = 1$ is given by the parametric equations $x = \sin u$, $y = \sin v = \sin\!\left(\left(\frac{\pi}{2} + 2k\pi\right) - u\right) = \sin\!\left(\frac{\pi}{2} + 2k\pi\right)\cos u - \cos\!\left(\frac{\pi}{2} + 2k\pi\right)\sin u = \cos u$. This curve is equivalent to $x^2 + y^2 = 1$, $z = 1$, a circle of radius 1. Similarly, in $z = -1$ we have $z = \sin(u + v) = -1 \quad \Rightarrow$ $u + v = \frac{3\pi}{2} + 2k\pi \quad \Rightarrow \quad v = \left(\frac{3\pi}{2} + 2k\pi\right) - u$, so the trace is given by the parametric equations $x = \sin u$, $y = \sin v = \sin\!\left(\left(\frac{3\pi}{2} + 2k\pi\right) - u\right) = \sin\!\left(\frac{3\pi}{2} + 2k\pi\right)\cos u - \cos\!\left(\frac{3\pi}{2} + 2k\pi\right)\sin u = -\cos u$, which again is a circle, $x^2 + y^2 = 1$, $z = -1$.

If $z = \frac{1}{2}$, $z = \sin(u + v) = \frac{1}{2} \quad \Rightarrow \quad u + v = \alpha + 2k\pi$ where $\alpha = \frac{\pi}{6}$ or $\frac{5\pi}{6}$. Then $v = (\alpha + 2k\pi) - u$ and the trace in $z = \frac{1}{2}$ is given by the parametric equations $x = \sin u$, $y = \sin v = \sin[(\alpha + 2k\pi) - u] = \sin(\alpha + 2k\pi)\ \cos u - \cos(\alpha + 2k\pi)\ \sin u = \frac{1}{2}\cos u \pm \frac{\sqrt{3}}{2}\sin u$. In rectangular coordinates, $x = \sin u$ so $y = \frac{1}{2}\cos u \pm \frac{\sqrt{3}}{2}x \quad \Rightarrow \quad y \pm \frac{\sqrt{3}}{2}x = \frac{1}{2}\cos u \quad \Rightarrow \quad 2y \pm \sqrt{3}\,x = \cos u$. But then $x^2 + \left(2y \pm \sqrt{3}\,x\right)^2 = \sin^2 u + \cos^2 u = 1 \quad \Rightarrow \quad x^2 + 4y^2 \pm 4\sqrt{3}\,xy + 3x^2 = 1 \quad \Rightarrow \quad 4x^2 \pm 4\sqrt{3}\,xy + 4y^2 = 1$, which may be recognized as a conic section. In particular, each equation is an ellipse rotated $\pm 45^\circ$ from the standard orientation (see the following graph). The trace in $z = -\frac{1}{2}$ is similar: $z = \sin(u + v) = -\frac{1}{2} \quad \Rightarrow \quad u + v = \beta + 2k\pi$ where $\beta = \frac{7\pi}{6}$ or $\frac{11\pi}{6}$. Then $v = (\beta + 2k\pi) - u$ and the trace is given by the parametric equations $x = \sin u$, $y = \sin v = \sin[(\beta + 2k\pi) - u] = \sin(\beta + 2k\pi)\ \cos u - \cos(\beta + 2k\pi)\ \sin u = -\frac{1}{2}\cos u \pm \frac{\sqrt{3}}{2}\sin u$. If we convert to rectangular coordinates, we arrive at the same pair of equations, $4x^2 \pm 4\sqrt{3}\,xy + 4y^2 = 1$, so the trace is identical to the trace in $z = \frac{1}{2}$.

Graphing each of these, we have the following 5 traces.



$z=-1$ $z=-\frac{1}{2}$ $z=0$ $z=\frac{1}{2}$ $z=1$

Visualizing these traces on the surface reveals that horizontal cross sections are pairs of intersecting ellipses whose major axes are perpendicular to each other. At the bottom of the surface, $z=-1$, the ellipses coincide as circles of radius 1. As we move up the surface, the ellipses become narrower until at $z=0$ they collapse into line segments, after which the process is reversed, and the ellipses widen to again coincide as circles at $z=1$.

5. $$(\mathbf{F}\cdot\nabla)\,\mathbf{G}=\left(P_1\frac{\partial}{\partial x}+Q_1\frac{\partial}{\partial y}+R_1\frac{\partial}{\partial z}\right)(P_2\,\mathbf{i}+Q_2\,\mathbf{j}+R_2\,\mathbf{k})$$

$$=\left(P_1\frac{\partial P_2}{\partial x}+Q_1\frac{\partial P_2}{\partial y}+R_1\frac{\partial P_2}{\partial z}\right)\mathbf{i}+\left(P_1\frac{\partial Q_2}{\partial x}+Q_1\frac{\partial Q_2}{\partial y}+R_1\frac{\partial Q_2}{\partial z}\right)\mathbf{j}$$

$$+\left(P_1\frac{\partial R_2}{\partial x}+Q_1\frac{\partial R_2}{\partial y}+R_1\frac{\partial R_2}{\partial z}\right)\mathbf{k}$$

$$=(\mathbf{F}\cdot\nabla P_2)\,\mathbf{i}+(\mathbf{F}\cdot\nabla Q_2)\,\mathbf{j}+(\mathbf{F}\cdot\nabla R_2)\,\mathbf{k}.$$

Similarly, $(\mathbf{G}\cdot\nabla)\,\mathbf{F}=(\mathbf{G}\cdot\nabla P_1)\,\mathbf{i}+(\mathbf{G}\cdot\nabla Q_1)\,\mathbf{j}+(\mathbf{G}\cdot\nabla R_1)\,\mathbf{k}$. Then

$$\mathbf{F}\times\operatorname{curl}\mathbf{G}=\begin{vmatrix}\mathbf{i} & \mathbf{j} & \mathbf{k}\\ P_1 & Q_1 & R_1\\ \partial R_2/\partial y-\partial Q_2/\partial z & \partial P_2/\partial z-\partial R_2/\partial x & \partial Q_2/\partial x-\partial P_2/\partial y\end{vmatrix}$$

$$=\left(Q_1\frac{\partial Q_2}{\partial x}-Q_1\frac{\partial P_2}{\partial y}-R_1\frac{\partial P_2}{\partial z}+R_1\frac{\partial R_2}{\partial x}\right)\mathbf{i}+\left(R_1\frac{\partial R_2}{\partial y}-R_1\frac{\partial Q_2}{\partial z}-P_1\frac{\partial Q_2}{\partial x}+P_1\frac{\partial P_2}{\partial y}\right)\mathbf{j}$$

$$+\left(P_1\frac{\partial P_2}{\partial z}-P_1\frac{\partial R_2}{\partial x}-Q_1\frac{\partial R_2}{\partial y}+Q_1\frac{\partial Q_2}{\partial z}\right)\mathbf{k}$$

[continued]

and

$$\mathbf{G} \times \operatorname{curl} \mathbf{F} = \left(Q_2 \frac{\partial Q_1}{\partial x} - Q_2 \frac{\partial P_1}{\partial y} - R_2 \frac{\partial P_1}{\partial z} + R_2 \frac{\partial R_1}{\partial x} \right) \mathbf{i} + \left(R_2 \frac{\partial R_1}{\partial y} - R_2 \frac{\partial Q_1}{\partial z} - P_2 \frac{\partial Q_1}{\partial x} + P_2 \frac{\partial P_1}{\partial y} \right) \mathbf{j} + \left(P_2 \frac{\partial P_1}{\partial z} - P_2 \frac{\partial R_1}{\partial x} - Q_2 \frac{\partial R_1}{\partial y} + Q_2 \frac{\partial Q_1}{\partial z} \right) \mathbf{k}.$$

Then

$$(\mathbf{F} \cdot \nabla)\,\mathbf{G} + \mathbf{F} \times \operatorname{curl} \mathbf{G} = \left(P_1 \frac{\partial P_2}{\partial x} + Q_1 \frac{\partial Q_2}{\partial x} + R_1 \frac{\partial R_2}{\partial x} \right) \mathbf{i} + \left(P_1 \frac{\partial P_2}{\partial y} + Q_1 \frac{\partial Q_2}{\partial y} + R_1 \frac{\partial R_2}{\partial y} \right) \mathbf{j} + \left(P_1 \frac{\partial P_2}{\partial z} + Q_1 \frac{\partial Q_2}{\partial z} + R_1 \frac{\partial R_2}{\partial z} \right) \mathbf{k}$$

and

$$(\mathbf{G} \cdot \nabla)\,\mathbf{F} + \mathbf{G} \times \operatorname{curl} \mathbf{F} = \left(P_2 \frac{\partial P_1}{\partial x} + Q_2 \frac{\partial Q_1}{\partial x} + R_2 \frac{\partial R_1}{\partial x} \right) \mathbf{i} + \left(P_2 \frac{\partial P_1}{\partial y} + Q_2 \frac{\partial Q_1}{\partial y} + R_2 \frac{\partial R_1}{\partial y} \right) \mathbf{j} + \left(P_2 \frac{\partial P_1}{\partial z} + Q_2 \frac{\partial Q_1}{\partial z} + R_2 \frac{\partial R_1}{\partial z} \right) \mathbf{k}.$$

Hence

$$\begin{aligned}
&(\mathbf{F} \cdot \nabla)\,\mathbf{G} + \mathbf{F} \times \operatorname{curl} \mathbf{G} + (\mathbf{G} \cdot \nabla)\,\mathbf{F} + \mathbf{G} \times \operatorname{curl} \mathbf{F} \\
&\quad = \left[\left(P_1 \frac{\partial P_2}{\partial x} + P_2 \frac{\partial P_1}{\partial x} \right) + \left(Q_1 \frac{\partial Q_2}{\partial x} + Q_2 \frac{\partial Q_1}{\partial y} \right) + \left(R_1 \frac{\partial R_2}{\partial x} + R_2 \frac{\partial R_1}{\partial x} \right) \right] \mathbf{i} \\
&\qquad + \left[\left(P_1 \frac{\partial P_2}{\partial y} + P_2 \frac{\partial P_1}{\partial y} \right) + \left(Q_1 \frac{\partial Q_2}{\partial y} + Q_2 \frac{\partial Q_1}{\partial y} \right) + \left(R_1 \frac{\partial R_2}{\partial y} + R_2 \frac{\partial R_1}{\partial y} \right) \right] \mathbf{j} \\
&\qquad + \left[\left(P_1 \frac{\partial P_2}{\partial z} + P_2 \frac{\partial P_1}{\partial z} \right) + \left(Q_1 \frac{\partial Q_2}{\partial z} + Q_2 \frac{\partial Q_1}{\partial z} \right) + \left(R_1 \frac{\partial R_2}{\partial z} + R_2 \frac{\partial R_1}{\partial z} \right) \right] \mathbf{k} \\
&\quad = \nabla(P_1 P_2 + Q_1 Q_2 + R_1 R_2) = \nabla(\mathbf{F} \cdot \mathbf{G}).
\end{aligned}$$

6. (a) First we place the piston on coordinate axes so the top of the cylinder is at the origin and $x(t) \geq 0$ is the distance from the top of the cylinder to the piston at time t. Let C_1 be the curve traced out by the piston during one four-stroke cycle, so C_1 is given by $\mathbf{r}(t) = x(t)\,\mathbf{i}$, $a \leq t \leq b$. (Thus, the curve lies on the positive x-axis and reverses direction several times.) The force on the piston is $AP(t)\,\mathbf{i}$, where A is the area of the top of the piston and $P(t)$ is the pressure in the cylinder at time t. As in Section 16.2, the work done on the piston is $\int_{C_1} \mathbf{F} \cdot d\mathbf{r} = \int_a^b AP(t)\,\mathbf{i} \cdot x'(t)\,\mathbf{i}\,dt = \int_a^b AP(t)\,x'(t)\;dt$. Here, the volume of the cylinder at time t is $V(t) = Ax(t) \;\;\Rightarrow\;\; V'(t) = Ax'(t) \;\;\Rightarrow\;\; \int_a^b AP(t)\,x'(t)\;dt = \int_a^b P(t)\,V'(t)\;dt$. Since the curve C in the PV-plane corresponds to the values of P and V at time t, $a \leq t \leq b$, we have

$$W = \int_a^b AP(t)\,x'(t)\;dt = \int_a^b P(t)\,V'(t)\;dt = \int_C P\,dV$$

Another method: If we divide the time interval $[a, b]$ into n subintervals of equal length Δt, the amount of work done on the piston in the ith time interval is approximately $AP(t_i)[x(t_i) - x(t_{i-1})]$. Thus we estimate the total work done during one cycle to be $\sum_{i=1}^{n} AP(t_i)[x(t_i) - x(t_{i-1})]$. If we allow $n \to \infty$, we have

$$W = \lim_{n\to\infty} \sum_{i=1}^{n} AP(t_i)[x(t_i) - x(t_{i-1})] = \lim_{n\to\infty} \sum_{i=1}^{n} P(t_i)[Ax(t_i) - Ax(t_{i-1})] = \lim_{n\to\infty} \sum_{i=1}^{n} P(t_i)[V(t_i) - V(t_{i-1})]$$
$$= \int_C P\,dV$$

(b) Let C_L be the lower loop of the curve C and C_U the upper loop. Then $C = C_L \cup C_U$. C_L is positively oriented, so from Formula 16.4.5 we know the area of the lower loop in the PV-plane is given by $-\oint_{C_L} P\,dV$. C_U is negatively oriented, so the area of the upper loop is given by $-\left(-\oint_{C_U} P\,dV\right) = \oint_{C_U} P\,dV$. From part (a),

$$W = \int_C P\,dV = \int_{C_L \cup C_U} P\,dV = \oint_{C_L} P\,dV + \oint_{C_U} P\,dV = \oint_{C_U} P\,dV - \left(-\oint_{C_L} P\,dV\right),$$

the difference of the areas enclosed by the two loops of C.

17 ☐ SECOND-ORDER DIFFERENTIAL EQUATIONS

17.1 Second-Order Linear Equations

1. The auxiliary equation is $r^2 - r - 6 = 0 \quad\Rightarrow\quad (r-3)(r+2) = 0 \quad\Rightarrow\quad r = 3, r = -2$. Then by (8) the general solution is $y = c_1 e^{3x} + c_2 e^{-2x}$.

2. The auxiliary equation is $r^2 - 6r + 9 = 0 \quad\Rightarrow\quad (r-3)^2 = 0 \quad\Rightarrow\quad r = 3$. Then by (10), the general solution is $y = c_1 e^{3x} + c_2 x e^{3x}$.

3. The auxiliary equation is $r^2 + 2 = 0 \quad\Rightarrow\quad r = \pm\sqrt{2}\,i$. Then by (11) the general solution is $y = e^{0x}\left(c_1 \cos\left(\sqrt{2}\,x\right) + c_2 \sin\left(\sqrt{2}\,x\right)\right) = c_1 \cos\left(\sqrt{2}\,x\right) + c_2 \sin\left(\sqrt{2}\,x\right)$.

4. The auxiliary equation is $r^2 + r - 12 = 0 \quad\Rightarrow\quad (r-3)(r+4) = 0 \quad\Rightarrow\quad r = 3, r = -4$. Then by (8) the general solution is $y = c_1 e^{3x} + c_2 e^{-4x}$.

5. The auxiliary equation is $4r^2 + 4r + 1 = 0 \quad\Rightarrow\quad (2r+1)^2 = 0 \quad\Rightarrow\quad r = -\frac{1}{2}$. Then by (10), the general solution is $y = c_1 e^{-x/2} + c_2 x e^{-x/2}$.

6. The auxiliary equation is $9r^2 + 4 = 0 \quad\Rightarrow\quad r^2 = -\frac{4}{9} \quad\Rightarrow\quad r = \pm\frac{2}{3}i$, so the general solution is $y = e^{0x}\left[c_1 \cos\left(\frac{2}{3}x\right) + c_2 \sin\left(\frac{2}{3}x\right)\right] = c_1 \cos\left(\frac{2}{3}x\right) + c_2 \sin\left(\frac{2}{3}x\right)$.

7. The auxiliary equation is $3r^2 - 4r = r(3r-4) = 0 \quad\Rightarrow\quad r = 0, r = \frac{4}{3}$, so $y = c_1 e^{0x} + c_2 e^{4x/3} = c_1 + c_2 e^{4x/3}$.

8. The auxiliary equation is $r^2 - 1 = (r-1)(r+1) = 0 \quad\Rightarrow\quad r = 1, r = -1$. Then the general solution is $y = c_1 e^{x} + c_2 e^{-x}$.

9. The auxiliary equation is $r^2 - 4r + 13 = 0 \quad\Rightarrow\quad r = \dfrac{4 \pm \sqrt{-36}}{2} = 2 \pm 3i$, so $y = e^{2x}(c_1 \cos 3x + c_2 \sin 3x)$.

10. The auxiliary equation is $3r^2 + 4r - 3 = 0 \quad\Rightarrow\quad r = \dfrac{-4 \pm \sqrt{52}}{6} = \dfrac{-2 \pm \sqrt{13}}{3}$, so $y = c_1 e^{(-2+\sqrt{13})x/3} + c_2 e^{(-2-\sqrt{13})x/3}$.

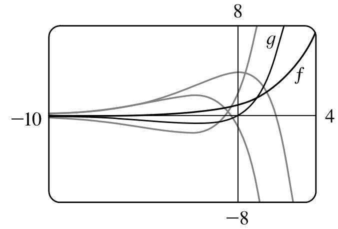
11. The auxiliary equation is $2r^2 + 2r - 1 = 0 \quad\Rightarrow\quad r = \dfrac{-2 \pm \sqrt{12}}{4} = \dfrac{-1 \pm \sqrt{3}}{2}$, so $y = c_1 e^{\left(-1+\sqrt{3}\right)t/2} + c_2 e^{\left(-1-\sqrt{3}\right)t/2}$.

12. The auxiliary equation is $r^2 + 6r + 34 = 0 \quad\Rightarrow\quad r = \dfrac{-6 \pm \sqrt{-100}}{2} = -3 \pm 5i$, so $R = e^{-3t}(c_1 \cos 5t + c_2 \sin 5t)$.

13. The auxiliary equation is $3r^2 + 4r + 3 = 0 \quad \Rightarrow \quad r = \dfrac{-4 \pm \sqrt{-20}}{6} = -\frac{2}{3} \pm \frac{\sqrt{5}}{3}i$, so

$V = e^{-2t/3}\left[c_1 \cos\left(\frac{\sqrt{5}}{3}t\right) + c_2 \sin\left(\frac{\sqrt{5}}{3}t\right)\right]$.

14. The auxiliary equation is $4r^2 - 4r + 1 = (2r-1)^2 = 0 \quad \Rightarrow \quad r = \frac{1}{2}$, so the general solution is $y = c_1 e^{x/2} + c_2 x e^{x/2}$. We graph the basic solutions $f(x) = e^{x/2}$, $g(x) = xe^{x/2}$ as well as $y = 2e^{x/2} + 3xe^{x/2}$, $y = -e^{x/2} - 3xe^{x/2}$, and $y = 4e^{x/2} - 2xe^{x/2}$. The graphs are all asymptotic to the x-axis as $x \to -\infty$, and as $x \to \infty$ the solutions approach $\pm\infty$.

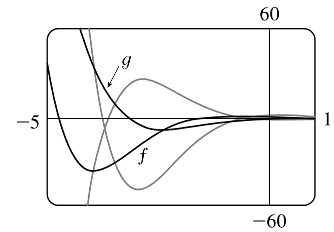


15. The auxiliary equation is $r^2 + 2r + 2 = 0 \quad \Rightarrow$

$r = \dfrac{-2 \pm \sqrt{-4}}{2} = -1 \pm i$, so the general solution is

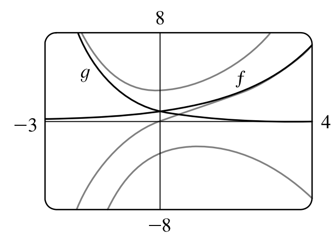
$y = e^{-x}(c_1 \cos x + c_2 \sin x)$. We graph the basic solutions

$f(x) = e^{-x} \cos x$, $g(x) = e^{-x} \sin x$ as well as



$y = e^{-x}(-\cos x - 2\sin x)$ and $y = e^{-x}(2\cos x + 3\sin x)$. All the solutions oscillate with amplitudes that become arbitrarily large as $x \to -\infty$ and the solutions are asymptotic to the x-axis as $x \to \infty$.

16. The auxiliary equation is $2r^2 + r - 1 = (2r-1)(r+1) = 0 \quad \Rightarrow$ $r = \frac{1}{2}$, $r = -1$, so the general solution is $y = c_1 e^{x/2} + c_2 e^{-x}$. We graph the basic solutions $f(x) = e^{x/2}$, $g(x) = e^{-x}$ as well as $y = 2e^{x/2} + e^{-x}$, $y = -e^{x/2} - 2e^{-x}$, and $y = e^{x/2} - e^{-x}$. Each solution consists of a single continuous curve that approaches either 0 or $\pm\infty$ as $x \to \pm\infty$.



17. $r^2 + 3 = 0 \quad \Rightarrow \quad r = \pm\sqrt{3}\,i$ and the general solution is

$y = e^{0x}\left[c_1 \cos\left(\sqrt{3}\,x\right) + c_2 \sin\left(\sqrt{3}\,x\right)\right] = c_1 \cos\left(\sqrt{3}\,x\right) + c_2 \sin\left(\sqrt{3}\,x\right)$. Then $y(0) = 1 \quad \Rightarrow \quad c_1 = 1$ and, since $y' = -\sqrt{3}\,c_1 \sin\left(\sqrt{3}\,x\right) + \sqrt{3}\,c_2 \cos\left(\sqrt{3}\,x\right)$, $y'(0) = 3 \quad \Rightarrow \quad \sqrt{3}\,c_2 = 3 \quad \Rightarrow \quad c_2 = \frac{3}{\sqrt{3}} = \sqrt{3}$, so the solution to the initial-value problem is $y = \cos\left(\sqrt{3}\,x\right) + \sqrt{3}\,\sin\left(\sqrt{3}\,x\right)$.

18. $r^2 - 2r - 3 = (r-3)(r+1) = 0$, so $r = 3$, $r = -1$ and the general solution is $y = c_1 e^{3x} + c_2 e^{-x}$. Then $y' = 3c_1 e^{3x} - c_2 e^{-x}$, so $y(0) = 2 \quad \Rightarrow \quad c_1 + c_2 = 2$ and $y'(0) = 2 \quad \Rightarrow \quad 3c_1 - c_2 = 2$, giving $c_1 = 1$ and $c_2 = 1$. Thus the solution to the initial-value problem is $y = e^{3x} + e^{-x}$.

19. $9r^2 + 12r + 4 = (3r+2)^2 = 0 \quad \Rightarrow \quad r = -\frac{2}{3}$ and the general solution is $y = c_1 e^{-2x/3} + c_2 x e^{-2x/3}$. Then $y(0) = 1 \quad \Rightarrow$ $c_1 = 1$ and, since $y' = -\frac{2}{3}c_1 e^{-2x/3} + c_2\left(1 - \frac{2}{3}x\right)e^{-2x/3}$, $y'(0) = 0 \quad \Rightarrow \quad -\frac{2}{3}c_1 + c_2 = 0$, so $c_2 = \frac{2}{3}$ and the solution to the initial-value problem is $y = e^{-2x/3} + \frac{2}{3}xe^{-2x/3}$.

20. $3r^2 - 2r - 1 = (3r+1)(r-1) = 0 \quad\Rightarrow\quad r = -\frac{1}{3}, r = 1$ and the general solution is $y = c_1 e^{-x/3} + c_2 e^x$. Then $y' = -\frac{1}{3}c_1 e^{-x/3} + c_2 e^x$, so $y(0) = 0 \quad\Rightarrow\quad c_1 + c_2 = 0$ and $y'(0) = -4 \quad\Rightarrow\quad -\frac{1}{3}c_1 + c_2 = -4$, giving $c_1 = 3$ and $c_2 = -3$. Thus the solution to the initial-value problem is $y = 3e^{-x/3} - 3e^x$.

21. $r^2 - 6r + 10 = 0 \quad\Rightarrow\quad r = 3 \pm i$ and the general solution is $y = e^{3x}(c_1 \cos x + c_2 \sin x)$. Then $2 = y(0) = c_1$ and $3 = y'(0) = c_2 + 3c_1 \quad\Rightarrow\quad c_2 = -3$ and the solution to the initial-value problem is $y = e^{3x}(2\cos x - 3\sin x)$.

22. $4r^2 - 20r + 25 = (2r-5)^2 = 0 \quad\Rightarrow\quad r = \frac{5}{2}$ and the general solution is $y = c_1 e^{5x/2} + c_2 x e^{5x/2}$. Then $2 = y(0) = c_1$ and $-3 = y'(0) = \frac{5}{2}c_1 + c_2 \quad\Rightarrow\quad c_2 = -8$. The solution to the initial-value problem is $y = 2e^{5x/2} - 8xe^{5x/2}$.

23. $r^2 - r - 12 = (r-4)(r+3) = 0 \quad\Rightarrow\quad r = 4, r = -3$ and the general solution is $y = c_1 e^{4x} + c_2 e^{-3x}$. Then $0 = y(1) = c_1 e^4 + c_2 e^{-3}$ and $1 = y'(1) = 4c_1 e^4 - 3c_2 e^{-3}$ so $c_1 = \frac{1}{7}e^{-4}$, $c_2 = -\frac{1}{7}e^3$ and the solution to the initial-value problem is $y = \frac{1}{7}e^{-4}e^{4x} - \frac{1}{7}e^3 e^{-3x} = \frac{1}{7}e^{4x-4} - \frac{1}{7}e^{3-3x}$.

24. $4r^2 + 4r + 3 = 0 \quad\Rightarrow\quad r = -\frac{1}{2} \pm \frac{\sqrt{2}}{2}i$ and the general solution is $y = e^{-x/2}\left(c_1 \cos \frac{\sqrt{2}}{2}x + c_2 \sin \frac{\sqrt{2}}{2}x\right)$. Then $0 = y(0) = c_1$ and $1 = y'(0) = \frac{\sqrt{2}}{2}c_2 - \frac{1}{2}c_1 \quad\Rightarrow\quad c_2 = \sqrt{2}$ and the solution to the initial-value problem is $y = e^{-x/2}\left(0 + \sqrt{2}\sin \frac{\sqrt{2}}{2}x\right) = \sqrt{2}\,e^{-x/2}\sin \frac{\sqrt{2}}{2}x$.

25. $r^2 + 16 = 0 \quad\Rightarrow\quad r = \pm 4i$ and the general solution is $y = c_1 \cos 4x + c_2 \sin 4x$. Then $-3 = y(0) = c_1$ and $2 = y(\pi/8) = c_2$, so the solution of the boundary-value problem is $y = -3\cos 4x + 2\sin 4x$.

26. $r^2 + 6r = r(r+6) = 0 \quad\Rightarrow\quad r = 0, r = -6$ and the general solution is $y = c_1 + c_2 e^{-6x}$. Then $1 = y(0) = c_1 + c_2$ and $0 = y(1) = c_1 + c_2 e^{-6}$ so $c_1 = \dfrac{1}{1-e^6}$, $c_2 = -\dfrac{e^6}{1-e^6}$. The solution of the boundary-value problem is $y = \dfrac{1}{1-e^6} - \dfrac{e^6}{1-e^6} \cdot e^{-6x} = \dfrac{1}{1-e^6} - \dfrac{e^{6-6x}}{1-e^6}$.

27. $r^2 + 4r + 4 = (r+2)^2 = 0 \quad\Rightarrow\quad r = -2$ and the general solution is $y = c_1 e^{-2x} + c_2 x e^{-2x}$. Then $2 = y(0) = c_1$ and $0 = y(1) = c_1 e^{-2} + c_2 e^{-2}$ so $c_2 = -2$, and the solution of the boundary-value problem is $y = 2e^{-2x} - 2xe^{-2x}$.

28. $r^2 - 8r + 17 = 0 \quad\Rightarrow\quad r = 4 \pm i$ and the general solution is $y = e^{4x}(c_1 \cos x + c_2 \sin x)$. But $3 = y(0) = c_1$ and $2 = y(\pi) = -c_1 e^{4\pi} \quad\Rightarrow\quad c_1 = -2/e^{4\pi}$, so there is no solution.

29. $r^2 - r = r(r-1) = 0 \quad\Rightarrow\quad r = 0, r = 1$ and the general solution is $y = c_1 + c_2 e^x$. Then $1 = y(0) = c_1 + c_2$ and $2 = y(1) = c_1 + c_2 e$ so $c_1 = \dfrac{e-2}{e-1}$, $c_2 = \dfrac{1}{e-1}$. The solution of the boundary-value problem is $y = \dfrac{e-2}{e-1} + \dfrac{e^x}{e-1}$.

30. $4r^2 - 4r + 1 = (2r-1)^2 = 0 \quad\Rightarrow\quad r = \frac{1}{2}$ and the general solution is $y = c_1 e^{x/2} + c_2 x e^{x/2}$. Then $4 = y(0) = c_1$ and $0 = y(2) = c_1 e + 2c_2 e \quad\Rightarrow\quad c_2 = -2$. The solution of the boundary-value problem is $y = 4e^{x/2} - 2xe^{x/2}$.

31. $r^2 + 4r + 20 = 0 \quad \Rightarrow \quad r = -2 \pm 4i$ and the general solution is $y = e^{-2x}(c_1 \cos 4x + c_2 \sin 4x)$. But $1 = y(0) = c_1$ and $2 = y(\pi) = c_1 e^{-2\pi} \quad \Rightarrow \quad c_1 = 2e^{2\pi}$, so there is no solution.

32. $r^2 + 4r + 20 = 0 \quad \Rightarrow \quad r = -2 \pm 4i$ and the general solution is $y = e^{-2x}(c_1 \cos 4x + c_2 \sin 4x)$. But $1 = y(0) = c_1$ and $e^{-2\pi} = y(\pi) = c_1 e^{-2\pi} \quad \Rightarrow \quad c_1 = 1$, so c_2 can vary and the solution of the boundary-value problem is $y = e^{-2x}(\cos 4x + c \sin 4x)$, where c is any constant.

33. (a) *Case 1* ($\lambda = 0$)*:* $y'' + \lambda y = 0 \quad \Rightarrow \quad y'' = 0$ which has an auxiliary equation $r^2 = 0 \quad \Rightarrow \quad r = 0 \quad \Rightarrow \quad y = c_1 + c_2 x$ where $y(0) = 0$ and $y(L) = 0$. Thus, $0 = y(0) = c_1$ and $0 = y(L) = c_2 L \quad \Rightarrow \quad c_1 = c_2 = 0$. Thus $y = 0$.

Case 2 ($\lambda < 0$)*:* $y'' + \lambda y = 0$ has auxiliary equation $r^2 = -\lambda \quad \Rightarrow \quad r = \pm\sqrt{-\lambda}$ [distinct and real since $\lambda < 0$] $\quad \Rightarrow$ $y = c_1 e^{\sqrt{-\lambda}x} + c_2 e^{-\sqrt{-\lambda}x}$ where $y(0) = 0$ and $y(L) = 0$. Thus $0 = y(0) = c_1 + c_2$ $(*)$ and $0 = y(L) = c_1 e^{\sqrt{-\lambda}L} + c_2 e^{-\sqrt{-\lambda}L}$ $(\dagger)$.

Multiplying $(*)$ by $e^{\sqrt{-\lambda}L}$ and subtracting $(\dagger)$ gives $c_2\left(e^{\sqrt{-\lambda}L} - e^{-\sqrt{-\lambda}L}\right) = 0 \quad \Rightarrow \quad c_2 = 0$ and thus $c_1 = 0$ from $(*)$.

Thus $y = 0$ for the cases $\lambda = 0$ and $\lambda < 0$.

(b) $y'' + \lambda y = 0$ has an auxiliary equation $r^2 + \lambda = 0 \quad \Rightarrow \quad r = \pm i\sqrt{\lambda} \quad \Rightarrow \quad y = c_1 \cos\sqrt{\lambda}\,x + c_2 \sin\sqrt{\lambda}\,x$ where $y(0) = 0$ and $y(L) = 0$. Thus, $0 = y(0) = c_1$ and $0 = y(L) = c_2 \sin\sqrt{\lambda}L$ since $c_1 = 0$. Since we cannot have a trivial solution, $c_2 \neq 0$ and thus $\sin\sqrt{\lambda}\,L = 0 \quad \Rightarrow \quad \sqrt{\lambda}\,L = n\pi$ where n is an integer $\quad \Rightarrow \quad \lambda = n^2\pi^2/L^2$ and $y = c_2 \sin(n\pi x/L)$ where n is an integer.

34. The auxiliary equation is $ar^2 + br + c = 0$. If $b^2 - 4ac > 0$, then any solution is of the form $y(x) = c_1 e^{r_1 x} + c_2 e^{r_2 x}$ where $r_1 = \dfrac{-b + \sqrt{b^2 - 4ac}}{2a}$ and $r_2 = \dfrac{-b - \sqrt{b^2 - 4ac}}{2a}$. But a, b, and c are all positive so both r_1 and r_2 are negative and $\lim_{x\to\infty} y(x) = 0$. If $b^2 - 4ac = 0$, then any solution is of the form $y(x) = c_1 e^{rx} + c_2 x e^{rx}$ where $r = -b/(2a) < 0$ since a, b are positive. Hence $\lim_{x\to\infty} y(x) = 0$. Finally if $b^2 - 4ac < 0$, then any solution is of the form $y(x) = e^{\alpha x}(c_1 \cos\beta x + c_2 \sin\beta x)$ where $\alpha = -b/(2a) < 0$ since a and b are positive. Thus $\lim_{x\to\infty} y(x) = 0$.

35. (a) $r^2 - 2r + 2 = 0 \quad \Rightarrow \quad r = 1 \pm i$ and the general solution is $y = e^x\,(c_1 \cos x + c_2 \sin x)$. If $y(a) = c$ and $y(b) = d$ then $e^a\,(c_1 \cos a + c_2 \sin a) = c \quad \Rightarrow \quad c_1 \cos a + c_2 \sin a = ce^{-a}$ and $e^b\,(c_1 \cos b + c_2 \sin b) = d \quad \Rightarrow$ $c_1 \cos b + c_2 \sin b = de^{-b}$. This gives a linear system in c_1 and c_2 which has a unique solution if the lines are not parallel. If the lines are not vertical or horizontal, we have parallel lines if $\cos a = k \cos b$ and $\sin a = k \sin b$ for some nonzero constant k or $\dfrac{\cos a}{\cos b} = k = \dfrac{\sin a}{\sin b} \quad \Rightarrow \quad \dfrac{\sin a}{\cos a} = \dfrac{\sin b}{\cos b} \quad \Rightarrow \quad \tan a = \tan b \quad \Rightarrow \quad b - a = n\pi$, n any integer. (Note that none of $\cos a$, $\cos b$, $\sin a$, $\sin b$ are zero.) If the lines are both horizontal then $\cos a = \cos b = 0 \quad \Rightarrow \quad b - a = n\pi$, and similarly vertical lines means $\sin a = \sin b = 0 \quad \Rightarrow \quad b - a = n\pi$. Thus the system has a unique solution if $b - a \neq n\pi$.

(b) The linear system has no solution if the lines are parallel but not identical. From part (a) the lines are parallel if $b - a = n\pi$. If the lines are not horizontal, they are identical if $ce^{-a} = kde^{-b} \Rightarrow \dfrac{ce^{-a}}{de^{-b}} = k = \dfrac{\cos a}{\cos b} \Rightarrow$ $\dfrac{c}{d} = e^{a-b}\dfrac{\cos a}{\cos b}$. (If $d = 0$ then $c = 0$ also.) If they are horizontal then $\cos b = 0$, but $k = \dfrac{\sin a}{\sin b}$ also (and $\sin b \neq 0$) so we require $\dfrac{c}{d} = e^{a-b}\dfrac{\sin a}{\sin b}$. Thus the system has no solution if $b - a = n\pi$ and $\dfrac{c}{d} \neq e^{a-b}\dfrac{\cos a}{\cos b}$ unless $\cos b = 0$, in which case $\dfrac{c}{d} \neq e^{a-b}\dfrac{\sin a}{\sin b}$.

(c) The linear system has infinitely many solution if the lines are identical (and necessarily parallel). From part (b) this occurs when $b - a = n\pi$ and $\dfrac{c}{d} = e^{a-b}\dfrac{\cos a}{\cos b}$ unless $\cos b = 0$, in which case $\dfrac{c}{d} = e^{a-b}\dfrac{\sin a}{\sin b}$.

17.2 Nonhomogeneous Linear Equations

1. The auxiliary equation is $r^2 + 2r - 8 = (r-2)(r+4) = 0 \Rightarrow r = 2, r = -4$, so the complementary solution is $y_c(x) = c_1 e^{2x} + c_2 e^{-4x}$. We try the particular solution $y_p(x) = Ax^2 + Bx + C$, so $y_p' = 2Ax + B$ and $y_p'' = 2A$. Substituting into the differential equation, we have $(2A) + 2(2Ax + B) - 8(Ax^2 + Bx + C) = 1 - 2x^2$ or $-8Ax^2 + (4A - 8B)x + (2A + 2B - 8C) = -2x^2 + 1$. Comparing coefficients gives $-8A = -2 \Rightarrow$ $A = \frac{1}{4}$, $4A - 8B = 0 \Rightarrow B = \frac{1}{8}$, and $2A + 2B - 8C = 1 \Rightarrow C = -\frac{1}{32}$, so the general solution is $y(x) = y_c(x) + y_p(x) = c_1 e^{2x} + c_2 e^{-4x} + \frac{1}{4}x^2 + \frac{1}{8}x - \frac{1}{32}$.

2. The auxiliary equation is $r^2 - 3r = r(r-3) = 0 \Rightarrow r = 0, r = 3$, so the complementary solution is $y_c(x) = c_1 + c_2 e^{3x}$. We try the particular solution $y_p(x) = A\cos 2x + B\sin 2x$, so $y_p' = -2A\sin 2x + 2B\cos 2x$ and $y_p'' = -4A\cos 2x - 4B\sin 2x$. Substitution into the differential equation gives $(-4A\cos 2x - 4B\sin 2x) - 3(-2A\sin 2x + 2B\cos 2x) = \sin 2x \Rightarrow$ $(-4A - 6B)\cos 2x + (6A - 4B)\sin 2x = \sin 2x$. Then $-4A - 6B = 0$ and $6A - 4B = 1 \Rightarrow A = \frac{3}{26}$ and $B = -\frac{1}{13}$. Thus the general solution is $y(x) = y_c(x) + y_p(x) = c_1 + c_2 e^{3x} + \frac{3}{26}\cos 2x - \frac{1}{13}\sin 2x$.

3. The auxiliary equation is $9r^2 + 1 = 0$ with roots $r = \pm\frac{1}{3}i$, so the complementary solution is $y_c(x) = c_1\cos(x/3) + c_2\sin(x/3)$. Try the particular solution $y_p(x) = Ae^{2x}$, so $y_p' = 2Ae^{2x}$ and $y_p'' = 4Ae^{2x}$. Substitution into the differential equation gives $9\left(4Ae^{2x}\right) + \left(Ae^{2x}\right) = e^{2x}$ or $37Ae^{2x} = e^{2x}$. Thus $37A = 1 \Rightarrow A = \frac{1}{37}$ and the general solution is $y(x) = y_c(x) + y_p(x) = c_1\cos(x/3) + c_2\sin(x/3) + \frac{1}{37}e^{2x}$.

4. The auxiliary equation is $r^2 - 2r + 2 = 0$ with roots $r = 1 \pm i$, so the complementary solution is $y_c(x) = e^x(c_1\cos x + c_2\sin x)$. Try the particular solution $y_p(x) = Ax + B + Ce^x$, so $y_p' = A + Ce^x$ and $y_p'' = Ce^x$. Substitution into the differential equation gives $(Ce^x) - 2(A + Ce^x) + 2(Ax + B + Ce^x) = x + e^x \Rightarrow$

$2Ax + (-2A + 2B) + Ce^x = x + e^x$. Comparing coefficients, we have $2A = 1 \Rightarrow A = \frac{1}{2}$, $-2A + 2B = 0 \Rightarrow$ $B = \frac{1}{2}$, and $C = 1$, so the general solution is $y(x) = y_c(x) + y_p(x) = e^x(c_1 \cos x + c_2 \sin x) + \frac{1}{2}x + \frac{1}{2} + e^x$.

5. The auxiliary equation is $r^2 - 4r + 5 = 0$ with roots $r = 2 \pm i$, so the complementary solution is $y_c(x) = e^{2x}(c_1 \cos x + c_2 \sin x)$. Try $y_p(x) = Ae^{-x}$, so $y_p' = -Ae^{-x}$ and $y_p'' = Ae^{-x}$. Substitution gives $Ae^{-x} - 4(-Ae^{-x}) + 5(Ae^{-x}) = e^{-x} \Rightarrow 10Ae^{-x} = e^{-x} \Rightarrow A = \frac{1}{10}$. Thus the general solution is $y(x) = e^{2x}(c_1 \cos x + c_2 \sin x) + \frac{1}{10}e^{-x}$.

6. The auxiliary equation is $r^2 - 4r + 4 = (r-2)^2 = 0 \Rightarrow r = 2$, so the complementary solution is $y_c(x) = c_1 e^{2x} + c_2 x e^{2x}$. For $y'' - 4y' + 4y = x$ try $y_{p_1}(x) = Ax + B$. Then $y_{p_1}' = A$ and $y_{p_1}'' = 0$, and substitution into the differential equation gives $0 - 4A + 4(Ax + B) = x$ or $4Ax + (4B - 4A) = x$, so $4A = 1 \Rightarrow A = \frac{1}{4}$ and $4B - 4A = 0 \Rightarrow B = \frac{1}{4}$. Thus $y_{p_1}(x) = \frac{1}{4}x + \frac{1}{4}$. For $y'' - 4y' + 4y = -\sin x$ try $y_{p_2}(x) = A \cos x + B \sin x$. Then $y_{p_2}' = -A \sin x + B \cos x$ and $y_{p_2}'' = -A \cos x - B \sin x$. Substituting, we have
$(-A \cos x - B \sin x) - 4(-A \sin x + B \cos x) + 4(A \cos x + B \sin x) = -\sin x \Rightarrow$
$(3A - 4B) \cos x + (4A + 3B) \sin x = -\sin x$. Thus $3A - 4B = 0$ and $4A + 3B = -1$, giving $A = -\frac{4}{25}$ and $B = -\frac{3}{25}$, so $y_{p_2}(x) = -\frac{4}{25} \cos x - \frac{3}{25} \sin x$. The general solution is
$y(x) = y_c(x) + y_{p_1}(x) + y_{p_2}(x) = c_1 e^{2x} + c_2 x e^{2x} + \frac{1}{4}x + \frac{1}{4} - \frac{4}{25} \cos x - \frac{3}{25} \sin x$.

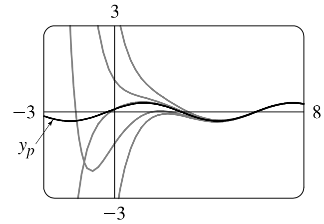
7. The auxiliary equation is $r^2 - 2r + 5 = 0$ with roots $r = 1 \pm 2i$, so the complementary solution is $y_c(x) = e^x(c_1 \cos 2x + c_2 \sin 2x)$. Try the particular solution $y_p(x) = A \cos x + B \sin x$, so $y_p' = -A \sin x + B \cos x$ and $y_p'' = -A \cos x - B \sin x$. Substituting, we have
$(-A \cos x - B \sin x) - 2(-A \sin x + B \cos x) + 5(A \cos x + B \sin x) = \sin x \Rightarrow$
$(4A - 2B) \cos x + (2A + 4B) \sin x = \sin x$. Then $4A - 2B = 0$, $2A + 4B = 1 \Rightarrow A = \frac{1}{10}$, $B = \frac{1}{5}$ and the general solution is $y(x) = y_c(x) + y_p(x) = e^x(c_1 \cos 2x + c_2 \sin 2x) + \frac{1}{10} \cos x + \frac{1}{5} \sin x$. But $1 = y(0) = c_1 + \frac{1}{10} \Rightarrow c_1 = \frac{9}{10}$ and $1 = y'(0) = 2c_2 + c_1 + \frac{1}{5} \Rightarrow c_2 = -\frac{1}{20}$. Thus the solution to the initial-value problem is
$y(x) = e^x\left(\frac{9}{10} \cos 2x - \frac{1}{20} \sin 2x\right) + \frac{1}{10} \cos x + \frac{1}{5} \sin x$.

8. The auxiliary equation is $r^2 - 1 = 0$ with roots $r = \pm 1$, so the complementary solution is $y_c(x) = c_1 e^x + c_2 e^{-x}$. Try the particular solution $y_p(x) = (Ax + B)e^{2x}$, so $y_p' = (2Ax + A + 2B)e^{2x}$ and $y_p'' = (4Ax + 4A + 4B)e^{2x}$. Substituting, we have $(4Ax + 4A + 4B)e^{2x} - (Ax + B)e^{2x} = xe^{2x} \Rightarrow (3Ax + 4A + 3B)e^{2x} = xe^{2x}$. Then $3A = 1 \Rightarrow A = \frac{1}{3}$ and $4A + 3B = 0 \Rightarrow B = -\frac{4}{9}$, and the general solution is $y(x) = y_c(x) + y_p(x) = c_1 e^x + c_2 e^{-x} + \left(\frac{1}{3}x - \frac{4}{9}\right)e^{2x}$. But $0 = y(0) = c_1 + c_2 - \frac{4}{9}$ and $1 = y'(0) = c_1 - c_2 - \frac{5}{9} \Rightarrow c_1 = 1$, $c_2 = -\frac{5}{9}$. Thus the solution to the initial-value problem is $y(x) = e^x - \frac{5}{9}e^{-x} + \left(\frac{1}{3}x - \frac{4}{9}\right)e^{2x}$.

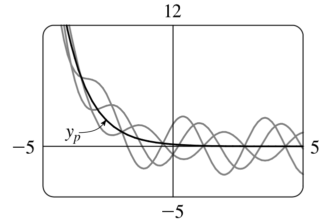
9. The auxiliary equation is $r^2 - r = 0$ with roots $r = 0$, $r = 1$ so the complementary solution is $y_c(x) = c_1 + c_2e^x$.
Try $y_p(x) = x(Ax + B)e^x$ so that no term in y_p is a solution of the complementary equation. Then
$y_p' = (Ax^2 + (2A + B)x + B)e^x$ and $y_p'' = (Ax^2 + (4A + B)x + (2A + 2B))e^x$. Substitution into the differential equation gives $(Ax^2 + (4A + B)x + (2A + 2B))e^x - (Ax^2 + (2A + B)x + B)e^x = xe^x \Rightarrow (2Ax + (2A + B))e^x = xe^x \Rightarrow$
$A = \frac{1}{2}$, $B = -1$. Thus $y_p(x) = \left(\frac{1}{2}x^2 - x\right)e^x$ and the general solution is $y(x) = c_1 + c_2e^x + \left(\frac{1}{2}x^2 - x\right)e^x$. But $2 = y(0) = c_1 + c_2$ and $1 = y'(0) = c_2 - 1$, so $c_2 = 2$ and $c_1 = 0$. The solution to the initial-value problem is
$y(x) = 2e^x + \left(\frac{1}{2}x^2 - x\right)e^x = e^x\left(\frac{1}{2}x^2 - x + 2\right)$.

10. $y_c(x) = c_1e^x + c_2e^{-2x}$. For $y'' + y' - 2y = x$ try $y_{p_1}(x) = Ax + B$. Then $y_{p_1}' = A$, $y_{p_1}'' = 0$, and substitution gives $0 + A - 2(Ax + B) = x \Rightarrow A = -\frac{1}{2}$, $B = -\frac{1}{4}$, so $y_{p_1}(x) = -\frac{1}{2}x - \frac{1}{4}$. For $y'' + y' - 2y = \sin 2x$ try $y_{p_2}(x) = A\cos 2x + B\sin 2x$. Then $y_{p_2}' = -2A\sin 2x + 2B\cos 2x$, $y_{p_2}'' = -4A\cos 2x - 4B\sin 2x$, and substitution gives $(-4A\cos 2x - 4B\sin 2x) + (-2A\sin 2x + 2B\cos 2x) - 2(A\cos 2x + B\sin 2x) = \sin 2x \Rightarrow A = -\frac{1}{20}$, $B = -\frac{3}{20}$. Thus $y_{p_2}(x) = -\frac{1}{20}\cos 2x + -\frac{3}{20}\sin 2x$ and the general solution is
$y(x) = c_1e^x + c_2e^{-2x} - \frac{1}{2}x - \frac{1}{4} - \frac{1}{20}\cos 2x - \frac{3}{20}\sin 2x$. But $1 = y(0) = c_1 + c_2 - \frac{1}{4} - \frac{1}{20}$ and $0 = y'(0) = c_1 - 2c_2 - \frac{1}{2} - \frac{3}{10} \Rightarrow c_1 = \frac{17}{15}$ and $c_2 = \frac{1}{6}$. Thus the solution to the initial-value problem is
$y(x) = \frac{17}{15}e^x + \frac{1}{6}e^{-2x} - \frac{1}{2}x - \frac{1}{4} - \frac{1}{20}\cos 2x - \frac{3}{20}\sin 2x$.

11. The auxiliary equation is $r^2 + 3r + 2 = (r + 1)(r + 2) = 0$, so $r = -1$, $r = -2$ and $y_c(x) = c_1e^{-x} + c_2e^{-2x}$.
Try $y_p = A\cos x + B\sin x \Rightarrow y_p' = -A\sin x + B\cos x$, $y_p'' = -A\cos x - B\sin x$. Substituting into the differential equation gives $(-A\cos x - B\sin x) + 3(-A\sin x + B\cos x) + 2(A\cos x + B\sin x) = \cos x$ or $(A + 3B)\cos x + (-3A + B)\sin x = \cos x$. Then solving the equations $A + 3B = 1$, $-3A + B = 0$ gives $A = \frac{1}{10}$, $B = \frac{3}{10}$ and the general solution is $y(x) = c_1e^{-x} + c_2e^{-2x} + \frac{1}{10}\cos x + \frac{3}{10}\sin x$. The graph shows y_p and several other solutions. Notice that all solutions are asymptotic to y_p as $x \to \infty$. Except for y_p, all solutions approach either ∞ or $-\infty$ as $x \to -\infty$.



12. The auxiliary equation is $r^2 + 4 = 0 \Rightarrow r = \pm 2i$, so $y_c(x) = c_1\cos 2x + c_2\sin 2x$. Try $y_p = Ae^{-x} \Rightarrow$ $y_p' = -Ae^{-x}$, $y_p'' = Ae^{-x}$. Substituting into the differential equation gives $Ae^{-x} + 4Ae^{-x} = e^{-x} \Rightarrow$ $5A = 1 \Rightarrow A = \frac{1}{5}$, so $y_p = \frac{1}{5}e^{-x}$ and the general solution is $y(x) = c_1\cos 2x + c_2\sin 2x + \frac{1}{5}e^{-x}$. We graph y_p along with several other solutions. All of the solutions except y_p oscillate around $y_p = \frac{1}{5}e^{-x}$, and all solutions approach ∞ as $x \to -\infty$.



13. Here $y_c(x) = c_1 e^{2x} + c_2 e^{-x}$, and a trial solution is $y_p(x) = (Ax + B)e^x \cos x + (Cx + D)e^x \sin x$.

14. Here $y_c(x) = c_1 \cos 2x + c_2 \sin 2x$. For $y'' + 4y = \cos 4x$ try $y_{p_1}(x) = A \cos 4x + B \sin 4x$ and for $y'' + 4y = \cos 2x$ try $y_{p_2}(x) = x\,(C \cos 2x + D \sin 2x)$ (so that no term of y_{p_2} is a solution of the complementary equation). Thus a trial solution is $y_p(x) = y_{p_1}(x) + y_{p_2}(x) = A \cos 4x + B \sin 4x + Cx \cos 2x + Dx \sin 2x$.

15. Here $y_c(x) = c_1 e^{2x} + c_2 e^x$. For $y'' - 3y' + 2y = e^x$ try $y_{p_1}(x) = Axe^x$ (since $y = Ae^x$ is a solution of the complementary equation) and for $y'' - 3y' + 2y = \sin x$ try $y_{p_2}(x) = B \cos x + C \sin x$. Thus a trial solution is
$y_p(x) = y_{p_1}(x) + y_{p_2}(x) = Axe^x + B \cos x + C \sin x$.

16. Since $y_c(x) = c_1 e^x + c_2 e^{-4x}$ try $y_p(x) = x(Ax^3 + Bx^2 + Cx + D)e^x$ so that no term of $y_p(x)$ satisfies the complementary equation.

17. Since $y_c(x) = e^{-x}(c_1 \cos 3x + c_2 \sin 3x)$ we try $y_p(x) = x(Ax^2 + Bx + C)e^{-x} \cos 3x + x(Dx^2 + Ex + F)e^{-x} \sin 3x$ (so that no term of y_p is a solution of the complementary equation).

18. Here $y_c(x) = c_1 \cos 2x + c_2 \sin 2x$. For $y'' + 4y = e^{3x}$ try $y_{p_1}(x) = Ae^{3x}$ and for $y'' + 4y = x \sin 2x$ try
$y_{p_2}(x) = x(Bx + C) \cos 2x + x(Dx + E) \sin 2x$ (so that no term of y_{p_2} is a solution of the complementary equation).

Note: Solving Equations (7) and (9) in The Method of Variation of Parameters gives

$$u_1' = -\frac{Gy_2}{a\,(y_1 y_2' - y_2 y_1')} \qquad \text{and} \qquad u_2' = \frac{Gy_1}{a\,(y_1 y_2' - y_2 y_1')}$$

We will use these equations rather than resolving the system in each of the remaining exercises in this section.

19. (a) Here $4r^2 + 1 = 0 \;\Rightarrow\; r = \pm\frac{1}{2}i$ and $y_c(x) = c_1 \cos\left(\frac{1}{2}x\right) + c_2 \sin\left(\frac{1}{2}x\right)$. We try a particular solution of the form $y_p(x) = A \cos x + B \sin x \;\Rightarrow\; y_p' = -A \sin x + B \cos x$ and $y_p'' = -A \cos x - B \sin x$. Then the equation $4y'' + y = \cos x$ becomes $4(-A \cos x - B \sin x) + (A \cos x + B \sin x) = \cos x$ or
$-3A \cos x - 3B \sin x = \cos x \;\Rightarrow\; A = -\frac{1}{3}, B = 0$. Thus, $y_p(x) = -\frac{1}{3} \cos x$ and the general solution is
$y(x) = y_c(x) + y_p(x) = c_1 \cos\left(\frac{1}{2}x\right) + c_2 \sin\left(\frac{1}{2}x\right) - \frac{1}{3} \cos x$.

(b) From (a) we know that $y_c(x) = c_1 \cos \frac{x}{2} + c_2 \sin \frac{x}{2}$. Setting $y_1 = \cos \frac{x}{2}$, $y_2 = \sin \frac{x}{2}$, we have

$y_1 y_2' - y_2 y_1' = \frac{1}{2} \cos^2 \frac{x}{2} + \frac{1}{2} \sin^2 \frac{x}{2} = \frac{1}{2}$. Thus $u_1' = -\dfrac{\cos x\, \sin \frac{x}{2}}{4 \cdot \frac{1}{2}} = -\frac{1}{2} \cos\left(2 \cdot \frac{x}{2}\right) \sin \frac{x}{2} = -\frac{1}{2}\left(2 \cos^2 \frac{x}{2} - 1\right) \sin \frac{x}{2}$

and $u_2' = \dfrac{\cos x\, \cos \frac{x}{2}}{4 \cdot \frac{1}{2}} = \frac{1}{2} \cos\left(2 \cdot \frac{x}{2}\right) \cos \frac{x}{2} = \frac{1}{2}\left(1 - 2 \sin^2 \frac{x}{2}\right) \cos \frac{x}{2}$. Then

$u_1(x) = \int \left(\frac{1}{2} \sin \frac{x}{2} - \cos^2 \frac{x}{2}\, \sin \frac{x}{2}\right) dx = -\cos \frac{x}{2} + \frac{2}{3} \cos^3 \frac{x}{2}$ and

$u_2(x) = \int \left(\frac{1}{2} \cos \frac{x}{2} - \sin^2 \frac{x}{2}\, \cos \frac{x}{2}\right) dx = \sin \frac{x}{2} - \frac{2}{3} \sin^3 \frac{x}{2}$. Thus

$$\begin{aligned} y_p(x) &= \left(-\cos \tfrac{x}{2} + \tfrac{2}{3} \cos^3 \tfrac{x}{2}\right) \cos \tfrac{x}{2} + \left(\sin \tfrac{x}{2} - \tfrac{2}{3} \sin^3 \tfrac{x}{2}\right) \sin \tfrac{x}{2} = -\left(\cos^2 \tfrac{x}{2} - \sin^2 \tfrac{x}{2}\right) + \tfrac{2}{3}\left(\cos^4 \tfrac{x}{2} - \sin^4 \tfrac{x}{2}\right) \\ &= -\cos\left(2 \cdot \tfrac{x}{2}\right) + \tfrac{2}{3}\left(\cos^2 \tfrac{x}{2} + \sin^2 \tfrac{x}{2}\right)\left(\cos^2 \tfrac{x}{2} - \sin^2 \tfrac{x}{2}\right) = -\cos x + \tfrac{2}{3} \cos x = -\tfrac{1}{3} \cos x \end{aligned}$$

and the general solution is $y(x) = y_c(x) + y_p(x) = c_1 \cos \frac{x}{2} + c_2 \sin \frac{x}{2} - \frac{1}{3} \cos x$.

20. (a) Here $r^2 - 2r - 3 = (r-3)(r+1) = 0 \quad \Rightarrow \quad r = 3, r = -1$ and the complementary solution is

$y_c(x) = c_1 e^{3x} + c_2 e^{-x}$. A particular solution is of the form $y_p(x) = Ax + B \quad \Rightarrow \quad y_p' = A, y_p'' = 0$, and

substituting into the differential equation gives $0 - 2A - 3(Ax + B) = x + 2$ or $-3Ax + (-2A - 3B) = x + 2$,

so $A = -\frac{1}{3}$ and $-2A - 3B = 2 \quad \Rightarrow \quad B = -\frac{4}{9}$. Thus $y_p(x) = -\frac{1}{3}x - \frac{4}{9}$ and the general solution is

$y(x) = y_c(x) + y_p(x) = c_1 e^{3x} + c_2 e^{-x} - \frac{1}{3}x - \frac{4}{9}$.

(b) In (a), $y_c(x) = c_1 e^{3x} + c_2 e^{-x}$, so set $y_1 = e^{3x}$, $y_2 = e^{-x}$. Then $y_1 y_2' - y_2 y_1' = -e^{3x}e^{-x} - 3e^{3x}e^{-x} = -4e^{2x}$ so

$u_1' = -\dfrac{(x+2)e^{-x}}{-4e^{2x}} = \frac{1}{4}(x+2)e^{-3x} \quad \Rightarrow \quad u_1(x) = \frac{1}{4}\int (x+2)e^{-3x}\,dx = \frac{1}{4}\left[-\frac{1}{3}(x+2)e^{-3x} - \frac{1}{9}e^{-3x}\right]$ [by parts]

and $u_2' = \dfrac{(x+2)e^{3x}}{-4e^{2x}} = -\frac{1}{4}(x+2)e^{x} \quad \Rightarrow \quad u_2(x) = -\frac{1}{4}\int (x+2)e^{x}\,dx = -\frac{1}{4}[(x+2)e^{x} - e^{x}]$ [by parts].

Hence $y_p(x) = \frac{1}{4}\left[\left(-\frac{1}{3}x - \frac{7}{9}\right)e^{-3x}\right]e^{3x} - \frac{1}{4}[(x+1)e^{x}]\,e^{-x} = -\frac{1}{3}x - \frac{4}{9}$ and

$y(x) = y_c(x) + y_p(x) = c_1 e^{3x} + c_2 e^{-x} - \frac{1}{3}x - \frac{4}{9}$.

21. (a) $r^2 - 2r + 1 = (r-1)^2 = 0 \quad \Rightarrow \quad r = 1$, so the complementary solution is $y_c(x) = c_1 e^{x} + c_2 x e^{x}$. A particular solution is of the form $y_p(x) = Ae^{2x}$. Thus $4Ae^{2x} - 4Ae^{2x} + Ae^{2x} = e^{2x} \quad \Rightarrow \quad Ae^{2x} = e^{2x} \quad \Rightarrow \quad A = 1 \quad \Rightarrow \quad y_p(x) = e^{2x}$.

So a general solution is $y(x) = y_c(x) + y_p(x) = c_1 e^{x} + c_2 x e^{x} + e^{2x}$.

(b) From (a), $y_c(x) = c_1 e^{x} + c_2 x e^{x}$, so set $y_1 = e^{x}$, $y_2 = xe^{x}$. Then, $y_1 y_2' - y_2 y_1' = e^{2x}(1+x) - xe^{2x} = e^{2x}$ and so

$u_1' = -xe^{x} \quad \Rightarrow \quad u_1(x) = -\int xe^{x}\,dx = -(x-1)e^{x}$ [by parts] and $u_2' = e^{x} \quad \Rightarrow \quad u_2(x) = \int e^{x}\,dx = e^{x}$. Hence

$y_p(x) = (1-x)e^{2x} + xe^{2x} = e^{2x}$ and the general solution is $y(x) = y_c(x) + y_p(x) = c_1 e^{x} + c_2 x e^{x} + e^{2x}$.

22. (a) Here $r^2 - r = r(r-1) = 0 \quad \Rightarrow \quad r = 0, 1$ and $y_c(x) = c_1 + c_2 e^{x}$ and so we try a particular solution of the form

$y_p(x) = Axe^{x}$. Thus, after calculating the necessary derivatives, we get $y'' - y' = e^{x} \quad \Rightarrow$

$Ae^{x}(2+x) - Ae^{x}(1+x) = e^{x} \quad \Rightarrow \quad A = 1$. Thus $y_p(x) = xe^{x}$ and the general solution is $y(x) = c_1 + c_2 e^{x} + xe^{x}$.

(b) From (a) we know that $y_c(x) = c_1 + c_2 e^{x}$, so setting $y_1 = 1$, $y_2 = e^{x}$, then $y_1 y_2' - y_2 y_1' = e^{x} - 0 = e^{x}$. Thus

$u_1' = -e^{2x}/e^{x} = -e^{x}$ and $u_2' = e^{x}/e^{x} = 1$. Then $u_1(x) = -\int e^{x}\,dx = -e^{x}$ and $u_2(x) = x$. Thus

$y_p(x) = -e^{x} + xe^{x}$ and the general solution is $y(x) = c_1 + c_2 e^{x} - e^{x} + xe^{x} = c_1 + c_3 e^{x} + xe^{x}$.

23. As in Example 5, $y_c(x) = c_1 \sin x + c_2 \cos x$, so set $y_1 = \sin x$, $y_2 = \cos x$. Then $y_1 y_2' - y_2 y_1' = -\sin^2 x - \cos^2 x = -1$,

so $u_1' = -\dfrac{\sec^2 x \,\cos x}{-1} = \sec x \quad \Rightarrow \quad u_1(x) = \int \sec x\,dx = \ln(\sec x + \tan x)$ for $0 < x < \frac{\pi}{2}$,

and $u_2' = \dfrac{\sec^2 x \,\sin x}{-1} = -\sec x\,\tan x \quad \Rightarrow \quad u_2(x) = -\sec x$. Hence

$y_p(x) = \ln(\sec x + \tan x)\cdot \sin x - \sec x \cdot \cos x = \sin x \ln(\sec x + \tan x) - 1$ and the general solution is

$y(x) = c_1 \sin x + c_2 \cos x + \sin x\,\ln(\sec x + \tan x) - 1$.

24. As in Exercise 23, $y_c(x) = c_1 \sin x + c_2 \cos x$, $y_1 = \sin x$, $y_2 = \cos x$, and $y_1 y_2' - y_2 y_1' = -1$. Then

$u_1' = -\dfrac{\sec^3 x \cos x}{-1} = \sec^2 x \quad \Rightarrow \quad u_1(x) = \tan x$ and $u_2' = \dfrac{\sec^3 x \sin x}{-1} = -\sec^2 x \tan x \quad \Rightarrow$

$u_2(x) = -\int \tan x \sec^2 x\, dx = -\frac{1}{2}\tan^2 x$. Hence

$y_p(x) = \tan x \sin x - \frac{1}{2}\tan^2 x \cos x = \tan x \sin x - \frac{1}{2}\tan x \sin x = \frac{1}{2}\tan x \sin x$ and the general solution is $y(x) = c_1 \sin x + c_2 \cos x + \frac{1}{2}\tan x \sin x$.

25. $y_1 = e^x$, $y_2 = e^{2x}$ and $y_1 y_2' - y_2 y_1' = e^{3x}$. So $u_1' = \dfrac{-e^{2x}}{(1+e^{-x})e^{3x}} = -\dfrac{e^{-x}}{1+e^{-x}}$ and

$u_1(x) = \displaystyle\int -\frac{e^{-x}}{1+e^{-x}}\,dx = \ln(1+e^{-x})$. $\quad u_2' = \dfrac{e^x}{(1+e^{-x})e^{3x}} = \dfrac{e^x}{e^{3x}+e^{2x}}$ so

$u_2(x) = \displaystyle\int \frac{e^x}{e^{3x}+e^{2x}}\,dx = \ln\!\left(\frac{e^x+1}{e^x}\right) - e^{-x} = \ln(1+e^{-x}) - e^{-x}$. Hence

$y_p(x) = e^x \ln(1+e^{-x}) + e^{2x}[\ln(1+e^{-x}) - e^{-x}]$ and the general solution is

$y(x) = [c_1 + \ln(1+e^{-x})]e^x + [c_2 - e^{-x} + \ln(1+e^{-x})]e^{2x}$.

26. $y_1 = e^{-x}$, $y_2 = e^{-2x}$ and $y_1 y_2' - y_2 y_1' = -e^{-3x}$. So $u_1' = -\dfrac{(\sin e^x)e^{-2x}}{-e^{-3x}} = e^x \sin e^x$

and $u_2' = \dfrac{(\sin e^x)e^{-x}}{-e^{-3x}} = -e^{2x}\sin e^x$. Hence $u_1(x) = \int e^x \sin e^x dx = -\cos e^x$ and

$u_2(x) = \int -e^{2x}\sin e^x dx = e^x \cos e^x - \sin e^x$. Then $y_p(x) = -e^{-x}\cos e^x - e^{-2x}[\sin e^x - e^x \cos e^x]$

and the general solution is $y(x) = (c_1 - \cos e^x)e^{-x} + [c_2 - \sin e^x + e^x \cos e^x]e^{-2x}$.

27. $r^2 - 2r + 1 = (r-1)^2 = 0 \quad \Rightarrow \quad r = 1$ so $y_c(x) = c_1 e^x + c_2 x e^x$. Thus $y_1 = e^x$, $y_2 = xe^x$ and

$y_1 y_2' - y_2 y_1' = e^x(x+1)e^x - xe^x e^x = e^{2x}$. So $u_1' = -\dfrac{xe^x \cdot e^x/(1+x^2)}{e^{2x}} = -\dfrac{x}{1+x^2} \quad \Rightarrow$

$u_1 = -\displaystyle\int \frac{x}{1+x^2}\,dx = -\frac{1}{2}\ln\left(1+x^2\right)$, $u_2' = \dfrac{e^x \cdot e^x/(1+x^2)}{e^{2x}} = \dfrac{1}{1+x^2} \quad \Rightarrow \quad u_2 = \displaystyle\int \frac{1}{1+x^2}\,dx = \tan^{-1} x$ and

$y_p(x) = -\frac{1}{2}e^x \ln(1+x^2) + xe^x \tan^{-1} x$. Hence the general solution is $y(x) = e^x\left[c_1 + c_2 x - \frac{1}{2}\ln(1+x^2) + x\tan^{-1} x\right]$.

28. $y_1 = e^{-2x}$, $y_2 = xe^{-2x}$ and $y_1 y_2' - y_2 y_1' = e^{-4x}$. Then $u_1' = \dfrac{-e^{-2x}xe^{-2x}}{x^3 e^{-4x}} = -\dfrac{1}{x^2}$ so $u_1(x) = x^{-1}$ and

$u_2' = \dfrac{e^{-2x}e^{-2x}}{x^3 e^{-4x}} = \dfrac{1}{x^3}$ so $u_2(x) = -\dfrac{1}{2x^2}$. Thus $y_p(x) = \dfrac{e^{-2x}}{x} - \dfrac{xe^{-2x}}{2x^2} = \dfrac{e^{-2x}}{2x}$ and the general solution is

$y(x) = e^{-2x}[c_1 + c_2 x + 1/(2x)]$.

17.3 Applications of Second-Order Differential Equations

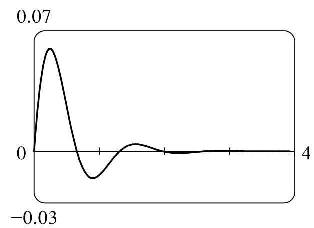
1. By Hooke's Law $k(0.25) = 25$ so $k = 100$ is the spring constant and the differential equation is $5x'' + 100x = 0$. The auxiliary equation is $5r^2 + 100 = 0$ with roots $r = \pm 2\sqrt{5}\,i$, so the general solution to the differential equation is $x(t) = c_1 \cos\left(2\sqrt{5}\,t\right) + c_2 \sin\left(2\sqrt{5}\,t\right)$. We are given that $x(0) = 0.35 \Rightarrow c_1 = 0.35$ and $x'(0) = 0 \Rightarrow 2\sqrt{5}\,c_2 = 0 \Rightarrow c_2 = 0$, so the position of the mass after t seconds is $x(t) = 0.35\cos\left(2\sqrt{5}\,t\right)$.

2. By Hooke's Law $k(0.4) = 32$ so $k = \frac{32}{0.4} = 80$ is the spring constant and the differential equation is $8x'' + 80x = 0$. The general solution is $x(t) = c_1 \cos\left(\sqrt{10}\,t\right) + c_2 \sin\left(\sqrt{10}\,t\right)$. But $0 = x(0) = c_1$ and $1 = x'(0) = \sqrt{10}\,c_2 \Rightarrow c_2 = \frac{1}{\sqrt{10}}$, so the position of the mass after t seconds is $x(t) = \frac{1}{\sqrt{10}}\sin\left(\sqrt{10}\,t\right)$.

3. $k(0.5) = 6$ or $k = 12$ is the spring constant, so the initial-value problem is $2x'' + 14x' + 12x = 0$, $x(0) = 1$, $x'(0) = 0$. The general solution is $x(t) = c_1 e^{-6t} + c_2 e^{-t}$. But $1 = x(0) = c_1 + c_2$ and $0 = x'(0) = -6c_1 - c_2$. Thus the position is given by $x(t) = -\frac{1}{5}e^{-6t} + \frac{6}{5}e^{-t}$.

4. (a) $k(0.25) = 13 \Rightarrow k = 52$, so the differential equation is $2x'' + 8x' + 52x = 0$ with general solution $x(t) = e^{-2t}\left[c_1 \cos\left(\sqrt{22}\,t\right) + c_2 \sin\left(\sqrt{22}\,t\right)\right]$. Then $0 = x(0) = c_1$ and $0.5 = x'(0) = \sqrt{22}\,c_2 \Rightarrow c_2 = \frac{1}{2\sqrt{22}}$, so the position is given by $x(t) = \frac{1}{2\sqrt{22}}e^{-2t}\sin\left(\sqrt{22}\,t\right)$.

(b)



5. For critical damping we need $c^2 - 4mk = 0$ or $m = c^2/(4k) = 14^2/(4 \cdot 12) = \frac{49}{12}$ kg.

6. For critical damping we need $c^2 = 4mk$ or $c = 2\sqrt{mk} = 2\sqrt{2 \cdot 52} = 4\sqrt{26}$.

7. We are given $m = 1$, $k = 100$, $x(0) = -0.1$ and $x'(0) = 0$. From (3), the differential equation is $\dfrac{d^2x}{dt^2} + c\dfrac{dx}{dt} + 100x = 0$ with auxiliary equation $r^2 + cr + 100 = 0$.

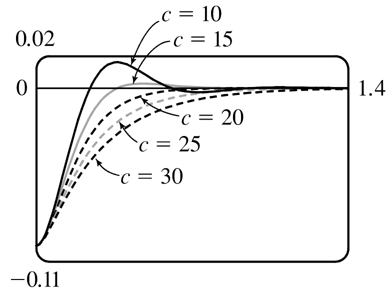
If $c = 10$, we have two complex roots $r = -5 \pm 5\sqrt{3}\,i$, so the motion is underdamped and the solution is $x = e^{-5t}\left[c_1 \cos\left(5\sqrt{3}\,t\right) + c_2 \sin\left(5\sqrt{3}\,t\right)\right]$. Then $-0.1 = x(0) = c_1$ and $0 = x'(0) = 5\sqrt{3}\,c_2 - 5c_1 \Rightarrow c_2 = -\frac{1}{10\sqrt{3}}$, so $x = e^{-5t}\left[-0.1\cos\left(5\sqrt{3}\,t\right) - \frac{1}{10\sqrt{3}}\sin\left(5\sqrt{3}\,t\right)\right]$.

If $c = 15$, we again have underdamping since the auxiliary equation has roots $r = -\frac{15}{2} \pm \frac{5\sqrt{7}}{2}i$. The general solution is $x = e^{-15t/2}\left[c_1 \cos\left(\frac{5\sqrt{7}}{2}t\right) + c_2 \sin\left(\frac{5\sqrt{7}}{2}t\right)\right]$, so $-0.1 = x(0) = c_1$ and $0 = x'(0) = \frac{5\sqrt{7}}{2}c_2 - \frac{15}{2}c_1 \Rightarrow c_2 = -\frac{3}{10\sqrt{7}}$. Thus $x = e^{-15t/2}\left[-0.1\cos\left(\frac{5\sqrt{7}}{2}t\right) - \frac{3}{10\sqrt{7}}\sin\left(\frac{5\sqrt{7}}{2}t\right)\right]$.

For $c = 20$, we have equal roots $r_1 = r_2 = -10$, so the oscillation is critically damped and the solution is $x = (c_1 + c_2 t)e^{-10t}$. Then $-0.1 = x(0) = c_1$ and $0 = x'(0) = -10c_1 + c_2 \Rightarrow c_2 = -1$, so $x = (-0.1 - t)e^{-10t}$.

If $c = 25$ the auxiliary equation has roots $r_1 = -5$, $r_2 = -20$, so we have overdamping and the solution is $x = c_1 e^{-5t} + c_2 e^{-20t}$. Then $-0.1 = x(0) = c_1 + c_2$ and $0 = x'(0) = -5c_1 - 20c_2 \Rightarrow c_1 = -\frac{2}{15}$ and $c_2 = \frac{1}{30}$, so $x = -\frac{2}{15}e^{-5t} + \frac{1}{30}e^{-20t}$.

If $c = 30$ we have roots $r = -15 \pm 5\sqrt{5}$, so the motion is overdamped and the solution is $x = c_1 e^{\left(-15+5\sqrt{5}\right)t} + c_2 e^{\left(-15-5\sqrt{5}\right)t}$.
Then $-0.1 = x(0) = c_1 + c_2$ and
$0 = x'(0) = \left(-15 + 5\sqrt{5}\right)c_1 + \left(-15 - 5\sqrt{5}\right)c_2 \Rightarrow$
$c_1 = \frac{-5-3\sqrt{5}}{100}$ and $c_2 = \frac{-5+3\sqrt{5}}{100}$, so
$x = \left(\frac{-5-3\sqrt{5}}{100}\right)e^{\left(-15+5\sqrt{5}\right)t} + \left(\frac{-5+3\sqrt{5}}{100}\right)e^{\left(-15-5\sqrt{5}\right)t}$.



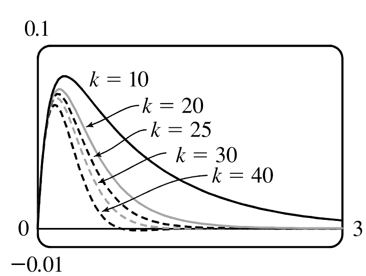
8. We are given $m = 1$, $c = 10$, $x(0) = 0$ and $x'(0) = 1$. The differential equation is $\frac{d^2x}{dt^2} + 10\frac{dx}{dt} + kx = 0$ with auxiliary equation $r^2 + 10r + k = 0$. $k = 10$: the auxiliary equation has roots $r = -5 \pm \sqrt{15}$ so we have overdamping and the solution is $x = c_1 e^{\left(-5+\sqrt{15}\right)t} + c_2 e^{\left(-5-\sqrt{15}\right)t}$. Entering the initial conditions gives $c_1 = \frac{1}{2\sqrt{15}}$ and $c_2 = -\frac{1}{2\sqrt{15}}$, so $x = \frac{1}{2\sqrt{15}}e^{\left(-5+\sqrt{15}\right)t} - \frac{1}{2\sqrt{15}}e^{\left(-5-\sqrt{15}\right)t}$.

$k = 20$: $r = -5 \pm \sqrt{5}$ and the solution is $x = c_1 e^{\left(-5+\sqrt{5}\right)t} + c_2 e^{\left(-5-\sqrt{5}\right)t}$ so again the motion is overdamped. The initial conditions give $c_1 = \frac{1}{2\sqrt{5}}$ and $c_2 = -\frac{1}{2\sqrt{5}}$, so $x = \frac{1}{2\sqrt{5}}e^{\left(-5+\sqrt{5}\right)t} - \frac{1}{2\sqrt{5}}e^{\left(-5-\sqrt{5}\right)t}$.

$k = 25$: we have equal roots $r_1 = r_2 = -5$, so the motion is critically damped and the solution is $x = (c_1 + c_2 t)e^{-5t}$. The initial conditions give $c_1 = 0$ and $c_2 = 1$, so $x = te^{-5t}$.

$k = 30$: $r = -5 \pm \sqrt{5}\,i$ so the motion is underdamped and the solution is $x = e^{-5t}\left[c_1 \cos\left(\sqrt{5}\,t\right) + c_2 \sin\left(\sqrt{5}\,t\right)\right]$. The initial conditions give $c_1 = 0$ and $c_2 = \frac{1}{\sqrt{5}}$, so $x = \frac{1}{\sqrt{5}}e^{-5t}\sin\left(\sqrt{5}\,t\right)$.

$k = 40$: $r = -5 \pm \sqrt{15}\,i$ so we again have underdamping.
The solution is $x = e^{-5t}\left[c_1 \cos\left(\sqrt{15}\,t\right) + c_2 \sin\left(\sqrt{15}\,t\right)\right]$,
and the initial conditions give $c_1 = 0$ and $c_2 = \frac{1}{\sqrt{15}}$.
Thus $x = \frac{1}{\sqrt{15}}e^{-5t}\sin\left(\sqrt{15}\,t\right)$.



9. The differential equation is $mx'' + kx = F_0 \cos \omega_0 t$ and $\omega_0 \neq \omega = \sqrt{k/m}$. Here the auxiliary equation is $mr^2 + k = 0$ with roots $\pm\sqrt{k/m}\,i = \pm\omega i$ so $x_c(t) = c_1 \cos \omega t + c_2 \sin \omega t$. Since $\omega_0 \neq \omega$, try $x_p(t) = A\cos\omega_0 t + B\sin\omega_0 t$. Then we need $(m)\left(-\omega_0^2\right)(A\cos\omega_0 t + B\sin\omega_0 t) + k(A\cos\omega_0 t + B\sin\omega_0 t) = F_0\cos\omega_0 t$ or $A\left(k - m\omega_0^2\right) = F_0$ and

$B(k - m\omega_0^2) = 0$. Hence $B = 0$ and $A = \dfrac{F_0}{k - m\omega_0^2} = \dfrac{F_0}{m(\omega^2 - \omega_0^2)}$ since $\omega^2 = \dfrac{k}{m}$. Thus the motion of the mass is given by $x(t) = c_1 \cos \omega t + c_2 \sin \omega t + \dfrac{F_0}{m(\omega^2 - \omega_0^2)} \cos \omega_0 t$.

10. As in Exercise 9, $x_c(t) = c_1 \cos \omega t + c_2 \sin \omega t$. But the natural frequency of the system equals the frequency of the external force, so try $x_p(t) = t(A \cos \omega t + B \sin \omega t)$. Then we need

$m(2\omega B - \omega^2 At) \cos \omega t - m(2\omega A + \omega^2 Bt) \sin \omega t + kAt \cos \omega t + kBt \sin \omega t = F_0 \cos \omega t$ or $2m\omega B = F_0$ and $-2m\omega A = 0$ [noting $-m\omega^2 A + kA = 0$ and $-m\omega^2 B + kB = 0$ since $\omega^2 = k/m$]. Hence the general solution is $x(t) = c_1 \cos \omega t + c_2 \sin \omega t + [F_0 t/(2m\omega)] \sin \omega t$.

11. From Equation 6, $x(t) = f(t) + g(t)$ where $f(t) = c_1 \cos \omega t + c_2 \sin \omega t$ and $g(t) = \dfrac{F_0}{m(\omega^2 - \omega_0^2)} \cos \omega_0 t$. Then f is periodic, with period $\frac{2\pi}{\omega}$, and if $\omega \neq \omega_0$, g is periodic with period $\frac{2\pi}{\omega_0}$. If $\frac{\omega}{\omega_0}$ is a rational number, then we can say $\frac{\omega}{\omega_0} = \frac{a}{b} \;\Rightarrow\; a = \frac{b\omega}{\omega_0}$ where a and b are non-zero integers. Then

$x\left(t + a \cdot \frac{2\pi}{\omega}\right) = f\left(t + a \cdot \frac{2\pi}{\omega}\right) + g\left(t + a \cdot \frac{2\pi}{\omega}\right) = f(t) + g\left(t + \frac{b\omega}{\omega_0} \cdot \frac{2\pi}{\omega}\right) = f(t) + g\left(t + b \cdot \frac{2\pi}{\omega_0}\right) = f(t) + g(t) = x(t)$

so $x(t)$ is periodic.

12. (a) The graph of $x = c_1 e^{rt} + c_2 t e^{rt}$ has a t-intercept when $c_1 e^{rt} + c_2 t e^{rt} = 0 \;\Leftrightarrow\; e^{rt}(c_1 + c_2 t) = 0 \;\Leftrightarrow\; c_1 = -c_2 t$. Since $t > 0$, x has a t-intercept if and only if c_1 and c_2 have opposite signs.

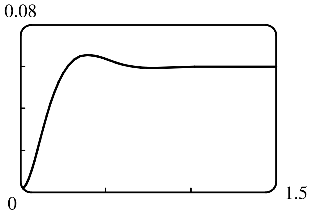
(b) For $t > 0$, the graph of x crosses the t-axis when $c_1 e^{r_1 t} + c_2 e^{r_2 t} = 0 \;\Leftrightarrow\; c_2 e^{r_2 t} = -c_1 e^{r_1 t} \;\Leftrightarrow$ $c_2 = -c_1 \dfrac{e^{r_1 t}}{e^{r_2 t}} = -c_1 e^{(r_1 - r_2)t}$. But $r_1 > r_2 \;\Rightarrow\; r_1 - r_2 > 0$ and since $t > 0$, $e^{(r_1 - r_2)t} > 1$. Thus $|c_2| = |c_1|\, e^{(r_1 - r_2)t} > |c_1|$, and the graph of x can cross the t-axis only if $|c_2| > |c_1|$.

13. Here the initial-value problem for the charge is $Q'' + 20Q' + 500Q = 12$, $Q(0) = Q'(0) = 0$. Then $Q_c(t) = e^{-10t}(c_1 \cos 20t + c_2 \sin 20t)$ and try $Q_p(t) = A \;\Rightarrow\; 500A = 12$ or $A = \frac{3}{125}$.

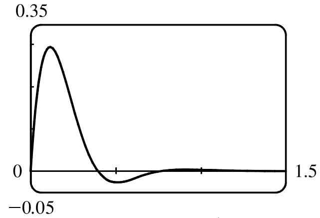
The general solution is $Q(t) = e^{-10t}(c_1 \cos 20t + c_2 \sin 20t) + \frac{3}{125}$. But $0 = Q(0) = c_1 + \frac{3}{125}$ and $Q'(t) = I(t) = e^{-10t}[(-10c_1 + 20c_2) \cos 20t + (-10c_2 - 20c_1) \sin 20t]$ but $0 = Q'(0) = -10c_1 + 20c_2$. Thus the charge is $Q(t) = -\frac{1}{250} e^{-10t}(6 \cos 20t + 3 \sin 20t) + \frac{3}{125}$ and the current is $I(t) = e^{-10t}\left(\frac{3}{5}\right) \sin 20t$.

14. (a) Here the initial-value problem for the charge is $2Q'' + 24Q' + 200Q = 12$ with $Q(0) = 0.001$ and $Q'(0) = 0$. Then $Q_c(t) = e^{-6t}(c_1 \cos 8t + c_2 \sin 8t)$ and try $Q_p(t) = A \;\Rightarrow\; A = \frac{3}{50}$ and the general solution is $Q(t) = e^{-6t}(c_1 \cos 8t + c_2 \sin 8t) + \frac{3}{50}$. But $0.001 = Q(0) = c + \frac{3}{50}$ so $c_1 = -0.059$. Also $Q'(t) = I(t) = e^{-6t}[(-6c_1 + 8c_2) \cos 8t + (-6c_2 - 8c_1) \sin 8t]$ and $0 = Q'(0) = -6c_1 + 8c_2$ so $c_2 = -0.04425$. Hence the charge is $Q(t) = -e^{-6t}(0.059 \cos 8t + 0.04425 \sin 8t) + \frac{3}{50}$ and the current is $I(t) = e^{-6t}(0.7375) \sin 8t$.

(b)



charge, $Q(t)$

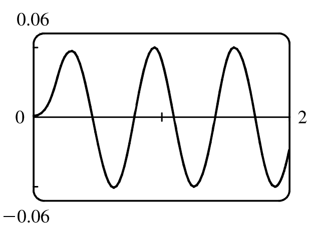


current, $I(t) = Q'(t)$

15. As in Exercise 13, $Q_c(t) = e^{-10t}(c_1 \cos 20t + c_2 \sin 20t)$ but $E(t) = 12 \sin 10t$ so try $Q_p(t) = A \cos 10t + B \sin 10t$. Substituting into the differential equation gives $(-100A + 200B + 500A) \cos 10t + (-100B - 200A + 500B) \sin 10t = 12 \sin 10t \quad \Rightarrow$ $400A + 200B = 0$ and $400B - 200A = 12$. Thus $A = -\frac{3}{250}$, $B = \frac{3}{125}$ and the general solution is $Q(t) = e^{-10t}(c_1 \cos 20t + c_2 \sin 20t) - \frac{3}{250} \cos 10t + \frac{3}{125} \sin 10t$. But $0 = Q(0) = c_1 - \frac{3}{250}$ so $c_1 = \frac{3}{250}$. Also $Q'(t) = \frac{3}{25} \sin 10t + \frac{6}{25} \cos 10t + e^{-10t}[(-10c_1 + 20c_2) \cos 20t + (-10c_2 - 20c_1) \sin 20t]$ and $0 = Q'(0) = \frac{6}{25} - 10c_1 + 20c_2$ so $c_2 = -\frac{3}{500}$. Hence the charge is given by $Q(t) = e^{-10t}\left[\frac{3}{250} \cos 20t - \frac{3}{500} \sin 20t\right] - \frac{3}{250} \cos 10t + \frac{3}{125} \sin 10t$.

16. (a) As in Exercise 14, $Q_c(t) = e^{-6t}(c_1 \cos 8t + c_2 \sin 8t)$ but try $Q_p(t) = A \cos 10t + B \sin 10t$. Substituting into the differential equation gives $(-200A + 240B + 200A) \cos 10t + (-200B - 240A + 200B) \sin 10t = 12 \sin 10t$, so $B = 0$ and $A = -\frac{1}{20}$. Hence, the general solution is $Q(t) = e^{-6t}(c_1 \cos 8t + c_2 \sin 8t) - \frac{1}{20} \cos 10t$. But $0.001 = Q(0) = c_1 - \frac{1}{20}$, $Q'(t) = e^{-6t}[(-6c_1 + 8c_2) \cos 8t + (-6c_2 - 8c_1) \sin 8t] - \frac{1}{2} \sin 10t$ and $0 = Q'(0) = -6c_1 + 8c_2$, so $c_1 = 0.051$ and $c_2 = 0.03825$. Thus the charge is given by $Q(t) = e^{-6t}(0.051 \cos 8t + 0.03825 \sin 8t) - \frac{1}{20} \cos 10t$.

(b)



17. $x(t) = A\cos(\omega t + \delta) \quad \Leftrightarrow \quad x(t) = A[\cos \omega t \cos \delta - \sin \omega t \sin \delta] \quad \Leftrightarrow \quad x(t) = A\left(\dfrac{c_1}{A} \cos \omega t + \dfrac{c_2}{A} \sin \omega t\right)$ where $\cos \delta = c_1/A$ and $\sin \delta = -c_2/A \quad \Leftrightarrow \quad x(t) = c_1 \cos \omega t + c_2 \sin \omega t$. [Note that $\cos^2 \delta + \sin^2 \delta = 1 \quad \Rightarrow \quad c_1^2 + c_2^2 = A^2$.]

18. (a) We approximate $\sin \theta$ by θ and, with $L = 1$ and $g = 9.8$, the differential equation becomes $\dfrac{d^2\theta}{dt^2} + 9.8\theta = 0$. The auxiliary equation is $r^2 + 9.8 = 0 \quad \Rightarrow \quad r = \pm\sqrt{9.8}\, i$, so the general solution is $\theta(t) = c_1 \cos\left(\sqrt{9.8}\, t\right) + c_2 \sin\left(\sqrt{9.8}\, t\right)$.

Then $0.2 = \theta(0) = c_1$ and $1 = \theta'(0) = \sqrt{9.8}\,c_2 \quad \Rightarrow \quad c_2 = \frac{1}{\sqrt{9.8}}$, so the equation is

$\theta(t) = 0.2\cos\left(\sqrt{9.8}\,t\right) + \frac{1}{\sqrt{9.8}}\sin\left(\sqrt{9.8}\,t\right)$.

(b) $\theta'(t) = -0.2\sqrt{9.8}\sin\left(\sqrt{9.8}\,t\right) + \cos\left(\sqrt{9.8}\,t\right) = 0$ or $\tan\left(\sqrt{9.8}\,t\right) = \frac{5}{\sqrt{9.8}}$, so the critical numbers are

$t = \frac{1}{\sqrt{9.8}}\tan^{-1}\left(\frac{5}{\sqrt{9.8}}\right) + \frac{n}{\sqrt{9.8}}\,\pi$ (n any integer). The maximum angle from the vertical is

$\theta\left(\frac{1}{\sqrt{9.8}}\tan^{-1}\left(\frac{5}{\sqrt{9.8}}\right)\right) \approx 0.377$ radians (or about 21.7°).

(c) From part (b), the critical numbers of $\theta(t)$ are spaced $\frac{\pi}{\sqrt{9.8}}$ apart, and the time between successive maximum values is $2\left(\frac{\pi}{\sqrt{9.8}}\right)$. Thus the period of the pendulum is $\frac{2\pi}{\sqrt{9.8}} \approx 2.007$ seconds.

(d) $\theta(t) = 0 \quad \Rightarrow \quad 0.2\cos\left(\sqrt{9.8}\,t\right) + \frac{1}{\sqrt{9.8}}\sin\left(\sqrt{9.8}\,t\right) = 0 \quad \Rightarrow \quad \tan\left(\sqrt{9.8}\,t\right) = -0.2\sqrt{9.8} \quad \Rightarrow$

$t = \frac{1}{\sqrt{9.8}}\left[\tan^{-1}\left(-0.2\sqrt{9.8}\right) + \pi\right] \approx 0.825$ seconds.

(e) $\theta'(0.825) \approx -1.180$ rad/s.

17.4 Series Solutions

1. Let $y(x) = \sum\limits_{n=0}^{\infty} c_n x^n$. Then $y'(x) = \sum\limits_{n=1}^{\infty} nc_n x^{n-1}$ and the given equation, $y' - y = 0$, becomes

$\sum\limits_{n=1}^{\infty} nc_n x^{n-1} - \sum\limits_{n=0}^{\infty} c_n x^n = 0$. Replacing n by $n+1$ in the first sum gives $\sum\limits_{n=0}^{\infty} (n+1)c_{n+1}x^n - \sum\limits_{n=0}^{\infty} c_n x^n = 0$, so

$\sum\limits_{n=0}^{\infty} [(n+1)c_{n+1} - c_n]x^n = 0$. Equating coefficients gives $(n+1)c_{n+1} - c_n = 0$, so the recursion relation is

$c_{n+1} = \dfrac{c_n}{n+1}$, $n = 0, 1, 2, \ldots$. Then $c_1 = c_0$, $c_2 = \dfrac{1}{2}c_1 = \dfrac{c_0}{2}$, $c_3 = \dfrac{1}{3}c_2 = \dfrac{1}{3}\cdot\dfrac{1}{2}c_0 = \dfrac{c_0}{3!}$, $c_4 = \dfrac{1}{4}c_3 = \dfrac{c_0}{4!}$, and

in general, $c_n = \dfrac{c_0}{n!}$. Thus, the solution is $y(x) = \sum\limits_{n=0}^{\infty} c_n x^n = \sum\limits_{n=0}^{\infty} \dfrac{c_0}{n!}\,x^n = c_0\sum\limits_{n=0}^{\infty} \dfrac{x^n}{n!} = c_0 e^x$.

2. Let $y(x) = \sum\limits_{n=0}^{\infty} c_n x^n$. Then $y' = xy \quad \Rightarrow \quad y' - xy = 0 \quad \Rightarrow \quad \sum\limits_{n=1}^{\infty} nc_n x^{n-1} - x\sum\limits_{n=0}^{\infty} c_n x^n = 0$ or

$\sum\limits_{n=1}^{\infty} nc_n x^{n-1} - \sum\limits_{n=0}^{\infty} c_n x^{n+1} = 0$. Replacing n with $n+1$ in the first sum and n with $n-1$ in the second

gives $\sum\limits_{n=0}^{\infty} (n+1)c_{n+1}x^n - \sum\limits_{n=1}^{\infty} c_{n-1}x^n = 0$ or $c_1 + \sum\limits_{n=1}^{\infty} (n+1)\,c_{n+1}x^n - \sum\limits_{n=1}^{\infty} c_{n-1}x^n = 0$. Thus,

$c_1 + \sum\limits_{n=1}^{\infty} [(n+1)c_{n+1} - c_{n-1}]\,x^n = 0$. Equating coefficients gives $c_1 = 0$ and $(n+1)\,c_{n+1} - c_{n-1} = 0$. Thus, the

recursion relation is $c_{n+1} = \dfrac{c_{n-1}}{n+1}$, $n = 1, 2, \ldots$. But $c_1 = 0$, so $c_3 = 0$ and $c_5 = 0$ and in general $c_{2n+1} = 0$. Also,

$c_2 = \frac{c_0}{2}$, $c_4 = \frac{c_2}{4} = \frac{c_0}{4 \cdot 2} = \frac{c_0}{2^2 \cdot 2!}$, $c_6 = \frac{c_4}{6} = \frac{c_0}{6 \cdot 4 \cdot 2} = \frac{c_0}{2^3 \cdot 3!}$ and in general $c_{2n} = \frac{c_0}{2^n \cdot n!}$. Thus, the solution is $y(x) = \sum_{n=0}^{\infty} c_n x^n = \sum_{n=0}^{\infty} c_{2n} x^{2n} = \sum_{n=0}^{\infty} \frac{c_0}{2^n \cdot n!} x^{2n} = c_0 \sum_{n=0}^{\infty} \frac{(x^2/2)^n}{n!} = c_0 e^{x^2/2}$.

3. Assuming $y(x) = \sum_{n=0}^{\infty} c_n x^n$, we have $y'(x) = \sum_{n=1}^{\infty} n c_n x^{n-1} = \sum_{n=0}^{\infty} (n+1) c_{n+1} x^n$ and

$-x^2 y = -\sum_{n=0}^{\infty} c_n x^{n+2} = -\sum_{n=2}^{\infty} c_{n-2} x^n$. Hence, the equation $y' = x^2 y$ becomes $\sum_{n=0}^{\infty} (n+1) c_{n+1} x^n - \sum_{n=2}^{\infty} c_{n-2} x^n = 0$

or $c_1 + 2c_2 x + \sum_{n=2}^{\infty} [(n+1)c_{n+1} - c_{n-2}]\, x^n = 0$. Equating coefficients gives $c_1 = c_2 = 0$ and $c_{n+1} = \frac{c_{n-2}}{n+1}$

for $n = 2, 3, \ldots$. But $c_1 = 0$, so $c_4 = 0$ and $c_7 = 0$ and in general $c_{3n+1} = 0$. Similarly $c_2 = 0$ so $c_{3n+2} = 0$. Finally

$c_3 = \frac{c_0}{3}$, $c_6 = \frac{c_3}{6} = \frac{c_0}{6 \cdot 3} = \frac{c_0}{3^2 \cdot 2!}$, $c_9 = \frac{c_6}{9} = \frac{c_0}{9 \cdot 6 \cdot 3} = \frac{c_0}{3^3 \cdot 3!}$, ..., and $c_{3n} = \frac{c_0}{3^n \cdot n!}$. Thus, the solution

is $y(x) = \sum_{n=0}^{\infty} c_n x^n = \sum_{n=0}^{\infty} c_{3n} x^{3n} = \sum_{n=0}^{\infty} \frac{c_0}{3^n \cdot n!} x^{3n} = c_0 \sum_{n=0}^{\infty} \frac{x^{3n}}{3^n n!} = c_0 \sum_{n=0}^{\infty} \frac{(x^3/3)^n}{n!} = c_0 e^{x^3/3}$.

4. Let $y(x) = \sum_{n=0}^{\infty} c_n x^n \;\Rightarrow\; y'(x) = \sum_{n=1}^{\infty} n c_n x^{n-1} = \sum_{n=0}^{\infty} (n+1) c_{n+1} x^n$. Then the differential equation becomes

$$(x-3) \sum_{n=0}^{\infty} (n+1) c_{n+1} x^n + 2 \sum_{n=0}^{\infty} c_n x^n = 0 \;\Rightarrow\; \sum_{n=0}^{\infty} (n+1) c_{n+1} x^{n+1} - 3 \sum_{n=0}^{\infty} (n+1) c_{n+1} x^n + 2 \sum_{n=0}^{\infty} c_n x^n = 0 \;\Rightarrow$$

$$\sum_{n=1}^{\infty} n c_n x^n - \sum_{n=0}^{\infty} 3(n+1) c_{n+1} x^n + \sum_{n=0}^{\infty} 2 c_n x^n = 0 \;\Rightarrow\; \sum_{n=0}^{\infty} [(n+2)c_n - 3(n+1)c_{n+1}] x^n = 0$$

$\left[\text{since } \sum_{n=1}^{\infty} n c_n x^n = \sum_{n=0}^{\infty} n c_n x^n\right]$. Equating coefficients gives $(n+2)c_n - 3(n+1)c_{n+1} = 0$, thus the recursion relation is

$c_{n+1} = \frac{(n+2)c_n}{3(n+1)}$, $n = 0, 1, 2, \ldots$. Then $c_1 = \frac{2c_0}{3}$, $c_2 = \frac{3c_1}{3(2)} = \frac{3c_0}{3^2}$, $c_3 = \frac{4c_2}{3(3)} = \frac{4c_0}{3^3}$, $c_4 = \frac{5c_3}{3(4)} = \frac{5c_0}{3^4}$, and

in general, $c_n = \frac{(n+1)c_0}{3^n}$. Thus the solution is $y(x) = \sum_{n=0}^{\infty} c_n x^n = c_0 \sum_{n=0}^{\infty} \frac{n+1}{3^n} x^n$.

$\left[\text{Note that } c_0 \sum_{n=0}^{\infty} \frac{n+1}{3^n} x^n = \frac{9c_0}{(3-x)^2} \text{ for } |x| < 3.\right]$

5. Let $y(x) = \sum_{n=0}^{\infty} c_n x^n \;\Rightarrow\; y'(x) = \sum_{n=1}^{\infty} n c_n x^{n-1}$ and $y''(x) = \sum_{n=0}^{\infty} (n+2)(n+1) c_{n+2} x^n$. The differential equation

becomes $\sum_{n=0}^{\infty} (n+2)(n+1) c_{n+2} x^n + x \sum_{n=1}^{\infty} n c_n x^{n-1} + \sum_{n=0}^{\infty} c_n x^n = 0$ or $\sum_{n=0}^{\infty} [(n+2)(n+1)c_{n+2} + n c_n + c_n] x^n = 0$

$\left[\text{since } \sum_{n=1}^{\infty} n c_n x^n = \sum_{n=0}^{\infty} n c_n x^n\right]$. Equating coefficients gives $(n+2)(n+1)c_{n+2} + (n+1)c_n = 0$, thus the recursion

relation is $c_{n+2} = \frac{-(n+1)c_n}{(n+2)(n+1)} = -\frac{c_n}{n+2}$, $n = 0, 1, 2, \ldots$. Then the even

coefficients are given by $c_2 = -\frac{c_0}{2}$, $c_4 = -\frac{c_2}{4} = \frac{c_0}{2 \cdot 4}$, $c_6 = -\frac{c_4}{6} = -\frac{c_0}{2 \cdot 4 \cdot 6}$, and in general,

$c_{2n} = (-1)^n \dfrac{c_0}{2 \cdot 4 \cdot \cdots \cdot 2n} = \dfrac{(-1)^n c_0}{2^n\, n!}$. The odd coefficients are $c_3 = -\dfrac{c_1}{3}$, $c_5 = -\dfrac{c_3}{5} = \dfrac{c_1}{3 \cdot 5}$, $c_7 = -\dfrac{c_5}{7} = -\dfrac{c_1}{3 \cdot 5 \cdot 7}$,

and in general, $c_{2n+1} = (-1)^n \dfrac{c_1}{3 \cdot 5 \cdot 7 \cdot \cdots \cdot (2n+1)} = \dfrac{(-2)^n\, n!\, c_1}{(2n+1)!}$. The solution is

$$y(x) = c_0 \sum_{n=0}^{\infty} \frac{(-1)^n}{2^n\, n!} x^{2n} + c_1 \sum_{n=0}^{\infty} \frac{(-2)^n\, n!}{(2n+1)!} x^{2n+1}.$$

6. Let $y(x) = \sum\limits_{n=0}^{\infty} c_n x^n$. Then $y''(x) = \sum\limits_{n=2}^{\infty} n(n-1)c_n x^{n-2} = \sum\limits_{n=0}^{\infty} (n+2)(n+1)c_{n+2} x^n$. Hence, the equation $y'' = y$ becomes $\sum\limits_{n=0}^{\infty} (n+2)(n+1)c_{n+2}x^n - \sum\limits_{n=0}^{\infty} c_n x^n = 0$ or $\sum\limits_{n=0}^{\infty} [(n+2)(n+1)c_{n+2} - c_n]x^n = 0$. So the recursion relation is $c_{n+2} = \dfrac{c_n}{(n+2)(n+1)}$, $n = 0, 1, \ldots$. Given c_0 and c_1, $c_2 = \dfrac{c_0}{2 \cdot 1}$, $c_4 = \dfrac{c_2}{4 \cdot 3} = \dfrac{c_0}{4!}$, $c_6 = \dfrac{c_4}{6 \cdot 5} = \dfrac{c_0}{6!}, \ldots,$ $c_{2n} = \dfrac{c_0}{(2n)!}$ and $c_3 = \dfrac{c_1}{3 \cdot 2}$, $c_5 = \dfrac{c_3}{5 \cdot 4} = \dfrac{c_1}{5 \cdot 4 \cdot 3 \cdot 2} = \dfrac{c_1}{5!}$, $c_7 = \dfrac{c_5}{7 \cdot 6} = \dfrac{c_1}{7!}, \ldots, c_{2n+1} = \dfrac{c_1}{(2n+1)!}$. Thus, the solution is $y(x) = \sum\limits_{n=0}^{\infty} c_n x^n = \sum\limits_{n=0}^{\infty} c_{2n}x^{2n} + \sum\limits_{n=0}^{\infty} c_{2n+1}x^{2n+1} = c_0 \sum\limits_{n=0}^{\infty} \dfrac{x^{2n}}{(2n)!} + c_1 \sum\limits_{n=0}^{\infty} \dfrac{x^{2n+1}}{(2n+1)!}$. The solution can be written as $y(x) = c_0 \cosh x + c_1 \sinh x$ $\left[\text{or } y(x) = c_0 \dfrac{e^x + e^{-x}}{2} + c_1 \dfrac{e^x - e^{-x}}{2} = \dfrac{c_0 + c_1}{2} e^x + \dfrac{c_0 - c_1}{2} e^{-x}\right]$.

7. Let $y(x) = \sum\limits_{n=0}^{\infty} c_n x^n \;\Rightarrow\; y'(x) = \sum\limits_{n=1}^{\infty} nc_n x^{n-1} = \sum\limits_{n=0}^{\infty} (n+1)c_{n+1}x^n$ and $y''(x) = \sum\limits_{n=0}^{\infty} (n+2)(n+1)c_{n+2}x^n$. Then

$$(x-1)y''(x) = \sum_{n=0}^{\infty} (n+2)(n+1)c_{n+2}x^{n+1} - \sum_{n=0}^{\infty} (n+2)(n+1)c_{n+2}x^n = \sum_{n=1}^{\infty} n(n+1)c_{n+1}x^n - \sum_{n=0}^{\infty} (n+2)(n+1)c_{n+2}x^n.$$

Since $\sum\limits_{n=1}^{\infty} n(n+1)c_{n+1}x^n = \sum\limits_{n=0}^{\infty} n(n+1)c_{n+1}x^n$, the differential equation becomes

$$\sum_{n=0}^{\infty} n(n+1)c_{n+1}x^n - \sum_{n=0}^{\infty} (n+2)(n+1)c_{n+2}x^n + \sum_{n=0}^{\infty} (n+1)c_{n+1}x^n = 0 \quad\Rightarrow$$

$$\sum_{n=0}^{\infty} [n(n+1)c_{n+1} - (n+2)(n+1)c_{n+2} + (n+1)c_{n+1}]x^n = 0 \;\text{ or }\; \sum_{n=0}^{\infty} [(n+1)^2 c_{n+1} - (n+2)(n+1)c_{n+2}]x^n = 0.$$

Equating coefficients gives $(n+1)^2 c_{n+1} - (n+2)(n+1)c_{n+2} = 0$ for $n = 0, 1, 2, \ldots$. Then the recursion relation is $c_{n+2} = \dfrac{(n+1)^2}{(n+2)(n+1)} c_{n+1} = \dfrac{n+1}{n+2} c_{n+1}$, so given c_0 and c_1, we have $c_2 = \frac{1}{2}c_1$, $c_3 = \frac{2}{3}c_2 = \frac{1}{3}c_1$, $c_4 = \frac{3}{4}c_3 = \frac{1}{4}c_1$, and in general $c_n = \dfrac{c_1}{n}$, $n = 1, 2, 3, \ldots$. Thus the solution is $y(x) = c_0 + c_1 \sum\limits_{n=1}^{\infty} \dfrac{x^n}{n}$. Note that the solution can be expressed as $c_0 - c_1 \ln(1 - x)$ for $|x| < 1$.

8. Assuming $y(x) = \sum\limits_{n=0}^{\infty} c_n x^n$, $y''(x) = \sum\limits_{n=2}^{\infty} n(n-1)c_n x^{n-2} = \sum\limits_{n=0}^{\infty} (n+2)(n+1)c_{n+2}x^n$ and $-xy(x) = -\sum\limits_{n=0}^{\infty} c_n x^{n+1} = -\sum\limits_{n=1}^{\infty} c_{n-1}x^n$. The equation $y'' = xy$ becomes

$\sum_{n=0}^{\infty}(n+2)(n+1)c_{n+2}x^n - \sum_{n=1}^{\infty}c_{n-1}x^n = 0$ or $2c_2 + \sum_{n=1}^{\infty}[(n+2)(n+1)c_{n+2} - c_{n-1}]x^n = 0$. Equating coefficients gives $c_2 = 0$ and $c_{n+2} = \dfrac{c_{n-1}}{(n+2)(n+1)}$ for $n = 1, 2, \ldots$. Since $c_2 = 0$, $c_{3n+2} = 0$ for $n = 0, 1, 2, \ldots$. Given c_0, $c_3 = \dfrac{c_0}{3 \cdot 2}$, $c_6 = \dfrac{c_3}{6 \cdot 5} = \dfrac{c_0}{6 \cdot 5 \cdot 3 \cdot 2}, \ldots, c_{3n} = \dfrac{c_0}{3n(3n-1)(3n-3)(3n-4) \cdot \cdots \cdot 6 \cdot 5 \cdot 3 \cdot 2}$. Given c_1, $c_4 = \dfrac{c_1}{4 \cdot 3}$, $c_7 = \dfrac{c_4}{7 \cdot 6} = \dfrac{c_1}{7 \cdot 6 \cdot 4 \cdot 3}, \ldots, c_{3n+1} = \dfrac{c_1}{(3n+1)3n(3n-2)(3n-3) \ldots 7 \cdot 6 \cdot 4 \cdot 3}$. The solution can be written as $y(x) = c_0 \sum_{n=0}^{\infty} \dfrac{(3n-2)(3n-5) \cdot \cdots \cdot 7 \cdot 4 \cdot 1}{(3n)!} x^{3n} + c_1 \sum_{n=0}^{\infty} \dfrac{(3n-1)(3n-4) \cdot \cdots \cdot 8 \cdot 5 \cdot 2}{(3n+1)!} x^{3n+1}$.

9. Let $y(x) = \sum_{n=0}^{\infty} c_n x^n$. Then $-xy'(x) = -x \sum_{n=1}^{\infty} nc_n x^{n-1} = -\sum_{n=1}^{\infty} nc_n x^n = -\sum_{n=0}^{\infty} nc_n x^n$,

$y''(x) = \sum_{n=0}^{\infty}(n+2)(n+1)c_{n+2}x^n$, and the equation $y'' - xy' - y = 0$ becomes

$\sum_{n=0}^{\infty}[(n+2)(n+1)c_{n+2} - nc_n - c_n]x^n = 0$. Thus, the recursion relation is

$c_{n+2} = \dfrac{nc_n + c_n}{(n+2)(n+1)} = \dfrac{c_n(n+1)}{(n+2)(n+1)} = \dfrac{c_n}{n+2}$ for $n = 0, 1, 2, \ldots$. One of the given conditions is $y(0) = 1$. But $y(0) = \sum_{n=0}^{\infty} c_n(0)^n = c_0 + 0 + 0 + \cdots = c_0$, so $c_0 = 1$. Hence, $c_2 = \dfrac{c_0}{2} = \dfrac{1}{2}$, $c_4 = \dfrac{c_2}{4} = \dfrac{1}{2 \cdot 4}$, $c_6 = \dfrac{c_4}{6} = \dfrac{1}{2 \cdot 4 \cdot 6}, \ldots,$ $c_{2n} = \dfrac{1}{2^n n!}$. The other given condition is $y'(0) = 0$. But $y'(0) = \sum_{n=1}^{\infty} nc_n(0)^{n-1} = c_1 + 0 + 0 + \cdots = c_1$, so $c_1 = 0$. By the recursion relation, $c_3 = \dfrac{c_1}{3} = 0$, $c_5 = 0, \ldots, c_{2n+1} = 0$ for $n = 0, 1, 2, \ldots$. Thus, the solution to the initial-value problem is $y(x) = \sum_{n=0}^{\infty} c_n x^n = \sum_{n=0}^{\infty} c_{2n} x^{2n} = \sum_{n=0}^{\infty} \dfrac{x^{2n}}{2^n n!} = \sum_{n=0}^{\infty} \dfrac{(x^2/2)^n}{n!} = e^{x^2/2}$.

10. Assuming that $y(x) = \sum_{n=0}^{\infty} c_n x^n$, we have $x^2 y = \sum_{n=0}^{\infty} c_n x^{n+2}$ and

$y''(x) = \sum_{n=2}^{\infty} n(n-1)c_n x^{n-2} = \sum_{n=-2}^{\infty}(n+4)(n+3)c_{n+4}x^{n+2} = 2c_2 + 6c_3 x + \sum_{n=0}^{\infty}(n+4)(n+3)c_{n+4}x^{n+2}$.

Thus, the equation $y'' + x^2 y = 0$ becomes $2c_2 + 6c_3 x + \sum_{n=0}^{\infty}[(n+4)(n+3)c_{n+4} + c_n]\, x^{n+2} = 0$. So $c_2 = c_3 = 0$ and the recursion relation is $c_{n+4} = -\dfrac{c_n}{(n+4)(n+3)}$, $n = 0, 1, 2, \ldots$. But $c_1 = y'(0) = 0 = c_2 = c_3$ and by the recursion relation, $c_{4n+1} = c_{4n+2} = c_{4n+3} = 0$ for $n = 0, 1, 2, \ldots$. Also, $c_0 = y(0) = 1$, so $c_4 = -\dfrac{c_0}{4 \cdot 3} = -\dfrac{1}{4 \cdot 3}$, $c_8 = -\dfrac{c_4}{8 \cdot 7} = \dfrac{(-1)^2}{8 \cdot 7 \cdot 4 \cdot 3}, \ldots, c_{4n} = \dfrac{(-1)^n}{4n(4n-1)(4n-4)(4n-5) \cdot \cdots \cdot 4 \cdot 3}$. Thus, the solution to the initial-value problem is $y(x) = \sum_{n=0}^{\infty} c_n x^n = c_0 + \sum_{n=0}^{\infty} c_{4n} x^{4n} = 1 + \sum_{n=1}^{\infty} (-1)^n \dfrac{x^{4n}}{4n(4n-1)(4n-4)(4n-5) \cdot \cdots \cdot 4 \cdot 3}$.

11. Assuming that $y(x) = \sum_{n=0}^{\infty} c_n x^n$, we have $xy = x\sum_{n=0}^{\infty} c_n x^n = \sum_{n=0}^{\infty} c_n x^{n+1}$, $x^2 y' = x^2 \sum_{n=1}^{\infty} nc_n x^{n-1} = \sum_{n=0}^{\infty} nc_n x^{n+1}$,

$$y''(x) = \sum_{n=2}^{\infty} n(n-1)c_n x^{n-2} = \sum_{n=-1}^{\infty} (n+3)(n+2)c_{n+3}x^{n+1} \qquad \text{[replace } n \text{ with } n+3\text{]}$$

$$= 2c_2 + \sum_{n=0}^{\infty} (n+3)(n+2)c_{n+3}x^{n+1},$$

and the equation $y'' + x^2 y' + xy = 0$ becomes $2c_2 + \sum_{n=0}^{\infty} [(n+3)(n+2)c_{n+3} + nc_n + c_n]\, x^{n+1} = 0$. So $c_2 = 0$ and the recursion relation is $c_{n+3} = \dfrac{-nc_n - c_n}{(n+3)(n+2)} = -\dfrac{(n+1)c_n}{(n+3)(n+2)}$, $n = 0, 1, 2, \ldots$. But $c_0 = y(0) = 0 = c_2$ and by the recursion relation, $c_{3n} = c_{3n+2} = 0$ for $n = 0, 1, 2, \ldots$. Also, $c_1 = y'(0) = 1$, so $c_4 = -\dfrac{2c_1}{4 \cdot 3} = -\dfrac{2}{4 \cdot 3}$,

$c_7 = -\dfrac{5c_4}{7 \cdot 6} = (-1)^2 \dfrac{2 \cdot 5}{7 \cdot 6 \cdot 4 \cdot 3} = (-1)^2 \dfrac{2^2 5^2}{7!}, \ldots, c_{3n+1} = (-1)^n \dfrac{2^2 5^2 \cdot \cdots \cdot (3n-1)^2}{(3n+1)!}$. Thus, the solution is

$y(x) = \sum_{n=0}^{\infty} c_n x^n = x + \sum_{n=1}^{\infty} \left[(-1)^n \dfrac{2^2 5^2 \cdot \cdots \cdot (3n-1)^2 x^{3n+1}}{(3n+1)!} \right]$.

12. (a) Let $y(x) = \sum_{n=0}^{\infty} c_n x^n$. Then $x^2 y''(x) = \sum_{n=2}^{\infty} n(n-1)c_n x^n = \sum_{n=0}^{\infty} (n+2)(n+1)c_{n+2}x^{n+2}$,

$xy'(x) = \sum_{n=1}^{\infty} nc_n x^n = \sum_{n=-1}^{\infty} (n+2)c_{n+2}x^{n+2} = c_1 x + \sum_{n=0}^{\infty} (n+2)c_{n+2}x^{n+2}$, and the equation

$x^2 y'' + xy' + x^2 y = 0$ becomes $c_1 x + \sum_{n=0}^{\infty} \{[(n+2)(n+1) + (n+2)]c_{n+2} + c_n\}x^{n+2} = 0$. So $c_1 = 0$ and the recursion relation is $c_{n+2} = -\dfrac{c_n}{(n+2)^2}$, $n = 0, 1, 2, \ldots$. But $c_1 = y'(0) = 0$ so $c_{2n+1} = 0$ for $n = 0, 1, 2, \ldots$.

Also, $c_0 = y(0) = 1$, so $c_2 = -\dfrac{1}{2^2}$, $c_4 = -\dfrac{c_2}{4^2} = (-1)^2 \dfrac{1}{4^2 2^2} = (-1)^2 \dfrac{1}{2^4 (2!)^2}$, $c_6 = -\dfrac{c_4}{6^2} = (-1)^3 \dfrac{1}{2^6 (3!)^2}, \ldots$,

$c_{2n} = (-1)^n \dfrac{1}{2^{2n} (n!)^2}$. The solution is $y(x) = \sum_{n=0}^{\infty} c_n x^n = \sum_{n=0}^{\infty} (-1)^n \dfrac{x^{2n}}{2^{2n} (n!)^2}$.

(b) The Taylor polynomials T_0 to T_{12} are shown in the graph. Because T_{10} and T_{12} are close together throughout the interval $[-5, 5]$, it is reasonable to assume that T_{12} is a good approximation to the Bessel function on that interval.

TRUE-FALSE QUIZ

1. True. See Theorem 17.1.3.
2. False. The differential equation is not homogeneous.
3. True. $\cosh x$ and $\sinh x$ are linearly independent solutions of this linear homogeneous equation.
4. False. $y = Ae^x$ is a solution of the complementary equation, so we have to take $y_p(x) = Axe^x$.

EXERCISES

1. The auxiliary equation is $4r^2 - 1 = 0 \Rightarrow (2r+1)(2r-1) = 0 \Rightarrow r = \pm\frac{1}{2}$. Then the general solution is $y = c_1 e^{x/2} + c_2 e^{-x/2}$.

2. The auxiliary equation is $r^2 - 2r + 10 = 0 \Rightarrow r = 1 \pm 3i$, so $y = e^x(c_1 \cos 3x + c_2 \sin 3x)$.

3. The auxiliary equation is $r^2 + 3 = 0 \Rightarrow r = \pm\sqrt{3}\,i$. Then the general solution is $y = c_1 \cos(\sqrt{3}\,x) + c_2 \sin(\sqrt{3}\,x)$.

4. The auxiliary equation is $r^2 + 8r + 16 = 0 \Rightarrow (r+4)^2 = 0 \Rightarrow r = -4$, so the general solution is $y = c_1 e^{-4x} + c_2 x e^{-4x}$.

5. $r^2 - 4r + 5 = 0 \Rightarrow r = 2 \pm i$, so $y_c(x) = e^{2x}(c_1 \cos x + c_2 \sin x)$. Try $y_p(x) = Ae^{2x} \Rightarrow y_p' = 2Ae^{2x}$ and $y_p'' = 4Ae^{2x}$. Substitution into the differential equation gives $4Ae^{2x} - 8Ae^{2x} + 5Ae^{2x} = e^{2x} \Rightarrow A = 1$ and the general solution is $y(x) = e^{2x}(c_1 \cos x + c_2 \sin x) + e^{2x}$.

6. $r^2 + r - 2 = 0 \Rightarrow r = 1, r = -2$ and $y_c(x) = c_1 e^x + c_2 e^{-2x}$. Try $y_p(x) = Ax^2 + Bx + C \Rightarrow y_p' = 2Ax + B$ and $y_p'' = 2A$. Substitution gives $2A + 2Ax + B - 2Ax^2 - 2Bx - 2C = x^2 \Rightarrow A = B = -\frac{1}{2}, C = -\frac{3}{4}$ so the general solution is $y(x) = c_1 e^x + c_2 e^{-2x} - \frac{1}{2}x^2 - \frac{1}{2}x - \frac{3}{4}$.

7. $r^2 - 2r + 1 = 0 \Rightarrow r = 1$ and $y_c(x) = c_1 e^x + c_2 x e^x$. Try $y_p(x) = (Ax + B)\cos x + (Cx + D)\sin x \Rightarrow$ $y_p' = (C - Ax - B)\sin x + (A + Cx + D)\cos x$ and $y_p'' = (2C - B - Ax)\cos x + (-2A - D - Cx)\sin x$. Substitution gives $(-2Cx + 2C - 2A - 2D)\cos x + (2Ax - 2A + 2B - 2C)\sin x = x\cos x \Rightarrow A = 0, B = C = D = -\frac{1}{2}$. The general solution is $y(x) = c_1 e^x + c_2 x e^x - \frac{1}{2}\cos x - \frac{1}{2}(x+1)\sin x$.

8. $r^2 + 4 = 0 \Rightarrow r = \pm 2i$ and $y_c(x) = c_1 \cos 2x + c_2 \sin 2x$. Try $y_p(x) = Ax\cos 2x + Bx \sin 2x$ so that no term of y_p is a solution of the complementary equation. Then $y_p' = (A + 2Bx)\cos 2x + (B - 2Ax)\sin 2x$ and $y_p'' = (4B - 4Ax)\cos 2x + (-4A - 4Bx)\sin 2x$. Substitution gives $4B\cos 2x - 4A\sin 2x = \sin 2x \Rightarrow$ $A = -\frac{1}{4}$ and $B = 0$. The general solution is $y(x) = c_1 \cos 2x + c_2 \sin 2x - \frac{1}{4}x\cos 2x$.

9. $r^2 - r - 6 = 0 \quad \Rightarrow \quad r = -2, r = 3$ and $y_c(x) = c_1 e^{-2x} + c_2 e^{3x}$. For $y'' - y' - 6y = 1$, try $y_{p_1}(x) = A$. Then $y'_{p_1}(x) = y''_{p_1}(x) = 0$ and substitution into the differential equation gives $A = -\frac{1}{6}$. For $y'' - y' - 6y = e^{-2x}$ try $y_{p_2}(x) = Bxe^{-2x}$ [since $y = Be^{-2x}$ satisfies the complementary equation]. Then $y'_{p_2} = (B - 2Bx)e^{-2x}$ and $y''_{p_2} = (4Bx - 4B)e^{-2x}$, and substitution gives $-5Be^{-2x} = e^{-2x} \quad \Rightarrow \quad B = -\frac{1}{5}$. The general solution then is $y(x) = c_1 e^{-2x} + c_2 e^{3x} + y_{p_1}(x) + y_{p_2}(x) = c_1 e^{-2x} + c_2 e^{3x} - \frac{1}{6} - \frac{1}{5} x e^{-2x}$.

10. Using variation of parameters, $y_c(x) = c_1 \cos x + c_2 \sin x$, $u'_1(x) = -\csc x \sin x = -1 \quad \Rightarrow \quad u_1(x) = -x$, and $u'_2(x) = \dfrac{\csc x \cos x}{x} = \cot x \quad \Rightarrow \quad u_2(x) = \ln|\sin x| \quad \Rightarrow \quad y_p = -x \cos x + \sin x \ln|\sin x|$. The solution is $y(x) = (c_1 - x)\cos x + (c_2 + \ln|\sin x|)\sin x$.

11. The auxiliary equation is $r^2 + 6r = 0$ and the general solution is $y(x) = c_1 + c_2 e^{-6x} = k_1 + k_2 e^{-6(x-1)}$. But $3 = y(1) = k_1 + k_2$ and $12 = y'(1) = -6k^2$. Thus $k_2 = -2$, $k_1 = 5$ and the solution is $y(x) = 5 - 2e^{-6(x-1)}$.

12. The auxiliary equation is $r^2 - 6r + 25 = 0$ and the general solution is $y(x) = e^{3x}(c_1 \cos 4x + c_2 \sin 4x)$. But $2 = y(0) = c_1$ and $1 = y'(0) = 3c_1 + 4c_2$. Thus the solution is $y(x) = e^{3x}\left(2\cos 4x - \frac{5}{4}\sin 4x\right)$.

13. The auxiliary equation is $r^2 - 5r + 4 = 0$ and the general solution is $y(x) = c_1 e^x + c_2 e^{4x}$. But $0 = y(0) = c_1 + c_2$ and $1 = y'(0) = c_1 + 4c_2$, so the solution is $y(x) = \frac{1}{3}(e^{4x} - e^x)$.

14. $y_c(x) = c_1 \cos(x/3) + c_2 \sin(x/3)$. For $9y'' + y = 3x$, try $y_{p_1}(x) = Ax + B$. Then $y_{p_1}(x) = 3x$. For $9y'' + y = e^{-x}$, try $y_{p_2}(x) = Ae^{-x}$. Then $9Ae^{-x} + Ae^{-x} = e^{-x}$ or $y_{p_2}(x) = \frac{1}{10}e^{-x}$. Thus the general solution is $y(x) = c_1 \cos(x/3) + c_2 \sin(x/3) + 3x + \frac{1}{10}e^{-x}$. But $1 = y(0) = c_1 + \frac{1}{10}$ and $2 = y'(0) = \frac{1}{3}c_2 + 3 - \frac{1}{10}$, so $c_1 = \frac{9}{10}$ and $c_2 = -\frac{27}{10}$. Hence the solution is $y(x) = \frac{1}{10}[9\cos(x/3) - 27\sin(x/3)] + 3x + \frac{1}{10}e^{-x}$.

15. $r^2 + 4r + 29 = 0 \quad \Rightarrow \quad r = -2 \pm 5i$ and the general solution is $y = e^{-2x}(c_1 \cos 5x + c_2 \sin 5x)$. But $1 = y(0) = c_1$ and $-1 = y(\pi) = -c_1 e^{-2\pi} \quad \Rightarrow \quad c_1 = e^{2\pi}$, so there is no solution.

16. $r^2 + 4r + 29 = 0 \quad \Rightarrow \quad r = -2 \pm 5i$ and the general solution is $y = e^{-2x}(c_1 \cos 5x + c_2 \sin 5x)$. But $1 = y(0) = c_1$ and $-e^{-2\pi} = y(\pi) = -c_1 e^{-2\pi} \quad \Rightarrow \quad c_1 = 1$, so c_2 can vary and the solution of the boundary-value problem is $y = e^{-2x}(\cos 5x + c \sin 5x)$, where c is any constant.

17. Let $y(x) = \sum\limits_{n=0}^{\infty} c_n x^n$. Then $y''(x) = \sum\limits_{n=0}^{\infty} n(n-1)c_n x^{n-2} = \sum\limits_{n=0}^{\infty} (n+2)(n+1)c_{n+2}x^n$ and the differential equation becomes $\sum\limits_{n=0}^{\infty} [(n+2)(n+1)c_{n+2} + (n+1)c_n]x^n = 0$. Thus the recursion relation is $c_{n+2} = -c_n/(n+2)$ for $n = 0, 1, 2, \ldots$. But $c_0 = y(0) = 0$, so $c_{2n} = 0$ for $n = 0, 1, 2, \ldots$. Also $c_1 = y'(0) = 1$, so $c_3 = -\dfrac{1}{3}$, $c_5 = \dfrac{(-1)^2}{3 \cdot 5}$,

$c_7 = \dfrac{(-1)^3}{3 \cdot 5 \cdot 7} = \dfrac{(-1)^3 2^3 3!}{7!}, \ldots, c_{2n+1} = \dfrac{(-1)^n\, 2^n\, n!}{(2n+1)!}$ for $n = 0, 1, 2, \ldots$. Thus the solution to the initial-value problem is $y(x) = \sum\limits_{n=0}^{\infty} c_n x^n = \sum\limits_{n=0}^{\infty} \dfrac{(-1)^n\, 2^n\, n!}{(2n+1)!}\, x^{2n+1}$.

18. Let $y(x) = \sum\limits_{n=0}^{\infty} c_n x^n$. Then $y''(x) = \sum\limits_{n=0}^{\infty} n\,(n-1)\, c_n x^{n-2} = \sum\limits_{n=0}^{\infty} (n+2)(n+1) c_{n+2} x^n$ and the differential equation becomes $\sum\limits_{n=0}^{\infty} [(n+2)(n+1)c_{n+2} - (n+2)c_n]x^n = 0$. Thus the recursion relation is $c_{n+2} = \dfrac{c_n}{n+1}$ for $n = 0, 1, 2, \ldots$. Given c_0 and c_1, we have $c_2 = \dfrac{c_0}{1}$, $c_4 = \dfrac{c_2}{3} = \dfrac{c_0}{1 \cdot 3}$, $c_6 = \dfrac{c_4}{5} = \dfrac{c_0}{1 \cdot 3 \cdot 5}, \ldots,$

$c_{2n} = \dfrac{c_0}{1 \cdot 3 \cdot 5 \cdot \cdots \cdot (2n-1)} = c_0 \dfrac{2^{n-1}(n-1)!}{(2n-1)!}$. Similarly $c_3 = \dfrac{c_1}{2}$, $c_5 = \dfrac{c_3}{4} = \dfrac{c_1}{2 \cdot 4}$,

$c_7 = \dfrac{c_5}{6} = \dfrac{c_1}{2 \cdot 4 \cdot 6}, \ldots, c_{2n+1} = \dfrac{c_1}{2 \cdot 4 \cdot 6 \cdot \cdots \cdot 2n} = \dfrac{c_1}{2^n\, n!}$. Thus the general solution is

$y(x) = \sum\limits_{n=0}^{\infty} c_n x^n = c_0 + c_0 \sum\limits_{n=1}^{\infty} \dfrac{2^{n-1}(n-1)!\, x^{2n}}{(2n-1)!} + c \sum\limits_{n=0}^{\infty} \dfrac{x^{2n+1}}{2^n\, n!}$. But $\sum\limits_{n=0}^{\infty} \dfrac{x^{2n+1}}{2^n\, n!} = x \sum\limits_{n=0}^{\infty} \dfrac{\left(\frac{1}{2}x^2\right)^n}{n!} = xe^{x^2/2}$,

so $y(x) = c_1 xe^{x^2/2} + c_0 + c_0 \sum\limits_{n=1}^{\infty} \dfrac{2^{n-1}(n-1)!\, x^{2n}}{(2n-1)!}$.

19. Here the initial-value problem is $2Q'' + 40Q' + 400Q = 12$, $Q\,(0) = 0.01$, $Q'(0) = 0$. Then $Q_c(t) = e^{-10t}(c_1 \cos 10t + c_2 \sin 10t)$ and we try $Q_p(t) = A$. Thus the general solution is $Q(t) = e^{-10t}(c_1 \cos 10t + c_2 \sin 10t) + \frac{3}{100}$. But $0.01 = Q'(0) = c_1 + 0.03$ and $0 = Q''(0) = -10c_1 + 10c_2$, so $c_1 = -0.02 = c_2$. Hence the charge is given by $Q(t) = -0.02e^{-10t}(\cos 10t + \sin 10t) + 0.03$.

20. By Hooke's Law the spring constant is $k = 64$ and the initial-value problem is $2x'' + 16x' + 64x = 0$, $x(0) = 0$, $x'(0) = 2.4$. Thus the general solution is $x(t) = e^{-4t}(c_1 \cos 4t + c_2 \sin 4t)$. But $0 = x(0) = c_1$ and $2.4 = x'(0) = -4c_1 + 4c_2 \;\Rightarrow\; c_1 = 0, c_2 = 0.6$. Thus the position of the mass is given by $x(t) = 0.6e^{-4t} \sin 4t$.

21. (a) Since we are assuming that the earth is a solid sphere of uniform density, we can calculate the density ρ as follows: $\rho = \dfrac{\text{mass of earth}}{\text{volume of earth}} = \dfrac{M}{\frac{4}{3}\pi R^3}$. If V_r is the volume of the portion of the earth which lies within a distance r of the center, then $V_r = \frac{4}{3}\pi r^3$ and $M_r = \rho V_r = \dfrac{Mr^3}{R^3}$. Thus $F_r = -\dfrac{GM_r m}{r^2} = -\dfrac{GMm}{R^3} r$.

(b) The particle is acted upon by a varying gravitational force during its motion. By Newton's Second Law of Motion, $m\,\dfrac{d^2y}{dt^2} = F_y = -\dfrac{GMm}{R^3}\, y$, so $y''(t) = -k^2 y\,(t)$ where $k^2 = \dfrac{GM}{R^3}$. At the surface, $-mg = F_R = -\dfrac{GMm}{R^2}$, so $g = \dfrac{GM}{R^2}$. Therefore $k^2 = \dfrac{g}{R}$.

(c) The differential equation $y'' + k^2 y = 0$ has auxiliary equation $r^2 + k^2 = 0$. (This is the r of Section 17.1, not the r measuring distance from the earth's center.) The roots of the auxiliary equation are $\pm ik$, so by (11) in Section 17.1, the general solution of our differential equation for t is $y(t) = c_1 \cos kt + c_2 \sin kt$. It follows that $y'(t) = -c_1 k \sin kt + c_2 k \cos kt$. Now $y(0) = R$ and $y'(0) = 0$, so $c_1 = R$ and $c_2 k = 0$. Thus $y(t) = R \cos kt$ and $y'(t) = -kR \sin kt$. This is simple harmonic motion (see Section 17.3) with amplitude R, frequency k, and phase angle 0. The period is $T = 2\pi/k$. $R \approx 3960 \text{ mi} = 3960 \cdot 5280$ ft and $g = 32 \text{ ft/s}^2$, so $k = \sqrt{g/R} \approx 1.24 \times 10^{-3} \text{ s}^{-1}$ and $T = 2\pi/k \approx 5079 \text{ s} \approx 85 \text{ min}$.

(d) $y(t) = 0 \quad \Leftrightarrow \quad \cos kt = 0 \quad \Leftrightarrow \quad kt = \frac{\pi}{2} + \pi n$ for some integer $n \quad \Rightarrow \quad y'(t) = -kR \sin\left(\frac{\pi}{2} + \pi n\right) = \pm kR$. Thus the particle passes through the center of the earth with speed $kR \approx 4.899 \text{ mi/s} \approx 17{,}600 \text{ mi/h}$.

APPENDIXES

A Numbers, Inequalities, and Absolute Values

1. $|5 - 23| = |-18| = 18$

2. $|5| - |-23| = 5 - 23 = -18$

3. $|-\pi| = \pi$ because $\pi > 0$.

4. $|\pi - 2| = \pi - 2$ because $\pi - 2 > 0$.

5. $\left|\sqrt{5} - 5\right| = -\left(\sqrt{5} - 5\right) = 5 - \sqrt{5}$ because $\sqrt{5} - 5 < 0$.

6. $\Big| |-2| - |-3| \Big| = |2 - 3| = |-1| = 1$

7. If $x < 2$, $x - 2 < 0$, so $|x - 2| = -(x - 2) = 2 - x$.

8. If $x > 2$, $x - 2 > 0$, so $|x - 2| = x - 2$.

9. $|x + 1| = \begin{cases} x + 1 & \text{if } x + 1 \geq 0 \\ -(x + 1) & \text{if } x + 1 < 0 \end{cases} = \begin{cases} x + 1 & \text{if } x \geq -1 \\ -x - 1 & \text{if } x < -1 \end{cases}$

10. $|2x - 1| = \begin{cases} 2x - 1 & \text{if } 2x - 1 \geq 0 \\ -(2x - 1) & \text{if } 2x - 1 < 0 \end{cases} = \begin{cases} 2x - 1 & \text{if } x \geq \frac{1}{2} \\ 1 - 2x & \text{if } x < \frac{1}{2} \end{cases}$

11. $\left|x^2 + 1\right| = x^2 + 1$ [since $x^2 + 1 \geq 0$ for all x].

12. Determine when $1 - 2x^2 < 0 \quad \Leftrightarrow \quad 1 < 2x^2 \quad \Leftrightarrow \quad x^2 > \frac{1}{2} \quad \Leftrightarrow \quad \sqrt{x^2} > \sqrt{\frac{1}{2}} \quad \Leftrightarrow \quad |x| > \sqrt{\frac{1}{2}} \quad \Leftrightarrow$

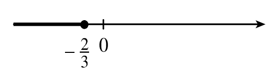
$x < -\frac{1}{\sqrt{2}}$ or $x > \frac{1}{\sqrt{2}}$. Thus, $\left|1 - 2x^2\right| = \begin{cases} 1 - 2x^2 & \text{if } -\frac{1}{\sqrt{2}} \leq x \leq \frac{1}{\sqrt{2}} \\ 2x^2 - 1 & \text{if } x < -\frac{1}{\sqrt{2}} \text{ or } x > \frac{1}{\sqrt{2}} \end{cases}$

13. $2x + 7 > 3 \quad \Leftrightarrow \quad 2x > -4 \quad \Leftrightarrow \quad x > -2$, so $x \in (-2, \infty)$.

14. $3x - 11 < 4 \quad \Leftrightarrow \quad 3x < 15 \quad \Leftrightarrow \quad x < 5$, so $x \in (-\infty, 5)$.

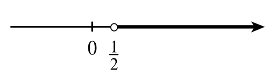
15. $1 - x \leq 2 \quad \Leftrightarrow \quad -x \leq 1 \quad \Leftrightarrow \quad x \geq -1$, so $x \in [-1, \infty)$.

16. $4 - 3x \geq 6 \quad \Leftrightarrow \quad -3x \geq 2 \quad \Leftrightarrow \quad x \leq -\frac{2}{3}$, so $x \in \left(-\infty, -\frac{2}{3}\right]$.



17. $2x + 1 < 5x - 8 \quad \Leftrightarrow \quad 9 < 3x \quad \Leftrightarrow \quad 3 < x$, so $x \in (3, \infty)$.

18. $1 + 5x > 5 - 3x \quad \Leftrightarrow \quad 8x > 4 \quad \Leftrightarrow \quad x > \frac{1}{2}$, so $x \in \left(\frac{1}{2}, \infty\right)$.



19. $-1 < 2x - 5 < 7 \quad \Leftrightarrow \quad 4 < 2x < 12 \quad \Leftrightarrow \quad 2 < x < 6$, so $x \in (2, 6)$.

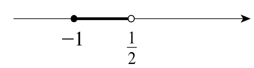
20. $1 < 3x + 4 \le 16 \quad \Leftrightarrow \quad -3 < 3x \le 12 \quad \Leftrightarrow \quad -1 < x \le 4$, so $x \in (-1, 4]$.

21. $0 \le 1 - x < 1 \quad \Leftrightarrow \quad -1 \le -x < 0 \quad \Leftrightarrow \quad 1 \ge x > 0$, so $x \in (0, 1]$.

22. $-5 \le 3 - 2x \le 9 \quad \Leftrightarrow \quad -8 \le -2x \le 6 \quad \Leftrightarrow \quad 4 \ge x \ge -3$, so $x \in [-3, 4]$.

23. $4x < 2x + 1 \le 3x + 2$. So $4x < 2x + 1 \quad \Leftrightarrow \quad 2x < 1 \quad \Leftrightarrow \quad x < \frac{1}{2}$, and

$2x + 1 \le 3x + 2 \quad \Leftrightarrow \quad -1 \le x$. Thus, $x \in \left[-1, \frac{1}{2}\right)$.



24. $2x - 3 < x + 4 < 3x - 2$. So $2x - 3 < x + 4 \quad \Leftrightarrow \quad x < 7$, and

$x + 4 < 3x - 2 \quad \Leftrightarrow \quad 6 < 2x \quad \Leftrightarrow \quad 3 < x$, so $x \in (3, 7)$.

25. $(x - 1)(x - 2) > 0$.

Case 1: (both factors are positive, so their product is positive) $x - 1 > 0 \quad \Leftrightarrow \quad x > 1$,

and $x - 2 > 0 \quad \Leftrightarrow \quad x > 2$, so $x \in (2, \infty)$.

Case 2: (both factors are negative, so their product is positive) $x - 1 < 0 \quad \Leftrightarrow \quad x < 1$,

and $x - 2 < 0 \quad \Leftrightarrow \quad x < 2$, so $x \in (-\infty, 1)$.

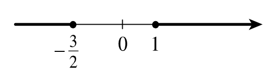
Thus, the solution set is $(-\infty, 1) \cup (2, \infty)$.

26. $(2x + 3)(x - 1) \ge 0$.

Case 1: $2x + 3 \ge 0 \quad \Leftrightarrow \quad x \ge -\frac{3}{2}$, and $x - 1 \ge 0 \quad \Leftrightarrow \quad x \ge 1$, so $x \in [1, \infty)$.

Case 2: $2x + 3 \le 0 \quad \Leftrightarrow \quad x \le -\frac{3}{2}$, and $x - 1 \le 0 \quad \Leftrightarrow \quad x \le 1$, so $x \in \left(-\infty, -\frac{3}{2}\right]$.

Thus, the solution set is $\left(-\infty, -\frac{3}{2}\right] \cup [1, \infty)$.



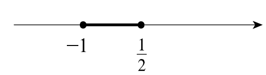
27. $2x^2 + x \le 1 \quad \Leftrightarrow \quad 2x^2 + x - 1 \le 0 \quad \Leftrightarrow \quad (2x - 1)(x + 1) \le 0$.

Case 1: $2x - 1 \ge 0 \quad \Leftrightarrow \quad x \ge \frac{1}{2}$, and $x + 1 \le 0 \quad \Leftrightarrow \quad x \le -1$,

which is an impossible combination.

Case 2: $2x - 1 \le 0 \quad \Leftrightarrow \quad x \le \frac{1}{2}$, and $x + 1 \ge 0 \quad \Leftrightarrow \quad x \ge -1$, so $x \in \left[-1, \frac{1}{2}\right]$.

Thus, the solution set is $\left[-1, \frac{1}{2}\right]$.



28. $x^2 < 2x + 8 \quad \Leftrightarrow \quad x^2 - 2x - 8 < 0 \quad \Leftrightarrow \quad (x - 4)(x + 2) < 0$.

Case 1: $x > 4$ and $x < -2$, which is impossible.

Case 2: $x < 4$ and $x > -2$.

Thus, the solution set is $(-2, 4)$.

29. $x^2 + x + 1 > 0 \quad \Leftrightarrow \quad x^2 + x + \frac{1}{4} + \frac{3}{4} > 0 \quad \Leftrightarrow \quad \left(x + \frac{1}{2}\right)^2 + \frac{3}{4} > 0$. But since

$\left(x + \frac{1}{2}\right)^2 \ge 0$ for every real x, the original inequality will be true for all real x as well.

Thus, the solution set is $(-\infty, \infty)$.

30. $x^2 + x > 1 \quad \Leftrightarrow \quad x^2 + x - 1 > 0$. Using the quadratic formula, we obtain

$x^2 + x - 1 = \left(x - \frac{-1-\sqrt{5}}{2}\right)\left(x - \frac{-1+\sqrt{5}}{2}\right) > 0.$

Case 1: $x - \frac{-1-\sqrt{5}}{2} > 0$ and $x - \frac{-1+\sqrt{5}}{2} > 0$, so that $x > \frac{-1+\sqrt{5}}{2}$.

Case 2: $x - \frac{-1-\sqrt{5}}{2} < 0$ and $x - \frac{-1+\sqrt{5}}{2} < 0$, so that $x < \frac{-1-\sqrt{5}}{2}$.

Thus, the solution set is $\left(-\infty, \frac{-1-\sqrt{5}}{2}\right) \cup \left(\frac{-1+\sqrt{5}}{2}, \infty\right)$.

31. $x^2 < 3 \quad \Leftrightarrow \quad x^2 - 3 < 0 \quad \Leftrightarrow \quad \left(x - \sqrt{3}\right)\left(x + \sqrt{3}\right) < 0$.

Case 1: $x > \sqrt{3}$ and $x < -\sqrt{3}$, which is impossible.

Case 2: $x < \sqrt{3}$ and $x > -\sqrt{3}$.

Thus, the solution set is $\left(-\sqrt{3}, \sqrt{3}\right)$.

Another method: $x^2 < 3 \quad \Leftrightarrow \quad |x| < \sqrt{3} \quad \Leftrightarrow \quad -\sqrt{3} < x < \sqrt{3}$.

32. $x^2 \geq 5 \quad \Leftrightarrow \quad x^2 - 5 \geq 0 \quad \Leftrightarrow \quad \left(x - \sqrt{5}\right)\left(x + \sqrt{5}\right) \geq 0$.

Case 1: $x \geq \sqrt{5}$ and $x \geq -\sqrt{5}$, so $x \in \left[\sqrt{5}, \infty\right)$.

Case 2: $x \leq \sqrt{5}$ and $x \leq -\sqrt{5}$, so $x \in \left(-\infty, -\sqrt{5}\,\right]$.

Thus, the solution set is $\left(-\infty, -\sqrt{5}\,\right] \cup \left[\sqrt{5}, \infty\right)$.

Another method: $x^2 \geq 5 \quad \Leftrightarrow \quad |x| \geq \sqrt{5} \quad \Leftrightarrow \quad x \geq \sqrt{5}$ or $x \leq -\sqrt{5}$.

33. $x^3 - x^2 \leq 0 \quad \Leftrightarrow \quad x^2(x-1) \leq 0$. Since $x^2 \geq 0$ for all x, the inequality is satisfied when $x - 1 \leq 0 \quad \Leftrightarrow \quad x \leq 1$.

Thus, the solution set is $(-\infty, 1]$.

34. $(x+1)(x-2)(x+3) = 0 \quad \Leftrightarrow \quad x = -1, 2$, or -3. Construct a chart:

Interval	$x+1$	$x-2$	$x+3$	$(x+1)(x-2)(x+3)$
$x < -3$	$-$	$-$	$-$	$-$
$-3 < x < -1$	$-$	$-$	$+$	$+$
$-1 < x < 2$	$+$	$-$	$+$	$-$
$x > 2$	$+$	$+$	$+$	$+$

Thus, $(x+1)(x-2)(x+3) \geq 0$ on $[-3, -1]$ and $[2, \infty)$, and the solution set is $[-3, -1] \cup [2, \infty)$.

35. $x^3 > x \quad \Leftrightarrow \quad x^3 - x > 0 \quad \Leftrightarrow \quad x\left(x^2 - 1\right) > 0 \quad \Leftrightarrow \quad x(x-1)(x+1) > 0$. Construct a chart:

Interval	x	$x-1$	$x+1$	$x(x-1)(x+1)$
$x < -1$	$-$	$-$	$-$	$-$
$-1 < x < 0$	$-$	$-$	$+$	$+$
$0 < x < 1$	$+$	$-$	$+$	$-$
$x > 1$	$+$	$+$	$+$	$+$

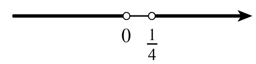
Since $x^3 > x$ when the last column is positive, the solution set is $(-1, 0) \cup (1, \infty)$.

36. $x^3 + 3x < 4x^2 \quad \Leftrightarrow \quad x^3 - 4x^2 + 3x < 0 \quad \Leftrightarrow \quad x(x^2 - 4x + 3) < 0 \quad \Leftrightarrow \quad x(x-1)(x-3) < 0.$

Interval	x	$x-1$	$x-3$	$x(x-1)(x-3)$
$x < 0$	$-$	$-$	$-$	$-$
$0 < x < 1$	$+$	$-$	$-$	$+$
$1 < x < 3$	$+$	$+$	$-$	$-$
$x > 3$	$+$	$+$	$+$	$+$

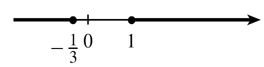
Thus, the solution set is $(-\infty, 0) \cup (1, 3)$.

37. $1/x < 4$. This is clearly true for $x < 0$. So suppose $x > 0$. then $1/x < 4 \quad \Leftrightarrow$ $1 < 4x \quad \Leftrightarrow \quad \frac{1}{4} < x$. Thus, the solution set is $(-\infty, 0) \cup \left(\frac{1}{4}, \infty\right)$.



38. $-3 < 1/x \leq 1$. We solve the two inequalities separately and take the intersection of the solution sets. First, $-3 < 1/x$ is clearly true for $x > 0$. So suppose $x < 0$. Then $-3 < 1/x \quad \Leftrightarrow \quad -3x > 1 \quad \Leftrightarrow \quad x < -\frac{1}{3}$, so for this inequality, the solution set is $\left(-\infty, -\frac{1}{3}\right) \cup (0, \infty)$. Now $1/x \leq 1$ is clearly true if $x < 0$. So suppose $x > 0$. Then $1/x \leq 1 \quad \Leftrightarrow \quad 1 \leq x$, and the solution set here is $(-\infty, 0) \cup [1, \infty)$.

Taking the intersection of the two solution sets gives the final solution set: $\left(-\infty, -\frac{1}{3}\right) \cup [1, \infty)$.



39. $C = \frac{5}{9}(F - 32) \quad \Rightarrow \quad F = \frac{9}{5}C + 32$. So $50 \leq F \leq 95 \quad \Rightarrow \quad 50 \leq \frac{9}{5}C + 32 \leq 95 \quad \Rightarrow \quad 18 \leq \frac{9}{5}C \leq 63 \quad \Rightarrow$ $10 \leq C \leq 35$. So the interval is $[10, 35]$.

40. Since $20 \leq C \leq 30$ and $C = \frac{5}{9}(F - 32)$, we have $20 \leq \frac{5}{9}(F - 32) \leq 30 \quad \Rightarrow \quad 36 \leq F - 32 \leq 54 \quad \Rightarrow \quad 68 \leq F \leq 86$. So the interval is $[68, 86]$.

41. (a) Let T represent the temperature in degrees Celsius and h the height in km. $T = 20$ when $h = 0$ and T decreases by 10°C for every km (1°C for each 100-m rise). Thus, $T = 20 - 10h$ when $0 \leq h \leq 12$.

(b) From part (a), $T = 20 - 10h \quad \Rightarrow \quad 10h = 20 - T \quad \Rightarrow \quad h = 2 - T/10$. So $0 \leq h \leq 5 \quad \Rightarrow \quad 0 \leq 2 - T/10 \leq 5 \quad \Rightarrow$ $-2 \leq -T/10 \leq 3 \quad \Rightarrow \quad -20 \leq -T \leq 30 \quad \Rightarrow \quad 20 \geq T \geq -30 \quad \Rightarrow \quad -30 \leq T \leq 20$. Thus, the range of temperatures (in $^\circ$C) to be expected is $[-30, 20]$.

42. The ball will be at least 32 ft above the ground if $h \geq 32 \quad \Leftrightarrow \quad 128 + 16t - 16t^2 \geq 32 \quad \Leftrightarrow \quad 16t^2 - 16t - 96 \leq 0 \quad \Leftrightarrow$ $16(t-3)(t+2) \leq 0$. $t = 3$ and $t = -2$ are endpoints of the interval we're looking for, and constructing a table gives $-2 \leq t \leq 3$. But $t \geq 0$, so the ball will be at least 32 ft above the ground in the time interval $[0, 3]$.

43. $|2x| = 3 \quad \Leftrightarrow \quad$ either $2x = 3$ or $2x = -3 \quad \Leftrightarrow \quad x = \frac{3}{2}$ or $x = -\frac{3}{2}$.

44. $|3x + 5| = 1 \quad \Leftrightarrow \quad$ either $3x + 5 = 1$ or -1. In the first case, $3x = -4 \quad \Leftrightarrow \quad x = -\frac{4}{3}$, and in the second case, $3x = -6 \quad \Leftrightarrow \quad x = -2$. So the solutions are -2 and $-\frac{4}{3}$.

45. $|x+3| = |2x+1| \quad \Leftrightarrow \quad$ either $x+3 = 2x+1$ or $x+3 = -(2x+1)$. In the first case, $x=2$, and in the second case, $x+3=-2x-1 \quad \Leftrightarrow \quad 3x=-4 \quad \Leftrightarrow \quad x=-\frac{4}{3}$. So the solutions are $-\frac{4}{3}$ and 2.

46. $\left|\dfrac{2x-1}{x+1}\right| = 3 \quad \Leftrightarrow \quad$ either $\dfrac{2x-1}{x+1} = 3$ or $\dfrac{2x-1}{x+1} = -3$. In the first case, $2x-1 = 3x+3 \quad \Leftrightarrow \quad x=-4$, and in the second case, $2x-1=-3x-3 \quad \Leftrightarrow \quad x=-\frac{2}{5}$.

47. By Property 5 of absolute values, $|x| < 3 \quad \Leftrightarrow \quad -3 < x < 3$, so $x \in (-3, 3)$.

48. By Properties 4 and 6 of absolute values, $|x| \geq 3 \quad \Leftrightarrow \quad x \leq -3$ or $x \geq 3$, so $x \in (-\infty, -3] \cup [3, \infty)$.

49. $|x-4| < 1 \quad \Leftrightarrow \quad -1 < x-4 < 1 \quad \Leftrightarrow \quad 3 < x < 5$, so $x \in (3, 5)$.

50. $|x-6| < 0.1 \quad \Leftrightarrow \quad -0.1 < x-6 < 0.1 \quad \Leftrightarrow \quad 5.9 < x < 6.1$, so $x \in (5.9, 6.1)$.

51. $|x+5| \geq 2 \quad \Leftrightarrow \quad x+5 \geq 2$ or $x+5 \leq -2 \quad \Leftrightarrow \quad x \geq -3$ or $x \leq -7$, so $x \in (-\infty, -7] \cup [-3, \infty)$.

52. $|x+1| \geq 3 \quad \Leftrightarrow \quad x+1 \geq 3$ or $x+1 \leq -3 \quad \Leftrightarrow \quad x \geq 2$ or $x \leq -4$, so $x \in (-\infty, -4] \cup [2, \infty)$.

53. $|2x-3| \leq 0.4 \quad \Leftrightarrow \quad -0.4 \leq 2x-3 \leq 0.4 \quad \Leftrightarrow \quad 2.6 \leq 2x \leq 3.4 \quad \Leftrightarrow \quad 1.3 \leq x \leq 1.7$, so $x \in [1.3, 1.7]$.

54. $|5x-2| < 6 \quad \Leftrightarrow \quad -6 < 5x-2 < 6 \quad \Leftrightarrow \quad -4 < 5x < 8 \quad \Leftrightarrow \quad -\frac{4}{5} < x < \frac{8}{5}$, so $x \in \left(-\frac{4}{5}, \frac{8}{5}\right)$.

55. $1 \leq |x| \leq 4$. So either $1 \leq x \leq 4$ or $1 \leq -x \leq 4 \quad \Leftrightarrow \quad -1 \geq x \geq -4$. Thus, $x \in [-4, -1] \cup [1, 4]$.

56. $0 < |x-5| < \frac{1}{2}$. Clearly $0 < |x-5|$ for $x \neq 5$. Now $|x-5| < \frac{1}{2} \quad \Leftrightarrow \quad -\frac{1}{2} < x-5 < \frac{1}{2} \quad \Leftrightarrow \quad 4.5 < x < 5.5$. So the solution set is $(4.5, 5) \cup (5, 5.5)$.

57. $a(bx-c) \geq bc \quad \Leftrightarrow \quad bx - c \geq \dfrac{bc}{a} \quad \Leftrightarrow \quad bx \geq \dfrac{bc}{a} + c = \dfrac{bc+ac}{a} \quad \Leftrightarrow \quad x \geq \dfrac{bc+ac}{ab}$

58. $a \leq bx + c < 2a \quad \Leftrightarrow \quad a - c \leq bx < 2a - c \quad \Leftrightarrow \quad \dfrac{a-c}{b} \leq x < \dfrac{2a-c}{b}$ (since $b > 0$)

59. $ax + b < c \quad \Leftrightarrow \quad ax < c - b \quad \Leftrightarrow \quad x > \dfrac{c-b}{a}$ [since $a < 0$]

60. $\dfrac{ax+b}{c} \leq b \quad \Leftrightarrow \quad ax + b \geq bc$ [since $c < 0$] $\quad \Leftrightarrow \quad ax \geq bc - b \quad \Leftrightarrow \quad x \leq \dfrac{b(c-1)}{a}$ [since $a < 0$]

61. $|(x+y)-5| = |(x-2)+(y-3)| \leq |x-2| + |y-3| < 0.01 + 0.04 = 0.05$

62. Use the Triangle Inequality: $|x+3| < \frac{1}{2} \quad \Rightarrow$

$|4x+13| = |4(x+3)+1| \leq |4(x+3)| + |1| = 4|x+3| + 1 < 4\left(\frac{1}{2}\right) + 1 = 3$

Another method: $|x+3| < \frac{1}{2} \quad \Rightarrow \quad -\frac{1}{2} < x+3 < \frac{1}{2} \quad \Rightarrow \quad -2 < 4x+12 < 2 \quad \Rightarrow \quad -1 < 4x+13 < 3 \quad \Rightarrow$ $|4x+13| < 3$

63. If $a < b$ then $a + a < a + b$ and $a + b < b + b$. So $2a < a + b < 2b$. Dividing by 2, we get $a < \frac{1}{2}(a+b) < b$.

64. If $0 < a < b$, then $\frac{1}{ab} > 0$. So $a < b \quad \Rightarrow \quad \frac{1}{ab} \cdot a < \frac{1}{ab} \cdot b \quad \Leftrightarrow \quad \frac{1}{b} < \frac{1}{a}$.

65. $|ab| = \sqrt{(ab)^2} = \sqrt{a^2 b^2} = \sqrt{a^2}\,\sqrt{b^2} = |a|\,|b|$

66. $\left|\frac{a}{b}\right| |b| = \left|\frac{a}{b} \cdot b\right| = |a|$ [using the result of Exercise 65]. Dividing the equation through by $|b|$ gives $\left|\frac{a}{b}\right| = \frac{|a|}{|b|}$.

67. If $0 < a < b$, then $a \cdot a < a \cdot b$ and $a \cdot b < b \cdot b$ [using Rule 3 of Inequalities]. So $a^2 < ab < b^2$ and hence $a^2 < b^2$.

68. Following the hint, the Triangle Inequality becomes $|(x - y) + y| \le |x - y| + |y| \quad \Leftrightarrow \quad |x| \le |x - y| + |y| \quad \Leftrightarrow$ $|x - y| \ge |x| - |y|$.

69. Observe that the sum, difference and product of two integers is always an integer. Let the rational numbers be represented by $r = m/n$ and $s = p/q$ (where m, n, p and q are integers with $n \ne 0$, $q \ne 0$). Now $r + s = \frac{m}{n} + \frac{p}{q} = \frac{mq + pn}{nq}$, but $mq + pn$ and nq are both integers, so $\frac{mq + pn}{nq} = r + s$ is a rational number by definition. Similarly, $r - s = \frac{m}{n} - \frac{p}{q} = \frac{mq - pn}{nq}$ is a rational number. Finally, $r \cdot s = \frac{m}{n} \cdot \frac{p}{q} = \frac{mp}{nq}$ but mp and nq are both integers, so $\frac{mp}{nq} = r \cdot s$ is a rational number by definition.

70. (a) No. Consider the case of $\sqrt{2}$ and $-\sqrt{2}$. Both are irrational numbers, yet $\sqrt{2} + \left(-\sqrt{2}\right) = 0$ and 0, being an integer, is not irrational.

(b) No. Consider the case of $\sqrt{2}$ and $\sqrt{2}$. Both are irrational numbers, yet $\sqrt{2} \cdot \sqrt{2} = 2$ is not irrational.

B Coordinate Geometry and Lines

1. Use the distance formula with $P_1(x_1, y_1) = (1, 1)$ and $P_2(x_2, y_2) = (4, 5)$ to get

$$|P_1 P_2| = \sqrt{(4 - 1)^2 + (5 - 1)^2} = \sqrt{3^2 + 4^2} = \sqrt{25} = 5$$

2. The distance from $(1, -3)$ to $(5, 7)$ is $\sqrt{(5 - 1)^2 + [7 - (-3)]^2} = \sqrt{4^2 + 10^2} = \sqrt{116} = 2\sqrt{29}$.

3. The distance from $(6, -2)$ to $(-1, 3)$ is $\sqrt{-1 - 6)^2 + [3 - (-2)]^2} = \sqrt{(-7)^2 + 5^2} = \sqrt{74}$.

4. The distance from $(1, -6)$ to $(-1, -3)$ is $\sqrt{(-1 - 1)^2 + [-3 - (-6)]^2} = \sqrt{(-2)^2 + 3^2} = \sqrt{13}$.

5. The distance from $(2, 5)$ to $(4, -7)$ is $\sqrt{(4 - 2)^2 + (-7 - 5)^2} = \sqrt{2^2 + (-12)^2} = \sqrt{148} = 2\sqrt{37}$.

6. The distance from (a, b) to (b, a) is $\sqrt{(b - a)^2 + (a - b)^2} = \sqrt{(a - b)^2 + (a - b)^2} = \sqrt{2(a - b)^2} = \sqrt{2}\,|a - b|$.

7. The slope m of the line through $P(1, 5)$ and $Q(4, 11)$ is $m = \frac{11 - 5}{4 - 1} = \frac{6}{3} = 2$.

8. The slope m of the line through $P(-1, 6)$ and $Q(4, -3)$ is $m = \frac{-3 - 6}{4 - (-1)} = -\frac{9}{5}$.

9. The slope m of the line through $P(-3,3)$ and $Q(-1,-6)$ is $m = \dfrac{-6-3}{-1-(-3)} = -\dfrac{9}{2}$.

10. The slope m of the line through $P(-1,-4)$ and $Q(6,0)$ is $m = \dfrac{0-(-4)}{6-(-1)} = \dfrac{4}{7}$.

11. Using $A(0,2)$, $B(-3,-1)$, and $C(-4,3)$, we have $|AC| = \sqrt{(-4-0)^2+(3-2)^2} = \sqrt{(-4)^2+1^2} = \sqrt{17}$ and $|BC| = \sqrt{[-4-(-3)]^2+[3-(-1)]^2} = \sqrt{(-1)^2+4^2} = \sqrt{17}$, so the triangle has two sides of equal length, and is isosceles.

12. (a) Using $A(6,-7)$, $B(11,-3)$, and $C(2,-2)$, we have

$|AB| = \sqrt{(11-6)^2+[-3-(-7)]^2} = \sqrt{5^2+4^2} = \sqrt{41}$,

$|AC| = \sqrt{(2-6)^2+[-2-(-7)]^2} = \sqrt{(-4)^2+5^2} = \sqrt{41}$, and

$|BC| = \sqrt{(2-11)^2+[-2-(-3)]^2} = \sqrt{(-9)^2+1^2} = \sqrt{82}$.

Thus, $|AB|^2+|AC|^2 = 41+41 = 82 = |BC|^2$ and so $\triangle ABC$ is a right triangle.

(b) $m_{AB} = \dfrac{-3-(-7)}{11-6} = \dfrac{4}{5}$ and $m_{AC} = \dfrac{-2-(-7)}{2-6} = -\dfrac{5}{4}$. Thus $m_{AB}\cdot m_{AC} = -1$ and so AB is perpendicular to AC and $\triangle ABC$ must be a right triangle.

(c) Taking lengths from part (a), the base is $\sqrt{41}$ and the height is $\sqrt{41}$. Thus the area is $\frac{1}{2}bh = \frac{1}{2}\sqrt{41}\sqrt{41} = \frac{41}{2}$.

13. Using $A(-2,9)$, $B(4,6)$, $C(1,0)$, and $D(-5,3)$, we have

$|AB| = \sqrt{[4-(-2)]^2+(6-9)^2} = \sqrt{6^2+(-3)^2} = \sqrt{45} = \sqrt{9}\sqrt{5} = 3\sqrt{5}$,

$|BC| = \sqrt{(1-4)^2+(0-6)^2} = \sqrt{(-3)^2+(-6)^2} = \sqrt{45} = \sqrt{9}\sqrt{5} = 3\sqrt{5}$,

$|CD| = \sqrt{(-5-1)^2+(3-0)^2} = \sqrt{(-6)^2+3^2} = \sqrt{45} = \sqrt{9}\sqrt{5} = 3\sqrt{5}$, and

$|DA| = \sqrt{[-2-(-5)]^2+(9-3)^2} = \sqrt{3^2+6^2} = \sqrt{45} = \sqrt{9}\sqrt{5} = 3\sqrt{5}$. So all sides are of equal length and we have a rhombus. Moreover, $m_{AB} = \dfrac{6-9}{4-(-2)} = -\dfrac{1}{2}$, $m_{BC} = \dfrac{0-6}{1-4} = 2$, $m_{CD} = \dfrac{3-0}{-5-1} = -\dfrac{1}{2}$, and

$m_{DA} = \dfrac{9-3}{-2-(-5)} = 2$, so the sides are perpendicular. Thus, A, B, C, and D are vertices of a square.

14. (a) Using $A(-1,3)$, $B(3,11)$, and $C(5,15)$, we have

$|AB| = \sqrt{[3-(-1)]^2+(11-3)^2} = \sqrt{4^2+8^2} = \sqrt{80} = 4\sqrt{5}$,

$|BC| = \sqrt{(5-3)^2+(15-11)^2} = \sqrt{2^2+4^2} = \sqrt{20} = 2\sqrt{5}$, and

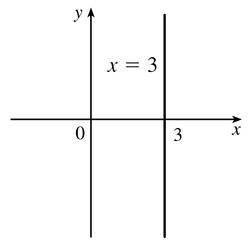
$|AC| = \sqrt{[5-(-1)]^2+(15-3)^2} = \sqrt{6^2+12^2} = \sqrt{180} = 6\sqrt{5}$. Thus, $|AC| = |AB|+|BC|$.

(b) $m_{AB} = \dfrac{11-3}{3-(-1)} = \dfrac{8}{4} = 2$ and $m_{AC} = \dfrac{15-3}{5-(-1)} = \dfrac{12}{6} = 2$. Since the segments AB and AC have the same slope, A, B and C must be collinear.

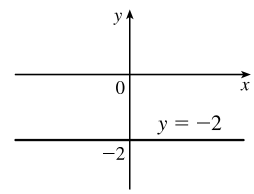
15. For the vertices $A(1,1)$, $B(7,4)$, $C(5,10)$, and $D(-1,7)$, the slope of the line segment AB is $\dfrac{4-1}{7-1}=\dfrac{1}{2}$, the slope of CD is $\dfrac{7-10}{-1-5}=\dfrac{1}{2}$, the slope of BC is $\dfrac{10-4}{5-7}=-3$, and the slope of DA is $\dfrac{1-7}{1-(-1)}=-3$. So AB is parallel to CD and BC is parallel to DA. Hence $ABCD$ is a parallelogram.

16. For the vertices $A(1,1)$, $B(11,3)$, $C(10,8)$, and $D(0,6)$, the slopes of the four sides are $m_{AB}=\dfrac{3-1}{11-1}=\dfrac{1}{5}$, $m_{BC}=\dfrac{8-3}{10-11}=-5$, $m_{CD}=\dfrac{6-8}{0-10}=\dfrac{1}{5}$, and $m_{DA}=\dfrac{1-6}{1-0}=-5$. Hence $AB \parallel CD$, $BC \parallel DA$, $AB \perp BC$, $BC \perp CD$, $CD \perp DA$, and $DA \perp AB$, and so $ABCD$ is a rectangle.

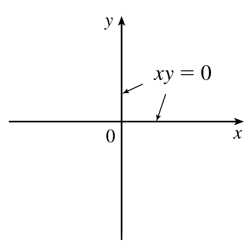
17. The graph of the equation $x=3$ is a vertical line with x-intercept 3. The line does not have a slope.



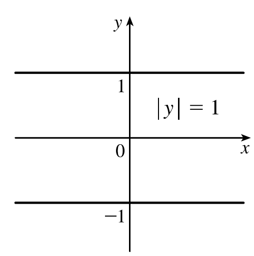
18. The graph of the equation $y=-2$ is a horizontal line with y-intercept -2. The line has slope 0.



19. $xy=0 \quad \Leftrightarrow \quad x=0$ or $y=0$. The graph consists of the coordinate axes.



20. $|y|=1 \quad \Leftrightarrow \quad y=1$ or $y=-1$



21. By the point-slope form of the equation of a line, an equation of the line through $(2,-3)$ with slope 6 is $y-(-3)=6(x-2)$ or $y=6x-15$.

22. $y-4=-3[x-(-1)]$ or $y=-3x+1$

23. $y-7=\frac{2}{3}(x-1)$ or $y=\frac{2}{3}x+\frac{19}{3}$

24. $y-(-5)=-\frac{7}{2}[x-(-3)]$ or $y=-\frac{7}{2}x-\frac{31}{2}$

25. The slope of the line through $(2,1)$ and $(1,6)$ is $m=\dfrac{6-1}{1-2}=-5$, so an equation of the line is $y-1=-5(x-2)$ or $y=-5x+11$.

26. For $(-1,-2)$ and $(4,3)$, $m = \dfrac{3-(-2)}{4-(-1)} = 1$. An equation of the line is $y - 3 = 1(x-4)$ or $y = x - 1$.

27. By the slope-intercept form of the equation of a line, an equation of the line is $y = 3x - 2$.

28. By the slope-intercept form of the equation of a line, an equation of the line is $y = \frac{2}{5}x + 4$.

29. Since the line passes through $(1,0)$ and $(0,-3)$, its slope is $m = \dfrac{-3-0}{0-1} = 3$, so an equation is $y = 3x - 3$.

Another method: From Exercise 61, $\dfrac{x}{1} + \dfrac{y}{-3} = 1 \;\Rightarrow\; -3x + y = -3 \;\Rightarrow\; y = 3x - 3$.

30. For $(-8,0)$ and $(0,6)$, $m = \dfrac{6-0}{0-(-8)} = \dfrac{3}{4}$. So an equation is $y = \frac{3}{4}x + 6$.

Another method: From Exercise 61, $\dfrac{x}{-8} + \dfrac{y}{6} = 1 \;\Rightarrow\; -3x + 4y = 24 \;\Rightarrow\; y = \frac{3}{4}x + 6$.

31. The line is parallel to the x-axis, so it is horizontal and must have the form $y = k$. Since it goes through the point $(x,y) = (4,5)$, the equation is $y = 5$.

32. The line is parallel to the y-axis, so it is vertical and must have the form $x = k$. Since it goes through the point $(x,y) = (4,5)$, the equation is $x = 4$.

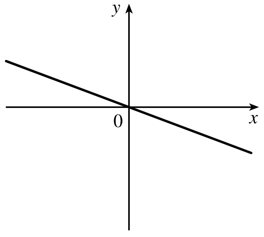
33. Putting the line $x + 2y = 6$ into its slope-intercept form gives us $y = -\frac{1}{2}x + 3$, so we see that this line has slope $-\frac{1}{2}$. Thus, we want the line of slope $-\frac{1}{2}$ that passes through the point $(1,-6)$: $y - (-6) = -\frac{1}{2}(x-1) \;\Leftrightarrow\; y = -\frac{1}{2}x - \frac{11}{2}$.

34. $2x + 3y + 4 = 0 \;\Leftrightarrow\; y = -\frac{2}{3}x - \frac{4}{3}$, so $m = -\frac{2}{3}$ and the required line is $y = -\frac{2}{3}x + 6$.

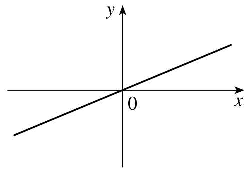
35. $2x + 5y + 8 = 0 \;\Leftrightarrow\; y = -\frac{2}{5}x - \frac{8}{5}$. Since this line has slope $-\frac{2}{5}$, a line perpendicular to it would have slope $\frac{5}{2}$, so the required line is $y - (-2) = \frac{5}{2}[x - (-1)] \;\Leftrightarrow\; y = \frac{5}{2}x + \frac{1}{2}$.

36. $4x - 8y = 1 \;\Leftrightarrow\; y = \frac{1}{2}x - \frac{1}{8}$. Since this line has slope $\frac{1}{2}$, a line perpendicular to it would have slope -2, so the required line is $y - \left(-\frac{2}{3}\right) = -2\left(x - \frac{1}{2}\right) \;\Leftrightarrow\; y = -2x + \frac{1}{3}$.

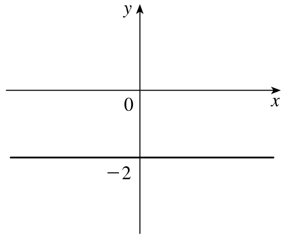
37. $x + 3y = 0 \;\Leftrightarrow\; y = -\frac{1}{3}x$, so the slope is $-\frac{1}{3}$ and the y-intercept is 0.



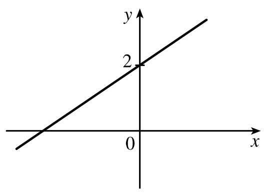
38. $2x - 5y = 0 \;\Leftrightarrow\; y = \frac{2}{5}x$, so the slope is $\frac{2}{5}$ and the y-intercept is 0.



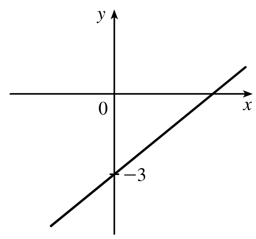
39. $y = -2$ is a horizontal line with slope 0 and y-intercept -2.



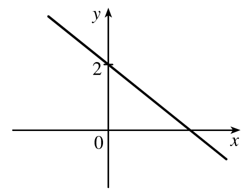
40. $2x - 3y + 6 = 0 \quad \Leftrightarrow$
$y = \frac{2}{3}x + 2$, so the slope is $\frac{2}{3}$ and the y-intercept is 2.



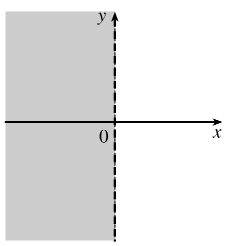
41. $3x - 4y = 12 \quad \Leftrightarrow$
$y = \frac{3}{4}x - 3$, so the slope is $\frac{3}{4}$ and the y-intercept is -3.



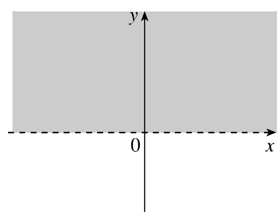
42. $4x + 5y = 10 \quad \Leftrightarrow$
$y = -\frac{4}{5}x + 2$, so the slope is $-\frac{4}{5}$ and the y-intercept is 2.



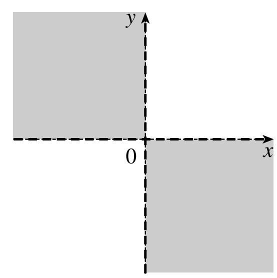
43. $\{(x, y) \mid x < 0\}$



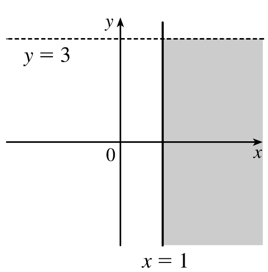
44. $\{(x, y) \mid y > 0\}$



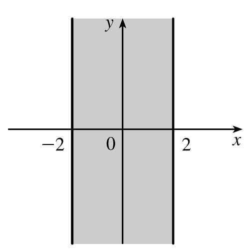
45. $\{(x, y) \mid xy < 0\} =$
$\{(x, y) \mid x < 0 \text{ and } y > 0\}$
$\cup \{(x, y) \mid x > 0 \text{ and } y < 0\}$



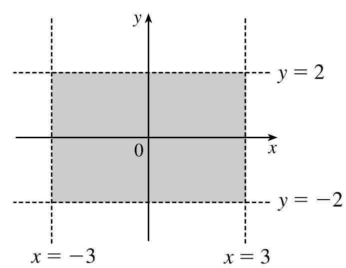
46. $\{(x, y) \mid x \geq 1 \text{ and } y < 3\}$



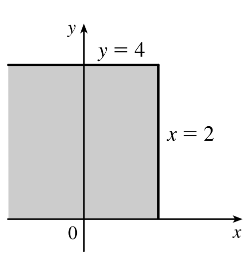
47. $\left\{(x, y) \,\middle|\, |x| \leq 2\right\} =$
$\{(x, y) \mid -2 \leq x \leq 2\}$



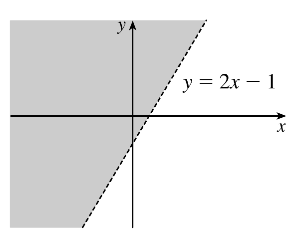
48. $\left\{(x, y) \,\middle|\, |x| < 3 \text{ and } |y| < 2\right\}$



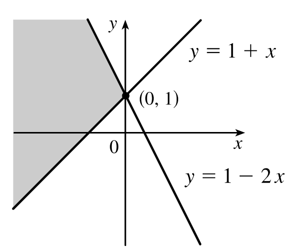
49. $\{(x, y) \mid 0 \leq y \leq 4, x \leq 2\}$



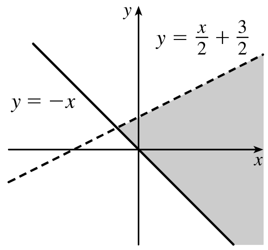
50. $\{(x, y) \mid y > 2x - 1\}$



51. $\{(x, y) \mid 1 + x \leq y \leq 1 - 2x\}$



52. $\{(x, y) \mid -x \le y < \frac{1}{2}(x+3)\}$



53. Let $P(0, y)$ be a point on the y-axis. The distance from P to $(5, -5)$ is $\sqrt{(5-0)^2 + (-5-y)^2} = \sqrt{5^2 + (y+5)^2}$. The distance from P to $(1, 1)$ is $\sqrt{(1-0)^2 + (1-y)^2} = \sqrt{1^2 + (y-1)^2}$. We want these distances to be equal: $\sqrt{5^2 + (y+5)^2} = \sqrt{1^2 + (y-1)^2} \Leftrightarrow 5^2 + (y+5)^2 = 1^2 + (y-1)^2 \Leftrightarrow 25 + (y^2 + 10y + 25) = 1 + (y^2 - 2y + 1) \Leftrightarrow 12y = -48 \Leftrightarrow y = -4$. So the desired point is $(0, -4)$.

54. Let M be the point $\left(\frac{x_1 + x_2}{2}, \frac{y_1 + y_2}{2}\right)$. Then

$$|MP_1|^2 = \left(x_1 - \frac{x_1 + x_2}{2}\right)^2 + \left(y_1 - \frac{y_1 + y_2}{2}\right)^2 = \left(\frac{x_1 - x_2}{2}\right)^2 + \left(\frac{y_1 - y_2}{2}\right)^2$$

$$|MP_2|^2 = \left(x_2 - \frac{x_1 + x_2}{2}\right)^2 + \left(y_2 - \frac{y_1 + y_2}{2}\right)^2 = \left(\frac{x_2 - x_1}{2}\right)^2 + \left(\frac{y_2 - y_1}{2}\right)^2$$

Hence, $|MP_1| = |MP_2|$; that is, M is equidistant from P_1 and P_2.

55. (a) Using the midpoint formula from Exercise 54 with $(1, 3)$ and $(7, 15)$, we get $\left(\frac{1+7}{2}, \frac{3+15}{2}\right) = (4, 9)$.

(b) Using the midpoint formula from Exercise 54 with $(-1, 6)$ and $(8, -12)$, we get $\left(\frac{-1+8}{2}, \frac{6+(-12)}{2}\right) = \left(\frac{7}{2}, -3\right)$.

56. With $A(1, 0)$, $B(3, 6)$, and $C(8, 2)$, the midpoint M_1 of AB is $\left(\frac{1+3}{2}, \frac{0+6}{2}\right) = (2, 3)$, the midpoint M_2 of BC is $\left(\frac{3+8}{2}, \frac{6+2}{2}\right) = \left(\frac{11}{2}, 4\right)$, and the midpoint M_3 of CA is $\left(\frac{8+1}{2}, \frac{2+0}{2}\right) = \left(\frac{9}{2}, 1\right)$. The lengths of the medians are

$$|AM_2| = \sqrt{\left(\tfrac{11}{2} - 1\right)^2 + (4-0)^2} = \sqrt{\left(\tfrac{9}{2}\right)^2 + 4^2} = \sqrt{\tfrac{145}{4}} = \tfrac{\sqrt{145}}{2}$$

$$|BM_3| = \sqrt{\left(\tfrac{9}{2} - 3\right)^2 + (1-6)^2} = \sqrt{\left(\tfrac{3}{2}\right)^2 + (-5)^2} = \sqrt{\tfrac{109}{4}} = \tfrac{\sqrt{109}}{2}$$

$$|CM_1| = \sqrt{(2-8)^2 + (3-2)^2} = \sqrt{(-6)^2 + 1^2} = \sqrt{37}$$

57. $2x - y = 4 \Leftrightarrow y = 2x - 4 \Rightarrow m_1 = 2$ and $6x - 2y = 10 \Leftrightarrow 2y = 6x - 10 \Leftrightarrow y = 3x - 5 \Rightarrow m_2 = 3$. Since $m_1 \ne m_2$, the two lines are not parallel. To find the point of intersection: $2x - 4 = 3x - 5 \Leftrightarrow x = 1 \Rightarrow y = -2$. Thus, the point of intersection is $(1, -2)$.

58. $3x - 5y + 19 = 0 \Leftrightarrow 5y = 3x + 19 \Leftrightarrow y = \frac{3}{5}x + \frac{19}{5} \Rightarrow m_1 = \frac{3}{5}$ and $10x + 6y - 50 = 0 \Leftrightarrow 6y = -10x + 50 \Leftrightarrow y = -\frac{5}{3}x + \frac{25}{3} \Rightarrow m_2 = -\frac{5}{3}$. Since $m_1 m_2 = \frac{3}{5}\left(-\frac{5}{3}\right) = -1$, the two lines are perpendicular. To find the point of intersection: $\frac{3}{5}x + \frac{19}{5} = -\frac{5}{3}x + \frac{25}{3} \Leftrightarrow 9x + 57 = -25x + 125 \Leftrightarrow 34x = 68 \Leftrightarrow x = 2 \Rightarrow y = \frac{3}{5} \cdot 2 + \frac{19}{5} = \frac{25}{5} = 5$. Thus, the point of intersection is $(2, 5)$.

59. With $A(1, 4)$ and $B(7, -2)$, the slope of segment AB is $\frac{-2-4}{7-1} = -1$, so its perpendicular bisector has slope 1. The midpoint of AB is $\left(\frac{1+7}{2}, \frac{4+(-2)}{2}\right) = (4, 1)$, so an equation of the perpendicular bisector is $y - 1 = 1(x - 4)$ or $y = x - 3$.

60. (a) Side PQ has slope $\frac{4-0}{3-1} = 2$, so its equation is $y - 0 = 2(x-1) \quad\Leftrightarrow\quad y = 2x - 2$. Side QR has slope $\frac{6-4}{-1-3} = -\frac{1}{2}$, so its equation is $y - 4 = -\frac{1}{2}(x-3) \quad\Leftrightarrow\quad y = -\frac{1}{2}x + \frac{11}{2}$. Side RP has slope $\frac{0-6}{1-(-1)} = -3$, so its equation is $y - 0 = -3(x-1) \quad\Leftrightarrow\quad y = -3x + 3$.

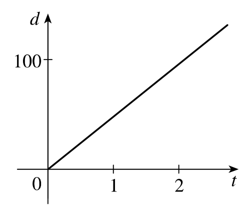
(b) M_1 (the midpoint of PQ) has coordinates $\left(\frac{1+3}{2}, \frac{0+4}{2}\right) = (2, 2)$. M_2 (the midpoint of QR) has coordinates $\left(\frac{3-1}{2}, \frac{4+6}{2}\right) = (1, 5)$. M_3 (the midpoint of RP) has coordinates $\left(\frac{1-1}{2}, \frac{0+6}{2}\right) = (0, 3)$. RM_1 has slope $\frac{2-6}{2-(-1)} = -\frac{4}{3}$ and hence equation $y - 2 = -\frac{4}{3}(x-2) \quad\Leftrightarrow\quad y = -\frac{4}{3}x + \frac{14}{3}$. PM_2 is a vertical line with equation $x = 1$. QM_3 has slope $\frac{3-4}{0-3} = \frac{1}{3}$ and hence equation $y - 3 = \frac{1}{3}(x-0) \quad\Leftrightarrow\quad y = \frac{1}{3}x + 3$. PM_2 and RM_1 intersect where $x = 1$ and $y = -\frac{4}{3}(1) + \frac{14}{3} = \frac{10}{3}$, or at $\left(1, \frac{10}{3}\right)$. PM_2 and QM_3 intersect where $x = 1$ and $y = \frac{1}{3}(1) + 3 = \frac{10}{3}$, or at $\left(1, \frac{10}{3}\right)$, so this is the point where all three medians intersect.

61. (a) Since the x-intercept is a, the point $(a, 0)$ is on the line, and similarly since the y-intercept is b, $(0, b)$ is on the line. Hence, the slope of the line is $m = \dfrac{b-0}{0-a} = -\dfrac{b}{a}$. Substituting into $y = mx + b$ gives $y = -\dfrac{b}{a}x + b \quad\Leftrightarrow\quad \dfrac{b}{a}x + y = b \quad\Leftrightarrow\quad \dfrac{x}{a} + \dfrac{y}{b} = 1$.

(b) Letting $a = 6$ and $b = -8$ gives $\dfrac{x}{6} + \dfrac{y}{-8} = 1 \quad\Leftrightarrow\quad -8x + 6y = -48$ [multiply by -48] $\Leftrightarrow\quad 6y = 8x - 48 \quad\Leftrightarrow\quad 3y = 4x - 24 \quad\Leftrightarrow\quad y = \frac{4}{3}x - 8$.

62. (a) Let $d =$ distance traveled (in miles) and $t =$ time elapsed (in hours). At $t = 0$, $d = 0$ and at $t = 50$ minutes $= 50 \cdot \frac{1}{60} = \frac{5}{6}$ h, $d = 40$. Thus, we have two points: $(0, 0)$ and $\left(\frac{5}{6}, 40\right)$, so $m = \dfrac{40-0}{5/6-0} = 48$ and $d = 48t$.

(b)



(c) The slope is 48 and represents the car's speed in mi/h.

C Graphs of Second-Degree Equations

1. An equation of the circle with center $(3, -1)$ and radius 5 is $(x-3)^2 + (y+1)^2 = 5^2 = 25$.

2. An equation of the circle with center $(-2, -8)$ and radius 10 is $(x+2)^2 + (y+8)^2 = 10^2 = 100$.

3. The equation has the form $x^2 + y^2 = r^2$. Since $(4, 7)$ lies on the circle, we have $4^2 + 7^2 = r^2 \quad\Rightarrow\quad r^2 = 65$. So the required equation is $x^2 + y^2 = 65$.

4. The equation has the form $(x+1)^2 + (y-5)^2 = r^2$. Since $(-4, -6)$ lies on the circle, we have $r^2 = (-4+1)^2 + (-6-5)^2 = 130$. So an equation is $(x+1)^2 + (y-5)^2 = 130$.

5. $x^2 + y^2 - 4x + 10y + 13 = 0 \quad\Leftrightarrow\quad x^2 - 4x + y^2 + 10y = -13 \quad\Leftrightarrow\quad (x^2 - 4x + 4) + (y^2 + 10y + 25) = -13 + 4 + 25 = 16 \quad\Leftrightarrow\quad (x-2)^2 + (y+5)^2 = 4^2$. Thus, we have a circle with center $(2, -5)$ and radius 4.

6. $x^2 + y^2 + 6y + 2 = 0 \quad\Leftrightarrow\quad x^2 + (y^2 + 6y + 9) = -2 + 9 \quad\Leftrightarrow\quad x^2 + (y+3)^2 = 7$. Thus, we have a circle with center $(0, -3)$ and radius $\sqrt{7}$.

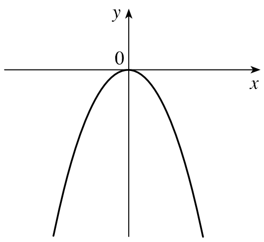
7. $x^2 + y^2 + x = 0 \iff \left(x^2 + x + \frac{1}{4}\right) + y^2 = \frac{1}{4} \iff \left(x + \frac{1}{2}\right)^2 + y^2 = \left(\frac{1}{2}\right)^2$. Thus, we have a circle with center $\left(-\frac{1}{2}, 0\right)$ and radius $\frac{1}{2}$.

8. $16x^2 + 16y^2 + 8x + 32y + 1 = 0 \iff 16\left(x^2 + \frac{1}{2}x + \frac{1}{16}\right) + 16(y^2 + 2y + 1) = -1 + 1 + 16 \iff$ $16\left(x + \frac{1}{4}\right)^2 + 16(y + 1)^2 = 16 \iff \left(x + \frac{1}{4}\right)^2 + (y + 1)^2 = 1$. Thus, we have a circle with center $\left(-\frac{1}{4}, -1\right)$ and radius 1.

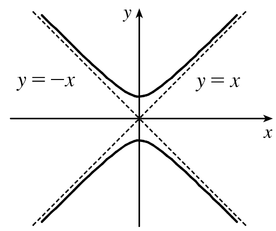
9. $2x^2 + 2y^2 - x + y = 1 \iff 2\left(x^2 - \frac{1}{2}x + \frac{1}{16}\right) + 2\left(y^2 + \frac{1}{2}y + \frac{1}{16}\right) = 1 + \frac{1}{8} + \frac{1}{8} \iff$ $2\left(x - \frac{1}{4}\right)^2 + 2\left(y + \frac{1}{4}\right)^2 = \frac{5}{4} \iff \left(x - \frac{1}{4}\right)^2 + \left(y + \frac{1}{4}\right)^2 = \frac{5}{8}$. Thus, we have a circle with center $\left(\frac{1}{4}, -\frac{1}{4}\right)$ and radius $\frac{\sqrt{5}}{2\sqrt{2}} = \frac{\sqrt{10}}{4}$.

10. $x^2 + y^2 + ax + by + c = 0 \iff \left(x^2 + ax + \frac{1}{4}a^2\right) + \left(y^2 + by + \frac{1}{4}b^2\right) = -c + \frac{1}{4}a^2 + \frac{1}{4}b^2 \iff$ $\left(x + \frac{1}{2}a\right)^2 + \left(y + \frac{1}{2}b\right)^2 = \frac{1}{4}(a^2 + b^2 - 4c)$. For this to represent a nondegenerate circle, $\frac{1}{4}(a^2 + b^2 - 4c) > 0$ or $a^2 + b^2 > 4c$. If this condition is satisfied, the circle has center $\left(-\frac{1}{2}a, -\frac{1}{2}b\right)$ and radius $\frac{1}{2}\sqrt{a^2 + b^2 - 4c}$.

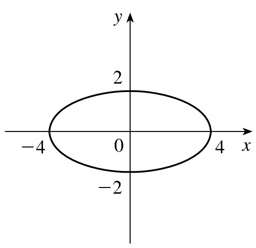
11. $y = -x^2$. Parabola



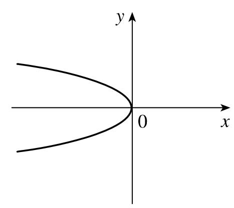
12. $y^2 - x^2 = 1$. Hyperbola



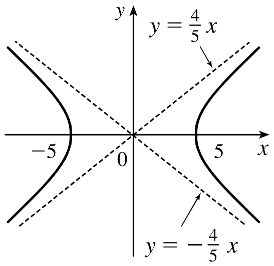
13. $x^2 + 4y^2 = 16 \iff \dfrac{x^2}{16} + \dfrac{y^2}{4} = 1$. Ellipse



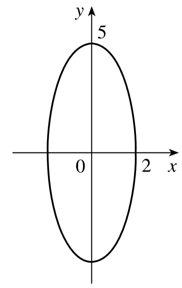
14. $x = -2y^2$. Parabola



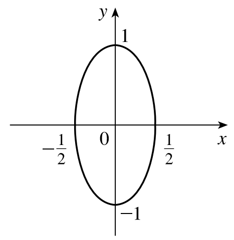
15. $16x^2 - 25y^2 = 400 \iff \dfrac{x^2}{25} - \dfrac{y^2}{16} = 1$. Hyperbola



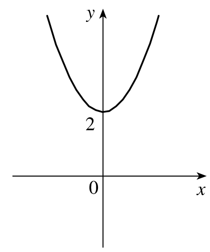
16. $25x^2 + 4y^2 = 100 \iff \dfrac{x^2}{4} + \dfrac{y^2}{25} = 1$. Ellipse



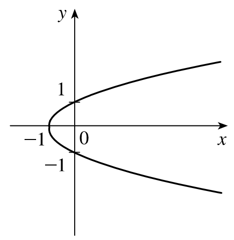
17. $4x^2 + y^2 = 1 \quad \Leftrightarrow \quad \dfrac{x^2}{1/4} + y^2 = 1$. Ellipse



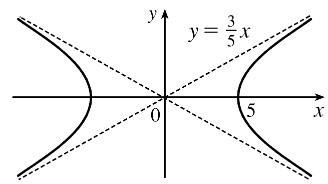
18. $y = x^2 + 2$. Parabola with vertex at $(0, 2)$



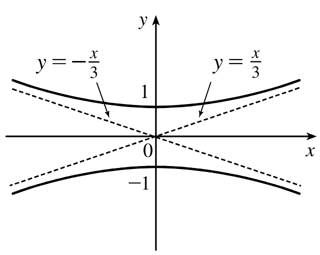
19. $x = y^2 - 1$. Parabola with vertex at $(-1, 0)$



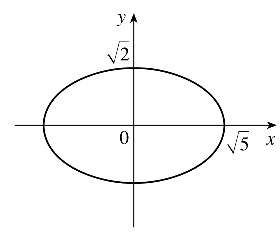
20. $9x^2 - 25y^2 = 225 \quad \Leftrightarrow \quad \dfrac{x^2}{25} - \dfrac{y^2}{9} = 1$. Hyperbola



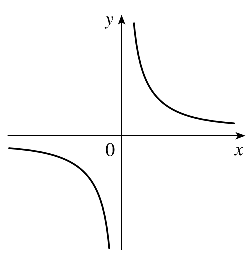
21. $9y^2 - x^2 = 9 \quad \Leftrightarrow \quad y^2 - \dfrac{x^2}{9} = 1$. Hyperbola



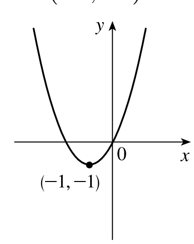
22. $2x^2 + 5y^2 = 10 \quad \Leftrightarrow \quad \dfrac{x^2}{5} + \dfrac{y^2}{2} = 1$. Ellipse



23. $xy = 4$. Hyperbola

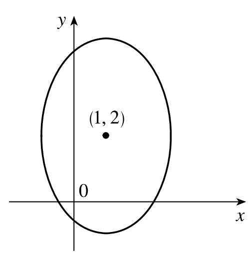


24. $y = x^2 + 2x = \left(x^2 + 2x + 1\right) - 1 = (x + 1)^2 - 1$.
Parabola with vertex at $(-1, -1)$



25. $9(x - 1)^2 + 4(y - 2)^2 = 36 \quad \Leftrightarrow$

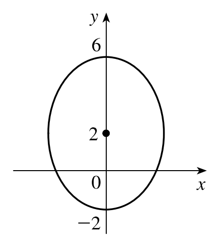
$\dfrac{(x - 1)^2}{4} + \dfrac{(y - 2)^2}{9} = 1$. Ellipse centered at $(1, 2)$



26. $16x^2 + 9y^2 - 36y = 108 \quad \Leftrightarrow$

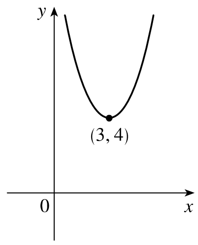
$16x^2 + 9(y^2 - 4y + 4) = 108 + 36 = 144 \quad \Leftrightarrow$

$\dfrac{x^2}{9} + \dfrac{(y - 2)^2}{16} = 1$. Ellipse centered at $(0, 2)$



27. $y = x^2 - 6x + 13 = \left(x^2 - 6x + 9\right) + 4 = (x-3)^2 + 4.$

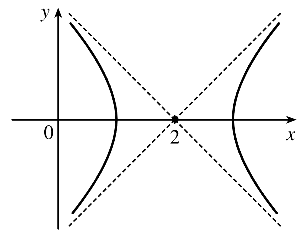
Parabola with vertex at $(3, 4)$



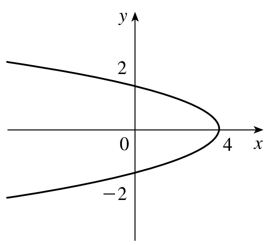
28. $x^2 - y^2 - 4x + 3 = 0 \quad \Leftrightarrow$

$\left(x^2 - 4x + 4\right) - y^2 = -3 + 4 = 1 \quad \Leftrightarrow$

$(x-2)^2 - y^2 = 1$. Hyperbola centered at $(2, 0)$

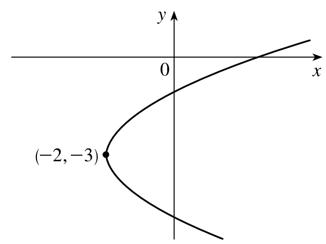


29. $x = 4 - y^2 = -y^2 + 4$. Parabola with vertex at $(4, 0)$



30. $y^2 - 2x + 6y + 5 = 0 \quad \Leftrightarrow \quad y^2 + 6y + 9 = 2x + 4 \quad \Leftrightarrow$

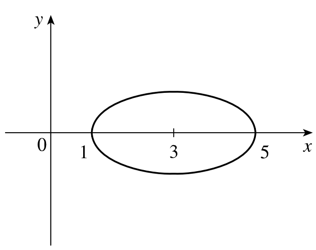
$(y+3)^2 = 2\,(x+2)$. Parabola with vertex $(-2, -3)$



31. $x^2 + 4y^2 - 6x + 5 = 0 \quad \Leftrightarrow$

$(x^2 - 6x + 9) + 4y^2 = -5 + 9 = 4 \quad \Leftrightarrow$

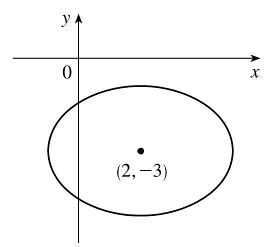
$\dfrac{(x-3)^2}{4} + y^2 = 1$. Ellipse centered at $(3, 0)$



32. $4x^2 + 9y^2 - 16x + 54y + 61 = 0 \quad \Leftrightarrow$

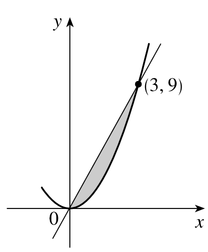
$4(x^2 - 4x + 4) + 9(y^2 + 6y + 9) = -61 + 16 + 81 = 36$

$\Leftrightarrow \quad \dfrac{(x-2)^2}{9} + \dfrac{(y+3)^2}{4} = 1$. Ellipse centered at $(2, -3)$



33. $y = 3x$ and $y = x^2$ intersect where $3x = x^2 \quad \Leftrightarrow$

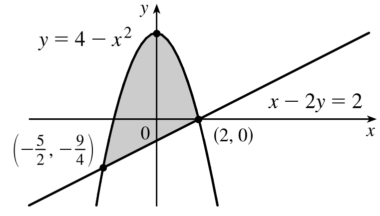
$0 = x^2 - 3x = x(x-3)$, that is, at $(0, 0)$ and $(3, 9)$.



34. $y = 4 - x^2$, $x - 2y = 2$. Substitute y from the first equation into the second: $x - 2(4 - x^2) = 2 \quad \Leftrightarrow$

$2x^2 + x - 10 = 0 \quad \Leftrightarrow \quad (2x+5)(x-2) = 0 \quad \Leftrightarrow$

$x = -\frac{5}{2}$ or 2. So the points of intersection are $\left(-\frac{5}{2}, -\frac{9}{4}\right)$ and $(2, 0)$.



35. The parabola must have an equation of the form $y = a(x-1)^2 - 1$. Substituting $x = 3$ and $y = 3$ into the equation gives $3 = a(3-1)^2 - 1$, so $a = 1$, and the equation is $y = (x-1)^2 - 1 = x^2 - 2x$. Note that using the other point $(-1, 3)$ would have given the same value for a, and hence the same equation.

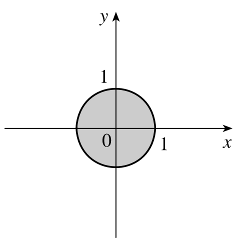
36. The ellipse has an equation of the form $\dfrac{x^2}{a^2} + \dfrac{y^2}{b^2} = 1$. Substituting $x = 1$ and $y = -\dfrac{10\sqrt{2}}{3}$ gives

$\dfrac{1^2}{a^2} + \dfrac{\left(-10\sqrt{2}/3\right)^2}{b^2} = \dfrac{1}{a^2} + \dfrac{200}{9b^2} = 1$. Substituting $x = -2$ and $y = \dfrac{5\sqrt{5}}{3}$ gives $\dfrac{(-2)^2}{a^2} + \dfrac{\left(5\sqrt{5}/3\right)^2}{b^2} = \dfrac{4}{a^2} + \dfrac{125}{9b^2} = 1$.

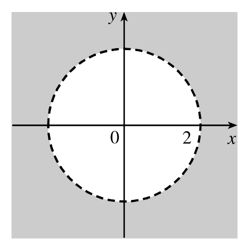
From the first equation, $\dfrac{1}{a^2} = 1 - \dfrac{200}{9b^2}$. Putting this into the second equation gives $4\left(1 - \dfrac{200}{9b^2}\right) + \dfrac{125}{9b^2} = 1 \;\Leftrightarrow$

$3 = \dfrac{675}{9b^2} \;\Leftrightarrow\; b^2 = \dfrac{675}{27} = 25$, so $b = 5$. Hence $\dfrac{1}{a^2} = 1 - \dfrac{200}{9(5)^2} = \dfrac{1}{9}$ and so $a = 3$. The equation of the ellipse is $\dfrac{x^2}{9} + \dfrac{y^2}{25} = 1$.

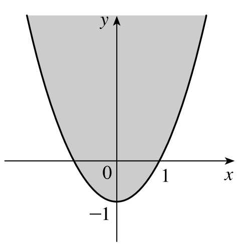
37. $\{(x,y) \mid x^2 + y^2 \le 1\}$



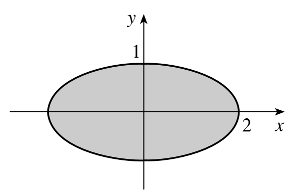
38. $\{(x,y) \mid x^2 + y^2 > 4\}$



39. $\{(x,y) \mid y \ge x^2 - 1\}$



40. $\{(x,y) \mid x^2 + 4y^2 \le 4\}$



D Trigonometry

1. $210^\circ = 210^\circ\left(\frac{\pi}{180^\circ}\right) = \frac{7\pi}{6}$ rad

2. $300^\circ = 300^\circ\left(\frac{\pi}{180^\circ}\right) = \frac{5\pi}{3}$ rad

3. $9^\circ = 9^\circ\left(\frac{\pi}{180^\circ}\right) = \frac{\pi}{20}$ rad

4. $-315^\circ = -315^\circ\left(\frac{\pi}{180^\circ}\right) = -\frac{7\pi}{4}$ rad

5. $900^\circ = 900^\circ\left(\frac{\pi}{180^\circ}\right) = 5\pi$ rad

6. $36^\circ = 36^\circ\left(\frac{\pi}{180^\circ}\right) = \frac{\pi}{5}$ rad

7. 4π rad $= 4\pi\left(\frac{180^\circ}{\pi}\right) = 720^\circ$

8. $-\frac{7\pi}{2}$ rad $= -\frac{7\pi}{2}\left(\frac{180^\circ}{\pi}\right) = -630^\circ$

9. $\frac{5\pi}{12}$ rad $= \frac{5\pi}{12}\left(\frac{180^\circ}{\pi}\right) = 75^\circ$

10. $\frac{8\pi}{3}$ rad $= \frac{8\pi}{3}\left(\frac{180^\circ}{\pi}\right) = 480^\circ$

11. $-\frac{3\pi}{8}$ rad $= -\frac{3\pi}{8}\left(\frac{180^\circ}{\pi}\right) = -67.5^\circ$

12. 5 rad $= 5\left(\frac{180^\circ}{\pi}\right) = \left(\frac{900}{\pi}\right)^\circ$

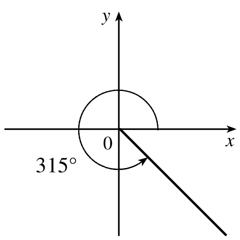
13. Using Formula 3, $a = r\theta = 36 \cdot \frac{\pi}{12} = 3\pi$ cm.

14. Using Formula 3, $a = r\theta = 10 \cdot 72^\circ\left(\frac{\pi}{180^\circ}\right) = 4\pi$ cm.

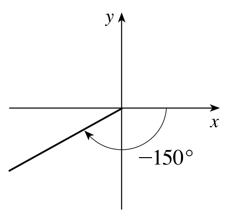
15. Using Formula 3, $\theta = a/r = \frac{1}{1.5} = \frac{2}{3}$ rad $= \frac{2}{3}\left(\frac{180^\circ}{\pi}\right) = \left(\frac{120}{\pi}\right)^\circ \approx 38.2^\circ$.

16. $a = r\theta \quad\Rightarrow\quad r = \frac{a}{\theta} = \frac{6}{3\pi/4} = \frac{8}{\pi}$ cm

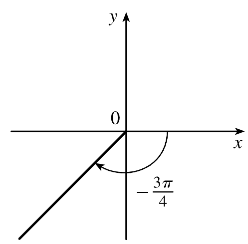
17.



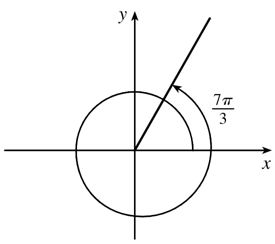
18.



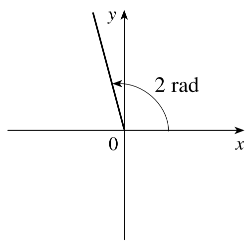
19.



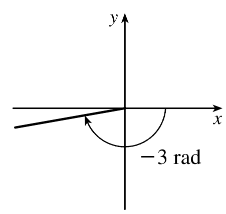
20.



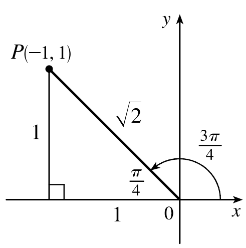
21.



22.

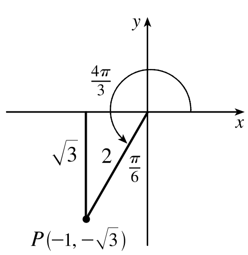


23.



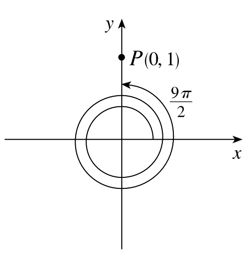
From the diagram we see that a point on the terminal side is $P(-1, 1)$. Therefore, taking $x = -1$, $y = 1$, $r = \sqrt{2}$ in the definitions of the trigonometric ratios, we have $\sin\frac{3\pi}{4} = \frac{1}{\sqrt{2}}$, $\cos\frac{3\pi}{4} = -\frac{1}{\sqrt{2}}$, $\tan\frac{3\pi}{4} = -1$, $\csc\frac{3\pi}{4} = \sqrt{2}$, $\sec\frac{3\pi}{4} = -\sqrt{2}$, and $\cot\frac{3\pi}{4} = -1$.

24.



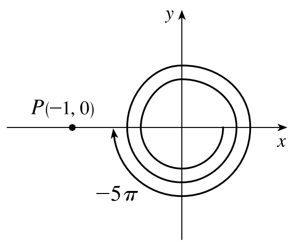
From the diagram and Figure 8, we see that a point on the terminal side is $P\left(-1, -\sqrt{3}\right)$. Therefore, taking $x = -1$, $y = -\sqrt{3}$, $r = 2$ in the definitions of the trigonometric ratios, we have $\sin\frac{4\pi}{3} = -\frac{\sqrt{3}}{2}$, $\cos\frac{4\pi}{3} = -\frac{1}{2}$, $\tan\frac{4\pi}{3} = \sqrt{3}$, $\csc\frac{4\pi}{3} = -\frac{2}{\sqrt{3}}$, $\sec\frac{4\pi}{3} = -2$, and $\cot\frac{4\pi}{3} = \frac{1}{\sqrt{3}}$.

25.



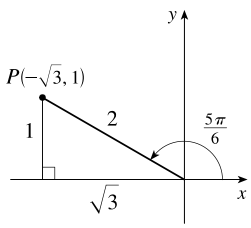
From the diagram we see that a point on the terminal side is $P(0, 1)$. Therefore taking $x = 0$, $y = 1$, $r = 1$ in the definitions of the trigonometric ratios, we have $\sin\frac{9\pi}{2} = 1$, $\cos\frac{9\pi}{2} = 0$, $\tan\frac{9\pi}{2} = y/x$ is undefined since $x = 0$, $\csc\frac{9\pi}{2} = 1$, $\sec\frac{9\pi}{2} = r/x$ is undefined since $x = 0$, and $\cot\frac{9\pi}{2} = 0$.

26.



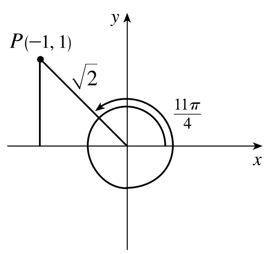
From the diagram, we see that a point on the terminal side is $P(-1,0)$. Therefore taking $x=-1$, $y=0$, $r=1$ in the definitions of the trigonometric ratios we have $\sin(-5\pi)=0$, $\cos(-5\pi)=-1$, $\tan(-5\pi)=0$, $\csc(-5\pi)$ is undefined, $\sec(-5\pi)=-1$, and $\cot(-5\pi)$ is undefined.

27.



Using Figure 8 we see that a point on the terminal side is $P\left(-\sqrt{3},1\right)$. Therefore taking $x=-\sqrt{3}$, $y=1$, $r=2$ in the definitions of the trigonometric ratios, we have $\sin\frac{5\pi}{6}=\frac{1}{2}$, $\cos\frac{5\pi}{6}=-\frac{\sqrt{3}}{2}$, $\tan\frac{5\pi}{6}=-\frac{1}{\sqrt{3}}$, $\csc\frac{5\pi}{6}=2$, $\sec\frac{5\pi}{6}=-\frac{2}{\sqrt{3}}$, and $\cot\frac{5\pi}{6}=-\sqrt{3}$.

28.



From the diagram, we see that a point on the terminal side is $P(-1,1)$. Therefore taking $x=-1$, $y=1$, $r=\sqrt{2}$ in the definitions of the trigonometric ratios we have $\sin\frac{11\pi}{4}=\frac{1}{\sqrt{2}}$, $\cos\frac{11\pi}{4}=-\frac{1}{\sqrt{2}}$, $\tan\frac{11\pi}{4}=-1$, $\csc\frac{11\pi}{4}=\sqrt{2}$, $\sec\frac{11\pi}{4}=-\sqrt{2}$, and $\cot\frac{11\pi}{4}=-1$.

29. $\sin\theta=y/r=\frac{3}{5}\ \Rightarrow\ y=3$, $r=5$, and $x=\sqrt{r^2-y^2}=4$ (since $0<\theta<\frac{\pi}{2}$). Therefore taking $x=4$, $y=3$, $r=5$ in the definitions of the trigonometric ratios, we have $\cos\theta=\frac{4}{5}$, $\tan\theta=\frac{3}{4}$, $\csc\theta=\frac{5}{3}$, $\sec\theta=\frac{5}{4}$, and $\cot\theta=\frac{4}{3}$.

30. Since $0<\alpha<\frac{\pi}{2}$, α is in the first quadrant where x and y are both positive. Therefore, $\tan\alpha=y/x=\frac{2}{1}\ \Rightarrow\ y=2$, $x=1$, and $r=\sqrt{x^2+y^2}=\sqrt{5}$. Taking $x=1$, $y=2$, $r=\sqrt{5}$ in the definitions of the trigonometric ratios, we have $\sin\alpha=\frac{2}{\sqrt{5}}$, $\cos\alpha=\frac{1}{\sqrt{5}}$, $\csc\alpha=\frac{\sqrt{5}}{2}$, $\sec\alpha=\sqrt{5}$, and $\cot\alpha=\frac{1}{2}$.

31. $\frac{\pi}{2}<\phi<\pi\ \Rightarrow\ \phi$ is in the second quadrant, where x is negative and y is positive. Therefore $\sec\phi=r/x=-1.5=-\frac{3}{2}\ \Rightarrow\ r=3$, $x=-2$, and $y=\sqrt{r^2-x^2}=\sqrt{5}$. Taking $x=-2$, $y=\sqrt{5}$, and $r=3$ in the definitions of the trigonometric ratios, we have $\sin\phi=\frac{\sqrt{5}}{3}$, $\cos\phi=-\frac{2}{3}$, $\tan\phi=-\frac{\sqrt{5}}{2}$, $\csc\phi=\frac{3}{\sqrt{5}}$, and $\cot\theta=-\frac{2}{\sqrt{5}}$.

32. Since $\pi<x<\frac{3\pi}{2}$, x is in the third quadrant where x and y are both negative. Therefore $\cos x=x/r=-\frac{1}{3}\ \Rightarrow\ x=-1$, $r=3$, and $y=-\sqrt{r^2-x^2}=-\sqrt{8}=-2\sqrt{2}$. Taking $x=-1$, $r=3$, $y=-2\sqrt{2}$ in the definitions of the trigonometric ratios, we have $\sin x=-\frac{2\sqrt{2}}{3}$, $\tan x=2\sqrt{2}$, $\csc x=-\frac{3}{2\sqrt{2}}$, $\sec x=-3$, and $\cot x=\frac{1}{2\sqrt{2}}$.

33. $\pi<\beta<2\pi$ means that β is in the third or fourth quadrant where y is negative. Also since $\cot\beta=x/y=3$ which is positive, x must also be negative. Therefore $\cot\beta=x/y=\frac{3}{1}\ \Rightarrow\ x=-3$, $y=-1$, and $r=\sqrt{x^2+y^2}=\sqrt{10}$. Taking $x=-3$, $y=-1$ and $r=\sqrt{10}$ in the definitions of the trigonometric ratios, we have $\sin\beta=-\frac{1}{\sqrt{10}}$, $\cos\beta=-\frac{3}{\sqrt{10}}$, $\tan\beta=\frac{1}{3}$, $\csc\beta=-\sqrt{10}$, and $\sec\beta=-\frac{\sqrt{10}}{3}$.

34. Since $\frac{3\pi}{2} < \theta < 2\pi$, θ is in the fourth quadrant where x is positive and y is negative. Therefore $\csc\theta = r/y = -\frac{4}{3}$ $\Rightarrow$ $r = 4$, $y = -3$, and $x = \sqrt{r^2 - y^2} = \sqrt{7}$. Taking $x = \sqrt{7}$, $y = -3$, and $r = 4$ in the definitions of the trigonometric ratios, we have $\sin\theta = -\frac{3}{4}$, $\cos\theta = \frac{\sqrt{7}}{4}$, $\tan\theta = -\frac{3}{\sqrt{7}}$, $\sec\theta = \frac{4}{\sqrt{7}}$, and $\cot\theta = -\frac{\sqrt{7}}{3}$.

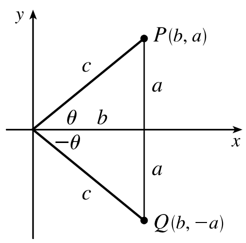
35. $\sin 35^\circ = \dfrac{x}{10} \quad\Rightarrow\quad x = 10\sin 35^\circ \approx 5.73576$ cm

36. $\cos 40^\circ = \dfrac{x}{25} \quad\Rightarrow\quad x = 25\cos 40^\circ \approx 19.15111$ cm

37. $\tan\frac{2\pi}{5} = \dfrac{x}{8} \quad\Rightarrow\quad x = 8\tan\frac{2\pi}{5} \approx 24.62147$ cm

38. $\cos\dfrac{3\pi}{8} = \dfrac{22}{x} \quad\Rightarrow\quad x = \dfrac{22}{\cos\dfrac{3\pi}{8}} \approx 57.48877$ cm

39.



(a) From the diagram we see that $\sin\theta = \dfrac{y}{r} = \dfrac{a}{c}$, and $\sin(-\theta) = \dfrac{-a}{c} = -\dfrac{a}{c} = -\sin\theta$.

(b) Again from the diagram we see that $\cos\theta = \dfrac{x}{r} = \dfrac{b}{c} = \cos(-\theta)$.

40. (a) Using (12a) and (12b), we have

$$\tan(x+y) = \frac{\sin(x+y)}{\cos(x+y)} = \frac{\sin x\,\cos y + \cos x\,\sin y}{\cos x\,\cos y - \sin x\,\sin y} = \frac{\dfrac{\sin x\,\cos y}{\cos x\,\cos y} + \dfrac{\cos x\,\sin y}{\cos x\,\cos y}}{\dfrac{\cos x\,\cos y}{\cos x\,\cos y} - \dfrac{\sin x\,\sin y}{\cos x\,\cos y}} = \frac{\tan x + \tan y}{1 - \tan x\,\tan y}$$

(b) From (10a) and (10b), we have $\tan(-\theta) = -\tan\theta$, so (14a) implies that

$$\tan(x-y) = \tan(x + (-y)) = \frac{\tan x + \tan(-y)}{1 - \tan x\,\tan(-y)} = \frac{\tan x - \tan y}{1 + \tan x\,\tan y}$$

41. (a) Using (12a) and (13a), we have

$\frac{1}{2}[\sin(x+y) + \sin(x-y)] = \frac{1}{2}[\sin x\,\cos y + \cos x\,\sin y + \sin x\,\cos y - \cos x\,\sin y] = \frac{1}{2}(2\sin x\,\cos y) = \sin x\,\cos y$.

(b) This time, using (12b) and (13b), we have

$\frac{1}{2}[\cos(x+y) + \cos(x-y)] = \frac{1}{2}[\cos x\,\cos y - \sin x\,\sin y + \cos x\,\cos y + \sin x\,\sin y] = \frac{1}{2}(2\cos x\,\cos y) = \cos x\,\cos y$.

(c) Again using (12b) and (13b), we have

$$\begin{aligned}\tfrac{1}{2}[\cos(x-y) - \cos(x+y)] &= \tfrac{1}{2}[\cos x\,\cos y + \sin x\,\sin y - \cos x\,\cos y + \sin x\,\sin y] \\ &= \tfrac{1}{2}(2\sin x\,\sin y) = \sin x\,\sin y\end{aligned}$$

42. Using (13b), $\cos\left(\frac{\pi}{2} - x\right) = \cos\frac{\pi}{2}\cos x + \sin\frac{\pi}{2}\sin x = 0\cdot\cos x + 1\cdot\sin x = \sin x$.

43. Using (12a), we have $\sin\left(\frac{\pi}{2} + x\right) = \sin\frac{\pi}{2}\cos x + \cos\frac{\pi}{2}\sin x = 1\cdot\cos x + 0\cdot\sin x = \cos x$.

44. Using (13a), we have $\sin(\pi - x) = \sin\pi\cos x - \cos\pi\,\sin x = 0\cdot\cos x - (-1)\sin x = \sin x$.

45. Using (6), we have $\sin\theta\cot\theta = \sin\theta\cdot\dfrac{\cos\theta}{\sin\theta} = \cos\theta$.

46. $(\sin x + \cos x)^2 = \sin^2 x + 2\sin x\,\cos x + \cos^2 x = (\sin^2 x + \cos^2 x) + \sin 2x$ [by (15a)] $= 1 + \sin 2x$ [by (7)]

47. $\sec y - \cos y = \dfrac{1}{\cos y} - \cos y$ [by (6)] $= \dfrac{1-\cos^2 y}{\cos y} = \dfrac{\sin^2 y}{\cos y}$ [by (7)] $= \dfrac{\sin y}{\cos y}\sin y = \tan y\,\sin y$ [by (6)]

48. $\tan^2\alpha - \sin^2\alpha = \dfrac{\sin^2\alpha}{\cos^2\alpha} - \sin^2\alpha = \dfrac{\sin^2\alpha - \sin^2\alpha\,\cos^2\alpha}{\cos^2\alpha} = \dfrac{\sin^2\alpha\,(1-\cos^2\alpha)}{\cos^2\alpha} = \tan^2\alpha\,\sin^2\alpha$ [by (6), (7)]

49. $\cot^2\theta + \sec^2\theta = \dfrac{\cos^2\theta}{\sin^2\theta} + \dfrac{1}{\cos^2\theta}$ [by (6)] $= \dfrac{\cos^2\theta\,\cos^2\theta + \sin^2\theta}{\sin^2\theta\,\cos^2\theta}$

$= \dfrac{(1-\sin^2\theta)(1-\sin^2\theta)+\sin^2\theta}{\sin^2\theta\cos^2\theta}$ [by (7)] $= \dfrac{1-\sin^2\theta+\sin^4\theta}{\sin^2\theta\cos^2\theta}$

$= \dfrac{\cos^2\theta+\sin^4\theta}{\sin^2\theta\cos^2\theta}$ [*by* (7)] $= \dfrac{1}{\sin^2\theta} + \dfrac{\sin^2\theta}{\cos^2\theta} = \csc^2\theta + \tan^2\theta$ [by (6)]

50. $2\csc 2t = \dfrac{2}{\sin 2t} = \dfrac{2}{2\sin t\,\cos t}$ [by (15a)] $= \dfrac{1}{\sin t\,\cos t} = \sec t\,\csc t$

51. Using (14a), we have $\tan 2\theta = \tan(\theta+\theta) = \dfrac{\tan\theta + \tan\theta}{1-\tan\theta\,\tan\theta} = \dfrac{2\tan\theta}{1-\tan^2\theta}$.

52. $\dfrac{1}{1-\sin\theta} + \dfrac{1}{1+\sin\theta} = \dfrac{1+\sin\theta+1-\sin\theta}{(1-\sin\theta)(1+\sin\theta)} = \dfrac{2}{1-\sin^2\theta} = \dfrac{2}{\cos^2\theta}$ [by (7)] $= 2\sec^2\theta$

53. Using (15a) and (16a),

$$\begin{aligned}\sin x\,\sin 2x + \cos x\,\cos 2x &= \sin x\,(2\sin x\cos x) + \cos x\,(2\cos^2 x - 1) = 2\sin^2 x\,\cos x + 2\cos^3 x - \cos x\\ &= 2(1-\cos^2 x)\,\cos x + 2\cos^3 x - \cos x \quad \text{[by (7)]}\\ &= 2\cos x - 2\cos^3 x + 2\cos^3 x - \cos x = \cos x\end{aligned}$$

Or: $\sin x\sin 2x + \cos x\,\cos 2x = \cos(2x - x)$ [by 13(b)] $= \cos x$

54. We start with the right side using equations (12a) and (13a):

$$\begin{aligned}\sin(x+y)\sin(x-y) &= (\sin x\,\cos y + \cos x\,\sin y)(\sin x\,\cos y - \cos x\,\sin y)\\ &= \sin^2 x\,\cos^2 y - \sin x\,\cos y\,\cos x\,\sin y + \cos x\,\sin y\,\sin x\,\cos y - \cos^2 x\,\sin^2 y\\ &= \sin^2 x\,(1-\sin^2 y) - (1-\sin^2 x)\,\sin^2 y \quad \text{[by (7)]}\\ &= \sin^2 x - \sin^2 x\,\sin^2 y - \sin^2 y + \sin^2 x\,\sin^2 y = \sin^2 x - \sin^2 y\end{aligned}$$

55. $\dfrac{\sin\phi}{1-\cos\phi} = \dfrac{\sin\phi}{1-\cos\phi}\cdot\dfrac{1+\cos\phi}{1+\cos\phi} = \dfrac{\sin\phi\,(1+\cos\phi)}{1-\cos^2\phi} = \dfrac{\sin\phi\,(1+\cos\phi)}{\sin^2\phi}$ [by (7)]

$= \dfrac{1+\cos\phi}{\sin\phi} = \dfrac{1}{\sin\phi} + \dfrac{\cos\phi}{\sin\phi} = \csc\phi + \cot\phi$ [by (6)]

56. $\tan x + \tan y = \dfrac{\sin x}{\cos x} + \dfrac{\sin y}{\cos y} = \dfrac{\sin x\,\cos y + \cos x\,\sin y}{\cos x\,\cos y} = \dfrac{\sin(x+y)}{\cos x\,\cos y}$ [by (12a)]

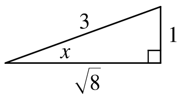
57. Using (12a),

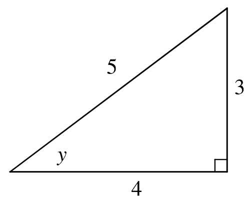
$$\begin{aligned}\sin 3\theta + \sin\theta &= \sin(2\theta+\theta) + \sin\theta = \sin 2\theta\,\cos\theta + \cos 2\theta\,\sin\theta + \sin\theta\\ &= \sin 2\theta\cos\theta + (2\cos^2\theta - 1)\,\sin\theta + \sin\theta \quad \text{[by (16a)]}\\ &= \sin 2\theta\,\cos\theta + 2\cos^2\theta\,\sin\theta - \sin\theta + \sin\theta = \sin 2\theta\,\cos\theta + \sin 2\theta\,\cos\theta \quad \text{[by (15a)]}\\ &= 2\sin 2\theta\,\cos\theta\end{aligned}$$

58. We use (12b) with $x = 2\theta$, $y = \theta$ to get

$$\begin{aligned}\cos 3\theta = \cos(2\theta + \theta) &= \cos 2\theta\,\cos\theta - \sin 2\theta\,\sin\theta \\ &= (2\cos^2\theta - 1)\cos\theta - 2\sin^2\theta\,\cos\theta \quad \text{[by (16a) and (15a)]} \\ &= (2\cos^2\theta - 1)\cos\theta - 2(1 - \cos^2\theta)\,\cos\theta \quad \text{[by (7)]} \\ &= 2\cos^3\theta - \cos\theta - 2\cos\theta + 2\cos^3\theta = 4\cos^3\theta - 3\cos\theta\end{aligned}$$

59. Since $\sin x = \frac{1}{3}$ we can label the opposite side as having length 1, the hypotenuse as having length 3, and use the Pythagorean Theorem to get that the adjacent side has length $\sqrt{8}$. Then, from the diagram, $\cos x = \frac{\sqrt{8}}{3}$. Similarly we have that $\sin y = \frac{3}{5}$. Now use (12a):





$\sin(x + y) = \sin x\,\cos y + \cos x\,\sin y = \frac{1}{3} \cdot \frac{4}{5} + \frac{\sqrt{8}}{3} \cdot \frac{3}{5} = \frac{4}{15} + \frac{3\sqrt{8}}{15} = \frac{4 + 6\sqrt{2}}{15}$.

60. Use (12b) and the values for $\sin y$ and $\cos x$ obtained in Exercise 59 to get

$$\cos(x + y) = \cos x\,\cos y - \sin x\,\sin y = \frac{\sqrt{8}}{3} \cdot \frac{4}{5} - \frac{1}{3} \cdot \frac{3}{5} = \frac{8\sqrt{2} - 3}{15}$$

61. Using (13b) and the values for $\cos x$ and $\sin y$ obtained in Exercise 59, we have

$$\cos(x - y) = \cos x\,\cos y + \sin x\,\sin y = \frac{\sqrt{8}}{3} \cdot \frac{4}{5} + \frac{1}{3} \cdot \frac{3}{5} = \frac{8\sqrt{2} + 3}{15}$$

62. Using (13a) and the values for $\sin y$ and $\cos x$ obtained in Exercise 59, we get

$$\sin(x - y) = \sin x\,\cos y - \cos x\,\sin y = \frac{1}{3} \cdot \frac{4}{5} - \frac{\sqrt{8}}{3} \cdot \frac{3}{5} = \frac{4 - 6\sqrt{2}}{15}$$

63. Using (15a) and the values for $\sin y$ and $\cos y$ obtained in Exercise 59, we have $\sin 2y = 2\sin y\,\cos y = 2 \cdot \frac{3}{5} \cdot \frac{4}{5} = \frac{24}{25}$.

64. Using (16a) with $\cos y = \frac{4}{5}$, we have $\cos 2y = 2\cos^2 y - 1 = 2\left(\frac{4}{5}\right)^2 - 1 = \frac{32}{25} - 1 = \frac{7}{25}$.

65. $2\cos x - 1 = 0 \quad \Leftrightarrow \quad \cos x = \frac{1}{2} \quad \Rightarrow \quad x = \frac{\pi}{3}, \frac{5\pi}{3}$ for $x \in [0, 2\pi]$.

66. $3\cot^2 x = 1 \quad \Leftrightarrow \quad 3 = 1/\cot^2 x \quad \Leftrightarrow \quad \tan^2 x = 3 \quad \Leftrightarrow \quad \tan x = \pm\sqrt{3} \quad \Rightarrow \quad x = \frac{\pi}{3}, \frac{2\pi}{3}, \frac{4\pi}{3}$, and $\frac{5\pi}{3}$.

67. $2\sin^2 x = 1 \quad \Leftrightarrow \quad \sin^2 x = \frac{1}{2} \quad \Leftrightarrow \quad \sin x = \pm\frac{1}{\sqrt{2}} \quad \Rightarrow \quad x = \frac{\pi}{4}, \frac{3\pi}{4}, \frac{5\pi}{4}, \frac{7\pi}{4}$.

68. $|\tan x| = 1 \quad \Leftrightarrow \quad \tan x = -1$ or $\tan x = 1 \quad \Leftrightarrow \quad x = \frac{3\pi}{4}, \frac{7\pi}{4}$ or $x = \frac{\pi}{4}, \frac{5\pi}{4}$.

69. Using (15a), we have $\sin 2x = \cos x \quad \Leftrightarrow \quad 2\sin x\,\cos x - \cos x = 0 \quad \Leftrightarrow \quad \cos x(2\sin x - 1) = 0 \quad \Leftrightarrow \quad \cos x = 0$ or $2\sin x - 1 = 0 \quad \Rightarrow \quad x = \frac{\pi}{2}, \frac{3\pi}{2}$ or $\sin x = \frac{1}{2} \quad \Rightarrow \quad x = \frac{\pi}{6}$ or $\frac{5\pi}{6}$. Therefore, the solutions are $x = \frac{\pi}{6}, \frac{\pi}{2}, \frac{5\pi}{6}, \frac{3\pi}{2}$.

70. By (15a), $2\cos x + \sin 2x = 0 \quad \Leftrightarrow \quad 2\cos x + 2\sin x\cos x = 0 \quad \Leftrightarrow \quad 2\cos x\,(1 + \sin x) = 0 \quad \Leftrightarrow \quad \cos x = 0$ or $1 + \sin x = 0 \quad \Leftrightarrow \quad x = \frac{\pi}{2}, \frac{3\pi}{2}$ or $\sin x = -1 \quad \Rightarrow \quad x = \frac{3}{2}\pi$. So the solutions are $x = \frac{\pi}{2}, \frac{3\pi}{2}$.

71. $\sin x = \tan x \quad \Leftrightarrow \quad \sin x - \tan x = 0 \quad \Leftrightarrow \quad \sin x - \dfrac{\sin x}{\cos x} = 0 \quad \Leftrightarrow \quad \sin x\left(1 - \dfrac{1}{\cos x}\right) = 0 \quad \Leftrightarrow \quad \sin x = 0$ or $1 - \dfrac{1}{\cos x} = 0 \quad \Rightarrow \quad x = 0, \pi, 2\pi$ or $1 = \dfrac{1}{\cos x} \quad \Rightarrow \quad \cos x = 1 \quad \Rightarrow \quad x = 0, 2\pi$. Therefore the solutions are $x = 0, \pi, 2\pi$.

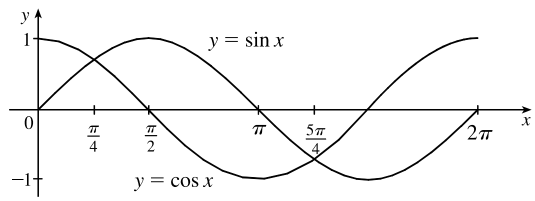
72. By (16a), $2 + \cos 2x = 3\cos x \quad \Leftrightarrow \quad 2 + 2\cos^2 x - 1 = 3\cos x \quad \Leftrightarrow \quad 2\cos^2 x - 3\cos x + 1 = 0 \quad \Leftrightarrow$ $(2\cos x - 1)(\cos x - 1) = 0 \quad \Leftrightarrow \quad \cos x = 1$ or $\cos x = \frac{1}{2} \quad \Rightarrow \quad x = 0, 2\pi$ or $x = \frac{\pi}{3}, \frac{5\pi}{3}$.

73. We know that $\sin x = \frac{1}{2}$ when $x = \frac{\pi}{6}$ or $\frac{5\pi}{6}$, and from Figure 13(a), we see that $\sin x \leq \frac{1}{2} \quad \Rightarrow \quad 0 \leq x \leq \frac{\pi}{6}$ or $\frac{5\pi}{6} \leq x \leq 2\pi$ for $x \in [0, 2\pi]$.

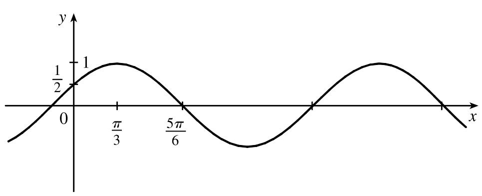
74. $2\cos x + 1 > 0 \quad \Rightarrow \quad 2\cos x > -1 \quad \Rightarrow \quad \cos x > -\frac{1}{2}$. $\cos x = -\frac{1}{2}$ when $x = \frac{2\pi}{3}, \frac{4\pi}{3}$ and from Figure 13(b), we see that $\cos\, x > -\frac{1}{2}$ when $0 \leq x < \frac{2\pi}{3}$, $\frac{4\pi}{3} < x \leq 2\pi$.

75. $\tan x = -1$ when $x = \frac{3\pi}{4}, \frac{7\pi}{4}$, and $\tan x = 1$ when $x = \frac{\pi}{4}$ or $\frac{5\pi}{4}$. From Figure 14(a) we see that $-1 < \tan x < 1 \quad \Rightarrow$ $0 \leq x < \frac{\pi}{4}$, $\frac{3\pi}{4} < x < \frac{5\pi}{4}$, and $\frac{7\pi}{4} < x \leq 2\pi$.

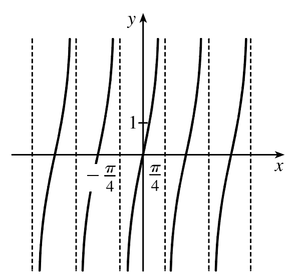
76. We know that $\sin x = \cos x$ when $x = \frac{\pi}{4}, \frac{5\pi}{4}$, and from the diagram we see that $\sin x > \cos x$ when $\frac{\pi}{4} < x < \frac{5\pi}{4}$.



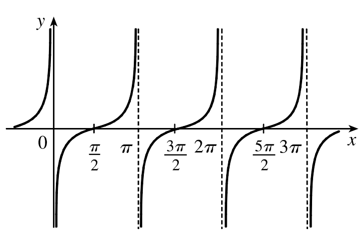
77. $y = \cos\left(x - \frac{\pi}{3}\right)$. We start with the graph of $y = \cos x$ and shift it $\frac{\pi}{3}$ units to the right.



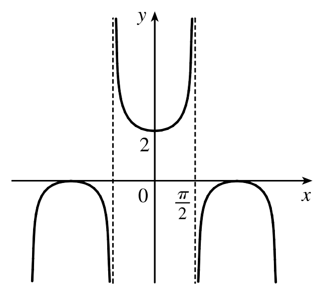
78. $y = \tan 2x$. Start with the graph of $y = \tan x$ with period π and compress it to a period of $\frac{\pi}{2}$.



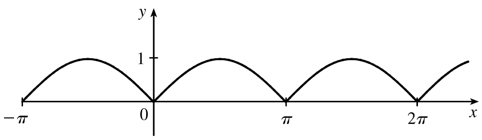
79. $y = \frac{1}{3}\tan\left(x - \frac{\pi}{2}\right)$. We start with the graph of $y = \tan x$, shift it $\frac{\pi}{2}$ units to the right and compress it to $\frac{1}{3}$ of its original vertical size.



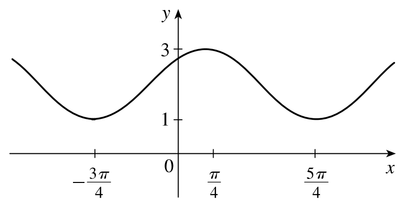
80. $y = 1 + \sec x$. Start with the graph of $y = \sec x$ and raise it by one unit.



81. $y = |\sin x|$. We start with the graph of $y = \sin x$ and reflect the parts below the x-axis about the x-axis.



82. $y = 2 + \sin\left(x + \frac{\pi}{4}\right)$. Start with the graph of $y = \sin x$, and shift it $\frac{\pi}{4}$ units to the left and 2 units up.



83. From the figure in the text, we see that $x = b\cos\theta$, $y = b\sin\theta$, and from the distance formula we have that the distance c from (x, y) to $(a, 0)$ is $c = \sqrt{(x-a)^2 + (y-0)^2} \quad\Rightarrow$

$$\begin{aligned} c^2 &= (b\cos\theta - a)^2 + (b\sin\theta)^2 = b^2\cos^2\theta - 2ab\cos\theta + a^2 + b^2\sin^2\theta \\ &= a^2 + b^2(\cos^2\theta + \sin^2\theta) - 2ab\cos\theta = a^2 + b^2 - 2ab\cos\theta \quad \text{[by (7)]} \end{aligned}$$

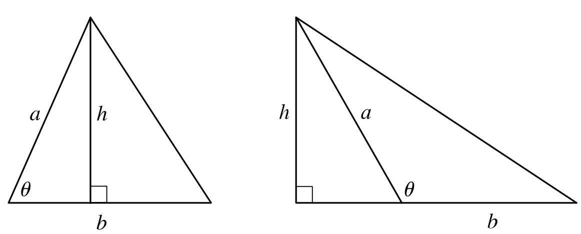
84. $|AB|^2 = |AC|^2 + |BC|^2 - 2\,|AC|\,|BC|\cos\angle C = (820)^2 + (910)^2 - 2(820)(910)\cos 103^\circ \approx 1{,}836{,}217 \quad\Rightarrow$ $|AB| \approx 1355$ m

85. Using the Law of Cosines, we have $c^2 = 1^2 + 1^2 - 2(1)(1)\cos(\alpha - \beta) = 2\,[1 - \cos(\alpha - \beta)]$. Now, using the distance formula, $c^2 = |AB|^2 = (\cos\alpha - \cos\beta)^2 + (\sin\alpha - \sin\beta)^2$. Equating these two expressions for c^2, we get $2[1 - \cos(\alpha - \beta)] = \cos^2\alpha + \sin^2\alpha + \cos^2\beta + \sin^2\beta - 2\cos\alpha\,\cos\beta - 2\sin\alpha\,\sin\beta \quad\Rightarrow$ $1 - \cos(\alpha - \beta) = 1 - \cos\alpha\,\cos\beta - \sin\alpha\,\sin\beta \quad\Rightarrow\quad \cos(\alpha - \beta) = \cos\alpha\,\cos\beta + \sin\alpha\,\sin\beta$.

86.
$$\begin{aligned} \cos(x + y) &= \cos(x - (-y)) = \cos x\,\cos(-y) + \sin x\,\sin(-y) \\ &= \cos x\,\cos y - \sin x\,\sin y \quad \text{[using Equations (10a) and (10b)]} \end{aligned}$$

87. In Exercise 86 we used the subtraction formula for cosine to prove the addition formula for cosine. Using that formula with $x = \frac{\pi}{2} - \alpha$, $y = \beta$, we get $\cos\left[\left(\frac{\pi}{2} - \alpha\right) + \beta\right] = \cos\left(\frac{\pi}{2} - \alpha\right)\cos\beta - \sin\left(\frac{\pi}{2} - \alpha\right)\sin\beta \quad\Rightarrow$ $\cos\left[\frac{\pi}{2} - (\alpha - \beta)\right] = \cos\left(\frac{\pi}{2} - \alpha\right)\cos\beta - \sin\left(\frac{\pi}{2} - \alpha\right)\sin\beta$. Now we use the identities given in the problem, $\cos\left(\frac{\pi}{2} - \theta\right) = \sin\theta$ and $\sin\left(\frac{\pi}{2} - \theta\right) = \cos\theta$, to get $\sin(\alpha - \beta) = \sin\alpha\,\cos\beta - \cos\alpha\,\sin\beta$.

88. If $0 < \theta < \frac{\pi}{2}$, we have the case depicted in the first diagram. In this case, we see that the height of the triangle is $h = a\sin\theta$. If $\frac{\pi}{2} \le \theta < \pi$, we have the case depicted in the second diagram. In this case, the height of the triangle is $h = a\sin(\pi - \theta) = a\sin\theta$ (by the identity proved in Exercise 44). So in either case, the area of the triangle is $\frac{1}{2}bh = \frac{1}{2}ab\sin\theta$.



89. Using the formula from Exercise 88, the area of the triangle is $\frac{1}{2}(10)(3)\sin 107^\circ \approx 14.34457\ \text{cm}^2$.

E Sigma Notation

1. $\sum_{i=1}^{5} \sqrt{i} = \sqrt{1} + \sqrt{2} + \sqrt{3} + \sqrt{4} + \sqrt{5}$

2. $\sum_{i=1}^{6} \frac{1}{i+1} = \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \frac{1}{5} + \frac{1}{6} + \frac{1}{7}$

14. $\frac{3}{7} + \frac{4}{8} + \frac{5}{9} + \frac{6}{10} + \cdots + \frac{23}{27} = \sum_{i=3}^{23} \frac{i}{i+4}$

15. $2 + 4 + 6 + 8 + \cdots + 2n = \sum_{i=1}^{n} 2i$

16. $1 + 3 + 5 + 7 + \cdots + (2n-1) = \sum_{i=1}^{n} (2i-1)$

17. $1 + 2 + 4 + 8 + 16 + 32 = \sum_{i=0}^{5} 2^i$

18. $\frac{1}{1} + \frac{1}{4} + \frac{1}{9} + \frac{1}{16} + \frac{1}{25} + \frac{1}{36} = \sum_{i=1}^{6} \frac{1}{i^2}$

19. $x + x^2 + x^3 + \cdots + x^n = \sum_{i=1}^{n} x^i$

20. $1 - x + x^2 - x^3 + \cdots + (-1)^n x^n = \sum_{i=0}^{n} (-1)^i x^i$

21. $\sum_{i=4}^{8} (3i-2) = [3(4)-2] + [3(5)-2] + [3(6)-2] + [3(7)-2] + [3(8)-2] = 10 + 13 + 16 + 19 + 22 = 80$

22. $\sum_{i=3}^{6} i(i+2) = 3 \cdot 5 + 4 \cdot 6 + 5 \cdot 7 + 6 \cdot 8 = 15 + 24 + 35 + 48 = 122$

23. $\sum_{j=1}^{6} 3^{j+1} = 3^2 + 3^3 + 3^4 + 3^5 + 3^6 + 3^7 = 9 + 27 + 81 + 243 + 729 + 2187 = 3276$

(For a more general method, see Exercise 47.)

24. $$\begin{aligned}\sum_{k=0}^{8} \cos k\pi &= \cos 0 + \cos \pi + \cos 2\pi + \cos 3\pi + \cos 4\pi + \cos 5\pi + \cos 6\pi + \cos 7\pi + \cos 8\pi \\ &= 1 - 1 + 1 - 1 + 1 - 1 + 1 - 1 + 1 = 1\end{aligned}$$

25. $\sum_{n=1}^{20} (-1)^n = -1 + 1 - 1 + 1 - 1 + 1 - 1 + 1 - 1 + 1 - 1 + 1 - 1 + 1 - 1 + 1 - 1 + 1 - 1 + 1 = 0$

26. $\sum_{i=1}^{100} 4 = \underbrace{4 + 4 + 4 + \cdots + 4}_{\text{(100 summands)}} = 100 \cdot 4 = 400$

27. $\sum_{i=0}^{4}(2^i+i^2)=(1+0)+(2+1)+(4+4)+(8+9)+(16+16)=61$

28. $\sum_{i=-2}^{4}2^{3-i}=2^5+2^4+2^3+2^2+2^1+2^0+2^{-1}=63.5$

29. $\sum_{i=1}^{n}2i=2\sum_{i=1}^{n}i=2\cdot\frac{n(n+1)}{2}$ [by Theorem 3(c)] $=n(n+1)$

30. $\sum_{i=1}^{n}(2-5i)=\sum_{i=1}^{n}2-\sum_{i=1}^{n}5i=2n-5\sum_{i=1}^{n}i=2n-\frac{5n(n+1)}{2}=\frac{4n}{2}-\frac{5n^2+5n}{2}=-\frac{n(5n+1)}{2}$

31. $\sum_{i=1}^{n}(i^2+3i+4)=\sum_{i=1}^{n}i^2+3\sum_{i=1}^{n}i+\sum_{i=1}^{n}4=\frac{n(n+1)(2n+1)}{6}+\frac{3n(n+1)}{2}+4n$

$$=\tfrac{1}{6}[(2n^3+3n^2+n)+(9n^2+9n)+24n]=\tfrac{1}{6}(2n^3+12n^2+34n)=\tfrac{1}{3}n(n^2+6n+17)$$

32. $\sum_{i=1}^{n}(3+2i)^2=\sum_{i=1}^{n}(9+12i+4i^2)=\sum_{i=1}^{n}9+12\sum_{i=1}^{n}i+4\sum_{i=1}^{n}i^2=9n+6n(n+1)+\frac{2n(n+1)(2n+1)}{3}$

$$=\frac{27n+18n^2+18n+4n^3+6n^2+2n}{3}=\tfrac{1}{3}(4n^3+24n^2+47n)=\tfrac{1}{3}n(4n^2+24n+47)$$

33. $\sum_{i=1}^{n}(i+1)(i+2)=\sum_{i=1}^{n}(i^2+3i+2)=\sum_{i=1}^{n}i^2+3\sum_{i=1}^{n}i+\sum_{i=1}^{n}2=\frac{n(n+1)(2n+1)}{6}+\frac{3n(n+1)}{2}+2n$

$$=\frac{n(n+1)}{6}[(2n+1)+9]+2n=\frac{n(n+1)}{3}(n+5)+2n$$

$$=\frac{n}{3}[(n+1)(n+5)+6]=\frac{n}{3}(n^2+6n+11)$$

34. $\sum_{i=1}^{n}i(i+1)(i+2)=\sum_{i=1}^{n}(i^3+3i^2+2i)=\sum_{i=1}^{n}i^3+3\sum_{i=1}^{n}i^2+2\sum_{i=1}^{n}i$

$$=\left[\frac{n(n+1)}{2}\right]^2+\frac{3n(n+1)(2n+1)}{6}+\frac{2n(n+1)}{2}$$

$$=n(n+1)\left[\frac{n(n+1)}{4}+\frac{2n+1}{2}+1\right]=\frac{n(n+1)}{4}(n^2+n+4n+2+4)$$

$$=\frac{n(n+1)}{4}(n^2+5n+6)=\frac{n(n+1)(n+2)(n+3)}{4}$$

35. $\sum_{i=1}^{n}(i^3-i-2)=\sum_{i=1}^{n}i^3-\sum_{i=1}^{n}i-\sum_{i=1}^{n}2=\left[\frac{n(n+1)}{2}\right]^2-\frac{n(n+1)}{2}-2n$

$$=\tfrac{1}{4}n(n+1)[n(n+1)-2]-2n=\tfrac{1}{4}n(n+1)(n+2)(n-1)-2n$$

$$=\tfrac{1}{4}n[(n+1)(n-1)(n+2)-8]=\tfrac{1}{4}n[(n^2-1)(n+2)-8]=\tfrac{1}{4}n(n^3+2n^2-n-10)$$

36. By Theorem 3(c) we have that $\sum_{i=1}^{n}i=\frac{n(n+1)}{2}=78 \Leftrightarrow n(n+1)=156 \Leftrightarrow n^2+n-156=0 \Leftrightarrow$ $(n+13)(n-12)=0 \Leftrightarrow n=12$ or -13. But $n=-13$ produces a negative answer for the sum, so $n=12$.

37. By Theorem 2(a) and Example 3, $\sum_{i=1}^{n}c=c\sum_{i=1}^{n}1=cn$.

38. Let S_n be the statement that $\sum_{i=1}^{n} i^3 = \left[\frac{n(n+1)}{2}\right]^2$.

1. S_1 is true because $1^3 = \left(\frac{1 \cdot 2}{2}\right)^2$.

2. Assume S_k is true. Then $\sum_{i=1}^{k} i^3 = \left[\frac{k(k+1)}{2}\right]^2$, so

$$\sum_{i=1}^{k+1} i^3 = \left[\frac{k(k+1)}{2}\right]^2 + (k+1)^3 = \frac{(k+1)^2}{4}\left[k^2 + 4(k+1)\right] = \frac{(k+1)^2}{4}(k+2)^2 = \left(\frac{(k+1)[(k+1)+1]}{2}\right)^2$$

showing that S_{k+1} is true.

Therefore, S_n is true for all n by mathematical induction.

39.
$$\sum_{i=1}^{n}[(i+1)^4 - i^4] = (2^4 - 1^4) + (3^4 - 2^4) + (4^4 - 3^4) + \cdots + \left[(n+1)^4 - n^4\right]$$
$$= (n+1)^4 - 1^4 = n^4 + 4n^3 + 6n^2 + 4n$$

On the other hand,

$$\sum_{i=1}^{n}[(i+1)^4 - i^4] = \sum_{i=1}^{n}(4i^3 + 6i^2 + 4i + 1) = 4\sum_{i=1}^{n} i^3 + 6\sum_{i=1}^{n} i^2 + 4\sum_{i=1}^{n} i + \sum_{i=1}^{n} 1$$
$$= 4S + n(n+1)(2n+1) + 2n(n+1) + n \qquad \left[\text{where } S = \sum_{i=1}^{n} i^3\right]$$
$$= 4S + 2n^3 + 3n^2 + n + 2n^2 + 2n + n = 4S + 2n^3 + 5n^2 + 4n$$

Thus, $n^4 + 4n^3 + 6n^2 + 4n = 4S + 2n^3 + 5n^2 + 4n$, from which it follows that

$4S = n^4 + 2n^3 + n^2 = n^2(n^2 + 2n + 1) = n^2(n+1)^2$ and $S = \left[\frac{n(n+1)}{2}\right]^2$.

40. The area of G_i is

$$\left(\sum_{k=1}^{i} k\right)^2 - \left(\sum_{k=1}^{i-1} k\right)^2 = \left[\frac{i(i+1)}{2}\right]^2 - \left[\frac{(i-1)i}{2}\right]^2 = \frac{i^2}{4}\left[(i+1)^2 - (i-1)^2\right]$$
$$= \frac{i^2}{4}\left[(i^2 + 2i + 1) - (i^2 - 2i + 1)\right] = \frac{i^2}{4}(4i) = i^3$$

Thus, the area of $ABCD$ is $\sum_{i=1}^{n} i^3 = \left[\frac{n(n+1)}{2}\right]^2$.

41. (a) $\sum_{i=1}^{n}\left[i^4 - (i-1)^4\right] = \left(1^4 - 0^4\right) + \left(2^4 - 1^4\right) + \left(3^4 - 2^4\right) + \cdots + \left[n^4 - (n-1)^4\right] = n^4 - 0 = n^4$

(b) $\sum_{i=1}^{100}\left(5^i - 5^{i-1}\right) = \left(5^1 - 5^0\right) + \left(5^2 - 5^1\right) + \left(5^3 - 5^2\right) + \cdots + \left(5^{100} - 5^{99}\right) = 5^{100} - 5^0 = 5^{100} - 1$

(c) $\sum_{i=3}^{99}\left(\frac{1}{i} - \frac{1}{i+1}\right) = \left(\frac{1}{3} - \frac{1}{4}\right) + \left(\frac{1}{4} - \frac{1}{5}\right) + \left(\frac{1}{5} - \frac{1}{6}\right) + \cdots + \left(\frac{1}{99} - \frac{1}{100}\right) = \frac{1}{3} - \frac{1}{100} = \frac{97}{300}$

(d) $\sum_{i=1}^{n}(a_i - a_{i-1}) = (a_1 - a_0) + (a_2 - a_1) + (a_3 - a_2) + \cdots + (a_n - a_{n-1}) = a_n - a_0$

42. Summing the inequalities $-|a_i| \le a_i \le |a_i|$ for $i = 1, 2, \ldots, n$, we get $-\sum_{i=1}^{n}|a_i| \le \sum_{i=1}^{n} a_i \le \sum_{i=1}^{n}|a_i|$. Since $|x| \le c \iff -c \le x \le c$, we have $\left|\sum_{i=1}^{n} a_i\right| \le \sum_{i=1}^{n}|a_i|$. *Another method:* Use mathematical induction.

43. $\lim\limits_{n\to\infty}\sum\limits_{i=1}^{n}\frac{1}{n}\left(\frac{i}{n}\right)^2=\lim\limits_{n\to\infty}\frac{1}{n^3}\sum\limits_{i=1}^{n}i^2=\lim\limits_{n\to\infty}\frac{1}{n^3}\frac{n(n+1)(2n+1)}{6}=\lim\limits_{n\to\infty}\frac{1}{6}\left(1+\frac{1}{n}\right)\left(2+\frac{1}{n}\right)=\frac{1}{6}(1)(2)=\frac{1}{3}$

44. $$\lim_{n\to\infty}\sum_{i=1}^{n}\frac{1}{n}\left[\left(\frac{i}{n}\right)^3+1\right]=\lim_{n\to\infty}\sum_{i=1}^{n}\left[\frac{i^3}{n^4}+\frac{1}{n}\right]=\lim_{n\to\infty}\left[\frac{1}{n^4}\sum_{i=1}^{n}i^3+\frac{1}{n}\sum_{i=1}^{n}1\right]=\lim_{n\to\infty}\left[\frac{1}{n^4}\left(\frac{n(n+1)}{2}\right)^2+\frac{1}{n}(n)\right]$$
$$=\lim_{n\to\infty}\frac{1}{4}\left(1+\frac{1}{n}\right)^2+1=\tfrac{1}{4}+1=\tfrac{5}{4}$$

45. $$\lim_{n\to\infty}\sum_{i=1}^{n}\frac{2}{n}\left[\left(\frac{2i}{n}\right)^3+5\left(\frac{2i}{n}\right)\right]=\lim_{n\to\infty}\sum_{i=1}^{n}\left[\frac{16}{n^4}i^3+\frac{20}{n^2}i\right]=\lim_{n\to\infty}\left[\frac{16}{n^4}\sum_{i=1}^{n}i^3+\frac{20}{n^2}\sum_{i=1}^{n}i\right]$$
$$=\lim_{n\to\infty}\left[\frac{16}{n^4}\frac{n^2(n+1)^2}{4}+\frac{20}{n^2}\frac{n(n+1)}{2}\right]=\lim_{n\to\infty}\left[\frac{4(n+1)^2}{n^2}+\frac{10n(n+1)}{n^2}\right]$$
$$=\lim_{n\to\infty}\left[4\left(1+\frac{1}{n}\right)^2+10\left(1+\frac{1}{n}\right)\right]=4\cdot 1+10\cdot 1=14$$

46. $$\lim_{n\to\infty}\sum_{i=1}^{n}\frac{3}{n}\left[\left(1+\frac{3i}{n}\right)^3-2\left(1+\frac{3i}{n}\right)\right]=\lim_{n\to\infty}\sum_{i=1}^{n}\frac{3}{n}\left[1+\frac{9i}{n}+\frac{27i^2}{n^2}+\frac{27i^3}{n^3}-2-\frac{6i}{n}\right]$$
$$=\lim_{n\to\infty}\sum_{i=1}^{n}\left[\frac{81}{n^4}i^3+\frac{81}{n^3}i^2+\frac{9}{n^2}i-\frac{3}{n}\right]$$
$$=\lim_{n\to\infty}\left[\frac{81}{n^4}\frac{n^2(n+1)^2}{4}+\frac{81}{n^3}\frac{n(n+1)(2n+1)}{6}+\frac{9}{n^2}\frac{n(n+1)}{2}-\frac{3}{n}n\right]$$
$$=\lim_{n\to\infty}\left[\frac{81}{4}\left(1+\frac{1}{n}\right)^2+\frac{27}{2}\left(1+\frac{1}{n}\right)\left(2+\frac{1}{n}\right)+\frac{9}{2}\left(1+\frac{1}{n}\right)-3\right]$$
$$=\tfrac{81}{4}+\tfrac{54}{2}+\tfrac{9}{2}-3=\tfrac{195}{4}$$

47. Let $S=\sum\limits_{i=1}^{n}ar^{i-1}=a+ar+ar^2+\cdots+ar^{n-1}$. Multiplying both sides by r gives us $rS=ar+ar^2+\cdots+ar^{n-1}+ar^n$. Subtracting the first equation from the second, we find $(r-1)S=ar^n-a=a(r^n-1)$, so $S=\dfrac{a(r^n-1)}{r-1}$ [since $r\neq 1$].

48. $\sum\limits_{i=1}^{n}\frac{3}{2^{i-1}}=3\sum\limits_{i=1}^{n}\left(\frac{1}{2}\right)^{i-1}=\dfrac{3\left[\left(\frac{1}{2}\right)^n-1\right]}{\frac{1}{2}-1}$ [using Exercise 47 with $a=3$ and $r=\frac{1}{2}$] $=6\left[1-\left(\frac{1}{2}\right)^n\right]$

49. $\sum\limits_{i=1}^{n}(2i+2^i)=2\sum\limits_{i=1}^{n}i+\sum\limits_{i=1}^{n}2\cdot 2^{i-1}=2\frac{n(n+1)}{2}+\frac{2(2^n-1)}{2-1}=2^{n+1}+n^2+n-2.$

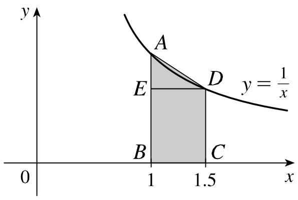
For the first sum we have used Theorems 2(a) and 3(c), and for the second, Exercise 47 with $a=r=2$.

50. $\sum\limits_{i=1}^{m}\left[\sum\limits_{j=1}^{n}(i+j)\right]=\sum\limits_{i=1}^{m}\left[\sum\limits_{j=1}^{n}i+\sum\limits_{j=1}^{n}j\right]$ [Theorem 2(b)] $=\sum\limits_{i=1}^{m}\left[ni+\frac{n(n+1)}{2}\right]$ [Theorem 3(b) and 3(c)]

$$=\sum_{i=1}^{m}ni+\sum_{i=1}^{m}\frac{n(n+1)}{2}=\frac{nm(m+1)}{2}+\frac{nm(n+1)}{2}=\frac{nm}{2}(m+n+2)$$

G The Logarithm Defined as an Integral

1. (a)



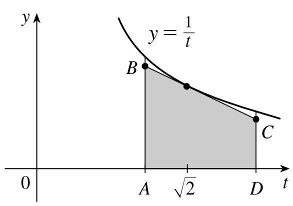
We interpret $\ln 1.5$ as the area under the curve $y = 1/x$ from $x = 1$ to $x = 1.5$. The area of the rectangle $BCDE$ is $\frac{1}{2} \cdot \frac{2}{3} = \frac{1}{3}$. The area of the trapezoid $ABCD$ is $\frac{1}{2} \cdot \frac{1}{2}\left(1 + \frac{2}{3}\right) = \frac{5}{12}$. Thus, by comparing areas, we observe that $\frac{1}{3} < \ln 1.5 < \frac{5}{12}$.

(b) $\ln x = \int_1^x (1/t)\,dt$, so $\ln 1.5 = \int_1^{1.5} (1/t)\,dt$. With $f(t) = 1/t$, $n = 10$, and $\Delta t = \frac{1.5 - 1}{10} = 0.05$, we have

$$\ln 1.5 = \int_1^{1.5} (1/t)\,dt \approx (0.05)[f(1.025) + f(1.075) + \cdots + f(1.475)] = (0.05)\left[\tfrac{1}{1.025} + \tfrac{1}{1.075} + \cdots + \tfrac{1}{1.475}\right]$$
$$\approx 0.4054$$

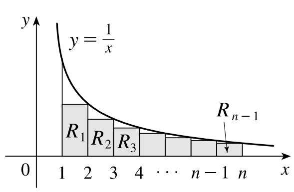
2. (a) $y = \dfrac{1}{t}$, $y' = -\dfrac{1}{t^2}$. The slope of the line through $A(1, 1)$ and $D\left(2, \frac{1}{2}\right)$ is $\dfrac{1/2 - 1}{2 - 1} = -\dfrac{1}{2}$. Let c be the t-coordinate of the point on $y = \dfrac{1}{t}$ with slope $-\dfrac{1}{2}$. Then $-\dfrac{1}{c^2} = -\dfrac{1}{2} \;\Rightarrow\; c^2 = 2 \;\Rightarrow\; c = \sqrt{2}$ since $c > 0$. Therefore, the tangent line is given by $y - \frac{1}{\sqrt{2}} = -\frac{1}{2}\left(t - \sqrt{2}\right)$, or $y = -\frac{1}{2}t + \sqrt{2}$.

(b)

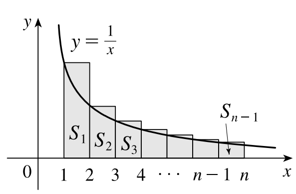


Since the graph of $y = 1/t$ is concave upward, the graph lies above the tangent line, that is, above the line segment BC. Now $|AB| = -\frac{1}{2} + \sqrt{2}$ and $|CD| = -1 + \sqrt{2}$. The area of the trapezoid $ABCD$ is $\frac{1}{2}\left[\left(-\frac{1}{2} + \sqrt{2}\right) + \left(-1 + \sqrt{2}\right)\right]1 = -\frac{3}{4} + \sqrt{2} \approx 0.6642$. So $\ln 2 >$ area of trapezoid $ABCD > 0.66$.

3.



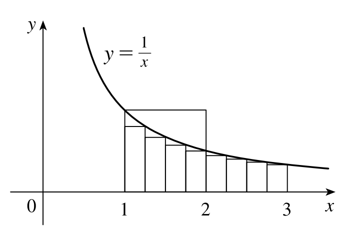
The area of R_i is $\dfrac{1}{i+1}$ and so $\dfrac{1}{2} + \dfrac{1}{3} + \cdots + \dfrac{1}{n} < \displaystyle\int_1^n \frac{1}{t}\,dt = \ln n$.



The area of S_i is $\dfrac{1}{i}$ and so $1 + \dfrac{1}{2} + \cdots + \dfrac{1}{n-1} > \displaystyle\int_1^n \frac{1}{t}\,dt = \ln n$.

Thus, $\dfrac{1}{2} + \dfrac{1}{3} + \cdots + \dfrac{1}{n} < \ln n < 1 + \dfrac{1}{2} + \cdots + \dfrac{1}{n-1}$.

4. (a) From the diagram, we see that the area under the graph of $y = 1/x$ between $x = 1$ and $x = 2$ is less than the area of the square, which is 1. So $\ln 2 = \int_1^2 (1/x)\,dx < 1$. To show the other side of the inequality, we must find an area larger than 1 which lies under the graph of $y = 1/x$ between $x = 1$ and $x = 3$. One way to do this is to partition the interval $[1, 3]$ into



8 intervals of equal length and calculate the resulting Riemann sum, using the right endpoints:

$$\frac{1}{4}\left(\frac{1}{5/4}+\frac{1}{3/2}+\frac{1}{7/4}+\frac{1}{2}+\frac{1}{9/4}+\frac{1}{5/2}+\frac{1}{11/4}+\frac{1}{3}\right)=\frac{28{,}271}{27{,}720}>1$$

and therefore $1<\int_1^3(1/x)\,dx=\ln 3$.

A slightly easier method uses the fact that since $y=1/x$ is concave upward, it lies above all its tangent lines. Drawing two such tangent lines at the points $\left(\frac{3}{2},\frac{2}{3}\right)$ and $\left(\frac{5}{2},\frac{2}{5}\right)$, we see that the area under the curve from $x=1$ to $x=3$ is more than the sum of the areas of the two trapezoids, that is, $\frac{2}{3}+\frac{2}{5}=\frac{16}{15}$. Thus, $1<\frac{16}{15}<\int_1^3(1/x)\,dx=\ln 3$.

(b) By part (a), $\ln 2<1<\ln 3$. But e is defined such that $\ln e=1$, and because the natural logarithm function is increasing, we have $\ln 2<\ln e<\ln 3 \quad\Leftrightarrow\quad 2<e<3$.

5. If $f(x)=\ln(x^r)$, then $f'(x)=(1/x^r)\left(rx^{r-1}\right)=r/x$. But if $g(x)=r\ln x$, then $g'(x)=r/x$. So f and g must differ by a constant: $\ln(x^r)=r\ln x+C$. Put $x=1$: $\ln(1^r)=r\ln 1+C \quad\Rightarrow\quad C=0$, so $\ln(x^r)=r\ln x$.

6. Using the second law of logarithms and Equation 10, we have $\ln(e^x/e^y)=\ln e^x-\ln e^y=x-y=\ln(e^{x-y})$. Since ln is a one-to-one function, it follows that $e^x/e^y=e^{x-y}$.

7. Using the third law of logarithms and Equation 10, we have $\ln e^{rx}=rx=r\ln e^x=\ln(e^x)^r$. Since ln is a one-to-one function, it follows that $e^{rx}=(e^x)^r$.

8. Using Definition 13 and the second law of exponents for e^x, we have $a^{x-y}=e^{(x-y)\ln a}=e^{x\ln a-y\ln a}=\dfrac{e^{x\ln a}}{e^{y\ln a}}=\dfrac{a^x}{a^y}$.

9. Using Definition 13, the first law of logarithms, and the first law of exponents for e^x, we have $(ab)^x=e^{x\ln(ab)}=e^{x(\ln a+\ln b)}=e^{x\ln a+x\ln b}=e^{x\ln a}e^{x\ln b}=a^xb^x$.

10. Let $\log_a x=r$ and $\log_a y=s$. Then $a^r=x$ and $a^s=y$.

(a) $xy=a^ra^s=a^{r+s} \quad\Rightarrow\quad \log_a(xy)=r+s=\log_a x+\log_a y$

(b) $\dfrac{x}{y}=\dfrac{a^r}{a^s}=a^{r-s} \quad\Rightarrow\quad \log_a\dfrac{x}{y}=r-s=\log_a x-\log_a y$

(c) $x^y=(a^r)^y=a^{ry} \quad\Rightarrow\quad \log_a(x^y)=ry=y\log_a x$

H Complex Numbers

1. $(5-6i)+(3+2i)=(5+3)+(-6+2)i=8+(-4)i=8-4i$

2. $\left(4-\frac{1}{2}i\right)-\left(9+\frac{5}{2}i\right)=(4-9)+\left(-\frac{1}{2}-\frac{5}{2}\right)i=-5+(-3)i=-5-3i$

3. $(2+5i)(4-i)=2(4)+2(-i)+(5i)(4)+(5i)(-i)=8-2i+20i-5i^2=8+18i-5(-1)$
$=8+18i+5=13+18i$

4. $(1-2i)(8-3i)=8-3i-16i+6(-1)=2-19i$

5. $\overline{12+7i}=12-7i$

6. $2i\left(\frac{1}{2} - i\right) = i - 2(-1) = 2 + i \quad \Rightarrow \quad \overline{2i\left(\frac{1}{2} - i\right)} = \overline{2 + i} = 2 - i$

7. $\dfrac{1+4i}{3+2i} = \dfrac{1+4i}{3+2i} \cdot \dfrac{3-2i}{3-2i} = \dfrac{3 - 2i + 12i - 8(-1)}{3^2 + 2^2} = \dfrac{11 + 10i}{13} = \dfrac{11}{13} + \dfrac{10}{13}i$

8. $\dfrac{3+2i}{1-4i} = \dfrac{3+2i}{1-4i} \cdot \dfrac{1+4i}{1+4i} = \dfrac{3 + 12i + 2i + 8(-1)}{1^2 + 4^2} = \dfrac{-5 + 14i}{17} = -\dfrac{5}{17} + \dfrac{14}{17}i$

9. $\dfrac{1}{1+i} = \dfrac{1}{1+i} \cdot \dfrac{1-i}{1-i} = \dfrac{1-i}{1-(-1)} = \dfrac{1-i}{2} = \dfrac{1}{2} - \dfrac{1}{2}i$

10. $\dfrac{3}{4-3i} = \dfrac{3}{4-3i} \cdot \dfrac{4+3i}{4+3i} = \dfrac{12 + 9i}{16 - 9(-1)} = \dfrac{12}{25} + \dfrac{9}{25}i$

11. $i^3 = i^2 \cdot i = (-1)i = -i$

12. $i^{100} = (i^2)^{50} = (-1)^{50} = 1$

13. $\sqrt{-25} = \sqrt{25}\, i = 5i$

14. $\sqrt{-3}\,\sqrt{-12} = \sqrt{3}\, i\, \sqrt{12}\, i = \sqrt{3 \cdot 12}\, i^2 = \sqrt{36}\,(-1) = -6$

15. $\overline{12 - 5i} = 12 + 15i$ and $|12 - 15i| = \sqrt{12^2 + (-5)^2} = \sqrt{144 + 25} = \sqrt{169} = 13$

16. $\overline{-1 + 2\sqrt{2}\, i} = -1 - 2\sqrt{2}\, i$ and $\left|-1 + 2\sqrt{2}\, i\right| = \sqrt{(-1)^2 + \left(2\sqrt{2}\right)^2} = \sqrt{1+8} = \sqrt{9} = 3$

17. $\overline{-4i} = \overline{0 - 4i} = 0 + 4i = 4i$ and $|-4i| = \sqrt{0^2 + (-4)^2} = \sqrt{16} = 4$

18. Let $z = a + bi$ and $w = c + di$.

(a) $\overline{z + w} = \overline{(a + bi) + (c + di)} = \overline{(a + c) + (b + d)i} = (a + c) - (b + d)i = (a - bi) + (c - di) = \overline{z} + \overline{w}$

(b) $\overline{zw} = \overline{(a + bi)(c + di)} = \overline{(ac - bd) + (ad + bc)i} = (ac - bd) - (ad + bc)i.$

On the other hand, $\overline{z}\,\overline{w} = (a - bi)(c - di) = (ac - bd) - (ad + bc)i = \overline{zw}.$

(c) Use mathematical induction and part (b): Let S_n be the statement that $\overline{z^n} = \overline{z}^{\,n}$. S_1 is true because $\overline{z^1} = \overline{z} = \overline{z}^{\,1}$.

Assume S_k is true, that is $\overline{z^k} = \overline{z}^{\,k}$. Then $\overline{z^{k+1}} = \overline{z^{1+k}} = \overline{zz^k} = \overline{z}\,\overline{z^k}$ [part (b) with $w = z^k$] $= \overline{z}^1 \overline{z}^k = \overline{z}^{1+k} = \overline{z}^{k+1}$,

which shows that S_{k+1} is true. Therefore, by mathematical induction, $\overline{z^n} = \overline{z}^n$ for every positive integer n.

Another proof: Use part (b) with $w = z$, and mathematical induction.

19. $4x^2 + 9 = 0 \quad \Leftrightarrow \quad 4x^2 = -9 \quad \Leftrightarrow \quad x^2 = -\frac{9}{4} \quad \Leftrightarrow \quad x = \pm\sqrt{-\frac{9}{4}} = \pm\sqrt{\frac{9}{4}}\, i = \pm\frac{3}{2}i.$

20. $x^4 = 1 \quad \Leftrightarrow \quad x^4 - 1 = 0 \quad \Leftrightarrow \quad (x^2 - 1)(x^2 + 1) = 0 \quad \Leftrightarrow \quad x^2 - 1 = 0$ or $x^2 + 1 = 0 \quad \Leftrightarrow \quad x = \pm 1$ or $x = \pm i$.

21. By the quadratic formula, $x^2 + 2x + 5 = 0 \quad \Leftrightarrow \quad x = \dfrac{-2 \pm \sqrt{2^2 - 4(1)(5)}}{2(1)} = \dfrac{-2 \pm \sqrt{-16}}{2} = \dfrac{-2 \pm 4i}{2} = -1 \pm 2i.$

22. $2x^2 - 2x + 1 = 0 \quad \Leftrightarrow \quad x = \dfrac{-(-2) \pm \sqrt{(-2)^2 - 4(2)(1)}}{2(2)} = \dfrac{2 \pm \sqrt{-4}}{4} = \dfrac{2 \pm 2i}{4} = \dfrac{1}{2} \pm \dfrac{1}{2}i$

23. By the quadratic formula, $z^2 + z + 2 = 0 \quad \Leftrightarrow \quad z = \dfrac{-1 \pm \sqrt{1^2 - 4(1)(2)}}{2(1)} = \dfrac{-1 \pm \sqrt{-7}}{2} = -\dfrac{1}{2} \pm \dfrac{\sqrt{7}}{2}i.$

24. $z^2 + \frac{1}{2}z + \frac{1}{4} = 0 \quad \Leftrightarrow \quad 4z^2 + 2z + 1 = 0 \quad \Leftrightarrow$

$$z = \frac{-2 \pm \sqrt{2^2 - 4(4)(1)}}{2(4)} = \frac{-2 \pm \sqrt{-12}}{8} = \frac{-2 \pm 2\sqrt{3}\,i}{8} = -\frac{1}{4} \pm \frac{\sqrt{3}}{4}i$$

25. For $z = -3 + 3i$, $r = \sqrt{(-3)^2 + 3^2} = 3\sqrt{2}$ and $\tan\theta = \frac{3}{-3} = -1 \quad \Rightarrow \quad \theta = \frac{3\pi}{4}$ (since z lies in the second quadrant).

Therefore, $-3 + 3i = 3\sqrt{2}\left(\cos\frac{3\pi}{4} + i\sin\frac{3\pi}{4}\right)$.

26. For $z = 1 - \sqrt{3}\,i$, $r = \sqrt{1^2 + \left(-\sqrt{3}\right)^2} = 2$ and $\tan\theta = \frac{-\sqrt{3}}{1} = -\sqrt{3} \quad \Rightarrow \quad \theta = \frac{5\pi}{3}$ (since z lies in the fourth quadrant).

Therefore, $1 - \sqrt{3}\,i = 2\left(\cos\frac{5\pi}{3} + i\sin\frac{5\pi}{3}\right)$.

27. For $z = 3 + 4i$, $r = \sqrt{3^2 + 4^2} = 5$ and $\tan\theta = \frac{4}{3} \quad \Rightarrow \quad \theta = \tan^{-1}\left(\frac{4}{3}\right)$ (since z lies in the first quadrant). Therefore,

$3 + 4i = 5\left[\cos\left(\tan^{-1}\frac{4}{3}\right) + i\sin\left(\tan^{-1}\frac{4}{3}\right)\right]$.

28. For $z = 8i$, $r = \sqrt{0^2 + 8^2} = 8$ and $\tan\theta = \frac{8}{0}$ is undefined, so $\theta = \frac{\pi}{2}$ (since z lies on the positive imaginary axis). Therefore,

$8i = 8\left(\cos\frac{\pi}{2} + i\sin\frac{\pi}{2}\right)$.

29. For $z = \sqrt{3} + i$, $r = \sqrt{\left(\sqrt{3}\right)^2 + 1^2} = 2$ and $\tan\theta = \frac{1}{\sqrt{3}} \quad \Rightarrow \quad \theta = \frac{\pi}{6} \quad \Rightarrow \quad z = 2\left(\cos\frac{\pi}{6} + i\sin\frac{\pi}{6}\right)$.

For $w = 1 + \sqrt{3}\,i$, $r = 2$ and $\tan\theta = \sqrt{3} \quad \Rightarrow \quad \theta = \frac{\pi}{3} \quad \Rightarrow \quad w = 2\left(\cos\frac{\pi}{3} + i\sin\frac{\pi}{3}\right)$.

Therefore, $zw = 2 \cdot 2\left[\cos\left(\frac{\pi}{6} + \frac{\pi}{3}\right) + i\sin\left(\frac{\pi}{6} + \frac{\pi}{3}\right)\right] = 4\left(\cos\frac{\pi}{2} + i\sin\frac{\pi}{2}\right)$,

$z/w = \frac{2}{2}\left[\cos\left(\frac{\pi}{6} - \frac{\pi}{3}\right) + i\sin\left(\frac{\pi}{6} - \frac{\pi}{3}\right)\right] = \cos\left(-\frac{\pi}{6}\right) + i\sin\left(-\frac{\pi}{6}\right)$, and $1 = 1 + 0i = 1(\cos 0 + i\sin 0) \quad \Rightarrow$

$1/z = \frac{1}{2}\left[\cos\left(0 - \frac{\pi}{6}\right) + i\sin\left(0 - \frac{\pi}{6}\right)\right] = \frac{1}{2}\left[\cos\left(-\frac{\pi}{6}\right) + i\sin\left(-\frac{\pi}{6}\right)\right]$. For $1/z$, we could also use the formula that precedes Example 5 to obtain $1/z = \frac{1}{2}\left(\cos\frac{\pi}{6} - i\sin\frac{\pi}{6}\right)$.

30. For $z = 4\sqrt{3} - 4i$, $r = \sqrt{\left(4\sqrt{3}\right)^2 + (-4)^2} = \sqrt{64} = 8$ and $\tan\theta = \frac{-4}{4\sqrt{3}} = -\frac{1}{\sqrt{3}} \quad \Rightarrow \quad \theta = \frac{11\pi}{6} \quad \Rightarrow$

$z = 8\left(\cos\frac{11\pi}{6} + i\sin\frac{11\pi}{6}\right)$. For $w = 8i$, $r = \sqrt{0^2 + 8^2} = 8$ and $\tan\theta = \frac{8}{0}$ is undefined, so $\theta = \frac{\pi}{2} \quad \Rightarrow$

$w = 8\left(\cos\frac{\pi}{2} + i\sin\frac{\pi}{2}\right)$. Therefore, $zw = 8 \cdot 8\left[\cos\left(\frac{11\pi}{6} + \frac{\pi}{2}\right) + i\sin\left(\frac{11\pi}{6} + \frac{\pi}{2}\right)\right] = 64\left(\cos\frac{\pi}{3} + i\sin\frac{\pi}{3}\right)$,

$z/w = \frac{8}{8}\left[\cos\left(\frac{11\pi}{6} - \frac{\pi}{2}\right) + i\sin\left(\frac{11\pi}{6} - \frac{\pi}{2}\right)\right] = \cos\frac{4\pi}{3} + i\sin\frac{4\pi}{3}$, and

$1 = 1 + 0i = 1(\cos 0 + i\sin 0) \quad \Rightarrow \quad 1/z = \frac{1}{8}\left[\cos\left(0 - \frac{11\pi}{6}\right) + i\sin\left(0 - \frac{11\pi}{6}\right)\right] = \frac{1}{8}\left[\cos\left(\frac{\pi}{6}\right) + i\sin\left(\frac{\pi}{6}\right)\right]$.

For $1/z$, we could also use the formula that precedes Example 5 to obtain $1/z = \frac{1}{8}\left(\cos\frac{11\pi}{6} - i\sin\frac{11\pi}{6}\right)$.

31. For $z = 2\sqrt{3} - 2i$, $r = \sqrt{\left(2\sqrt{3}\right)^2 + (-2)^2} = 4$ and $\tan\theta = \frac{-2}{2\sqrt{3}} = -\frac{1}{\sqrt{3}} \quad \Rightarrow \quad \theta = -\frac{\pi}{6} \quad \Rightarrow$

$z = 4\left[\cos\left(-\frac{\pi}{6}\right) + i\sin\left(-\frac{\pi}{6}\right)\right]$. For $w = -1 + i$, $r = \sqrt{2}$, $\tan\theta = \frac{1}{-1} = -1 \quad \Rightarrow \quad \theta = \frac{3\pi}{4} \quad \Rightarrow$

$w = \sqrt{2}\left(\cos\frac{3\pi}{4} + i\sin\frac{3\pi}{4}\right)$. Therefore, $zw = 4\sqrt{2}\left[\cos\left(-\frac{\pi}{6} + \frac{3\pi}{4}\right) + i\sin\left(-\frac{\pi}{6} + \frac{3\pi}{4}\right)\right] = 4\sqrt{2}\left(\cos\frac{7\pi}{12} + i\sin\frac{7\pi}{12}\right)$,

$z/w = \frac{4}{\sqrt{2}}\left[\cos\left(-\frac{\pi}{6} - \frac{3\pi}{4}\right) + i\sin\left(-\frac{\pi}{6} - \frac{3\pi}{4}\right)\right] = \frac{4}{\sqrt{2}}\left[\cos\left(-\frac{11\pi}{12}\right) + i\sin\left(-\frac{11\pi}{12}\right)\right] = 2\sqrt{2}\left(\cos\frac{13\pi}{12} + i\sin\frac{13\pi}{12}\right)$, and

$1/z = \frac{1}{4}\left[\cos\left(-\frac{\pi}{6}\right) - i\sin\left(-\frac{\pi}{6}\right)\right] = \frac{1}{4}\left(\cos\frac{\pi}{6} + i\sin\frac{\pi}{6}\right)$.

32. For $z = 4(\sqrt{3} + i) = 4\sqrt{3} + 4i$, $r = \sqrt{(4\sqrt{3})^2 + 4^2} = \sqrt{64} = 8$ and $\tan\theta = \frac{4}{4\sqrt{3}} = \frac{1}{\sqrt{3}} \Rightarrow \theta = \frac{\pi}{6} \Rightarrow$ $z = 8(\cos\frac{\pi}{6} + i\sin\frac{\pi}{6})$. For $w = -3 - 3i$, $r = \sqrt{(-3)^2 + (-3)^2} = \sqrt{18} = 3\sqrt{2}$ and $\tan\theta = \frac{-3}{-3} = 1 \Rightarrow \theta = \frac{5\pi}{4} \Rightarrow$ $w = 3\sqrt{2}\,(\cos\frac{5\pi}{4} + i\sin\frac{5\pi}{4})$. Therefore, $zw = 8 \cdot 3\sqrt{2}\left[\cos(\frac{\pi}{6} + \frac{5\pi}{4}) + i\sin(\frac{\pi}{6} + \frac{5\pi}{4})\right] = 24\sqrt{2}\,(\cos\frac{17\pi}{12} + i\sin\frac{17\pi}{12})$, $z/w = \frac{8}{3\sqrt{2}}\left[\cos(\frac{\pi}{6} - \frac{5\pi}{4}) + i\sin(\frac{\pi}{6} - \frac{5\pi}{4})\right] = \frac{4\sqrt{2}}{3}\left[\cos(-\frac{13\pi}{12}) + i\sin(-\frac{13\pi}{12})\right]$, and $1/z = \frac{1}{8}(\cos\frac{\pi}{6} - i\sin\frac{\pi}{6})$.

33. For $z = 1 + i$, $r = \sqrt{2}$ and $\tan\theta = \frac{1}{1} = 1 \Rightarrow \theta = \frac{\pi}{4} \Rightarrow z = \sqrt{2}\,(\cos\frac{\pi}{4} + i\sin\frac{\pi}{4})$. So by De Moivre's Theorem,

$$\begin{aligned}(1+i)^{20} &= \left[\sqrt{2}\,(\cos\tfrac{\pi}{4} + i\sin\tfrac{\pi}{4})\right]^{20} = (2^{1/2})^{20}(\cos\tfrac{20\cdot\pi}{4} + i\sin\tfrac{20\cdot\pi}{4}) = 2^{10}(\cos 5\pi + i\sin 5\pi)\\ &= 2^{10}[-1 + i(0)] = -2^{10} = -1024\end{aligned}$$

34. For $z = 1 - \sqrt{3}\,i$, $r = \sqrt{1^2 + (-\sqrt{3})^2} = 2$ and $\tan\theta = \frac{-\sqrt{3}}{1} = -\sqrt{3} \Rightarrow \theta = \frac{5\pi}{3} \Rightarrow z = 2\,(\cos\frac{5\pi}{3} + i\sin\frac{5\pi}{3})$.

So by De Moivre's Theorem,

$$\begin{aligned}(1 - \sqrt{3}\,i)^5 &= \left[2(\cos\tfrac{5\pi}{3} + i\sin\tfrac{5\pi}{3})\right]^5 = 2^5(\cos\tfrac{5\cdot 5\pi}{3} + i\sin\tfrac{5\cdot 5\pi}{3}) = 2^5(\cos\tfrac{\pi}{3} + i\sin\tfrac{\pi}{3})\\ &= 32\left(\tfrac{1}{2} + \tfrac{\sqrt{3}}{2}\,i\right) = 16 + 16\sqrt{3}\,i\end{aligned}$$

35. For $z = 2\sqrt{3} + 2i$, $r = \sqrt{(2\sqrt{3})^2 + 2^2} = \sqrt{16} = 4$ and $\tan\theta = \frac{2}{2\sqrt{3}} = \frac{1}{\sqrt{3}} \Rightarrow \theta = \frac{\pi}{6} \Rightarrow z = 4(\cos\frac{\pi}{6} + i\sin\frac{\pi}{6})$.

So by De Moivre's Theorem,

$(2\sqrt{3} + 2i)^5 = \left[4(\cos\frac{\pi}{6} + i\sin\frac{\pi}{6})\right]^5 = 4^5(\cos\frac{5\pi}{6} + i\sin\frac{5\pi}{6}) = 1024\left[-\frac{\sqrt{3}}{2} + \frac{1}{2}i\right] = -512\sqrt{3} + 512i.$

36. For $z = 1 - i$, $r = \sqrt{2}$ and $\tan\theta = \frac{-1}{1} = -1 \Rightarrow \theta = \frac{7\pi}{4} \Rightarrow z = \sqrt{2}\,(\cos\frac{7\pi}{4} + i\sin\frac{7\pi}{4}) \Rightarrow$

$(1 - i)^8 = \left[\sqrt{2}\,(\cos\frac{7\pi}{4} + i\sin\frac{7\pi}{4})\right]^8 = 2^4(\cos\frac{8\cdot 7\pi}{4} + i\sin\frac{8\cdot 7\pi}{4}) = 16(\cos 14\pi + i\sin 14\pi) = 16(1 + 0i) = 16.$

37. $1 = 1 + 0i = 1\,(\cos 0 + i\sin 0)$. Using Equation 3 with $r = 1$, $n = 8$, and $\theta = 0$, we have

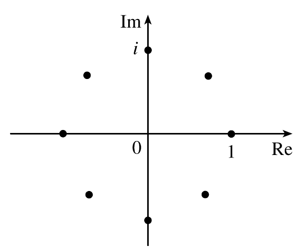
$w_k = 1^{1/8}\left[\cos\left(\dfrac{0 + 2k\pi}{8}\right) + i\sin\left(\dfrac{0 + 2k\pi}{8}\right)\right] = \cos\dfrac{k\pi}{4} + i\sin\dfrac{k\pi}{4}$, where $k = 0, 1, 2, \ldots, 7$.

$w_0 = 1(\cos 0 + i\sin 0) = 1$, $w_1 = 1(\cos\frac{\pi}{4} + i\sin\frac{\pi}{4}) = \frac{1}{\sqrt{2}} + \frac{1}{\sqrt{2}}i$,

$w_2 = 1(\cos\frac{\pi}{2} + i\sin\frac{\pi}{2}) = i$, $w_3 = 1(\cos\frac{3\pi}{4} + i\sin\frac{3\pi}{4}) = -\frac{1}{\sqrt{2}} + \frac{1}{\sqrt{2}}i$,

$w_4 = 1(\cos\pi + i\sin\pi) = -1$, $w_5 = 1(\cos\frac{5\pi}{4} + i\sin\frac{5\pi}{4}) = -\frac{1}{\sqrt{2}} - \frac{1}{\sqrt{2}}i$,

$w_6 = 1(\cos\frac{3\pi}{2} + i\sin\frac{3\pi}{2}) = -i$, $w_7 = 1(\cos\frac{7\pi}{4} + i\sin\frac{7\pi}{4}) = \frac{1}{\sqrt{2}} - \frac{1}{\sqrt{2}}i$



38. $32 = 32 + 0i = 32(\cos 0 + i\sin 0)$. Using Equation 3 with $r = 32$, $n = 5$, and $\theta = 0$, we have

$w_k = 32^{1/5}\left[\cos\left(\dfrac{0 + 2k\pi}{5}\right) + i\sin\left(\dfrac{0 + 2k\pi}{5}\right)\right] = 2(\cos\frac{2}{5}\pi k + i\sin\frac{2}{5}\pi k)$, where $k = 0, 1, 2, 3, 4$.

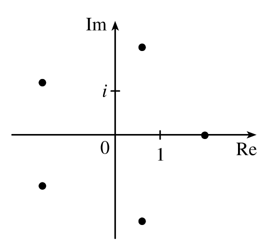
$w_0 = 2(\cos 0 + i\sin 0) = 2$

$w_1 = 2(\cos\frac{2\pi}{5} + i\sin\frac{2\pi}{5})$

$w_2 = 2(\cos\frac{4\pi}{5} + i\sin\frac{4\pi}{5})$

$w_3 = 2(\cos\frac{6\pi}{5} + i\sin\frac{6\pi}{5})$

$w_4 = 2(\cos\frac{8\pi}{5} + i\sin\frac{8\pi}{5})$



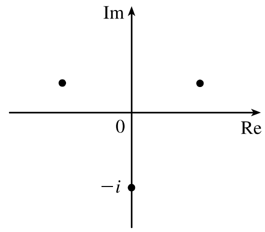
39. $i = 0 + i = 1\left(\cos\frac{\pi}{2} + i\sin\frac{\pi}{2}\right)$. Using Equation 3 with $r = 1$, $n = 3$, and $\theta = \frac{\pi}{2}$, we have

$$w_k = 1^{1/3}\left[\cos\left(\frac{\frac{\pi}{2} + 2k\pi}{3}\right) + i\sin\left(\frac{\frac{\pi}{2} + 2k\pi}{3}\right)\right], \text{ where } k = 0, 1, 2.$$

$$w_0 = \left(\cos\tfrac{\pi}{6} + i\sin\tfrac{\pi}{6}\right) = \tfrac{\sqrt{3}}{2} + \tfrac{1}{2}i$$

$$w_1 = \left(\cos\tfrac{5\pi}{6} + i\sin\tfrac{5\pi}{6}\right) = -\tfrac{\sqrt{3}}{2} + \tfrac{1}{2}i$$

$$w_2 = \left(\cos\tfrac{9\pi}{6} + i\sin\tfrac{9\pi}{6}\right) = -i$$



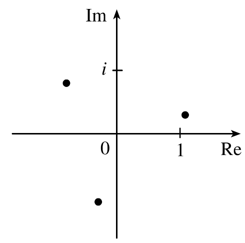
40. $1 + i = \sqrt{2}\left(\cos\frac{\pi}{4} + i\sin\frac{\pi}{4}\right)$. Using Equation 3 with $r = \sqrt{2}$, $n = 3$, and $\theta = \frac{\pi}{4}$, we have

$$w_k = \left(\sqrt{2}\right)^{1/3}\left[\cos\left(\frac{\frac{\pi}{4} + 2k\pi}{3}\right) + i\sin\left(\frac{\frac{\pi}{4} + 2k\pi}{3}\right)\right], \text{ where } k = 0, 1, 2.$$

$$w_0 = 2^{1/6}\left(\cos\tfrac{\pi}{12} + i\sin\tfrac{\pi}{12}\right)$$

$$w_1 = 2^{1/6}\left(\cos\tfrac{3\pi}{4} + i\sin\tfrac{3\pi}{4}\right) = 2^{1/6}\left(-\tfrac{1}{\sqrt{2}} + \tfrac{1}{\sqrt{2}}i\right) = -2^{-1/3} + 2^{-1/3}i$$

$$w_2 = 2^{1/6}\left(\cos\tfrac{17\pi}{12} + i\sin\tfrac{17\pi}{12}\right)$$



41. Using Euler's formula (6) with $y = \frac{\pi}{2}$, we have $e^{i\pi/2} = \cos\frac{\pi}{2} + i\sin\frac{\pi}{2} = 0 + 1i = i$.

42. Using Euler's formula (6) with $y = 2\pi$, we have $e^{2\pi i} = \cos 2\pi + i\sin 2\pi = 1$.

43. Using Euler's formula (6) with $y = \dfrac{\pi}{3}$, we have $e^{i\pi/3} = \cos\dfrac{\pi}{3} + i\sin\dfrac{\pi}{3} = \dfrac{1}{2} + \dfrac{\sqrt{3}}{2}i$.

44. Using Euler's formula (6) with $y = -\pi$, we have $e^{-i\pi} = \cos(-\pi) + i\sin(-\pi) = -1$.

45. Using Equation 7 with $x = 2$ and $y = \pi$, we have $e^{2+i\pi} = e^2e^{i\pi} = e^2(\cos\pi + i\sin\pi) = e^2(-1 + 0) = -e^2$.

46. Using Equation 7 with $x = \pi$ and $y = 1$, we have $e^{\pi+i} = e^\pi \cdot e^{1i} = e^\pi(\cos 1 + i\sin 1) = e^\pi\cos 1 + (e^\pi\sin 1)i$.

47. Take $r = 1$ and $n = 3$ in De Moivre's Theorem to get

$$\begin{aligned}
[1(\cos\theta + i\sin\theta)]^3 &= 1^3(\cos 3\theta + i\sin 3\theta)\\
(\cos\theta + i\sin\theta)^3 &= \cos 3\theta + i\sin 3\theta\\
\cos^3\theta + 3(\cos^2\theta)(i\sin\theta) + 3(\cos\theta)(i\sin\theta)^2 + (i\sin\theta)^3 &= \cos 3\theta + i\sin 3\theta\\
\cos^3\theta + (3\cos^2\theta\,\sin\theta)i - 3\cos\theta\,\sin^2\theta - (\sin^3\theta)i &= \cos 3\theta + i\sin 3\theta\\
(\cos^3\theta - 3\sin^2\theta\,\cos\theta) + (3\sin\theta\,\cos^2\theta - \sin^3\theta)i &= \cos 3\theta + i\sin 3\theta
\end{aligned}$$

Equating real and imaginary parts gives $\cos 3\theta = \cos^3\theta - 3\sin^2\theta\,\cos\theta$ and $\sin 3\theta = 3\sin\theta\,\cos^2\theta - \sin^3\theta$.

48. Using Formula 6,

$$e^{ix} + e^{-ix} = (\cos x + i\sin x) + [\cos(-x) + i\sin(-x)] = \cos x + i\sin x + \cos x - i\sin x = 2\cos x$$

Thus, $\cos x = \dfrac{e^{ix} + e^{-ix}}{2}$. Similarly,

$$e^{ix} - e^{-ix} = (\cos x + i\sin x) - [\cos(-x) + i\sin(-x)] = \cos x + i\sin x - \cos x - (-i\sin x) = 2i\sin x$$

Therefore, $\sin x = \dfrac{e^{ix} - e^{-ix}}{2i}$.

49. $F(x) = e^{rx} = e^{(a+bi)x} = e^{ax+bxi} = e^{ax}(\cos bx + i \sin bx) = e^{ax} \cos bx + i(e^{ax} \sin bx) \quad \Rightarrow$

$$\begin{aligned} F'(x) &= (e^{ax} \cos bx)' + i(e^{ax} \sin bx)' \\ &= (ae^{ax} \cos bx - be^{ax} \sin bx) + i(ae^{ax} \sin bx + be^{ax} \cos bx) \\ &= a[e^{ax}(\cos bx + i \sin bx)] + b[e^{ax}(-\sin bx + i \cos bx)] \\ &= ae^{rx} + b[e^{ax}(i^2 \sin bx + i \cos bx)] \\ &= ae^{rx} + bi[e^{ax}(\cos bx + i \sin bx)] = ae^{rx} + bie^{rx} = (a + bi)e^{rx} = re^{rx} \end{aligned}$$

50. (a) From Exercise 49, $F(x) = e^{(1+i)x} \quad \Rightarrow \quad F'(x) = (1 + i)e^{(1+i)x}$. So

$$\int e^{(1+i)x}\, dx = \frac{1}{1+i} \int F'(x)\, dx = \frac{1}{1+i}\, F(x) + C = \frac{1-i}{2}\, F(x) + C = \frac{1-i}{2}\, e^{(1+i)x} + C$$

(b) $\int e^{(1+i)x}\, dx = \int e^x e^{ix}\, dx = \int e^x(\cos x + i \sin x)\, dx = \int e^x \cos x\, dx + i \int e^x \sin x$ **(1)**.

Also,

$$\begin{aligned} \frac{1-i}{2}\, e^{(1+i)x} &= \tfrac{1}{2}e^{(1+i)x} - \tfrac{1}{2}ie^{(1+i)x} = \tfrac{1}{2}e^{x+ix} - \tfrac{1}{2}ie^{x+ix} \\ &= \tfrac{1}{2}e^x(\cos x + i \sin x) - \tfrac{1}{2}ie^x(\cos x + i \sin x) \\ &= \tfrac{1}{2}e^x \cos x + \tfrac{1}{2}e^x \sin x + \tfrac{1}{2}ie^x \sin x - \tfrac{1}{2}ie^x \cos x \\ &= \tfrac{1}{2}e^x(\cos x + \sin x) + i\left[\tfrac{1}{2}e^x(\sin x - \cos x)\right] \quad \textbf{(2)} \end{aligned}$$

Equating the real and imaginary parts in (**1**) and (**2**), we see that $\int e^x \cos x\, dx = \frac{1}{2}e^x(\cos x + \sin x) + C$ and $\int e^x \sin x\, dx = \frac{1}{2}e^x(\sin x - \cos x) + C$.
