$$\int\sqrt{r^2-x^2}\,dx = \int r\sin u\,(-r\sin u)\,du = -r^2\int\sin^2 u\,du = -\tfrac{1}{2}r^2(u - \sin u\,\cos u) + C$$

$$= -\tfrac{1}{2}r^2\cos^{-1}(x/r) + \tfrac{1}{2}x\sqrt{r^2-x^2} + C$$

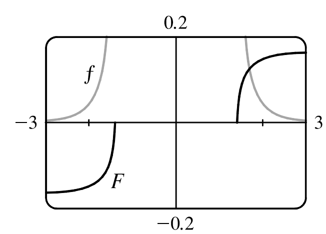
so

$$\text{area of region } PQR = \tfrac{1}{2}\left[-r^2\cos^{-1}(x/r) + x\sqrt{r^2-x^2}\,\right]_{r\cos\theta}^{r}$$

$$= \tfrac{1}{2}\left[0 - (-r^2\theta + r\cos\theta\,r\sin\theta)\right] = \tfrac{1}{2}r^2\theta - \tfrac{1}{2}r^2\sin\theta\,\cos\theta$$

and thus, (area of sector POR) = (area of $\triangle POQ$) + (area of region PQR) $= \frac{1}{2}r^2\theta$.

36. Let $x = \sqrt{2}\sec\theta$, where $0 \le \theta < \frac{\pi}{2}$ or $\pi \le \theta < \frac{3\pi}{2}$, so $dx = \sqrt{2}\,\sec\theta\tan\theta\,d\theta$. Then



$$\int\frac{dx}{x^4\sqrt{x^2-2}} = \int\frac{\sqrt{2}\sec\theta\,\tan\theta\,d\theta}{4\sec^4\theta\,\sqrt{2}\,\tan\theta}$$

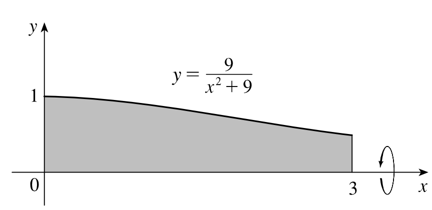
$$= \tfrac{1}{4}\int\cos^3\theta\,d\theta = \tfrac{1}{4}\int\left(1-\sin^2\theta\right)\cos\theta\,d\theta$$

$$= \tfrac{1}{4}\left[\sin\theta - \tfrac{1}{3}\sin^3\theta\right] + C \qquad [\text{substitute } u = \sin\theta]$$

$$= \frac{1}{4}\left[\frac{\sqrt{x^2-2}}{x} - \frac{\left(x^2-2\right)^{3/2}}{3x^3}\right] + C$$

From the graph, it appears that our answer is reasonable. [Notice that $f(x)$ is large when F increases rapidly and small when F levels out.]

37. Use disks about the x-axis:



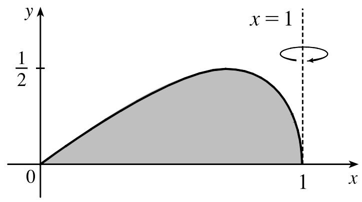
$$V = \int_0^3 \pi\left(\frac{9}{x^2+9}\right)^2 dx = 81\pi\int_0^3 \frac{1}{\left(x^2+9\right)^2}\,dx$$

Let $x = 3\tan\theta$, so $dx = 3\sec^2\theta\,d\theta$, $x = 0 \quad\Rightarrow\quad \theta = 0$ and $x = 3 \quad\Rightarrow\quad \theta = \frac{\pi}{4}$. Thus,

$$V = 81\pi\int_0^{\pi/4}\frac{1}{(9\sec^2\theta)^2}\,3\sec^2\theta\,d\theta = 3\pi\int_0^{\pi/4}\cos^2\theta\,d\theta = 3\pi\int_0^{\pi/4}\frac{1}{2}(1+\cos 2\theta)\,d\theta$$

$$= \tfrac{3\pi}{2}\left[\theta + \tfrac{1}{2}\sin 2\theta\right]_0^{\pi/4} = \tfrac{3\pi}{2}\left[\left(\tfrac{\pi}{4} + \tfrac{1}{2}\right) - 0\right] = \tfrac{3}{8}\pi^2 + \tfrac{3}{4}\pi$$

38. Use shells about $x = 1$:



$V = \int_0^1 2\pi(1-x)\,x\sqrt{1-x^2}\,dx$

$= 2\pi\int_0^1 x\sqrt{1-x^2}\,dx - 2\pi\int_0^1 x^2\sqrt{1-x^2}\,dx = 2\pi V_1 - 2\pi V_2$

For V_1, let $u = 1 - x^2$, so $du = -2x\,dx$, and

$V_1 = \int_1^0 \sqrt{u}\,\left(-\frac{1}{2}\,du\right) = \frac{1}{2}\int_0^1 u^{1/2}\,du = \frac{1}{2}\left[\frac{2}{3}u^{3/2}\right]_0^1 = \frac{1}{2}\left(\frac{2}{3}\right) = \frac{1}{3}.$

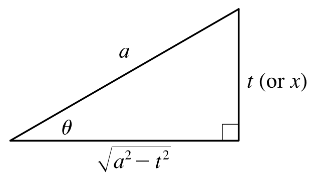
For V_2, let $x = \sin\theta$, so $dx = \cos\theta\,d\theta$, and

$$V_2 = \int_0^{\pi/2} \sin^2\theta\,\sqrt{\cos^2\theta}\,\cos\theta\,d\theta = \int_0^{\pi/2}\sin^2\theta\,\cos^2\theta\,d\theta = \int_0^{\pi/2}\tfrac{1}{4}(2\sin\theta\,\cos\theta)^2\,d\theta$$

$$= \tfrac{1}{4}\int_0^{\pi/2}\sin^2 2\theta\,d\theta = \tfrac{1}{4}\int_0^{\pi/2}\tfrac{1}{2}(1-\cos 2\theta)\,d\theta = \tfrac{1}{8}\left[\theta - \tfrac{1}{2}\sin 2\theta\right]_0^{\pi/2} = \tfrac{1}{8}\left(\tfrac{\pi}{2}\right) = \tfrac{\pi}{16}$$

Thus, $V = 2\pi\left(\frac{1}{3}\right) - 2\pi\left(\frac{\pi}{16}\right) = \frac{2}{3}\pi - \frac{1}{8}\pi^2.$

39. (a) Let $t = a\sin\theta$, $dt = a\cos\theta\,d\theta$, $t = 0 \Rightarrow \theta = 0$ and $t = x \Rightarrow$ $\theta = \sin^{-1}(x/a)$. Then



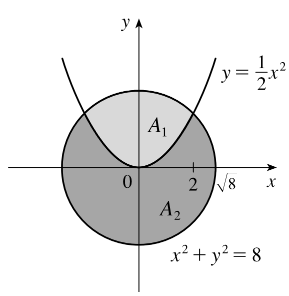
$$\int_0^x \sqrt{a^2 - t^2}\,dt = \int_0^{\sin^{-1}(x/a)} a\cos\theta\,(a\cos\theta\,d\theta) = a^2\int_0^{\sin^{-1}(x/a)}\cos^2\theta\,d\theta$$

$$= \frac{a^2}{2}\int_0^{\sin^{-1}(x/a)}(1+\cos 2\theta)\,d\theta = \frac{a^2}{2}\left[\theta + \tfrac{1}{2}\sin 2\theta\right]_0^{\sin^{-1}(x/a)} = \frac{a^2}{2}\left[\theta + \sin\theta\,\cos\theta\right]_0^{\sin^{-1}(x/a)}$$

$$= \frac{a^2}{2}\left[\left(\sin^{-1}\left(\frac{x}{a}\right) + \frac{x}{a}\cdot\frac{\sqrt{a^2-x^2}}{a}\right) - 0\right] = \tfrac{1}{2}a^2\sin^{-1}(x/a) + \tfrac{1}{2}x\sqrt{a^2-x^2}$$

(b) The integral $\int_0^x \sqrt{a^2-t^2}\,dt$ represents the area under the curve $y = \sqrt{a^2-t^2}$ between the vertical lines $t = 0$ and $t = x$. The figure shows that this area consists of a triangular region and a sector of the circle $t^2 + y^2 = a^2$. The triangular region has base x and height $\sqrt{a^2-x^2}$, so its area is $\frac{1}{2}x\sqrt{a^2-x^2}$. The sector has area $\frac{1}{2}a^2\theta = \frac{1}{2}a^2\sin^{-1}(x/a)$.

40. The curves intersect when $x^2 + \left(\frac{1}{2}x^2\right)^2 = 8 \Leftrightarrow x^2 + \frac{1}{4}x^4 = 8 \Leftrightarrow x^4 + 4x^2 - 32 = 0 \Leftrightarrow$ $(x^2+8)(x^2-4) = 0 \Leftrightarrow x = \pm 2$. The area inside the circle and above the parabola is given by



$A_1 = \int_{-2}^2 \left(\sqrt{8-x^2} - \frac{1}{2}x^2\right)dx = 2\int_0^2\sqrt{8-x^2}\,dx - 2\int_0^2 \frac{1}{2}x^2\,dx$

$= 2\left[\frac{1}{2}(8)\sin^{-1}\left(\frac{2}{\sqrt{8}}\right) + \frac{1}{2}(2)\sqrt{8-2^2} - \frac{1}{2}\left[\frac{1}{3}x^3\right]_0^2\right]$ [by Exercise 39]

$= 8\sin^{-1}\left(\frac{1}{\sqrt{2}}\right) + 2\sqrt{4} - \frac{8}{3} = 8\left(\frac{\pi}{4}\right) + 4 - \frac{8}{3} = 2\pi + \frac{4}{3}$

Since the area of the disk is $\pi\left(\sqrt{8}\right)^2 = 8\pi$, the area inside the circle and below the parabola ia $A_2 = 8\pi - \left(2\pi + \frac{4}{3}\right) = 6\pi - \frac{4}{3}$.

41. We use cylindrical shells and assume that $R > r$. $x^2 = r^2 - (y-R)^2 \;\Rightarrow\; x = \pm\sqrt{r^2-(y-R)^2}$,

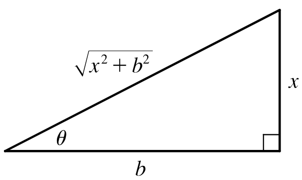
so $g(y) = 2\sqrt{r^2-(y-R)^2}$ and

$$\begin{aligned} V &= \int_{R-r}^{R+r} 2\pi y \cdot 2\sqrt{r^2-(y-R)^2}\,dy = \int_{-r}^{r} 4\pi(u+R)\sqrt{r^2-u^2}\,du \qquad [\text{where } u = y-R] \\ &= 4\pi\int_{-r}^{r} u\sqrt{r^2-u^2}\,du + 4\pi R\int_{-r}^{r}\sqrt{r^2-u^2}\,du \qquad \left[\begin{array}{c}\text{where } u = r\sin\theta,\ du = r\cos\theta\,d\theta \\ \text{in the second integral}\end{array}\right] \\ &= 4\pi\left[-\tfrac{1}{3}(r^2-u^2)^{3/2}\right]_{-r}^{r} + 4\pi R\int_{-\pi/2}^{\pi/2} r^2\cos^2\theta\,d\theta = -\tfrac{4\pi}{3}(0-0) + 4\pi R r^2\int_{-\pi/2}^{\pi/2}\cos^2\theta\,d\theta \\ &= 2\pi R r^2\int_{-\pi/2}^{\pi/2}(1+\cos 2\theta)\,d\theta = 2\pi R r^2\left[\theta + \tfrac{1}{2}\sin 2\theta\right]_{-\pi/2}^{\pi/2} = 2\pi^2 R r^2 \end{aligned}$$

Another method: Use washers instead of shells, so $V = 8\pi R\int_0^r \sqrt{r^2-y^2}\,dy$ as in Exercise 6.2.63(a), but evaluate the integral using $y = r\sin\theta$.

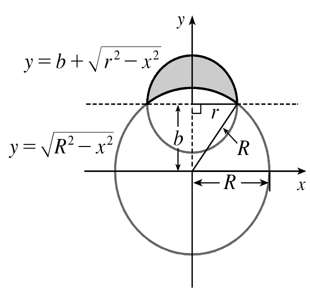
42. Let $x = b\tan\theta$, so that $dx = b\sec^2\theta\,d\theta$ and $\sqrt{x^2+b^2} = b\sec\theta$.

$$\begin{aligned} E(P) &= \int_{-a}^{L-a} \frac{\lambda b}{4\pi\varepsilon_0(x^2+b^2)^{3/2}}\,dx = \frac{\lambda b}{4\pi\varepsilon_0}\int_{\theta_1}^{\theta_2}\frac{1}{(b\sec\theta)^3}\,b\sec^2\theta\,d\theta \\ &= \frac{\lambda}{4\pi\varepsilon_0 b}\int_{\theta_1}^{\theta_2}\frac{1}{\sec\theta}\,d\theta = \frac{\lambda}{4\pi\varepsilon_0 b}\int_{\theta_1}^{\theta_2}\cos\theta\,d\theta = \frac{\lambda}{4\pi\varepsilon_0 b}\Big[\sin\theta\Big]_{\theta_1}^{\theta_2} \\ &= \frac{\lambda}{4\pi\varepsilon_0 b}\left[\frac{x}{\sqrt{x^2+b^2}}\right]_{-a}^{L-a} = \frac{\lambda}{4\pi\varepsilon_0 b}\left(\frac{L-a}{\sqrt{(L-a)^2+b^2}} + \frac{a}{\sqrt{a^2+b^2}}\right) \end{aligned}$$



43. Let the equation of the large circle be $x^2+y^2=R^2$. Then the equation of the small circle is $x^2+(y-b)^2=r^2$, where $b=\sqrt{R^2-r^2}$ is the distance between the centers of the circles. The desired area is

$$\begin{aligned} A &= \int_{-r}^{r}\left[\left(b+\sqrt{r^2-x^2}\right) - \sqrt{R^2-x^2}\right]dx \\ &= 2\int_0^r\left(b+\sqrt{r^2-x^2}-\sqrt{R^2-x^2}\right)dx \\ &= 2\int_0^r b\,dx + 2\int_0^r\sqrt{r^2-x^2}\,dx - 2\int_0^r\sqrt{R^2-x^2}\,dx \end{aligned}$$



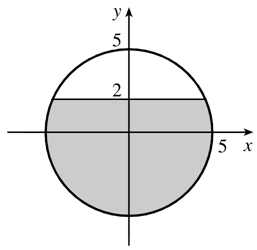
The first integral is just $2br = 2r\sqrt{R^2-r^2}$. The second integral represents the area of a quarter-circle of radius r, so its value is $\frac{1}{4}\pi r^2$. To evaluate the other integral, note that

$$\begin{aligned} \int\sqrt{a^2-x^2}\,dx &= \int a^2\cos^2\theta\,d\theta \quad [x = a\sin\theta,\ dx = a\cos\theta\,d\theta] \;= \left(\tfrac{1}{2}a^2\right)\int(1+\cos 2\theta)\,d\theta \\ &= \tfrac{1}{2}a^2\left(\theta+\tfrac{1}{2}\sin 2\theta\right)+C = \tfrac{1}{2}a^2(\theta+\sin\theta\,\cos\theta)+C \\ &= \frac{a^2}{2}\arcsin\left(\frac{x}{a}\right)+\frac{a^2}{2}\left(\frac{x}{a}\right)\frac{\sqrt{a^2-x^2}}{a}+C = \frac{a^2}{2}\arcsin\left(\frac{x}{a}\right)+\frac{x}{2}\sqrt{a^2-x^2}+C \end{aligned}$$

Thus, the desired area is

$$\begin{aligned} A &= 2r\sqrt{R^2-r^2}+2\left(\tfrac{1}{4}\pi r^2\right)-\left[R^2\arcsin(x/R)+x\sqrt{R^2-x^2}\right]_0^r \\ &= 2r\sqrt{R^2-r^2}+\tfrac{1}{2}\pi r^2-\left[R^2\arcsin(r/R)+r\sqrt{R^2-r^2}\right] = r\sqrt{R^2-r^2}+\tfrac{\pi}{2}r^2-R^2\arcsin(r/R) \end{aligned}$$

44. Note that the circular cross-sections of the tank are the same everywhere, so the percentage of the total capacity that is being used is equal to the percentage of any cross-section that is under water. The underwater area is



$$A = 2\int_{-5}^{2} \sqrt{25 - y^2}\,dy$$
$$= \left[25\arcsin(y/5) + y\sqrt{25 - y^2}\right]_{-5}^{2} \qquad \text{[substitute } y = 5\sin\theta\text{]}$$
$$= 25\arcsin\tfrac{2}{5} + 2\sqrt{21} + \tfrac{25}{2}\pi \approx 58.72 \text{ ft}^2$$

so the fraction of the total capacity in use is $\dfrac{A}{\pi(5)^2} \approx \dfrac{58.72}{25\pi} \approx 0.748$ or 74.8%.

7.4 Integration of Rational Functions by Partial Fractions

1. (a) $\dfrac{4+x}{(1+2x)(3-x)} = \dfrac{A}{1+2x} + \dfrac{B}{3-x}$

(b) $\dfrac{1-x}{x^3+x^4} = \dfrac{1-x}{x^3(1+x)} = \dfrac{A}{x} + \dfrac{B}{x^2} + \dfrac{C}{x^3} + \dfrac{D}{1+x}$

2. (a) $\dfrac{x-6}{x^2+x-6} = \dfrac{x-6}{(x+3)(x-2)} = \dfrac{A}{x+3} + \dfrac{B}{x-2}$

(b) $\dfrac{x^2}{x^2+x+6} = \dfrac{(x^2+x+6)-(x+6)}{x^2+x+6} = 1 - \dfrac{x+6}{x^2+x+6}$

Notice that x^2+x+6 can't be factored because its discriminant is $b^2 - 4ac = -23 < 0$.

3. (a) $\dfrac{1}{x^2+x^4} = \dfrac{1}{x^2(1+x^2)} = \dfrac{A}{x} + \dfrac{B}{x^2} + \dfrac{Cx+D}{1+x^2}$

(b) $\dfrac{x^3+1}{x^3-3x^2+2x} = \dfrac{(x^3-3x^2+2x)+3x^2-2x+1}{x^3-3x^2+2x} = 1 + \dfrac{3x^2-2x+1}{x(x^2-3x+2)}$ [or use long division]

$$= 1 + \frac{3x^2-2x+1}{x(x-1)(x-2)} = 1 + \frac{A}{x} + \frac{B}{x-1} + \frac{C}{x-2}$$

4. (a) $\dfrac{x^4-2x^3+x^2+2x-1}{x^2-2x+1} = \dfrac{x^2(x^2-2x+1)+2x-1}{x^2-2x+1} = x^2 + \dfrac{2x-1}{(x-1)^2}$ [or use long division]

$$= x^2 + \frac{A}{x-1} + \frac{B}{(x-1)^2}$$

(b) $\dfrac{x^2-1}{x^3+x^2+x} = \dfrac{x^2-1}{x(x^2+x+1)} = \dfrac{A}{x} + \dfrac{Bx+C}{x^2+x+1}$

5. (a) $\dfrac{x^6}{x^2-4} = x^4 + 4x^2 + 16 + \dfrac{64}{(x+2)(x-2)}$ [by long division]

$$= x^4 + 4x^2 + 16 + \frac{A}{x+2} + \frac{B}{x-2}$$

(b) $\dfrac{x^4}{(x^2-x+1)(x^2+2)^2} = \dfrac{Ax+B}{x^2-x+1} + \dfrac{Cx+D}{x^2+2} + \dfrac{Ex+F}{(x^2+2)^2}$

6. (a) $\dfrac{t^6+1}{t^6+t^3} = \dfrac{(t^6+t^3)-t^3+1}{t^6+t^3} = 1 + \dfrac{-t^3+1}{t^3(t^3+1)} = 1 + \dfrac{-t^3+1}{t^3(t+1)(t^2-t+1)} = 1 + \dfrac{A}{t} + \dfrac{B}{t^2} + \dfrac{C}{t^3} + \dfrac{D}{t+1} + \dfrac{Ex+F}{t^2-t+1}$

(b) $\dfrac{x^5+1}{(x^2-x)(x^4+2x^2+1)} = \dfrac{x^5+1}{x(x-1)(x^2+1)^2} = \dfrac{A}{x} + \dfrac{B}{x-1} + \dfrac{Cx+D}{x^2+1} + \dfrac{Ex+F}{(x^2+1)^2}$

7. $\displaystyle\int \frac{x^4}{x-1}\,dx = \int \left(x^3+x^2+x+1+\frac{1}{x-1}\right)dx$ [by division] $= \dfrac{1}{4}x^4 + \dfrac{1}{3}x^3 + \dfrac{1}{2}x^2 + x + \ln|x-1| + C$

8. $\displaystyle\int \frac{3t-2}{t+1}\,dt = \int \left(3 - \frac{5}{t+1}\right)dt = 3t - 5\ln|t+1| + C$

9. $\dfrac{5x+1}{(2x+1)(x-1)} = \dfrac{A}{2x+1} + \dfrac{B}{x-1}$. Multiply both sides by $(2x+1)(x-1)$ to get $5x+1 = A(x-1)+B(2x+1) \quad\Rightarrow$

$5x+1 = Ax - A + 2Bx + B \quad\Rightarrow\quad 5x+1 = (A+2B)x + (-A+B)$.

The coefficients of x must be equal and the constant terms are also equal, so $A+2B=5$ and $-A+B=1$. Adding these equations gives us $3B=6 \quad\Leftrightarrow\quad B=2$, and hence, $A=1$. Thus,

$$\int \frac{5x+1}{(2x+1)(x-1)}\,dx = \int \left(\frac{1}{2x+1} + \frac{2}{x-1}\right)dx = \tfrac{1}{2}\ln|2x+1| + 2\ln|x-1| + C.$$

Another method: Substituting 1 for x in the equation $5x+1 = A(x-1)+B(2x+1)$ gives $6=3B \quad\Leftrightarrow\quad B=2$.

Substituting $-\frac{1}{2}$ for x gives $-\frac{3}{2} = -\frac{3}{2}A \quad\Leftrightarrow\quad A=1$.

10. $\dfrac{y}{(y+4)(2y-1)} = \dfrac{A}{y+4} + \dfrac{B}{2y-1}$. Multiply both sides by $(y+4)(2y-1)$ to get $y = A(2y-1)+B(y+4) \quad\Rightarrow$

$y = 2Ay - A + By + 4B \quad\Rightarrow\quad y = (2A+B)y + (-A+4B)$. The coefficients of y must be equal and the constant terms are also equal, so $2A+B=1$ and $-A+4B=0$. Adding 2 times the second equation and the first equation gives us $9B=1 \quad\Leftrightarrow\quad B=\frac{1}{9}$ and hence, $A=\frac{4}{9}$. Thus,

$$\begin{aligned}\int \frac{y\,dy}{(y+4)(2y-1)} &= \int \left(\frac{\frac{4}{9}}{y+4} + \frac{\frac{1}{9}}{2y-1}\right)dy = \frac{4}{9}\ln|y+4| + \frac{1}{9}\cdot\frac{1}{2}\ln|2y-1| + C \\ &= \tfrac{4}{9}\ln|y+4| + \tfrac{1}{18}\ln|2y-1| + C\end{aligned}$$

Another method: Substituting $\frac{1}{2}$ for y in the equation $y = A(2y-1)+B(y+4)$ gives $\frac{1}{2} = \frac{9}{2}B \quad\Leftrightarrow\quad B=\frac{1}{9}$.

Substituting -4 for y gives $-4 = -9A \quad\Leftrightarrow\quad A=\frac{4}{9}$.

11. $\dfrac{2}{2x^2+3x+1} = \dfrac{2}{(2x+1)(x+1)} = \dfrac{A}{2x+1} + \dfrac{B}{x+1}$. Multiply both sides by $(2x+1)(x+1)$ to get

$2 = A(x+1)+B(2x+1)$. The coefficients of x must be equal and the constant terms are also equal, so $A+2B=0$ and $A+B=2$. Subtracting the second equation from the first gives $B=-2$, and hence, $A=4$. Thus,

$$\int_0^1 \frac{2}{2x^2+3x+1}\,dx = \int_0^1 \left(\frac{4}{2x+1} - \frac{2}{x+1}\right)dx = \left[\frac{4}{2}\ln|2x+1| - 2\ln|x+1|\right]_0^1 = (2\ln 3 - 2\ln 2) - 0 = 2\ln\frac{3}{2}.$$

Another method: Substituting -1 for x in the equation $2 = A(x+1)+B(2x+1)$ gives $2=-B \quad\Leftrightarrow\quad B=-2$.

Substituting $-\frac{1}{2}$ for x gives $2 = \frac{1}{2}A \quad\Leftrightarrow\quad A=4$.

12. $\dfrac{x-4}{x^2-5x+6} = \dfrac{A}{x-2} + \dfrac{B}{x-3}$. Multiply both sides by $(x-2)(x-3)$ to get $x-4 = A(x-3) + B(x-2) \Rightarrow$

$x - 4 = Ax - 3A + Bx - 2B \quad \Rightarrow \quad x - 4 = (A+B)x + (-3A - 2B)$.

The coefficients of x must be equal and the constant terms are also equal, so $A + B = 1$ and $-3A - 2B = -4$. Adding twice the first equation to the second gives us $-A = -2 \quad \Leftrightarrow \quad A = 2$, and hence, $B = -1$.Thus,

$$\int_0^1 \frac{x-4}{x^2-5x+6}\,dx = \int_0^1 \left(\frac{2}{x-2} - \frac{1}{x-3}\right) dx = \big[2\ln|x-2| - \ln|x-3|\big]_0^1$$

$$= (0 - \ln 2) - (2\ln 2 - \ln 3) = -3\ln 2 + \ln 3 \;\; [\text{or } \ln\tfrac{3}{8}]$$

Another method: Substituting 3 for x in the equation $x - 4 = A(x-3) + B(x-2)$ gives $-1 = B$. Substituting 2 for x gives $-2 = -A \quad \Leftrightarrow \quad A = 2$.

13. $\displaystyle\int \frac{ax}{x^2 - bx}\,dx = \int \frac{ax}{x(x-b)}\,dx = \int \frac{a}{x-b}\,dx = a\ln|x-b| + C$

14. If $a \neq b$, $\dfrac{1}{(x+a)(x+b)} = \dfrac{1}{b-a}\left(\dfrac{1}{x+a} - \dfrac{1}{x+b}\right)$, so if $a \neq b$, then

$$\int \frac{dx}{(x+a)(x+b)} = \frac{1}{b-a}\left(\ln|x+a| - \ln|x+b|\right) + C = \frac{1}{b-a}\ln\left|\frac{x+a}{x+b}\right| + C$$

If $a = b$, then $\displaystyle\int \frac{dx}{(x+a)^2} = -\frac{1}{x+a} + C$.

15. $\dfrac{x^3 - 4x + 1}{x^2 - 3x + 2} = x + 3 + \dfrac{3x-5}{(x-1)(x-2)}$. Write $\dfrac{3x-5}{(x-1)(x-2)} = \dfrac{A}{x-1} + \dfrac{B}{x-2}$. Multiplying both sides by $(x-1)(x-2)$ gives $3x - 5 = A(x-2) + B(x-1)$. Substituting 2 for x gives $1 = B$. Substituting 1 for x gives $-2 = -A \quad \Leftrightarrow \quad A = 2$. Thus,

$$\int_{-1}^0 \frac{x^3-4x+1}{x^2-3x+2}\,dx = \int_{-1}^0 \left(x + 3 + \frac{2}{x-1} + \frac{1}{x-2}\right) dx = \left[\tfrac{1}{2}x^2 + 3x + 2\ln|x-1| + \ln|x-2|\right]_{-1}^0$$

$$= (0 + 0 + 0 + \ln 2) - \left(\tfrac{1}{2} - 3 + 2\ln 2 + \ln 3\right) = \tfrac{5}{2} - \ln 2 - \ln 3, \text{ or } \tfrac{5}{2} - \ln 6$$

16. $\dfrac{x^3 + 4x^2 + x - 1}{x^3 + x^2} = 1 + \dfrac{3x^2 + x - 1}{x^2(x+1)}$. Write $\dfrac{3x^2 + x - 1}{x^2(x+1)} = \dfrac{A}{x} + \dfrac{B}{x^2} + \dfrac{C}{x+1}$. Multiplying both sides by $x^2(x+1)$ gives $3x^2 + x - 1 = Ax(x+1) + B(x+1) + Cx^2$. Substituting 0 for x gives $-1 = B$. Substituting -1 for x gives $1 = C$. Equating coefficients of x^2 gives $3 = A + C = A + 1$, so $A = 2$. Thus,

$$\int_1^2 \frac{x^3+4x^2+x-1}{x^3+x^2}\,dx = \int_1^2 \left(1 + \frac{2}{x} - \frac{1}{x^2} + \frac{1}{x+1}\right) dx = \left[x + 2\ln|x| + \frac{1}{x} + \ln|x+1|\right]_1^2$$

$$= \left(2 + 2\ln 2 + \tfrac{1}{2} + \ln 3\right) - (1 + 0 + 1 + \ln 2) = \tfrac{1}{2} + \ln 2 + \ln 3, \text{ or } \tfrac{1}{2} + \ln 6.$$

17. $\dfrac{4y^2 - 7y - 12}{y(y+2)(y-3)} = \dfrac{A}{y} + \dfrac{B}{y+2} + \dfrac{C}{y-3} \quad \Rightarrow \quad 4y^2 - 7y - 12 = A(y+2)(y-3) + By(y-3) + Cy(y+2)$. Setting $y = 0$ gives $-12 = -6A$, so $A = 2$. Setting $y = -2$ gives $18 = 10B$, so $B = \frac{9}{5}$. Setting $y = 3$ gives $3 = 15C$, so $C = \frac{1}{5}$.

Now

$$\int_1^2 \frac{4y^2-7y-12}{y(y+2)(y-3)}\,dy = \int_1^2 \left(\frac{2}{y}+\frac{9/5}{y+2}+\frac{1/5}{y-3}\right)dy = \left[2\ln|y|+\tfrac{9}{5}\ln|y+2|+\tfrac{1}{5}\ln|y-3|\right]_1^2$$

$$= 2\ln 2+\tfrac{9}{5}\ln 4+\tfrac{1}{5}\ln 1-2\ln 1-\tfrac{9}{5}\ln 3-\tfrac{1}{5}\ln 2$$

$$= 2\ln 2+\tfrac{18}{5}\ln 2-\tfrac{1}{5}\ln 2-\tfrac{9}{5}\ln 3=\tfrac{27}{5}\ln 2-\tfrac{9}{5}\ln 3=\tfrac{9}{5}(3\ln 2-\ln 3)=\tfrac{9}{5}\ln\tfrac{8}{3}$$

18. $\dfrac{3x^2+6x+2}{x^2+3x+2}=3+\dfrac{-3x-4}{(x+1)(x+2)}$. Write $\dfrac{-3x-4}{(x+1)(x+2)}=\dfrac{A}{x+1}+\dfrac{B}{x+2}$. Multiplying both sides by $(x+1)(x+2)$ gives $-3x-4=A(x+2)+B(x+1)$. Substituting -2 for x gives $2=-B \;\Leftrightarrow\; B=-2$. Substituting -1 for x gives $-1=A$. Thus,

$$\int_1^2 \frac{3x^2+6x+2}{x^2+3x+2}\,dx=\int_1^2\left(3-\frac{1}{x+1}-\frac{2}{x+2}\right)dx=\Big[3x-\ln|x+1|-2\ln|x+2|\Big]_1^2$$

$$=(6-\ln 3-2\ln 4)-(3-\ln 2-2\ln 3)=3+\ln 2+\ln 3-2\ln 4, \text{ or } 3+\ln\tfrac{3}{8}$$

19. $\dfrac{x^2+x+1}{(x+1)^2(x+2)}=\dfrac{A}{x+1}+\dfrac{B}{(x+1)^2}+\dfrac{C}{x+2}$. Multiplying both sides by $(x+1)^2(x+2)$ gives $x^2+x+1=A(x+1)(x+2)+B(x+2)+C(x+1)^2$. Substituting -1 for x gives $1=B$. Substituting -2 for x gives $3=C$. Equating coefficients of x^2 gives $1=A+C=A+3$, so $A=-2$. Thus,

$$\int_0^1 \frac{x^2+x+1}{(x+1)^2(x+2)}\,dx=\int_0^1\left(\frac{-2}{x+1}+\frac{1}{(x+1)^2}+\frac{3}{x+2}\right)dx=\left[-2\ln|x+1|-\frac{1}{x+1}+3\ln|x+2|\right]_0^1$$

$$=\left(-2\ln 2-\tfrac{1}{2}+3\ln 3\right)-(0-1+3\ln 2)=\tfrac{1}{2}-5\ln 2+3\ln 3, \text{ or } \tfrac{1}{2}+\ln\tfrac{27}{32}$$

20. $\dfrac{x(3-5x)}{(3x-1)(x-1)^2}=\dfrac{A}{3x-1}+\dfrac{B}{x-1}+\dfrac{C}{(x-1)^2}$. Multiplying both sides by $(3x-1)(x-1)^2$ gives $x(3-5x)=A(x-1)^2+B(x-1)(3x-1)+C(3x-1)$. Substituting 1 for x gives $-2=2C \;\Leftrightarrow\; C=-1$. Substituting $\frac{1}{3}$ for x gives $\frac{4}{9}=\frac{4}{9}A \;\Leftrightarrow\; A=1$. Substituting 0 for x gives $0=A+B-C=1+B+1$, so $B=-2$. Thus,

$$\int_2^3 \frac{x(3-5x)}{(3x-1)(x-1)^2}\,dx=\int_2^3\left[\frac{1}{3x-1}-\frac{2}{x-1}-\frac{1}{(x-1)^2}\right]dx=\left[\frac{1}{3}\ln|3x-1|-2\ln|x-1|+\frac{1}{x-1}\right]_2^3$$

$$=\left(\tfrac{1}{3}\ln 8-2\ln 2+\tfrac{1}{2}\right)-\left(\tfrac{1}{3}\ln 5-0+1\right)=-\ln 2-\tfrac{1}{3}\ln 5-\tfrac{1}{2}$$

21. $\dfrac{1}{(t^2-1)^2}=\dfrac{1}{(t+1)^2(t-1)^2}=\dfrac{A}{t+1}+\dfrac{B}{(t+1)^2}+\dfrac{C}{t-1}+\dfrac{D}{(t-1)^2}$. Multiplying both sides by $(t+1)^2(t-1)^2$ gives $1=A(t+1)(t-1)^2+B(t-1)^2+C(t-1)(t+1)^2+D(t+1)^2$. Substituting 1 for t gives $1=4D \;\Leftrightarrow\; D=\frac{1}{4}$. Substituting -1 for t gives $1=4B \;\Leftrightarrow\; B=\frac{1}{4}$. Substituting 0 for t gives $1=A+B-C+D=A+\frac{1}{4}-C+\frac{1}{4}$, so $\frac{1}{2}=A-C$. Equating coefficients of t^3 gives $0=A+C$. Adding the last two equations gives $2A=\frac{1}{2} \;\Leftrightarrow\; A=\frac{1}{4}$, and so $C=-\frac{1}{4}$. Thus,

$$\int\frac{dt}{(t^2-1)^2}=\int\left[\frac{1/4}{t+1}+\frac{1/4}{(t+1)^2}-\frac{1/4}{t-1}+\frac{1/4}{(t-1)^2}\right]dt$$

$$=\frac{1}{4}\left[\ln|t+1|-\frac{1}{t+1}-\ln|t-1|-\frac{1}{t-1}\right]+C, \text{ or } \frac{1}{4}\left(\ln\left|\frac{t+1}{t-1}\right|+\frac{2t}{1-t^2}\right)+C$$

22. $\displaystyle\int \frac{x^4+9x^2+x+2}{x^2+9}\,dx = \int\left(x^2+\frac{x+2}{x^2+9}\right)dx = \int\left(x^2+\frac{x}{x^2+9}+\frac{2}{x^2+9}\right)dx$

$$= \frac{1}{3}x^3 + \frac{1}{2}\ln(x^2+9) + \frac{2}{3}\tan^{-1}\frac{x}{3} + C$$

23. $\dfrac{10}{(x-1)(x^2+9)} = \dfrac{A}{x-1} + \dfrac{Bx+C}{x^2+9}$. Multiply both sides by $(x-1)(x^2+9)$ to get

$10 = A(x^2+9) + (Bx+C)(x-1)$ $(\star)$. Substituting 1 for x gives $10 = 10A \;\Leftrightarrow\; A = 1$. Substituting 0 for x gives $10 = 9A - C \;\Rightarrow\; C = 9(1) - 10 = -1$. The coefficients of the x^2-terms in $(\star)$ must be equal, so $0 = A + B \;\Rightarrow\; B = -1$. Thus,

$$\int \frac{10}{(x-1)(x^2+9)}\,dx = \int\left(\frac{1}{x-1}+\frac{-x-1}{x^2+9}\right)dx = \int\left(\frac{1}{x-1}-\frac{x}{x^2+9}-\frac{1}{x^2+9}\right)dx$$
$$= \ln|x-1| - \tfrac{1}{2}\ln(x^2+9) - \tfrac{1}{3}\tan^{-1}\left(\tfrac{x}{3}\right) + C$$

In the second term we used the substitution $u = x^2+9$ and in the last term we used Formula 10.

24. $\dfrac{x^2-x+6}{x^3+3x} = \dfrac{x^2-x+6}{x(x^2+3)} = \dfrac{A}{x} + \dfrac{Bx+C}{x^2+3}$. Multiply by $x(x^2+3)$ to get $x^2-x+6 = A(x^2+3) + (Bx+C)x$.

Substituting 0 for x gives $6 = 3A \;\Leftrightarrow\; A = 2$. The coefficients of the x^2-terms must be equal, so $1 = A + B \;\Rightarrow\; B = 1 - 2 = -1$. The coefficients of the x-terms must be equal, so $-1 = C$. Thus,

$$\int \frac{x^2-x+6}{x^3+3x}\,dx = \int\left(\frac{2}{x}+\frac{-x-1}{x^2+3}\right)dx = \int\left(\frac{2}{x}-\frac{x}{x^2+3}-\frac{1}{x^2+3}\right)dx$$
$$= 2\ln|x| - \frac{1}{2}\ln(x^2+3) - \frac{1}{\sqrt{3}}\tan^{-1}\frac{x}{\sqrt{3}} + C$$

25. $\dfrac{4x}{x^3+x^2+x+1} = \dfrac{4x}{x^2(x+1)+1(x+1)} = \dfrac{4x}{(x+1)(x^2+1)} = \dfrac{A}{x+1} + \dfrac{Bx+C}{x^2+1}$. Multiply both sides by

$(x+1)(x^2+1)$ to get $4x = A(x^2+1) + (Bx+C)(x+1) \;\Leftrightarrow\; 4x = Ax^2 + A + Bx^2 + Bx + Cx + C \;\Leftrightarrow\; 4x = (A+B)x^2 + (B+C)x + (A+C)$. Comparing coefficients gives us the following system of equations:

$$A + B = 0 \quad \textbf{(1)} \qquad B + C = 4 \quad \textbf{(2)} \qquad A + C = 0 \quad \textbf{(3)}$$

Subtracting equation **(1)** from equation **(2)** gives us $-A + C = 4$, and adding that equation to equation **(3)** gives us $2C = 4 \;\Leftrightarrow\; C = 2$, and hence $A = -2$ and $B = 2$. Thus,

$$\int \frac{4x}{x^3+x^2+x+1}\,dx = \int\left(\frac{-2}{x+1}+\frac{2x+2}{x^2+1}\right)dx = \int\left(\frac{-2}{x+1}+\frac{2x}{x^2+1}+\frac{2}{x^2+1}\right)dx$$
$$= -2\ln|x+1| + \ln(x^2+1) + 2\tan^{-1}x + C$$

26. $\displaystyle\int \frac{x^2+x+1}{(x^2+1)^2}\,dx = \int \frac{x^2+1}{(x^2+1)^2}\,dx + \int \frac{x}{(x^2+1)^2}\,dx = \int \frac{1}{x^2+1}\,dx + \frac{1}{2}\int \frac{1}{u^2}\,du \quad [u = x^2+1,\, du = 2x\,dx]$

$$= \tan^{-1}x + \frac{1}{2}\left(-\frac{1}{u}\right) + C = \tan^{-1}x - \frac{1}{2(x^2+1)} + C$$

27. $\dfrac{x^3+4x+3}{x^4+5x^2+4} = \dfrac{x^3+4x+3}{(x^2+1)(x^2+4)} = \dfrac{Ax+B}{x^2+1} + \dfrac{Cx+D}{x^2+4}$. Multiply both sides by $(x^2+1)(x^2+4)$ to get $x^3+4x+3 = (Ax+B)(x^2+4)+(Cx+D)(x^2+1) \quad \Leftrightarrow$

$x^3+4x+3 = Ax^3+Bx^2+4Ax+4B+Cx^3+Dx^2+Cx+D \quad \Leftrightarrow$

$x^3+4x+3 = (A+C)x^3+(B+D)x^2+(4A+C)x+(4B+D)$. Comparing coefficients gives us the following system of equations:

$A+C=1$ **(1)** $\quad B+D=0$ **(2)** $\quad 4A+C=4$ **(3)** $\quad 4B+D=3$ **(4)**

Subtracting equation **(1)** from equation **(3)** gives us $A=1$ and hence, $C=0$. Subtracting equation **(2)** from equation **(4)** gives us $B=1$ and hence, $D=-1$. Thus,

$$\int \frac{x^3+4x+3}{x^4+5x^2+4}\,dx = \int\left(\frac{x+1}{x^2+1}+\frac{-1}{x^2+4}\right)dx = \int\left(\frac{x}{x^2+1}+\frac{1}{x^2+1}-\frac{1}{x^2+4}\right)dx$$
$$= \frac{1}{2}\ln(x^2+1)+\tan^{-1}x-\frac{1}{2}\tan^{-1}\left(\frac{x}{2}\right)+C$$

28. $\dfrac{x^3+6x-2}{x^4+6x^2} = \dfrac{x^3+6x-2}{x^2(x^2+6)} = \dfrac{A}{x}+\dfrac{B}{x^2}+\dfrac{Cx+D}{x^2+6}$. Multiply both sides by $x^2(x^2+6)$ to get

$x^3+6x-2 = Ax(x^2+6)+B(x^2+6)+(Cx+D)x^2 \quad \Leftrightarrow$

$x^3+6x-2 = Ax^3+6Ax+Bx^2+6B+Cx^3+Dx^2 \quad \Leftrightarrow \quad x^3+6x-2 = (A+C)x^3+(B+D)x^2+6Ax+6B$.

Substituting 0 for x gives $-2=6B \quad \Leftrightarrow \quad B=-\frac{1}{3}$. Equating coefficients of x^2 gives $0=B+D$, so $D=\frac{1}{3}$. Equating coefficients of x gives $6=6A \quad \Leftrightarrow \quad A=1$. Equating coefficients of x^3 gives $1=A+C$, so $C=0$. Thus,

$$\int \frac{x^3+6x-2}{x^4+6x^2}\,dx = \int\left(\frac{1}{x}+\frac{-1/3}{x^2}+\frac{1/3}{x^2+6}\right)dx = \ln|x|+\frac{1}{3x}+\frac{1}{3\sqrt{6}}\tan^{-1}\left(\frac{x}{\sqrt{6}}\right)+C.$$

29. $$\int \frac{x+4}{x^2+2x+5}\,dx = \int \frac{x+1}{x^2+2x+5}\,dx + \int \frac{3}{x^2+2x+5}\,dx = \frac{1}{2}\int \frac{(2x+2)\,dx}{x^2+2x+5} + \int \frac{3\,dx}{(x+1)^2+4}$$
$$= \frac{1}{2}\ln\left|x^2+2x+5\right| + 3\int \frac{2\,du}{4(u^2+1)} \qquad \left[\begin{array}{l}\text{where } x+1=2u,\\ \text{and } dx=2\,du\end{array}\right]$$
$$= \frac{1}{2}\ln(x^2+2x+5)+\frac{3}{2}\tan^{-1}u+C = \frac{1}{2}\ln(x^2+2x+5)+\frac{3}{2}\tan^{-1}\left(\frac{x+1}{2}\right)+C$$

30. $\dfrac{x^3-2x^2+2x-5}{x^4+4x^2+3} = \dfrac{x^3-2x^2+2x-5}{(x^2+1)(x^2+3)} = \dfrac{Ax+B}{x^2+1}+\dfrac{Cx+D}{x^2+3}$. Multiply both sides by $(x^2+1)(x^2+3)$ to get

$x^3-2x^2+2x-5 = (Ax+B)(x^2+3)+(Cx+D)(x^2+1) \quad \Leftrightarrow$

$x^3-2x^2+2x-5 = Ax^3+Bx^2+3Ax+3B+Cx^3+Dx^2+Cx+D \quad \Leftrightarrow$

$x^3-2x^2+2x-5 = (A+C)x^3+(B+D)x^2+(3A+C)x+(3B+D)$. Comparing coefficients gives us the following system of equations:

$A+C=1$ **(1)** $\quad B+D=-2$ **(2)** $\quad 3A+C=2$ **(3)** $\quad 3B+D=-5$ **(4)**

Subtracting equation **(1)** from equation **(3)** gives us $2A=1 \quad \Leftrightarrow \quad A=\frac{1}{2}$, and hence, $C=\frac{1}{2}$. Subtracting equation **(2)** from equation **(4)** gives us $2B=-3 \quad \Leftrightarrow \quad B=-\frac{3}{2}$, and hence, $D=-\frac{1}{2}$.

Thus,

$$\int \frac{x^3-2x^2+2x-5}{x^4+4x^2+3}\,dx = \int \left(\frac{\frac{1}{2}x-\frac{3}{2}}{x^2+1} + \frac{\frac{1}{2}x-\frac{1}{2}}{x^2+3} \right) dx = \int \left(\frac{\frac{1}{2}x}{x^2+1} - \frac{\frac{3}{2}}{x^2+1} + \frac{\frac{1}{2}x}{x^2+3} - \frac{\frac{1}{2}}{x^2+3} \right) dx$$

$$= \tfrac{1}{4}\ln(x^2+1) - \tfrac{3}{2}\tan^{-1}x + \tfrac{1}{4}\ln(x^2+3) - \frac{1}{2\sqrt{3}}\tan^{-1}\left(\frac{x}{\sqrt{3}}\right) + C$$

31. $\dfrac{1}{x^3-1} = \dfrac{1}{(x-1)(x^2+x+1)} = \dfrac{A}{x-1} + \dfrac{Bx+C}{x^2+x+1} \quad \Rightarrow \quad 1 = A(x^2+x+1) + (Bx+C)(x-1).$

Take $x=1$ to get $A=\frac{1}{3}$. Equating coefficients of x^2 and then comparing the constant terms, we get $0=\frac{1}{3}+B$, $1=\frac{1}{3}-C$, so $B=-\frac{1}{3}$, $C=-\frac{2}{3}$ $\Rightarrow$

$$\int \frac{1}{x^3-1}dx = \int \frac{\frac{1}{3}}{x-1}\,dx + \int \frac{-\frac{1}{3}x-\frac{2}{3}}{x^2+x+1}\,dx = \tfrac{1}{3}\ln|x-1| - \frac{1}{3}\int \frac{x+2}{x^2+x+1}dx$$

$$= \tfrac{1}{3}\ln|x-1| - \frac{1}{3}\int \frac{x+1/2}{x^2+x+1}dx - \frac{1}{3}\int \frac{(3/2)\,dx}{(x+1/2)^2+3/4}$$

$$= \tfrac{1}{3}\ln|x-1| - \tfrac{1}{6}\ln(x^2+x+1) - \tfrac{1}{2}\left(\frac{2}{\sqrt{3}}\right)\tan^{-1}\left(\frac{x+\frac{1}{2}}{\sqrt{3}/2}\right) + K$$

$$= \tfrac{1}{3}\ln|x-1| - \tfrac{1}{6}\ln(x^2+x+1) - \tfrac{1}{\sqrt{3}}\tan^{-1}\left(\tfrac{1}{\sqrt{3}}(2x+1)\right) + K$$

32. $\displaystyle\int_0^1 \frac{x}{x^2+4x+13}\,dx = \int_0^1 \frac{\frac{1}{2}(2x+4)}{x^2+4x+13}\,dx - 2\int_0^1 \frac{dx}{(x+2)^2+9}$

$$= \frac{1}{2}\int_{13}^{18}\frac{dy}{y} - 2\int_{2/3}^{1}\frac{3\,du}{9u^2+9} \qquad \left[\begin{array}{c}\text{where } y=x^2+4x+13,\ dy=(2x+4)\,dx,\\ x+2=3u, \text{ and } dx=3\,du\end{array}\right]$$

$$= \tfrac{1}{2}\left[\ln y\right]_{13}^{18} - \tfrac{2}{3}\left[\tan^{-1}u\right]_{2/3}^{1} = \tfrac{1}{2}\ln\tfrac{18}{13} - \tfrac{2}{3}\left(\tfrac{\pi}{4} - \tan^{-1}\left(\tfrac{2}{3}\right)\right)$$

$$= \tfrac{1}{2}\ln\tfrac{18}{13} - \tfrac{\pi}{6} + \tfrac{2}{3}\tan^{-1}\left(\tfrac{2}{3}\right)$$

33. Let $u=x^4+4x^2+3$, so that $du=(4x^3+8x)\,dx=4(x^3+2x)\,dx$, $x=0 \;\Rightarrow\; u=3$, and $x=1 \;\Rightarrow\; u=8$.

Then $\displaystyle\int_0^1 \frac{x^3+2x}{x^4+4x^2+3}\,dx = \int_3^8 \frac{1}{u}\left(\frac{1}{4}\,du\right) = \frac{1}{4}\left[\ln|u|\right]_3^8 = \frac{1}{4}(\ln 8 - \ln 3) = \frac{1}{4}\ln\frac{8}{3}.$

34. $\dfrac{x^5+x-1}{x^3+1} = x^2 + \dfrac{-x^2+x-1}{x^3+1} = x^2 + \dfrac{-x^2+x-1}{(x+1)(x^2-x+1)} = x^2 + \dfrac{-1}{x+1}$, so

$$\int \frac{x^5+x-1}{x^3+1}\,dx = \int \left(x^2 - \frac{1}{x+1}\right) dx = \frac{1}{3}x^3 - \ln|x+1| + C$$

35. $\dfrac{5x^4+7x^2+x+2}{x(x^2+1)^2} = \dfrac{A}{x} + \dfrac{Bx+C}{x^2+1} + \dfrac{Dx+E}{(x^2+1)^2}$. Multiply by $x(x^2+1)^2$ to get

$5x^4+7x^2+x+2 = A(x^2+1)^2 + (Bx+C)x(x^2+1) + (Dx+E)x \quad \Leftrightarrow$

$5x^4+7x^2+x+2 = A(x^4+2x^2+1) + (Bx^2+Cx)(x^2+1) + Dx^2 + Ex \quad \Leftrightarrow$

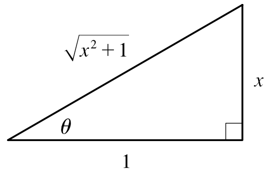
$5x^4+7x^2+x+2 = Ax^4 + 2Ax^2 + A + Bx^4 + Cx^3 + Bx^2 + Cx + Dx^2 + Ex \quad \Leftrightarrow$

$5x^4+7x^2+x+2 = (A+B)x^4 + Cx^3 + (2A+B+D)x^2 + (C+E)x + A$. Equating coefficients gives us $C=0$,

$A = 2$, $A + B = 5 \;\Rightarrow\; B = 3$, $C + E = 1 \;\Rightarrow\; E = 1$, and $2A + B + D = 7 \;\Rightarrow\; D = 0$. Thus,

$\displaystyle\int \frac{5x^4 + 7x^2 + x + 2}{x(x^2+1)^2}\,dx = \int \left[\frac{2}{x} + \frac{3x}{x^2+1} + \frac{1}{(x^2+1)^2}\right] dx = I$. Now

$$\int \frac{dx}{(x^2+1)^2} = \int \frac{\sec^2\theta\,d\theta}{(\tan^2\theta+1)^2} \qquad \begin{bmatrix} x = \tan\theta, \\ dx = \sec^2\theta\,d\theta \end{bmatrix}$$



$$= \int \frac{\sec^2\theta}{\sec^4\theta}\,d\theta = \int \cos^2\theta\,d\theta = \int \tfrac{1}{2}(1+\cos 2\theta)\,d\theta$$

$$= \tfrac{1}{2}\theta + \tfrac{1}{4}\sin 2\theta + C = \tfrac{1}{2}\theta + \tfrac{1}{2}\sin\theta\,\cos\theta + C$$

$$= \frac{1}{2}\tan^{-1}x + \frac{1}{2}\frac{x}{\sqrt{x^2+1}}\frac{1}{\sqrt{x^2+1}} + C$$

Therefore, $I = 2\ln|x| + \frac{3}{2}\ln(x^2+1) + \frac{1}{2}\tan^{-1}x + \dfrac{x}{2(x^2+1)} + C$.

36. Let $u = x^5 + 5x^3 + 5x$, so that $du = (5x^4 + 15x^2 + 5)dx = 5(x^4 + 3x^2 + 1)dx$. Then

$$\int \frac{x^4 + 3x^2 + 1}{x^5 + 5x^3 + 5x}\,dx = \int \frac{1}{u}\left(\frac{1}{5}\,du\right) = \frac{1}{5}\ln|u| + C = \frac{1}{5}\ln\left|x^5 + 5x^3 + 5x\right| + C$$

37. $\dfrac{x^2 - 3x + 7}{(x^2 - 4x + 6)^2} = \dfrac{Ax + B}{x^2 - 4x + 6} + \dfrac{Cx + D}{(x^2 - 4x + 6)^2} \;\Rightarrow\; x^2 - 3x + 7 = (Ax + B)(x^2 - 4x + 6) + Cx + D \;\Rightarrow$

$x^2 - 3x + 7 = Ax^3 + (-4A + B)x^2 + (6A - 4B + C)x + (6B + D)$. So $A = 0$, $-4A + B = 1 \;\Rightarrow\; B = 1$,

$6A - 4B + C = -3 \;\Rightarrow\; C = 1$, $6B + D = 7 \;\Rightarrow\; D = 1$. Thus,

$$I = \int \frac{x^2 - 3x + 7}{(x^2 - 4x + 6)^2}\,dx = \int \left(\frac{1}{x^2 - 4x + 6} + \frac{x+1}{(x^2 - 4x + 6)^2}\right) dx$$

$$= \int \frac{1}{(x-2)^2 + 2}\,dx + \int \frac{x-2}{(x^2 - 4x + 6)^2}\,dx + \int \frac{3}{(x^2 - 4x + 6)^2}\,dx$$

$$= I_1 + I_2 + I_3.$$

$$I_1 = \int \frac{1}{(x-2)^2 + \left(\sqrt{2}\right)^2}\,dx = \frac{1}{\sqrt{2}}\tan^{-1}\left(\frac{x-2}{\sqrt{2}}\right) + C_1$$

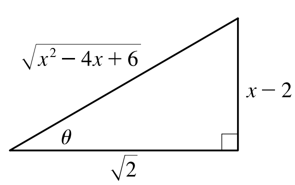
$$I_2 = \frac{1}{2}\int \frac{2x - 4}{(x^2 - 4x + 6)^2}\,dx = \tfrac{1}{2}\int \frac{1}{u^2}\,du = \tfrac{1}{2}\left(-\frac{1}{u}\right) + C_2 = -\frac{1}{2(x^2 - 4x + 6)} + C_2$$

$$I_3 = 3\int \frac{1}{\left[(x-2)^2 + \left(\sqrt{2}\right)^2\right]^2}\,dx = 3\int \frac{1}{[2(\tan^2\theta + 1)]^2}\,\sqrt{2}\sec^2\theta\,d\theta \qquad \begin{bmatrix} x - 2 = \sqrt{2}\tan\theta, \\ dx = \sqrt{2}\sec^2\theta\,d\theta \end{bmatrix}$$

$$= \frac{3\sqrt{2}}{4}\int \frac{\sec^2\theta}{\sec^4\theta}\,d\theta = \frac{3\sqrt{2}}{4}\int \cos^2\theta\,d\theta = \frac{3\sqrt{2}}{4}\int \tfrac{1}{2}(1 + \cos 2\theta)\,d\theta$$

$$= \frac{3\sqrt{2}}{8}\left(\theta + \tfrac{1}{2}\sin 2\theta\right) + C_3 = \frac{3\sqrt{2}}{8}\tan^{-1}\left(\frac{x-2}{\sqrt{2}}\right) + \frac{3\sqrt{2}}{8}\left(\tfrac{1}{2}\cdot 2\sin\theta\,\cos\theta\right) + C_3$$

$$= \frac{3\sqrt{2}}{8}\tan^{-1}\left(\frac{x-2}{\sqrt{2}}\right) + \frac{3\sqrt{2}}{8}\cdot\frac{x-2}{\sqrt{x^2 - 4x + 6}}\cdot\frac{\sqrt{2}}{\sqrt{x^2 - 4x + 6}} + C_3$$



$$= \frac{3\sqrt{2}}{8}\tan^{-1}\left(\frac{x-2}{\sqrt{2}}\right) + \frac{3(x-2)}{4(x^2 - 4x + 6)} + C_3$$

So $I = I_1 + I_2 + I_3 \qquad [C = C_1 + C_2 + C_3]$

$$= \frac{1}{\sqrt{2}} \tan^{-1}\left(\frac{x-2}{\sqrt{2}}\right) + \frac{-1}{2(x^2-4x+6)} + \frac{3\sqrt{2}}{8} \tan^{-1}\left(\frac{x-2}{\sqrt{2}}\right) + \frac{3(x-2)}{4(x^2-4x+6)} + C$$

$$= \left(\frac{4\sqrt{2}}{8} + \frac{3\sqrt{2}}{8}\right) \tan^{-1}\left(\frac{x-2}{\sqrt{2}}\right) + \frac{3(x-2)-2}{4(x^2-4x+6)} + C = \frac{7\sqrt{2}}{8} \tan^{-1}\left(\frac{x-2}{\sqrt{2}}\right) + \frac{3x-8}{4(x^2-4x+6)} + C$$

38. $\dfrac{x^3+2x^2+3x-2}{(x^2+2x+2)^2} = \dfrac{Ax+B}{x^2+2x+2} + \dfrac{Cx+D}{(x^2+2x+2)^2} \quad \Rightarrow$

$x^3+2x^2+3x-2 = (Ax+B)(x^2+2x+2) + Cx + D \quad \Rightarrow$

$x^3+2x^2+3x-2 = Ax^3 + (2A+B)x^2 + (2A+2B+C)x + 2B + D.$

So $A = 1, 2A + B = 2 \quad \Rightarrow \quad B = 0, 2A + 2B + C = 3 \quad \Rightarrow \quad C = 1$, and $2B + D = -2 \quad \Rightarrow \quad D = -2$. Thus,

$$I = \int \frac{x^3+2x^2+3x-2}{(x^2+2x+2)^2}\,dx = \int \left(\frac{x}{x^2+2x+2} + \frac{x-2}{(x^2+2x+2)^2}\right) dx$$

$$= \int \frac{x+1}{x^2+2x+2}\,dx + \int \frac{-1}{x^2+2x+2}\,dx + \int \frac{x+1}{(x^2+2x+2)^2}\,dx + \int \frac{-3}{(x^2+2x+2)^2}\,dx$$

$$= I_1 + I_2 + I_3 + I_4.$$

$$I_1 = \int \frac{x+1}{x^2+2x+2}\,dx = \int \frac{1}{u}\left(\frac{1}{2}\,du\right) \quad \begin{bmatrix} u = x^2+2x+2, \\ du = 2(x+1)\,dx \end{bmatrix} \quad = \frac{1}{2} \ln\left|x^2+2x+2\right| + C_1$$

$$I_2 = -\int \frac{1}{(x+1)^2+1}\,dx = -\frac{1}{1}\tan^{-1}\left(\frac{x+1}{1}\right) + C_2 = -\tan^{-1}(x+1) + C_2$$

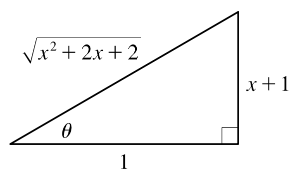
$$I_3 = \int \frac{x+1}{(x^2+2x+2)^2}\,dx = \int \frac{1}{u^2}\left(\frac{1}{2}\,du\right) = -\frac{1}{2u} + C_3 = -\frac{1}{2(x^2+2x+2)} + C_3$$

$$I_4 = -3\int \frac{1}{[(x+1)^2+1]^2}\,dx = -3\int \frac{1}{(\tan^2\theta+1)^2}\sec^2\theta\,d\theta \quad \begin{bmatrix} x+1 = 1\tan\theta, \\ dx = \sec^2\theta\,d\theta \end{bmatrix}$$

$$= -3\int \frac{1}{\sec^2\theta}\,d\theta = -3\int \cos^2\theta\,d\theta = -\frac{3}{2}\int (1+\cos 2\theta)\,d\theta$$

$$= -\tfrac{3}{2}\left(\theta + \tfrac{1}{2}\sin 2\theta\right) + C_4 = -\tfrac{3}{2}\theta - \tfrac{3}{2}\left(\tfrac{1}{2}\cdot 2\sin\theta\,\cos\theta\right) + C_4$$

$$= -\frac{3}{2}\tan^{-1}\left(\frac{x+1}{1}\right) - \frac{3}{2}\cdot\frac{x+1}{\sqrt{x^2+2x+2}}\cdot\frac{1}{\sqrt{x^2+2x+2}} + C_4$$



$$= -\frac{3}{2}\tan^{-1}(x+1) - \frac{3(x+1)}{2(x^2+2x+2)} + C_4$$

So $I = I_1 + I_2 + I_3 + I_4 \qquad [C = C_1 + C_2 + C_3 + C_4]$

$$= \frac{1}{2}\ln(x^2+2x+2) - \tan^{-1}(x+1) - \frac{1}{2(x^2+2x+2)} - \frac{3}{2}\tan^{-1}(x+1) - \frac{3(x+1)}{2(x^2+2x+2)} + C$$

$$= \frac{1}{2}\ln(x^2+2x+2) - \frac{5}{2}\tan^{-1}(x+1) - \frac{3x+4}{2(x^2+2x+2)} + C$$

39. $\displaystyle\int \frac{dx}{x\sqrt{x-1}} = \int \frac{2u}{u(u^2+1)}\,du \qquad \begin{bmatrix} u=\sqrt{x-1},\ x=u^2+1 \\ u^2=x-1,\quad dx=2u\,du \end{bmatrix}$

$\displaystyle = 2\int \frac{1}{u^2+1}\,du = 2\tan^{-1}u + C = 2\tan^{-1}\sqrt{x-1} + C$

40. Let $u = \sqrt{x+3}$, so $u^2 = x+3$ and $2u\,du = dx$. Then

$\displaystyle\int \frac{dx}{2\sqrt{x+3}+x} = \int \frac{2u\,du}{2u+(u^2-3)} = \int \frac{2u}{u^2+2u-3}\,du = \int \frac{2u}{(u+3)(u-1)}\,du$. Now

$\displaystyle\frac{2u}{(u+3)(u-1)} = \frac{A}{u+3} + \frac{B}{u-1} \quad\Rightarrow\quad 2u = A(u-1)+B(u+3)$. Setting $u=1$ gives $2=4B$, so $B=\frac{1}{2}$.

Setting $u=-3$ gives $-6=-4A$, so $A=\frac{3}{2}$. Thus,

$$\int \frac{2u}{(u+3)(u-1)}\,du = \int \left(\frac{\frac{3}{2}}{u+3} + \frac{\frac{1}{2}}{u-1}\,du\right)$$
$$= \tfrac{3}{2}\ln|u+3| + \tfrac{1}{2}\ln|u-1| + C = \tfrac{3}{2}\ln\!\left(\sqrt{x+3}+3\right) + \tfrac{1}{2}\ln\left|\sqrt{x+3}-1\right| + C$$

41. Let $u=\sqrt{x}$, so $u^2=x$ and $2u\,du=dx$. Then $\displaystyle\int \frac{dx}{x^2+x\sqrt{x}} = \int \frac{2u\,du}{u^4+u^3} = \int \frac{2\,du}{u^3+u^2} = \int \frac{2\,du}{u^2(u+1)}$.

$\displaystyle\frac{2}{u^2(u+1)} = \frac{A}{u} + \frac{B}{u^2} + \frac{C}{u+1} \quad\Rightarrow\quad 2 = Au(u+1)+B(u+1)+Cu^2$. Setting $u=0$ gives $B=2$. Setting $u=-1$

gives $C=2$. Equating coefficients of u^2, we get $0=A+C$, so $A=-2$. Thus,

$$\int \frac{2\,du}{u^2(u+1)} = \int\left(\frac{-2}{u} + \frac{2}{u^2} + \frac{2}{u+1}\right)du = -2\ln|u| - \frac{2}{u} + 2\ln|u+1| + C = -2\ln\sqrt{x} - \frac{2}{\sqrt{x}} + 2\ln\left(\sqrt{x}+1\right) + C.$$

42. Let $u=\sqrt[3]{x}$. Then $x=u^3$, $dx=3u^2\,du \quad\Rightarrow$

$$\int_0^1 \frac{1}{1+\sqrt[3]{x}}\,dx = \int_0^1 \frac{3u^2\,du}{1+u} = \int_0^1 \left(3u-3+\frac{3}{1+u}\right)du = \left[\tfrac{3}{2}u^2 - 3u + 3\ln(1+u)\right]_0^1 = 3\left(\ln 2 - \tfrac{1}{2}\right).$$

43. Let $u=\sqrt[3]{x^2+1}$. Then $x^2=u^3-1$, $2x\,dx = 3u^2\,du \quad\Rightarrow$

$$\int \frac{x^3\,dx}{\sqrt[3]{x^2+1}} = \int \frac{(u^3-1)\frac{3}{2}u^2\,du}{u} = \frac{3}{2}\int (u^4-u)\,du$$
$$= \tfrac{3}{10}u^5 - \tfrac{3}{4}u^2 + C = \tfrac{3}{10}(x^2+1)^{5/3} - \tfrac{3}{4}(x^2+1)^{2/3} + C$$

44. $\displaystyle\int \frac{dx}{(1+\sqrt{x}\,)^2} = \int \frac{2(u-1)}{u^2}\,du \qquad \begin{bmatrix} u=1+\sqrt{x}, \\ x=(u-1)^2,\ dx=2(u-1)\,du \end{bmatrix}$

$\displaystyle = 2\int\left(\frac{1}{u} - \frac{1}{u^2}\right)du = 2\ln|u| + \frac{2}{u} + C = 2\ln(1+\sqrt{x}\,) + \frac{2}{1+\sqrt{x}} + C$

45. If we were to substitute $u=\sqrt{x}$, then the square root would disappear but a cube root would remain. On the other hand, the substitution $u=\sqrt[3]{x}$ would eliminate the cube root but leave a square root. We can eliminate both roots by means of the substitution $u=\sqrt[6]{x}$. (Note that 6 is the least common multiple of 2 and 3.)

Let $u=\sqrt[6]{x}$. Then $x=u^6$, so $dx=6u^5\,du$ and $\sqrt{x}=u^3$, $\sqrt[3]{x}=u^2$. Thus,

$$\begin{aligned}\int \frac{dx}{\sqrt{x}-\sqrt[3]{x}} &= \int \frac{6u^5\,du}{u^3-u^2} = 6\int \frac{u^5}{u^2(u-1)}\,du = 6\int \frac{u^3}{u-1}\,du \\ &= 6\int \left(u^2+u+1+\frac{1}{u-1}\right)du \qquad \text{[by long division]} \\ &= 6\left(\tfrac{1}{3}u^3+\tfrac{1}{2}u^2+u+\ln|u-1|\right)+C = 2\sqrt{x}+3\sqrt[3]{x}+6\sqrt[6]{x}+6\ln\left|\sqrt[6]{x}-1\right|+C\end{aligned}$$

46. Let $u=\sqrt{1+\sqrt{x}}$, so that $u^2=1+\sqrt{x}$, $x=(u^2-1)^2$, and $dx=2(u^2-1)\cdot 2u\,du=4u(u^2-1)\,du$. Then

$\displaystyle\int \frac{\sqrt{1+\sqrt{x}}}{x}\,dx = \int \frac{u}{(u^2-1)^2}\cdot 4u(u^2-1)\,du = \int \frac{4u^2}{u^2-1}\,du = \int\left(4+\frac{4}{u^2-1}\right)du$. Now

$\dfrac{4}{u^2-1}=\dfrac{A}{u+1}+\dfrac{B}{u-1} \;\Rightarrow\; 4=A(u-1)+B(u+1)$. Setting $u=1$ gives $4=2B$, so $B=2$. Setting $u=-1$ gives $4=-2A$, so $A=-2$. Thus,

$$\begin{aligned}\int\left(4+\frac{4}{u^2-1}\right)du &= \int\left(4-\frac{2}{u+1}+\frac{2}{u-1}\right)du = 4u-2\ln|u+1|+2\ln|u-1|+C \\ &= 4\sqrt{1+\sqrt{x}}-2\ln\left(\sqrt{1+\sqrt{x}}+1\right)+2\ln\left(\sqrt{1+\sqrt{x}}-1\right)+C\end{aligned}$$

47. Let $u=e^x$. Then $x=\ln u$, $dx=\dfrac{du}{u} \;\Rightarrow$

$$\begin{aligned}\int \frac{e^{2x}\,dx}{e^{2x}+3e^x+2} &= \int \frac{u^2\,(du/u)}{u^2+3u+2} = \int \frac{u\,du}{(u+1)(u+2)} = \int\left[\frac{-1}{u+1}+\frac{2}{u+2}\right]du \\ &= 2\ln|u+2|-\ln|u+1|+C = \ln\frac{(e^x+2)^2}{e^x+1}+C\end{aligned}$$

48. Let $u=\cos x$, so that $du=-\sin x\,dx$. Then $\displaystyle\int \frac{\sin x}{\cos^2 x-3\cos x}\,dx = \int \frac{1}{u^2-3u}(-du) = \int \frac{-1}{u(u-3)}\,du$.

$\dfrac{-1}{u(u-3)}=\dfrac{A}{u}+\dfrac{B}{u-3} \;\Rightarrow\; -1=A(u-3)+Bu$. Setting $u=3$ gives $B=-\frac{1}{3}$. Setting $u=0$ gives $A=\frac{1}{3}$.

Thus, $\displaystyle\int \frac{-1}{u(u-3)}\,du = \int\left(\frac{\frac{1}{3}}{u}-\frac{\frac{1}{3}}{u-3}\right)du = \frac{1}{3}\ln|u|-\frac{1}{3}\ln|u-3|+C = \tfrac{1}{3}\ln|\cos x|-\tfrac{1}{3}\ln|\cos x-3|+C$.

49. Let $u=\tan t$, so that $du=\sec^2 t\,dt$. Then $\displaystyle\int \frac{\sec^2 t}{\tan^2 t+3\tan t+2}\,dt = \int \frac{1}{u^2+3u+2}\,du = \int \frac{1}{(u+1)(u+2)}\,du$.

Now $\dfrac{1}{(u+1)(u+2)}=\dfrac{A}{u+1}+\dfrac{B}{u+2} \;\Rightarrow\; 1=A(u+2)+B(u+1)$.

Setting $u=-2$ gives $1=-B$, so $B=-1$. Setting $u=-1$ gives $1=A$.

Thus, $\displaystyle\int \frac{1}{(u+1)(u+2)}\,du = \int\left(\frac{1}{u+1}-\frac{1}{u+2}\right)du = \ln|u+1|-\ln|u+2|+C = \ln|\tan t+1|-\ln|\tan t+2|+C$.

50. Let $u=e^x$, so that $du=e^x\,dx$. Then $\displaystyle\int \frac{e^x}{(e^x-2)(e^{2x}+1)}\,dx = \int \frac{1}{(u-2)(u^2+1)}\,du$. Now

$\dfrac{1}{(u-2)(u^2+1)}=\dfrac{A}{u-2}+\dfrac{Bu+C}{u^2+1} \;\Rightarrow\; 1=A(u^2+1)+(Bu+C)(u-2)$. Setting $u=2$ gives $1=5A$, so $A=\frac{1}{5}$.

Setting $u = 0$ gives $1 = \frac{1}{5} - 2C$, so $C = -\frac{2}{5}$. Comparing coefficients of u^2 gives $0 = \frac{1}{5} + B$, so $B = -\frac{1}{5}$. Thus,

$$\int \frac{1}{(u-2)(u^2+1)}\,du = \int \left(\frac{\frac{1}{5}}{u-2} + \frac{-\frac{1}{5}u - \frac{2}{5}}{u^2+1} \right) du = \frac{1}{5}\int \frac{1}{u-2}\,du - \frac{1}{5}\int \frac{u}{u^2+1}\,du - \frac{2}{5}\int \frac{1}{u^2+1}\,du$$
$$= \tfrac{1}{5}\ln|u-2| - \tfrac{1}{5}\cdot\tfrac{1}{2}\ln\left|u^2+1\right| - \tfrac{2}{5}\tan^{-1}u + C$$
$$= \tfrac{1}{5}\ln|e^x - 2| - \tfrac{1}{10}\ln(e^{2x}+1) - \tfrac{2}{5}\tan^{-1}e^x + C$$

51. Let $u = e^x$, so that $du = e^x\,dx$ and $dx = \dfrac{du}{u}$. Then $\displaystyle\int \frac{dx}{1+e^x} = \int \frac{du}{(1+u)u}$. $\dfrac{1}{u(u+1)} = \dfrac{A}{u} + \dfrac{B}{u+1} \Rightarrow$

$1 = A(u+1) + Bu$. Setting $u = -1$ gives $B = -1$. Setting $u = 0$ gives $A = 1$. Thus,

$$\int \frac{du}{u(u+1)} = \int \left(\frac{1}{u} - \frac{1}{u+1}\right) du = \ln|u| - \ln|u+1| + C = \ln e^x - \ln(e^x+1) + C = x - \ln(e^x+1) + C.$$

52. Let $u = \sinh t$, so that $du = \cosh t\,dt$. Then $\displaystyle\int \frac{\cosh t}{\sinh^2 t + \sinh^4 t}\,dt = \int \frac{1}{u^2+u^4}\,du = \int \frac{1}{u^2(u^2+1)}\,du$.

$\dfrac{1}{u^2(u^2+1)} = \dfrac{A}{u} + \dfrac{B}{u^2} + \dfrac{Cu+D}{u^2+1} \Rightarrow 1 = Au(u^2+1) + B(u^2+1) + (Cu+D)u^2$. Setting $u = 0$ gives $B = 1$.

Comparing coefficients of u^2, we get $0 = B + D$, so $D = -1$. Comparing coefficients of u, we get $0 = A$. Comparing coefficients of u^3, we get $0 = A + C$, so $C = 0$. Thus,

$$\int \frac{1}{u^2(u^2+1)}\,du = \int \left(\frac{1}{u^2} - \frac{1}{u^2+1}\right) du = -\frac{1}{u} - \tan^{-1}u + C = -\frac{1}{\sinh t} - \tan^{-1}(\sinh t) + C$$
$$= -\operatorname{csch} t - \tan^{-1}(\sinh t) + C$$

53. Let $u = \ln(x^2 - x + 2)$, $dv = dx$. Then $du = \dfrac{2x-1}{x^2-x+2}\,dx$, $v = x$, and (by integration by parts)

$$\int \ln(x^2-x+2)\,dx = x\ln(x^2-x+2) - \int \frac{2x^2-x}{x^2-x+2}\,dx = x\ln(x^2-x+2) - \int \left(2 + \frac{x-4}{x^2-x+2}\right) dx$$
$$= x\ln(x^2-x+2) - 2x - \int \frac{\frac{1}{2}(2x-1)}{x^2-x+2}\,dx + \frac{7}{2}\int \frac{dx}{(x-\frac{1}{2})^2 + \frac{7}{4}}$$
$$= x\ln(x^2-x+2) - 2x - \frac{1}{2}\ln(x^2-x+2) + \frac{7}{2}\int \frac{\frac{\sqrt{7}}{2}\,du}{\frac{7}{4}(u^2+1)} \quad \left[\begin{array}{c}\text{where } x - \frac{1}{2} = \frac{\sqrt{7}}{2}u,\\ dx = \frac{\sqrt{7}}{2}\,du,\\ (x-\frac{1}{2})^2 + \frac{7}{4} = \frac{7}{4}(u^2+1)\end{array}\right]$$
$$= (x - \tfrac{1}{2})\ln(x^2-x+2) - 2x + \sqrt{7}\tan^{-1}u + C$$
$$= (x - \tfrac{1}{2})\ln(x^2-x+2) - 2x + \sqrt{7}\tan^{-1}\frac{2x-1}{\sqrt{7}} + C$$

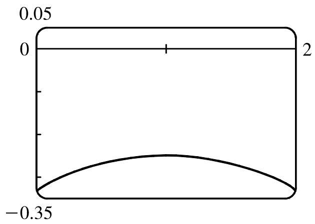
54. Let $u = \tan^{-1}x$, $dv = x\,dx \Rightarrow du = dx/(1+x^2)$, $v = \frac{1}{2}x^2$.

Then $\displaystyle\int x\tan^{-1}x\,dx = \tfrac{1}{2}x^2\tan^{-1}x - \frac{1}{2}\int \frac{x^2}{1+x^2}\,dx$. To evaluate the last integral, use long division or observe that

$\displaystyle\int \frac{x^2}{1+x^2}\,dx = \int \frac{(1+x^2)-1}{1+x^2}\,dx = \int 1\,dx - \int \frac{1}{1+x^2}\,dx = x - \tan^{-1}x + C_1$. So

$\int x\tan^{-1}x\,dx = \frac{1}{2}x^2\tan^{-1}x - \frac{1}{2}(x - \tan^{-1}x + C_1) = \frac{1}{2}(x^2\tan^{-1}x + \tan^{-1}x - x) + C$.

55.



From the graph, we see that the integral will be negative, and we guess that the area is about the same as that of a rectangle with width 2 and height 0.3, so we estimate the integral to be $-(2 \cdot 0.3) = -0.6$. Now

$$\frac{1}{x^2-2x-3} = \frac{1}{(x-3)(x+1)} = \frac{A}{x-3} + \frac{B}{x+1} \quad \Leftrightarrow$$

$1 = (A+B)x + A - 3B$, so $A = -B$ and $A - 3B = 1 \quad \Leftrightarrow \quad A = \frac{1}{4}$ and $B = -\frac{1}{4}$, so the integral becomes

$$\int_0^2 \frac{dx}{x^2-2x-3} = \frac{1}{4}\int_0^2 \frac{dx}{x-3} - \frac{1}{4}\int_0^2 \frac{dx}{x+1} = \frac{1}{4}\Big[\ln|x-3| - \ln|x+1|\Big]_0^2 = \frac{1}{4}\left[\ln\left|\frac{x-3}{x+1}\right|\right]_0^2$$

$$= \tfrac{1}{4}\left(\ln\tfrac{1}{3} - \ln 3\right) = -\tfrac{1}{2}\ln 3 \approx -0.55$$

56. $\boldsymbol{k=0}$: $\displaystyle\int \frac{dx}{x^2+k} = \int \frac{dx}{x^2} = -\frac{1}{x} + C$

$\boldsymbol{k>0}$: $\displaystyle\int \frac{dx}{x^2+k} = \int \frac{dx}{x^2+(\sqrt{k}\,)^2} = \frac{1}{\sqrt{k}}\tan^{-1}\left(\frac{x}{\sqrt{k}}\right) + C$

$\boldsymbol{k<0}$: $\displaystyle\int \frac{dx}{x^2+k} = \int \frac{dx}{x^2-(-k)} = \int \frac{dx}{x^2-\left(\sqrt{-k}\,\right)^2} = \frac{1}{2\sqrt{-k}}\ln\left|\frac{x-\sqrt{-k}}{x+\sqrt{-k}}\right| + C$ [by Example 3]

57. $\displaystyle\int \frac{dx}{x^2-2x} = \int \frac{dx}{(x-1)^2-1} = \int \frac{du}{u^2-1}$ [put $u = x-1$]

$\displaystyle = \frac{1}{2}\ln\left|\frac{u-1}{u+1}\right| + C$ [by Equation 6] $\displaystyle = \frac{1}{2}\ln\left|\frac{x-2}{x}\right| + C$

58. $\displaystyle\int \frac{(2x+1)\,dx}{4x^2+12x-7} = \frac{1}{4}\int \frac{(8x+12)\,dx}{4x^2+12x-7} - \int \frac{2\,dx}{(2x+3)^2-16}$

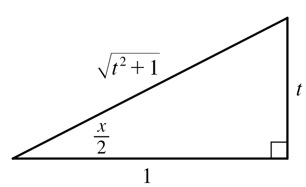
$\displaystyle = \tfrac{1}{4}\ln\left|4x^2+12x-7\right| - \int \frac{du}{u^2-16}$ [put $u = 2x+3$]

$= \tfrac{1}{4}\ln\left|4x^2+12x-7\right| - \tfrac{1}{8}\ln|(u-4)/(u+4)| + C$ [by Equation 6]

$= \tfrac{1}{4}\ln\left|4x^2+12x-7\right| - \tfrac{1}{8}\ln|(2x-1)/(2x+7)| + C$

59. (a) If $t = \tan\left(\dfrac{x}{2}\right)$, then $\dfrac{x}{2} = \tan^{-1} t$. The figure gives

$\cos\left(\dfrac{x}{2}\right) = \dfrac{1}{\sqrt{1+t^2}}$ and $\sin\left(\dfrac{x}{2}\right) = \dfrac{t}{\sqrt{1+t^2}}$.



(b) $\cos x = \cos\left(2\cdot\dfrac{x}{2}\right) = 2\cos^2\left(\dfrac{x}{2}\right) - 1$

$\displaystyle = 2\left(\frac{1}{\sqrt{1+t^2}}\right)^2 - 1 = \frac{2}{1+t^2} - 1 = \frac{1-t^2}{1+t^2}$

(c) $\dfrac{x}{2} = \arctan t \quad\Rightarrow\quad x = 2\arctan t \quad\Rightarrow\quad dx = \dfrac{2}{1+t^2}\,dt$

60. Let $t = \tan(x/2)$. Then, by using the expressions in Exercise 59, we have

$$\int \frac{dx}{1-\cos x} = \int \frac{2\,dt/(1+t^2)}{1-(1-t^2)/(1+t^2)} = \int \frac{2\,dt}{(1+t^2)-(1-t^2)} = \int \frac{2\,dt}{2t^2} = \int \frac{1}{t^2}\,dt$$
$$= -\frac{1}{t} + C = -\frac{1}{\tan(x/2)} + C = -\cot(x/2) + C$$

Another method: $$\int \frac{dx}{1-\cos x} = \int \left(\frac{1}{1-\cos x}\cdot\frac{1+\cos x}{1+\cos x}\right)dx = \int \frac{1+\cos x}{1-\cos^2 x}\,dx = \int \frac{1+\cos x}{\sin^2 x}\,dx$$
$$= \int\left(\frac{1}{\sin^2 x} + \frac{\cos x}{\sin^2 x}\right)dx = \int(\csc^2 x + \csc x\,\cot x)\,dx = -\cot x - \csc x + C$$

61. Let $t = \tan(x/2)$. Then, using the expressions in Exercise 59, we have

$$\int \frac{1}{3\sin x - 4\cos x}\,dx = \int \frac{1}{3\left(\frac{2t}{1+t^2}\right) - 4\left(\frac{1-t^2}{1+t^2}\right)}\,\frac{2\,dt}{1+t^2} = 2\int \frac{dt}{3(2t)-4(1-t^2)} = \int \frac{dt}{2t^2+3t-2}$$
$$= \int \frac{dt}{(2t-1)(t+2)} = \int \left[\frac{2}{5}\frac{1}{2t-1} - \frac{1}{5}\frac{1}{t+2}\right]dt \qquad \text{[using partial fractions]}$$
$$= \tfrac{1}{5}\Big[\ln|2t-1| - \ln|t+2|\Big] + C = \frac{1}{5}\ln\left|\frac{2t-1}{t+2}\right| + C = \frac{1}{5}\ln\left|\frac{2\tan(x/2)-1}{\tan(x/2)+2}\right| + C$$

62. Let $t = \tan(x/2)$. Then, by Exercise 59,

$$\int_{\pi/3}^{\pi/2} \frac{dx}{1+\sin x - \cos x} = \int_{1/\sqrt{3}}^{1} \frac{2\,dt/(1+t^2)}{1 + 2t/(1+t^2) - (1-t^2)/(1+t^2)} = \int_{1/\sqrt{3}}^{1} \frac{2\,dt}{1+t^2+2t-1+t^2}$$
$$= \int_{1/\sqrt{3}}^{1}\left[\frac{1}{t} - \frac{1}{t+1}\right]dt = \Big[\ln t - \ln(t+1)\Big]_{1/\sqrt{3}}^{1} = \ln\frac{1}{2} - \ln\frac{1}{\sqrt{3}+1} = \ln\frac{\sqrt{3}+1}{2}$$

63. Let $t = \tan(x/2)$. Then, by Exercise 59,

$$\int_0^{\pi/2} \frac{\sin 2x}{2+\cos x}\,dx = \int_0^{\pi/2} \frac{2\sin x\,\cos x}{2+\cos x}\,dx = \int_0^1 \frac{2\cdot\frac{2t}{1+t^2}\cdot\frac{1-t^2}{1+t^2}}{2+\frac{1-t^2}{1+t^2}}\,\frac{2}{1+t^2}\,dt = \int_0^1 \frac{\frac{8t(1-t^2)}{(1+t^2)^2}}{2(1+t^2)+(1-t^2)}\,dt$$
$$= \int_0^1 8t\cdot\frac{1-t^2}{(t^2+3)(t^2+1)^2}\,dt = I$$

If we now let $u = t^2$, then $\dfrac{1-t^2}{(t^2+3)(t^2+1)^2} = \dfrac{1-u}{(u+3)(u+1)^2} = \dfrac{A}{u+3} + \dfrac{B}{u+1} + \dfrac{C}{(u+1)^2} \quad\Rightarrow$

$1-u = A(u+1)^2 + B(u+3)(u+1) + C(u+3)$. Set $u=-1$ to get $2 = 2C$, so $C = 1$. Set $u = -3$ to get $4 = 4A$, so $A = 1$. Set $u = 0$ to get $1 = 1 + 3B + 3$, so $B = -1$. So

$$I = \int_0^1\left[\frac{8t}{t^2+3} - \frac{8t}{t^2+1} + \frac{8t}{(t^2+1)^2}\right]dt = \left[4\ln(t^2+3) - 4\ln(t^2+1) - \frac{4}{t^2+1}\right]_0^1$$
$$= (4\ln 4 - 4\ln 2 - 2) - (4\ln 3 - 0 - 4) = 8\ln 2 - 4\ln 2 - 4\ln 3 + 2 = 4\ln\tfrac{2}{3} + 2$$

64. $\dfrac{1}{x^3+x} = \dfrac{1}{x(x^2+1)} = \dfrac{A}{x} + \dfrac{Bx+C}{x^2+1} \quad\Rightarrow\quad 1 = A(x^2+1) + (Bx+C)x$. Set $x = 0$ to get $1 = A$. So

$1 = (1+B)x^2 + Cx + 1 \quad\Rightarrow\quad B + 1 = 0 \quad [B = -1]$ and $C = 0$. Thus, the area is

$$\int_1^2 \frac{1}{x^3+x}\,dx = \int_1^2 \left(\frac{1}{x} - \frac{x}{x^2+1}\right)dx = \left[\ln|x| - \tfrac{1}{2}\ln\left|x^2+1\right|\right]_1^2 = \left(\ln 2 - \tfrac{1}{2}\ln 5\right) - \left(0 - \tfrac{1}{2}\ln 2\right)$$
$$= \tfrac{3}{2}\ln 2 - \tfrac{1}{2}\ln 5 \quad \left[\text{or } \tfrac{1}{2}\ln\tfrac{8}{5}\right]$$

65. By long division, $\dfrac{x^2+1}{3x-x^2} = -1 + \dfrac{3x+1}{3x-x^2}$. Now

$\dfrac{3x+1}{3x-x^2} = \dfrac{3x+1}{x(3-x)} = \dfrac{A}{x} + \dfrac{B}{3-x} \quad\Rightarrow\quad 3x+1 = A(3-x)+Bx$. Set $x=3$ to get $10=3B$, so $B=\frac{10}{3}$. Set $x=0$ to get $1=3A$, so $A=\frac{1}{3}$. Thus, the area is

$$\int_1^2 \frac{x^2+1}{3x-x^2}\,dx = \int_1^2\left(-1+\frac{\frac{1}{3}}{x}+\frac{\frac{10}{3}}{3-x}\right)dx = \left[-x+\tfrac{1}{3}\ln|x| - \tfrac{10}{3}\ln|3-x|\right]_1^2$$
$$= \left(-2+\tfrac{1}{3}\ln 2 - 0\right) - \left(-1+0-\tfrac{10}{3}\ln 2\right) = -1+\tfrac{11}{3}\ln 2$$

66. (a) We use disks, so the volume is $V = \pi\displaystyle\int_0^1\left[\frac{1}{x^2+3x+2}\right]^2 dx = \pi\int_0^1 \frac{dx}{(x+1)^2(x+2)^2}$. To evaluate the integral, we use partial fractions: $\dfrac{1}{(x+1)^2(x+2)^2} = \dfrac{A}{x+1}+\dfrac{B}{(x+1)^2}+\dfrac{C}{x+2}+\dfrac{D}{(x+2)^2} \quad\Rightarrow$

$1 = A(x+1)(x+2)^2 + B(x+2)^2 + C(x+1)^2(x+2) + D(x+1)^2$. We set $x=-1$, giving $B=1$, then set $x=-2$, giving $D=1$. Now equating coefficients of x^3 gives $A=-C$, and then equating constants gives $1 = 4A+4+2(-A)+1 \quad\Rightarrow\quad A=-2 \quad\Rightarrow\quad C=2$. So the expression becomes

$$V = \pi\int_0^1\left[\frac{-2}{x+1}+\frac{1}{(x+1)^2}+\frac{2}{(x+2)}+\frac{1}{(x+2)^2}\right]dx = \pi\left[2\ln\left|\frac{x+2}{x+1}\right| - \frac{1}{x+1} - \frac{1}{x+2}\right]_0^1$$
$$= \pi\left[\left(2\ln\tfrac{3}{2}-\tfrac{1}{2}-\tfrac{1}{3}\right)-\left(2\ln 2 - 1 - \tfrac{1}{2}\right)\right] = \pi\left(2\ln\tfrac{3/2}{2}+\tfrac{2}{3}\right) = \pi\left(\tfrac{2}{3}+\ln\tfrac{9}{16}\right)$$

(b) In this case, we use cylindrical shells, so the volume is $V = 2\pi\displaystyle\int_0^1\frac{x\,dx}{x^2+3x+2} = 2\pi\int_0^1\frac{x\,dx}{(x+1)(x+2)}$. We use partial fractions to simplify the integrand: $\dfrac{x}{(x+1)(x+2)} = \dfrac{A}{x+1}+\dfrac{B}{x+2} \quad\Rightarrow\quad x = (A+B)x+2A+B$. So $A+B=1$ and $2A+B=0 \quad\Rightarrow\quad A=-1$ and $B=2$. So the volume is

$$2\pi\int_0^1\left[\frac{-1}{x+1}+\frac{2}{x+2}\right]dx = 2\pi\Big[-\ln|x+1| + 2\ \ln|x+2|\Big]_0^1$$
$$= 2\pi(-\ln 2+2\ln 3+\ln 1-2\ln 2) = 2\pi(2\ln 3-3\ln 2) = 2\pi\ln\tfrac{9}{8}$$

67. $t = \displaystyle\int\frac{P+S}{P[(r-1)P-S]}\,dP = \int\frac{P+S}{P(0.1P-S)}\,dP \quad [r=1.1]$. Now $\dfrac{P+S}{P(0.1P-S)} = \dfrac{A}{P}+\dfrac{B}{0.1P-S} \quad\Rightarrow$

$P+S = A(0.1P-S)+BP$. Substituting 0 for P gives $S=-AS \quad\Rightarrow\quad A=-1$. Substituting $10S$ for P gives

$11S = 10BS \quad\Rightarrow\quad B=\frac{11}{10}$. Thus, $t = \displaystyle\int\left(\frac{-1}{P}+\frac{11/10}{0.1P-S}\right)dP \quad\Rightarrow\quad t = -\ln P + 11\ln(0.1P-S)+C$.

When $t=0$, $P=10{,}000$ and $S=900$, so $0 = -\ln 10{,}000 + 11\ln(1000-900)+C \quad\Rightarrow$

$C = \ln 10{,}000 - 11\ln 100 \quad [=\ln 10^{-18}\approx -41.45]$.

Therefore, $t = -\ln P + 11\ln\left(\frac{1}{10}P-900\right)+\ln 10{,}000 - 11\ln 100 \quad\Rightarrow\quad t = \ln\dfrac{10{,}000}{P}+11\ln\dfrac{P-9000}{1000}$.

68. If we subtract and add $2x^2$, we get

$$x^4+1=x^4+2x^2+1-2x^2=\left(x^2+1\right)^2-2x^2=\left(x^2+1\right)^2-\left(\sqrt{2}\,x\right)^2$$
$$=\left[\left(x^2+1\right)-\sqrt{2}\,x\right]\left[\left(x^2+1\right)+\sqrt{2}\,x\right]=\left(x^2-\sqrt{2}\,x+1\right)\left(x^2+\sqrt{2}\,x+1\right)$$

So we can decompose $\dfrac{1}{x^4+1}=\dfrac{Ax+B}{x^2+\sqrt{2}\,x+1}+\dfrac{Cx+D}{x^2-\sqrt{2}\,x+1}\quad\Rightarrow$

$1=(Ax+B)\left(x^2-\sqrt{2}\,x+1\right)+(Cx+D)\left(x^2+\sqrt{2}\,x+1\right)$. Setting the constant terms equal gives $B+D=1$, then from the coefficients of x^3 we get $A+C=0$. Now from the coefficients of x we get $A+C+(B-D)\sqrt{2}=0\quad\Leftrightarrow$ $[(1-D)-D]\sqrt{2}=0\quad\Rightarrow\quad D=\frac{1}{2}\quad\Rightarrow\quad B=\frac{1}{2}$, and finally, from the coefficients of x^2 we get $\sqrt{2}\,(C-A)+B+D=0\quad\Rightarrow\quad C-A=-\frac{1}{\sqrt{2}}\quad\Rightarrow\quad C=-\frac{\sqrt{2}}{4}$ and $A=\frac{\sqrt{2}}{4}$. So we rewrite the integrand, splitting the terms into forms which we know how to integrate:

$$\frac{1}{x^4+1}=\frac{\frac{\sqrt{2}}{4}x+\frac{1}{2}}{x^2+\sqrt{2}\,x+1}+\frac{-\frac{\sqrt{2}}{4}x+\frac{1}{2}}{x^2-\sqrt{2}\,x+1}=\frac{1}{4\sqrt{2}}\left[\frac{2x+2\sqrt{2}}{x^2+\sqrt{2}\,x+1}-\frac{2x-2\sqrt{2}}{x^2-\sqrt{2}\,x+1}\right]$$
$$=\frac{\sqrt{2}}{8}\left[\frac{2x+\sqrt{2}}{x^2+\sqrt{2}\,x+1}-\frac{2x-\sqrt{2}}{x^2-\sqrt{2}\,x+1}\right]+\frac{1}{4}\left[\frac{1}{\left(x+\frac{1}{\sqrt{2}}\right)^2+\frac{1}{2}}+\frac{1}{\left(x-\frac{1}{\sqrt{2}}\right)^2+\frac{1}{2}}\right]$$

Now we integrate: $\displaystyle\int\frac{dx}{x^4+1}=\frac{\sqrt{2}}{8}\ln\!\left(\frac{x^2+\sqrt{2}\,x+1}{x^2-\sqrt{2}\,x+1}\right)+\frac{\sqrt{2}}{4}\left[\tan^{-1}\!\left(\sqrt{2}\,x+1\right)+\tan^{-1}\!\left(\sqrt{2}\,x-1\right)\right]+C.$

69. (a) In Maple, we define $f(x)$, and then use `convert(f,parfrac,x);` to obtain

$$f(x)=\frac{24{,}110/4879}{5x+2}-\frac{668/323}{2x+1}-\frac{9438/80{,}155}{3x-7}+\frac{(22{,}098x+48{,}935)/260{,}015}{x^2+x+5}$$

In Mathematica, we use the command `Apart`, and in Derive, we use `Expand`.

(b) $\displaystyle\int f(x)\,dx=\tfrac{24{,}110}{4879}\cdot\tfrac{1}{5}\ln|5x+2|-\tfrac{668}{323}\cdot\tfrac{1}{2}\ln|2x+1|-\tfrac{9438}{80{,}155}\cdot\tfrac{1}{3}\ln|3x-7|$

$$+\frac{1}{260{,}015}\int\frac{22{,}098\left(x+\frac{1}{2}\right)+37{,}886}{\left(x+\frac{1}{2}\right)^2+\frac{19}{4}}\,dx+C$$

$$=\tfrac{24{,}110}{4879}\cdot\tfrac{1}{5}\ln|5x+2|-\tfrac{668}{323}\cdot\tfrac{1}{2}\ln|2x+1|-\tfrac{9438}{80{,}155}\cdot\tfrac{1}{3}\ln|3x-7|$$
$$+\tfrac{1}{260{,}015}\left[22{,}098\cdot\tfrac{1}{2}\ln\left(x^2+x+5\right)+37{,}886\cdot\sqrt{\tfrac{4}{19}}\tan^{-1}\!\left(\tfrac{1}{\sqrt{19/4}}\left(x+\tfrac{1}{2}\right)\right)\right]+C$$
$$=\tfrac{4822}{4879}\ln|5x+2|-\tfrac{334}{323}\ln|2x+1|-\tfrac{3146}{80{,}155}\ln|3x-7|+\tfrac{11{,}049}{260{,}015}\ln\left(x^2+x+5\right)$$
$$+\tfrac{75{,}772}{260{,}015\sqrt{19}}\tan^{-1}\left[\tfrac{1}{\sqrt{19}}(2x+1)\right]+C$$

Using a CAS, we get

$$\frac{4822\ln(5x+2)}{4879}-\frac{334\ln(2x+1)}{323}-\frac{3146\ln(3x-7)}{80{,}155}$$
$$+\frac{11{,}049\ln(x^2+x+5)}{260{,}015}+\frac{3988\sqrt{19}}{260{,}015}\tan^{-1}\left[\frac{\sqrt{19}}{19}(2x+1)\right]$$

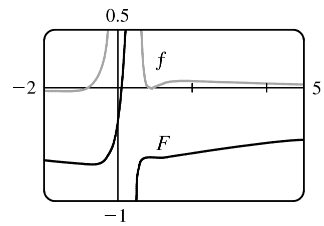
The main difference in this answer is that the absolute value signs and the constant of integration have been omitted. Also, the fractions have been reduced and the denominators rationalized.

70. (a) In Maple, we define $f(x)$, and then use `convert(f,parfrac,x);` to get

$$f(x) = \frac{5828/1815}{(5x-2)^2} - \frac{59{,}096/19{,}965}{5x-2} + \frac{2(2843x+816)/3993}{2x^2+1} + \frac{(313x-251)/363}{(2x^2+1)^2}.$$

In Mathematica, we use the command `Apart`, and in Derive, we use `Expand`.

(b) As we saw in Exercise 69, computer algebra systems omit the absolute value signs in $\int (1/y)\,dy = \ln|y|$. So we use the CAS to integrate the expression in part (a) and add the necessary absolute value signs and constant of integration to get



$$\int f(x)\,dx = -\frac{5828}{9075(5x-2)} - \frac{59{,}096\ln|5x-2|}{99{,}825} + \frac{2843\ln(2x^2+1)}{7986} + \frac{503}{15{,}972}\sqrt{2}\tan^{-1}(\sqrt{2}\,x) - \frac{1}{2904}\frac{1004x+626}{2x^2+1} + C$$

(c) From the graph, we see that f goes from negative to positive at $x \approx -0.78$, then back to negative at $x \approx 0.8$, and finally back to positive at $x = 1$. Also, $\lim_{x\to 0.4} f(x) = \infty$. So we see (by the First Derivative Test) that $\int f(x)\,dx$ has minima at $x \approx -0.78$ and $x = 1$, and a maximum at $x \approx 0.80$, and that $\int f(x)\,dx$ is unbounded as $x \to 0.4$. Note also that just to the right of $x = 0.4$, f has large values, so $\int f(x)\,dx$ increases rapidly, but slows down as f drops toward 0. $\int f(x)\,dx$ decreases from about 0.8 to 1, then increases slowly since f stays small and positive.

71. $\dfrac{x^4(1-x)^4}{1+x^2} = \dfrac{x^4(1-4x+6x^2-4x^3+x^4)}{1+x^2} = \dfrac{x^8-4x^7+6x^6-4x^5+x^4}{1+x^2} = x^6-4x^5+5x^4-4x^2+4-\dfrac{4}{1+x^2}$, so

$$\int_0^1 \frac{x^4(1-x)^4}{1+x^2}\,dx = \left[\frac{1}{7}x^7 - \frac{2}{3}x^6 + x^5 - \frac{4}{3}x^3 + 4x - 4\tan^{-1}x\right]_0^1 = \left(\frac{1}{7} - \frac{2}{3} + 1 - \frac{4}{3} + 4 - 4\cdot\frac{\pi}{4}\right) - 0 = \frac{22}{7} - \pi.$$

72. (a) Let $u = (x^2+a^2)^{-n}$, $dv = dx \quad\Rightarrow\quad du = -n(x^2+a^2)^{-n-1}\,2x\,dx$, $v = x$.

$$I_n = \int \frac{dx}{(x^2+a^2)^n} = \frac{x}{(x^2+a^2)^n} - \int \frac{-2nx^2}{(x^2+a^2)^{n+1}}\,dx \qquad \text{[by parts]}$$

$$= \frac{x}{(x^2+a^2)^n} + 2n\int \frac{(x^2+a^2)-a^2}{(x^2+a^2)^{n+1}}\,dx$$

$$= \frac{x}{(x^2+a^2)^n} + 2n\int \frac{dx}{(x^2+a^2)^n} - 2na^2\int \frac{dx}{(x^2+a^2)^{n+1}}$$

Recognizing the last two integrals as I_n and I_{n+1}, we can solve for I_{n+1} in terms of I_n.

$$2na^2 I_{n+1} = \frac{x}{(x^2+a^2)^n} + 2nI_n - I_n \quad\Rightarrow\quad I_{n+1} = \frac{x}{2a^2n(x^2+a^2)^n} + \frac{2n-1}{2a^2n}I_n \quad\Rightarrow$$

$$I_n = \frac{x}{2a^2(n-1)(x^2+a^2)^{n-1}} + \frac{2n-3}{2a^2(n-1)}I_{n-1}$$ [decrease n-values by 1], which is the desired result.

(b) Using part (a) with $a = 1$ and $n = 2$, we get

$$\int \frac{dx}{(x^2+1)^2} = \frac{x}{2(x^2+1)} + \frac{1}{2}\int \frac{dx}{x^2+1} = \frac{x}{2(x^2+1)} + \frac{1}{2}\tan^{-1}x + C$$

Using part (a) with $a = 1$ and $n = 3$, we get

$$\int \frac{dx}{(x^2+1)^3} = \frac{x}{2(2)(x^2+1)^2} + \frac{3}{2(2)} \int \frac{dx}{(x^2+1)^2} = \frac{x}{4(x^2+1)^2} + \frac{3}{4}\left[\frac{x}{2(x^2+1)} + \frac{1}{2}\tan^{-1} x\right] + C$$
$$= \frac{x}{4(x^2+1)^2} + \frac{3x}{8(x^2+1)} + \frac{3}{8}\tan^{-1} x + C$$

73. There are only finitely many values of x where $Q(x) = 0$ (assuming that Q is not the zero polynomial). At all other values of x, $F(x)/Q(x) = G(x)/Q(x)$, so $F(x) = G(x)$. In other words, the values of F and G agree at all except perhaps finitely many values of x. By continuity of F and G, the polynomials F and G must agree at those values of x too.

More explicitly: if a is a value of x such that $Q(a) = 0$, then $Q(x) \neq 0$ for all x sufficiently close to a. Thus,

$$\begin{aligned} F(a) &= \lim_{x\to a} F(x) && \text{[by continuity of } F\text{]} \\ &= \lim_{x\to a} G(x) && \text{[whenever } Q(x) \neq 0\text{]} \\ &= G(a) && \text{[by continuity of } G\text{]} \end{aligned}$$

74. Let $f(x) = ax^2 + bx + c$. We calculate the partial fraction decomposition of $\dfrac{f(x)}{x^2(x+1)^3}$. Since $f(0) = 1$, we must have $c = 1$, so $\dfrac{f(x)}{x^2(x+1)^3} = \dfrac{ax^2+bx+1}{x^2(x+1)^3} = \dfrac{A}{x} + \dfrac{B}{x^2} + \dfrac{C}{x+1} + \dfrac{D}{(x+1)^2} + \dfrac{E}{(x+1)^3}$. Now in order for the integral not to contain any logarithms (that is, in order for it to be a rational function), we must have $A = C = 0$, so $ax^2 + bx + 1 = B(x+1)^3 + Dx^2(x+1) + Ex^2$. Equating constant terms gives $B = 1$, then equating coefficients of x gives $3B = b \quad\Rightarrow\quad b = 3$. This is the quantity we are looking for, since $f'(0) = b$.

75. If $a \neq 0$ and n is a positive integer, then $f(x) = \dfrac{1}{x^n(x-a)} = \dfrac{A_1}{x} + \dfrac{A_2}{x^2} + \cdots + \dfrac{A_n}{x^n} + \dfrac{B}{x-a}$. Multiply both sides by $x^n(x-a)$ to get $1 = A_1x^{n-1}(x-a) + A_2x^{n-2}(x-a) + \cdots + A_n(x-a) + Bx^n$. Let $x = a$ in the last equation to get $1 = Ba^n \quad\Rightarrow\quad B = 1/a^n$. So

$$\begin{aligned} f(x) - \frac{B}{x-a} &= \frac{1}{x^n(x-a)} - \frac{1}{a^n(x-a)} = \frac{a^n - x^n}{x^n a^n (x-a)} = -\frac{x^n - a^n}{a^n x^n (x-a)} \\ &= -\frac{(x-a)(x^{n-1} + x^{n-2}a + x^{n-3}a^2 + \cdots + xa^{n-2} + a^{n-1})}{a^n x^n (x-a)} \\ &= -\left(\frac{x^{n-1}}{a^n x^n} + \frac{x^{n-2}a}{a^n x^n} + \frac{x^{n-3}a^2}{a^n x^n} + \cdots + \frac{xa^{n-2}}{a^n x^n} + \frac{a^{n-1}}{a^n x^n}\right) \\ &= -\frac{1}{a^n x} - \frac{1}{a^{n-1}x^2} - \frac{1}{a^{n-2}x^3} - \cdots - \frac{1}{a^2 x^{n-1}} - \frac{1}{ax^n} \end{aligned}$$

Thus, $f(x) = \dfrac{1}{x^n(x-a)} = -\dfrac{1}{a^n x} - \dfrac{1}{a^{n-1}x^2} - \cdots - \dfrac{1}{ax^n} + \dfrac{1}{a^n(x-a)}$.

7.5 Strategy for Integration

1. Let $u = 1 - \sin x$. Then $du = -\cos x\,dx \quad\Rightarrow$

$$\int \frac{\cos x}{1 - \sin x}\,dx = \int \frac{1}{u}(-du) = -\ln|u| + C = -\ln|1 - \sin x| + C = -\ln(1 - \sin x) + C$$

2. Let $u = 3x + 1$. Then $du = 3\,dx \quad\Rightarrow$

$$\int_0^1 (3x+1)^{\sqrt{2}}\,dx = \int_1^4 u^{\sqrt{2}}\left(\frac{1}{3}\,du\right) = \frac{1}{3}\left[\frac{1}{\sqrt{2}+1}\,u^{\sqrt{2}+1}\right]_1^4 = \frac{1}{3(\sqrt{2}+1)}\left(4^{\sqrt{2}+1}-1\right)$$

3. Let $u = \ln y$, $dv = \sqrt{y}\,dy \quad\Rightarrow\quad du = \dfrac{1}{y}\,dy$, $v = \dfrac{2}{3}y^{3/2}$. Then

$$\int_1^4 \sqrt{y}\ln y\,dy = \left[\frac{2}{3}y^{3/2}\ln y\right]_1^4 - \int_1^4 \frac{2}{3}y^{1/2}\,dy = \frac{2}{3}\cdot 8\ln 4 - 0 - \left[\frac{4}{9}y^{3/2}\right]_1^4 = \frac{16}{3}(2\ln 2) - \left(\frac{4}{9}\cdot 8 - \frac{4}{9}\right) = \frac{32}{3}\ln 2 - \frac{28}{9}$$

4. $$\int \frac{\sin^3 x}{\cos x}\,dx = \int \frac{\sin^2 x\,\sin x}{\cos x}\,dx = \int \frac{(1-\cos^2 x)\sin x}{\cos x}\,dx = \int \frac{1-u^2}{u}\,(-du) \qquad \begin{bmatrix} u = \cos x \\ du = -\sin x\,dx \end{bmatrix}$$

$$= \int \left(u - \tfrac{1}{u}\right)du = \tfrac{1}{2}u^2 - \ln|u| + C = \tfrac{1}{2}\cos^2 x - \ln|\cos x| + C$$

5. Let $u = t^2$. Then $du = 2t\,dt \quad\Rightarrow$

$$\int \frac{t}{t^4+2}\,dt = \int \frac{1}{u^2+2}\left(\frac{1}{2}\,du\right) = \frac{1}{2}\frac{1}{\sqrt{2}}\tan^{-1}\left(\frac{u}{\sqrt{2}}\right) + C \;\;[\text{by Formula 17}] = \frac{1}{2\sqrt{2}}\tan^{-1}\left(\frac{t^2}{\sqrt{2}}\right) + C$$

6. Let $u = 2x + 1$. Then $du = 2\,dx \quad\Rightarrow$

$$\int_0^1 \frac{x}{(2x+1)^3}\,dx = \int_1^3 \frac{(u-1)/2}{u^3}\left(\frac{1}{2}\,du\right) = \frac{1}{4}\int_1^3\left(\frac{1}{u^2} - \frac{1}{u^3}\right)du = \frac{1}{4}\left[-\frac{1}{u} + \frac{1}{2u^2}\right]_1^3$$

$$= \tfrac{1}{4}\left[\left(-\tfrac{1}{3} + \tfrac{1}{18}\right) - \left(-1 + \tfrac{1}{2}\right)\right] = \tfrac{1}{4}\left(\tfrac{2}{9}\right) = \tfrac{1}{18}$$

7. Let $u = \arctan y$. Then $du = \dfrac{dy}{1+y^2} \quad\Rightarrow\quad \displaystyle\int_{-1}^1 \frac{e^{\arctan y}}{1+y^2}\,dy = \int_{-\pi/4}^{\pi/4} e^u\,du = \left[e^u\right]_{-\pi/4}^{\pi/4} = e^{\pi/4} - e^{-\pi/4}$.

8. $\int t\sin t\,\cos t\,dt = \int t\cdot\frac{1}{2}(2\sin t\,\cos t)\,dt = \frac{1}{2}\int t\sin 2t\,dt$

$$= \tfrac{1}{2}\left(-\tfrac{1}{2}t\cos 2t - \int -\tfrac{1}{2}\cos 2t\,dt\right) \qquad \begin{bmatrix} u = t, & dv = \sin 2t\,dt \\ du = dt, & v = -\frac{1}{2}\cos 2t \end{bmatrix}$$

$$= -\tfrac{1}{4}t\cos 2t + \tfrac{1}{4}\int \cos 2t\,dt = -\tfrac{1}{4}t\cos 2t + \tfrac{1}{8}\sin 2t + C$$

9. $\dfrac{x+2}{x^2+3x-4} = \dfrac{x+2}{(x+4)(x-1)} = \dfrac{A}{x+4} + \dfrac{B}{x-1}$. Multiply by $(x+4)(x-1)$ to get $x + 2 = A(x-1) + B(x+4)$.

Substituting 1 for x gives $3 = 5B \;\Leftrightarrow\; B = \frac{3}{5}$. Substituting -4 for x gives $-2 = -5A \;\Leftrightarrow\; A = \frac{2}{5}$. Thus,

$$\int_2^4 \frac{x+2}{x^2+3x-4}\,dx = \int_2^4\left(\frac{2/5}{x+4} + \frac{3/5}{x-1}\right)dx = \left[\frac{2}{5}\ln|x+4| + \frac{3}{5}\ln|x-1|\right]_2^4$$

$$= \left(\tfrac{2}{5}\ln 8 + \tfrac{3}{5}\ln 3\right) - \left(\tfrac{2}{5}\ln 6 + 0\right) = \tfrac{2}{5}(3\ln 2) + \tfrac{3}{5}\ln 3 - \tfrac{2}{5}(\ln 2 + \ln 3)$$

$$= \tfrac{4}{5}\ln 2 + \tfrac{1}{5}\ln 3, \text{ or } \tfrac{1}{5}\ln 48$$

10. Let $u = \dfrac{1}{x}$, $dv = \dfrac{\cos(1/x)}{x^2} \quad\Rightarrow\quad du = -\dfrac{1}{x^2}\,dx$, $v = -\sin\left(\dfrac{1}{x}\right)$. Then

$$\int \frac{\cos(1/x)}{x^3}\,dx = -\frac{1}{x}\sin\left(\frac{1}{x}\right) - \int \frac{1}{x^2}\sin\left(\frac{1}{x}\right)dx = -\frac{1}{x}\sin\left(\frac{1}{x}\right) - \cos\left(\frac{1}{x}\right) + C.$$

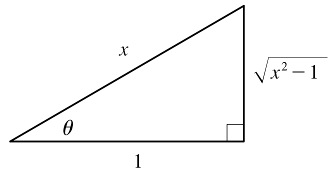
11. Let $x = \sec\theta$, where $0 \le \theta \le \frac{\pi}{2}$ or $\pi \le \theta < \frac{3\pi}{2}$. Then $dx = \sec\theta\,\tan\theta\,d\theta$ and

$\sqrt{x^2-1} = \sqrt{\sec^2\theta - 1} = \sqrt{\tan^2\theta} = |\tan\theta| = \tan\theta$ for the relevant values of θ, so

$$\int \frac{1}{x^3\sqrt{x^2-1}}\,dx = \int \frac{\sec\theta\,\tan\theta}{\sec^3\theta\,\tan\theta}\,d\theta = \int \cos^2\theta\,d\theta = \int \tfrac{1}{2}(1+\cos 2\theta)\,d\theta$$

$$= \tfrac{1}{2}\theta + \tfrac{1}{4}\sin 2\theta + C = \tfrac{1}{2}\theta + \tfrac{1}{2}\sin\theta\,\cos\theta + C$$

$$= \frac{1}{2}\sec^{-1}x + \frac{1}{2}\frac{\sqrt{x^2-1}}{x}\frac{1}{x} + C = \frac{1}{2}\sec^{-1}x + \frac{\sqrt{x^2-1}}{2x^2} + C$$



12. $\dfrac{2x-3}{x^3+3x} = \dfrac{2x-3}{x(x^2+3)} = \dfrac{A}{x} + \dfrac{Bx+C}{x^2+3}$. Multiply by $x(x^2+3)$ to get $2x-3 = A(x^2+3) + (Bx+C)x \quad\Leftrightarrow$

$2x-3 = (A+B)x^2 + Cx + 3A$. Equating coefficients gives us $C=2$, $3A=-3 \quad\Leftrightarrow\quad A=-1$, and $A+B=0$, so

$B=1$. Thus,

$$\int \frac{2x-3}{x^3+3x}\,dx = \int\left(\frac{-1}{x} + \frac{x+2}{x^2+3}\right)dx = \int\left(-\frac{1}{x} + \frac{x}{x^2+3} + \frac{2}{x^2+3}\right)dx$$

$$= -\ln|x| + \frac{1}{2}\ln(x^2+3) + \frac{2}{\sqrt{3}}\tan^{-1}\left(\frac{x}{\sqrt{3}}\right) + C$$

13. $\int \sin^5 t\,\cos^4 t\,dt = \int \sin^4 t\,\cos^4 t\,\sin t\,dt = \int(\sin^2 t)^2\cos^4 t\,\sin t\,dt$

$$= \int(1-\cos^2 t)^2\cos^4 t\,\sin t\,dt = \int(1-u^2)^2u^4\,(-du) \qquad [u=\cos t,\ du = -\sin t\,dt]$$

$$= \int(-u^4 + 2u^6 - u^8)\,du = -\tfrac{1}{5}u^5 + \tfrac{2}{7}u^7 - \tfrac{1}{9}u^9 + C = -\tfrac{1}{5}\cos^5 t + \tfrac{2}{7}\cos^7 t - \tfrac{1}{9}\cos^9 t + C$$

14. Let $u = \ln(1+x^2)$, $dv = dx \quad\Rightarrow\quad du = \dfrac{2x}{1+x^2}\,dx$, $v = x$. Then

$$\int \ln(1+x^2)\,dx = x\ln(1+x^2) - \int\frac{2x^2}{1+x^2}\,dx = x\ln(1+x^2) - 2\int\frac{(x^2+1)-1}{1+x^2}\,dx$$

$$= x\ln(1+x^2) - 2\int\left(1 - \frac{1}{1+x^2}\right)dx = x\ln(1+x^2) - 2x + 2\tan^{-1}x + C$$

15. Let $u = x$, $dv = \sec x\,\tan x\,dx \quad\Rightarrow\quad du = dx$, $v = \sec x$. Then

$\int x\sec x\,\tan x\,dx = x\sec x - \int\sec x\,dx = x\sec x - \ln|\sec x + \tan x| + C$.

16. $$\int_0^{\sqrt{2}/2}\frac{x^2}{\sqrt{1-x^2}}\,dx = \int_0^{\pi/4}\frac{\sin^2\theta}{\cos\theta}\cos\theta\,d\theta \qquad \begin{bmatrix} u = \sin\theta, \\ du = \cos\theta\,d\theta \end{bmatrix}$$

$$= \int_0^{\pi/4}\tfrac{1}{2}(1-\cos 2\theta)\,d\theta = \tfrac{1}{2}\left[\theta - \tfrac{1}{2}\sin 2\theta\right]_0^{\pi/4} = \tfrac{1}{2}\left[\left(\tfrac{\pi}{4} - \tfrac{1}{2}\right) - (0-0)\right] = \tfrac{\pi}{8} - \tfrac{1}{4}$$

17. $\int_0^\pi t\,\cos^2 t\,dt = \int_0^\pi t\left[\frac{1}{2}(1+\cos 2t)\right]dt = \frac{1}{2}\int_0^\pi t\,dt + \frac{1}{2}\int_0^\pi t\cos 2t\,dt$

$$= \tfrac{1}{2}\left[\tfrac{1}{2}t^2\right]_0^\pi + \tfrac{1}{2}\left[\tfrac{1}{2}t\sin 2t\right]_0^\pi - \tfrac{1}{2}\int_0^\pi \tfrac{1}{2}\sin 2t\,dt \qquad \begin{bmatrix} u = t, & dv = \cos 2t\,dt \\ du = dt, & v = \tfrac{1}{2}\sin 2t \end{bmatrix}$$

$$= \tfrac{1}{4}\pi^2 + 0 - \tfrac{1}{4}\left[-\tfrac{1}{2}\cos 2t\right]_0^\pi = \tfrac{1}{4}\pi^2 + \tfrac{1}{8}(1-1) = \tfrac{1}{4}\pi^2$$

18. Let $u = \sqrt{t}$. Then $du = \dfrac{1}{2\sqrt{t}}\,dt \quad\Rightarrow\quad \displaystyle\int_1^4 \frac{e^{\sqrt{t}}}{\sqrt{t}}\,dt = \int_1^2 e^u\,(2\,du) = 2\left[e^u\right]_1^2 = 2(e^2 - e)$.

19. Let $u = e^x$. Then $\int e^{x+e^x}\,dx = \int e^{e^x} e^x\,dx = \int e^u\,du = e^u + C = e^{e^x} + C$.

20. Since e^2 is a constant, $\int e^2\,dx = e^2 x + C$.

21. Let $t = \sqrt{x}$, so that $t^2 = x$ and $2t\,dt = dx$. Then $\int \arctan\sqrt{x}\,dx = \int \arctan t\,(2t\,dt) = I$. Now use parts with $u = \arctan t$, $dv = 2t\,dt \quad\Rightarrow\quad du = \dfrac{1}{1+t^2}\,dt$, $v = t^2$. Thus,

$$I = t^2\arctan t - \int \frac{t^2}{1+t^2}\,dt = t^2\arctan t - \int\left(1 - \frac{1}{1+t^2}\right)dt = t^2\arctan t - t + \arctan t + C$$

$$= x\arctan\sqrt{x} - \sqrt{x} + \arctan\sqrt{x} + C \quad \left[\text{or } (x+1)\arctan\sqrt{x} - \sqrt{x} + C\right]$$

22. Let $u = 1 + (\ln x)^2$, so that $du = \dfrac{2\ln x}{x}\,dx$. Then

$$\int \frac{\ln x}{x\sqrt{1+(\ln x)^2}}\,dx = \frac{1}{2}\int \frac{1}{\sqrt{u}}\,du = \frac{1}{2}\left(2\sqrt{u}\right) + C = \sqrt{1+(\ln x)^2} + C.$$

23. Let $u = 1 + \sqrt{x}$. Then $x = (u-1)^2$, $dx = 2(u-1)\,du \quad\Rightarrow$

$$\int_0^1 \left(1+\sqrt{x}\right)^8 dx = \int_1^2 u^8\cdot 2(u-1)\,du = 2\int_1^2 (u^9 - u^8)\,du = \left[\tfrac{1}{5}u^{10} - 2\cdot\tfrac{1}{9}u^9\right]_1^2 = \tfrac{1024}{5} - \tfrac{1024}{9} - \tfrac{1}{5} + \tfrac{2}{9} = \tfrac{4097}{45}.$$

24. $\int (1+\tan x)^2 \sec x\,dx = \int (1 + 2\tan x + \tan^2 x)\sec x\,dx$

$$= \int [\sec x + 2\sec x\,\tan x + (\sec^2 x - 1)\sec x]\,dx = \int (2\sec x\,\tan x + \sec^3 x)\,dx$$

$$= 2\sec x + \tfrac{1}{2}(\sec x\,\tan x + \ln|\sec x + \tan x| + C) \quad \text{[by Example 7.2.8]}$$

25. $\displaystyle\int_0^1 \frac{1+12t}{1+3t}\,dt = \int_0^1 \frac{(12t+4)-3}{3t+1}\,dt = \int_0^1 \left(4 - \frac{3}{3t+1}\right)dt = \Big[4t - \ln|3t+1|\Big]_0^1 = (4 - \ln 4) - (0 - 0) = 4 - \ln 4$

26. $\dfrac{3x^2+1}{x^3+x^2+x+1} = \dfrac{3x^2+1}{(x^2+1)(x+1)} = \dfrac{A}{x+1} + \dfrac{Bx+C}{x^2+1}$. Multiply by $(x+1)(x^2+1)$ to get $3x^2+1 = A(x^2+1) + (Bx+C)(x+1) \quad\Leftrightarrow\quad 3x^2+1 = (A+B)x^2 + (B+C)x + (A+C)$. Substituting -1 for x gives $4 = 2A \quad\Leftrightarrow\quad A = 2$. Equating coefficients of x^2 gives $3 = A + B = 2 + B \quad\Leftrightarrow\quad B = 1$. Equating coefficients of x gives $0 = B + C = 1 + C \quad\Leftrightarrow\quad C = -1$. Thus,

$$\int_0^1 \frac{3x^2+1}{x^3+x^2+x+1}\,dx = \int_0^1 \left(\frac{2}{x+1} + \frac{x-1}{x^2+1}\right)dx = \int_0^1 \left(\frac{2}{x+1} + \frac{x}{x^2+1} - \frac{1}{x^2+1}\right)dx$$

$$= \left[2\ln|x+1| + \tfrac{1}{2}\ln(x^2+1) - \tan^{-1}x\right]_0^1 = \left(2\ln 2 + \tfrac{1}{2}\ln 2 - \tfrac{\pi}{4}\right) - (0 + 0 - 0)$$

$$= \tfrac{5}{2}\ln 2 - \tfrac{\pi}{4}$$

27. Let $u = 1 + e^x$, so that $du = e^x\,dx = (u-1)\,dx$. Then $\displaystyle\int \frac{1}{1+e^x}\,dx = \int \frac{1}{u}\cdot\frac{du}{u-1} = \int \frac{1}{u(u-1)}\,du = I$. Now

$\dfrac{1}{u(u-1)} = \dfrac{A}{u} + \dfrac{B}{u-1} \quad\Rightarrow\quad 1 = A(u-1) + Bu$. Set $u = 1$ to get $1 = B$. Set $u = 0$ to get $1 = -A$, so $A = -1$.

Thus, $I = \int \left(\frac{-1}{u} + \frac{1}{u-1} \right) du = -\ln|u| + \ln|u-1| + C = -\ln(1+e^x) + \ln e^x + C = x - \ln(1+e^x) + C.$

Another method: Multiply numerator and denominator by e^{-x} and let $u = e^{-x} + 1$. This gives the answer in the form $-\ln(e^{-x}+1) + C$.

28. $\int \sin\sqrt{at}\,dt = \int \sin u \cdot \frac{2}{a} u\,du \quad [u = \sqrt{at},\, u^2 = at,\, 2u\,du = a\,dt] \quad = \frac{2}{a}\int u \sin u\,du$

$= \frac{2}{a}[-u\cos u + \sin u] + C \quad$ [integration by parts] $\quad = -\frac{2}{a}\sqrt{at}\,\cos\sqrt{at} + \frac{2}{a}\,\sin\sqrt{at} + C$

$= -2\sqrt{\frac{t}{a}}\,\cos\sqrt{at} + \frac{2}{a}\,\sin\sqrt{at} + C$

29. Use integration by parts with $u = \ln\left(x + \sqrt{x^2-1}\right)$, $dv = dx \quad \Rightarrow$

$$du = \frac{1}{x+\sqrt{x^2-1}}\left(1 + \frac{x}{\sqrt{x^2-1}}\right)dx = \frac{1}{x+\sqrt{x^2-1}}\left(\frac{\sqrt{x^2-1}+x}{\sqrt{x^2-1}}\right)dx = \frac{1}{\sqrt{x^2-1}}\,dx,\ v = x. \text{ Then}$$

$$\int \ln\left(x+\sqrt{x^2-1}\right)dx = x\ln\left(x+\sqrt{x^2-1}\right) - \int \frac{x}{\sqrt{x^2-1}}\,dx = x\ln\left(x+\sqrt{x^2-1}\right) - \sqrt{x^2-1} + C.$$

30. $|e^x - 1| = \begin{cases} e^x - 1 & \text{if } e^x - 1 \ge 0 \\ -(e^x-1) & \text{if } e^x - 1 < 0 \end{cases} = \begin{cases} e^x - 1 & \text{if } x \ge 0 \\ 1 - e^x & \text{if } x < 0 \end{cases}$

Thus, $\int_{-1}^{2} |e^x - 1|\ dx = \int_{-1}^{0}(1-e^x)\,dx + \int_0^2 (e^x - 1)\,dx = \Big[x - e^x\Big]_{-1}^{0} + \Big[e^x - x\Big]_0^2$

$= (0-1) - (-1-e^{-1}) + (e^2-2) - (1-0) = e^2 + e^{-1} - 3$

31. As in Example 5,

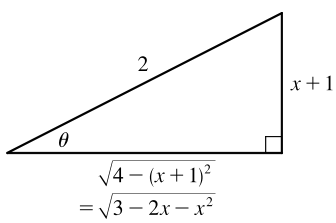
$$\int \sqrt{\frac{1+x}{1-x}}\,dx = \int \frac{\sqrt{1+x}}{\sqrt{1-x}} \cdot \frac{\sqrt{1+x}}{\sqrt{1+x}}\,dx = \int \frac{1+x}{\sqrt{1-x^2}}\,dx = \int \frac{dx}{\sqrt{1-x^2}} + \int \frac{x\,dx}{\sqrt{1-x^2}} = \sin^{-1}x - \sqrt{1-x^2} + C.$$

Another method: Substitute $u = \sqrt{(1+x)/(1-x)}$.

32. $\displaystyle\int_1^3 \frac{e^{3/x}}{x^2}\,dx = \int_3^1 e^u\ \left(-\tfrac{1}{3}\,du\right) \qquad \begin{bmatrix} u = 3/x, \\ du = -3/x^2\,dx \end{bmatrix}$

$= -\frac{1}{3}\Big[e^u\Big]_3^1 = -\frac{1}{3}(e - e^3) = \frac{1}{3}(e^3 - e)$

33. $3 - 2x - x^2 = -(x^2+2x+1) + 4 = 4 - (x+1)^2$. Let $x + 1 = 2\sin\theta$, where $-\frac{\pi}{2} \le \theta \le \frac{\pi}{2}$. Then $dx = 2\cos\theta\,d\theta$ and



$\int \sqrt{3-2x-x^2}\,dx = \int \sqrt{4-(x+1)^2}\,dx = \int \sqrt{4 - 4\sin^2\theta}\,2\cos\theta\,d\theta$

$= 4\int \cos^2\theta\,d\theta = 2\int (1+\cos 2\theta)\,d\theta$

$= 2\theta + \sin 2\theta + C = 2\theta + 2\sin\theta\cos\theta + C$

$= 2\sin^{-1}\left(\frac{x+1}{2}\right) + 2\cdot\frac{x+1}{2}\cdot\frac{\sqrt{3-2x-x^2}}{2} + C$

$= 2\sin^{-1}\left(\frac{x+1}{2}\right) + \frac{x+1}{2}\sqrt{3-2x-x^2} + C$

34. $\displaystyle\int_{\pi/4}^{\pi/2} \frac{1+4\cot x}{4-\cot x}\,dx = \int_{\pi/4}^{\pi/2}\left[\frac{(1+4\cos x/\sin x)}{(4-\cos x/\sin x)}\cdot\frac{\sin x}{\sin x}\right]dx = \int_{\pi/4}^{\pi/2}\frac{\sin x+4\cos x}{4\sin x-\cos x}\,dx$

$$= \int_{3/\sqrt{2}}^{4}\frac{1}{u}\,du \quad \begin{bmatrix} u = 4\sin x-\cos x, \\ du = (4\cos x+\sin x)\,dx \end{bmatrix}$$

$$= \Big[\ln|u|\Big]_{3/\sqrt{2}}^{4} = \ln 4 - \ln\frac{3}{\sqrt{2}} = \ln\frac{4}{3/\sqrt{2}} = \ln\left(\frac{4}{3}\sqrt{2}\right)$$

35. The integrand is an odd function, so $\displaystyle\int_{-\pi/2}^{\pi/2}\frac{x}{1+\cos^2 x}\,dx = 0$ [by 5.5.7(b)].

36. $\displaystyle\int\frac{1+\sin x}{1+\cos x}\,dx = \int\frac{(1+\sin x)(1-\cos x)}{(1+\cos x)(1-\cos x)}\,dx = \int\frac{1-\cos x+\sin x-\sin x\,\cos x}{\sin^2 x}\,dx$

$$= \int\left(\csc^2 x - \frac{\cos x}{\sin^2 x} + \csc x - \frac{\cos x}{\sin x}\right)dx$$

$$\overset{s}{=} -\cot x + \frac{1}{\sin x} + \ln|\csc x - \cot x| - \ln|\sin x| + C \quad \text{[by Exercise 7.2.39]}$$

The answer can be written as $\dfrac{1-\cos x}{\sin x} - \ln(1+\cos x) + C$.

37. Let $u = \tan\theta$. Then $du = \sec^2\theta\,d\theta \;\Rightarrow\; \int_0^{\pi/4}\tan^3\theta\,\sec^2\theta\,d\theta = \int_0^1 u^3\,du = \left[\frac{1}{4}u^4\right]_0^1 = \frac{1}{4}$.

38. $\displaystyle\int_{\pi/6}^{\pi/3}\frac{\sin\theta\,\cot\theta}{\sec\theta}\,d\theta = \int_{\pi/6}^{\pi/3}\cos^2\theta\,d\theta = \frac{1}{2}\int_{\pi/6}^{\pi/3}(1+\cos 2\theta)\,d\theta = \frac{1}{2}\left[\theta + \frac{1}{2}\sin 2\theta\right]_{\pi/6}^{\pi/3}$

$$= \frac{1}{2}\left[\left(\frac{\pi}{3}+\frac{\sqrt{3}}{4}\right) - \left(\frac{\pi}{6}+\frac{\sqrt{3}}{4}\right)\right] = \frac{1}{2}\left(\frac{\pi}{6}\right) = \frac{\pi}{12}$$

39. Let $u = \sec\theta$, so that $du = \sec\theta\,\tan\theta\,d\theta$. Then $\displaystyle\int\frac{\sec\theta\,\tan\theta}{\sec^2\theta - \sec\theta}\,d\theta = \int\frac{1}{u^2-u}\,du = \int\frac{1}{u(u-1)}\,du = I$. Now

$\dfrac{1}{u(u-1)} = \dfrac{A}{u} + \dfrac{B}{u-1} \;\Rightarrow\; 1 = A(u-1) + Bu$. Set $u = 1$ to get $1 = B$. Set $u = 0$ to get $1 = -A$, so $A = -1$.

Thus, $I = \displaystyle\int\left(\frac{-1}{u} + \frac{1}{u-1}\right)du = -\ln|u| + \ln|u-1| + C = \ln|\sec\theta - 1| - \ln|\sec\theta| + C$ [or $\ln|1-\cos\theta| + C$].

40. Using product formula 2(a) in Section 7.2, $\sin 6x\,\cos 3x = \frac{1}{2}[\sin(6x-3x) + \sin(6x+3x)] = \frac{1}{2}(\sin 3x + \sin 9x)$. Thus,

$$\int_0^{\pi}\sin 6x\,\cos 3x\,dx = \int_0^{\pi}\tfrac{1}{2}(\sin 3x + \sin 9x)\,dx = \tfrac{1}{2}\left[-\tfrac{1}{3}\cos 3x - \tfrac{1}{9}\cos 9x\right]_0^{\pi}$$

$$= \tfrac{1}{2}\left[\left(\tfrac{1}{3}+\tfrac{1}{9}\right) - \left(-\tfrac{1}{3}-\tfrac{1}{9}\right)\right] = \tfrac{1}{2}\left(\tfrac{4}{9}+\tfrac{4}{9}\right) = \tfrac{4}{9}$$

41. Let $u = \theta$, $dv = \tan^2\theta\,d\theta = \left(\sec^2\theta - 1\right)d\theta \;\Rightarrow\; du = d\theta$ and $v = \tan\theta - \theta$. So

$$\int\theta\tan^2\theta\,d\theta = \theta(\tan\theta - \theta) - \int(\tan\theta - \theta)\,d\theta = \theta\tan\theta - \theta^2 - \ln|\sec\theta| + \tfrac{1}{2}\theta^2 + C$$

$$= \theta\tan\theta - \tfrac{1}{2}\theta^2 - \ln|\sec\theta| + C$$

42. Let $u = \tan^{-1} x$, $dv = \dfrac{1}{x^2}\,dx \quad \Rightarrow \quad du = \dfrac{1}{1+x^2}\,dx$, $v = -\dfrac{1}{x}$. Then

$$I = \int \frac{\tan^{-1} x}{x^2}\,dx = -\frac{1}{x}\tan^{-1} x - \int \left(-\frac{1}{x(1+x^2)}\right) dx = -\frac{1}{x}\tan^{-1} x + \int \left(\frac{A}{x} + \frac{Bx+C}{1+x^2}\right) dx$$

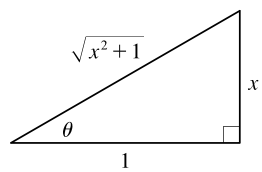
$\dfrac{1}{x(1+x^2)} = \dfrac{A}{x} + \dfrac{Bx+C}{1+x^2} \quad \Rightarrow \quad 1 = A(1+x^2) + (Bx+C)x \quad \Rightarrow \quad 1 = (A+B)x^2 + Cx + A$, so $C = 0$, $A = 1$,

and $A + B = 0 \quad \Rightarrow \quad B = -1$. Thus,

$$\begin{aligned} I &= -\frac{1}{x}\tan^{-1} x + \int \left(\frac{1}{x} - \frac{x}{1+x^2}\right) dx = -\frac{1}{x}\tan^{-1} x + \ln|x| - \frac{1}{2}\ln\left|1+x^2\right| + C \\ &= -\frac{\tan^{-1} x}{x} + \ln\left|\frac{x}{\sqrt{x^2+1}}\right| + C \end{aligned}$$

Or: Let $x = \tan\theta$, so that $dx = \sec^2\theta\,d\theta$. Then $\displaystyle\int \frac{\tan^{-1} x}{x^2}\,dx = \int \frac{\theta}{\tan^2\theta}\sec^2\theta\,d\theta = \int \theta\csc^2\theta\,d\theta = I$. Now use parts

with $u = \theta$, $dv = \csc^2\theta\,d\theta \quad \Rightarrow \quad du = d\theta$, $v = -\cot\theta$. Thus,



$$\begin{aligned} I &= -\theta\cot\theta - \textstyle\int(-\cot\theta)\,d\theta = -\theta\cot\theta + \ln|\sin\theta| + C \\ &= -\tan^{-1} x \cdot \frac{1}{x} + \ln\left|\frac{x}{\sqrt{x^2+1}}\right| + C = -\frac{\tan^{-1} x}{x} + \ln\left|\frac{x}{\sqrt{x^2+1}}\right| + C \end{aligned}$$

43. Let $u = \sqrt{x}$ so that $du = \dfrac{1}{2\sqrt{x}}\,dx$. Then

$$\begin{aligned} \int \frac{\sqrt{x}}{1+x^3}\,dx &= \int \frac{u}{1+u^6}\,(2u\,du) = 2\int \frac{u^2}{1+(u^3)^2}\,du = 2\int \frac{1}{1+t^2}\left(\frac{1}{3}\,dt\right) \qquad \begin{bmatrix} t = u^3 \\ dt = 3u^2\,du \end{bmatrix} \\ &= \tfrac{2}{3}\tan^{-1} t + C = \tfrac{2}{3}\tan^{-1} u^3 + C = \tfrac{2}{3}\tan^{-1}(x^{3/2}) + C \end{aligned}$$

Another method: Let $u = x^{3/2}$ so that $u^2 = x^3$ and $du = \frac{3}{2}x^{1/2}\,dx \quad \Rightarrow \quad \sqrt{x}\,dx = \frac{2}{3}\,du$. Then

$$\int \frac{\sqrt{x}}{1+x^3}\,dx = \int \frac{\frac{2}{3}}{1+u^2}\,du = \frac{2}{3}\tan^{-1} u + C = \frac{2}{3}\tan^{-1}(x^{3/2}) + C.$$

44. Let $u = \sqrt{1+e^x}$. Then $u^2 = 1 + e^x$, $2u\,du = e^x\,dx = (u^2-1)\,dx$, and $dx = \dfrac{2u}{u^2-1}\,du$, so

$$\begin{aligned} \int \sqrt{1+e^x}\,dx &= \int u \cdot \frac{2u}{u^2-1}\,du = \int \frac{2u^2}{u^2-1}\,du = \int \left(2 + \frac{2}{u^2-1}\right) du = \int \left(2 + \frac{1}{u-1} - \frac{1}{u+1}\right) du \\ &= 2u + \ln|u-1| - \ln|u+1| + C = 2\sqrt{1+e^x} + \ln\left(\sqrt{1+e^x} - 1\right) - \ln\left(\sqrt{1+e^x} + 1\right) + C \end{aligned}$$

45. Let $t = x^3$. Then $dt = 3x^2\,dx \quad \Rightarrow \quad I = \int x^5 e^{-x^3}\,dx = \frac{1}{3}\int te^{-t}\,dt$. Now integrate by parts with $u = t$, $dv = e^{-t}\,dt$:

$I = -\frac{1}{3}te^{-t} + \frac{1}{3}\int e^{-t}\,dt = -\frac{1}{3}te^{-t} - \frac{1}{3}e^{-t} + C = -\frac{1}{3}e^{-x^3}(x^3+1) + C.$

46. Use integration by parts with $u = (x-1)e^x$, $dv = \dfrac{1}{x^2}\,dx \quad \Rightarrow \quad du = [(x-1)e^x + e^x]\,dx = xe^x\,dx$, $v = -\dfrac{1}{x}$. Then

$$\int \frac{(x-1)e^x}{x^2}\,dx = (x-1)e^x\left(-\frac{1}{x}\right) - \int -e^x\,dx = -e^x + \frac{e^x}{x} + e^x + C = \frac{e^x}{x} + C.$$

47. Let $u = x - 1$, so that $du = dx$. Then

$$\int x^3(x-1)^{-4}\,dx = \int (u+1)^3 u^{-4}\,du = \int (u^3+3u^2+3u+1)u^{-4}\,du = \int (u^{-1}+3u^{-2}+3u^{-3}+u^{-4})\,du$$
$$= \ln|u| - 3u^{-1} - \tfrac{3}{2}u^{-2} - \tfrac{1}{3}u^{-3} + C = \ln|x-1| - 3(x-1)^{-1} - \tfrac{3}{2}(x-1)^{-2} - \tfrac{1}{3}(x-1)^{-3} + C$$

48. Let $u = \sqrt{1-x^2}$, so $u^2 = 1 - x^2$, and $2u\,du = -2x\,dx$. Then $\int_0^1 x\sqrt{2-\sqrt{1-x^2}}\,dx = \int_1^0 \sqrt{2-u}\,(-u\,du)$.

Now let $v = \sqrt{2-u}$, so $v^2 = 2 - u$, and $2v\,dv = -du$. Thus,

$$\int_1^0 \sqrt{2-u}\,(-u\,du) = \int_1^{\sqrt{2}} v(2-v^2)\,(2v\,dv) = \int_1^{\sqrt{2}} (4v^2 - 2v^4)\,dv = \left[\tfrac{4}{3}v^3 - \tfrac{2}{5}v^5\right]_1^{\sqrt{2}}$$
$$= \left(\tfrac{8}{3}\sqrt{2} - \tfrac{8}{5}\sqrt{2}\right) - \left(\tfrac{4}{3} - \tfrac{2}{5}\right) = \tfrac{16}{15}\sqrt{2} - \tfrac{14}{15}$$

49. Let $u = \sqrt{4x+1} \;\Rightarrow\; u^2 = 4x+1 \;\Rightarrow\; 2u\,du = 4\,dx \;\Rightarrow\; dx = \frac{1}{2}u\,du$. So

$$\int \frac{1}{x\sqrt{4x+1}}\,dx = \int \frac{\frac{1}{2}u\,du}{\frac{1}{4}(u^2-1)\,u} = 2\int \frac{du}{u^2-1} = 2\left(\tfrac{1}{2}\right)\ln\left|\frac{u-1}{u+1}\right| + C \qquad \text{[by Formula 19]}$$
$$= \ln\left|\frac{\sqrt{4x+1}-1}{\sqrt{4x+1}+1}\right| + C$$

50. As in Exercise 49, let $u = \sqrt{4x+1}$. Then $\displaystyle\int \frac{dx}{x^2\sqrt{4x+1}} = \int \frac{\frac{1}{2}u\,du}{\left[\frac{1}{4}(u^2-1)\right]^2 u} = 8\int \frac{du}{(u^2-1)^2}$. Now

$$\frac{1}{(u^2-1)^2} = \frac{1}{(u+1)^2(u-1)^2} = \frac{A}{u+1} + \frac{B}{(u+1)^2} + \frac{C}{u-1} + \frac{D}{(u-1)^2} \quad\Rightarrow$$

$1 = A(u+1)(u-1)^2 + B(u-1)^2 + C(u-1)(u+1)^2 + D(u+1)^2$. $u = 1 \;\Rightarrow\; D = \frac{1}{4}$, $u = -1 \;\Rightarrow\; B = \frac{1}{4}$.

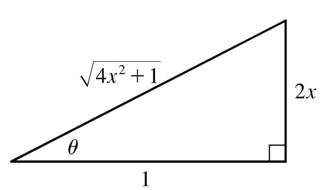
Equating coefficients of u^3 gives $A + C = 0$, and equating coefficients of 1 gives $1 = A + B - C + D \;\Rightarrow$

$1 = A + \frac{1}{4} - C + \frac{1}{4} \;\Rightarrow\; \frac{1}{2} = A - C$. So $A = \frac{1}{4}$ and $C = -\frac{1}{4}$. Therefore,

$$\int \frac{dx}{x^2\sqrt{4x+1}} = 8\int \left[\frac{1/4}{u+1} + \frac{1/4}{(u+1)^2} + \frac{-1/4}{u-1} + \frac{1/4}{(u-1)^2}\right] du$$
$$= \int \left[\frac{2}{u+1} + 2(u+1)^{-2} - \frac{2}{u-1} + 2(u-1)^{-2}\right] du$$
$$= 2\ln|u+1| - \frac{2}{u+1} - 2\ln|u-1| - \frac{2}{u-1} + C$$
$$= 2\ln\left(\sqrt{4x+1}+1\right) - \frac{2}{\sqrt{4x+1}+1} - 2\ln\left|\sqrt{4x+1}-1\right| - \frac{2}{\sqrt{4x+1}-1} + C$$

51. Let $2x = \tan\theta \;\Rightarrow\; x = \frac{1}{2}\tan\theta$, $dx = \frac{1}{2}\sec^2\theta\,d\theta$, $\sqrt{4x^2+1} = \sec\theta$, so

$$\int \frac{dx}{x\sqrt{4x^2+1}} = \int \frac{\frac{1}{2}\sec^2\theta\,d\theta}{\frac{1}{2}\tan\theta\,\sec\theta} = \int \frac{\sec\theta}{\tan\theta}\,d\theta = \int \csc\theta\,d\theta$$
$$= -\ln|\csc\theta + \cot\theta| + C \qquad [\text{or } \ln|\csc\theta - \cot\theta| + C]$$
$$= -\ln\left|\frac{\sqrt{4x^2+1}}{2x} + \frac{1}{2x}\right| + C \qquad \left[\text{or } \ln\left|\frac{\sqrt{4x^2+1}}{2x} - \frac{1}{2x}\right| + C\right]$$



52. Let $u = x^2$. Then $du = 2x\,dx \quad \Rightarrow$

$$\int \frac{dx}{x(x^4+1)} = \int \frac{x\,dx}{x^2(x^4+1)} = \frac{1}{2}\int \frac{du}{u(u^2+1)} = \frac{1}{2}\int \left[\frac{1}{u} - \frac{u}{u^2+1}\right] du = \tfrac{1}{2}\ln|u| - \tfrac{1}{4}\ln(u^2+1) + C$$

$$= \tfrac{1}{2}\ln(x^2) - \tfrac{1}{4}\ln(x^4+1) + C = \tfrac{1}{4}\left[\ln(x^4) - \ln(x^4+1)\right] + C = \frac{1}{4}\ln\left(\frac{x^4}{x^4+1}\right) + C$$

Or: Write $I = \displaystyle\int \frac{x^3\,dx}{x^4(x^4+1)}$ and let $u = x^4$.

53. $\displaystyle\int x^2 \sinh(mx)dx = \frac{1}{m}x^2\cosh(mx) - \frac{2}{m}\int x\cosh(mx)\,dx \qquad \begin{bmatrix} u = x^2, & dv = \sinh(mx)\,dx, \\ du = 2x\,dx & v = \frac{1}{m}\cosh(mx) \end{bmatrix}$

$$= \frac{1}{m}x^2\cosh(mx) - \frac{2}{m}\left(\tfrac{1}{m}x\sinh(mx) - \frac{1}{m}\textstyle\int \sinh(mx)\,dx\right) \qquad \begin{bmatrix} U = x, & dV = \cosh(mx)\,dx, \\ dU = dx & V = \frac{1}{m}\sinh(mx) \end{bmatrix}$$

$$= \frac{1}{m}x^2\cosh(mx) - \frac{2}{m^2}x\sinh(mx) + \frac{2}{m^3}\cosh(mx) + C$$

54. $\int (x+\sin x)^2\,dx = \int \left(x^2 + 2x\sin x + \sin^2 x\right)dx = \frac{1}{3}x^3 + 2(\sin x - x\cos x) + \frac{1}{2}(x - \sin x\cos x) + C$

$$= \tfrac{1}{3}x^3 + \tfrac{1}{2}x + 2\sin x - \tfrac{1}{2}\sin x\cos x - 2x\cos x + C$$

55. Let $u = \sqrt{x}$, so that $x = u^2$ and $dx = 2u\,du$. Then $\displaystyle\int \frac{dx}{x + x\sqrt{x}} = \int \frac{2u\,du}{u^2 + u^2\cdot u} = \int \frac{2}{u(1+u)}\,du = I.$

Now $\dfrac{2}{u(1+u)} = \dfrac{A}{u} + \dfrac{B}{1+u} \quad \Rightarrow \quad 2 = A(1+u) + Bu$. Set $u = -1$ to get $2 = -B$, so $B = -2$. Set $u = 0$ to get $2 = A$.

Thus, $I = \displaystyle\int \left(\frac{2}{u} - \frac{2}{1+u}\right) du = 2\ln|u| - 2\ln|1+u| + C = 2\ln\sqrt{x} - 2\ln\left(1+\sqrt{x}\right) + C.$

56. Let $u = \sqrt{x}$, so that $x = u^2$ and $dx = 2u\,du$. Then

$$\int \frac{dx}{\sqrt{x} + x\sqrt{x}} = \int \frac{2u\,du}{u + u^2\cdot u} = \int \frac{2}{1+u^2}\,du = 2\tan^{-1}u + C = 2\tan^{-1}\sqrt{x} + C.$$

57. Let $u = \sqrt[3]{x+c}$. Then $x = u^3 - c \quad \Rightarrow$

$$\int x\sqrt[3]{x+c}\,dx = \int (u^3 - c)u\cdot 3u^2\,du = 3\int (u^6 - cu^3)\,du = \tfrac{3}{7}u^7 - \tfrac{3}{4}cu^4 + C = \tfrac{3}{7}(x+c)^{7/3} - \tfrac{3}{4}c(x+c)^{4/3} + C$$

58. Let $t = \sqrt{x^2-1}$. Then $dt = \left(x/\sqrt{x^2-1}\right)dx$, $x^2 - 1 = t^2$, $x = \sqrt{t^2+1}$, so

$I = \displaystyle\int \frac{x\ln x}{\sqrt{x^2-1}}\,dx = \int \ln\sqrt{t^2+1}\,dt = \frac{1}{2}\int \ln(t^2+1)\,dt$. Now use parts with $u = \ln(t^2+1)$, $dv = dt$:

$$I = \tfrac{1}{2}t\ln\left(t^2+1\right) - \int \frac{t^2}{t^2+1}\,dt = \tfrac{1}{2}t\ln\left(t^2+1\right) - \int \left[1 - \frac{1}{t^2+1}\right]dt$$

$$= \tfrac{1}{2}t\ln\left(t^2+1\right) - t + \tan^{-1}t + C = \sqrt{x^2-1}\,\ln x - \sqrt{x^2-1} + \tan^{-1}\sqrt{x^2-1} + C$$

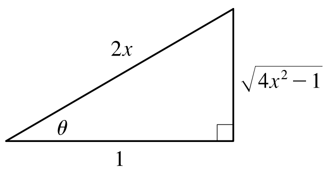
Another method: First integrate by parts with $u = \ln x$, $dv = \left(x/\sqrt{x^2-1}\right)dx$ and then use substitution $\left(x = \sec\theta \text{ or } u = \sqrt{x^2-1}\right)$.

59. $\dfrac{1}{x^4-16} = \dfrac{1}{(x^2-4)(x^2+4)} = \dfrac{1}{(x-2)(x+2)(x^2+4)} = \dfrac{A}{x-2} + \dfrac{B}{x+2} + \dfrac{Cx+D}{x^2+4}$. Multiply by $(x-2)(x+2)(x^2+4)$ to get $1 = A(x+2)(x^2+4) + B(x-2)(x^2+4) + (Cx+D)(x-2)(x+2)$. Substituting 2 for x gives $1 = 32A \quad\Leftrightarrow\quad A = \frac{1}{32}$. Substituting -2 for x gives $1 = -32B \quad\Leftrightarrow\quad B = -\frac{1}{32}$. Equating coefficients of x^3 gives $0 = A + B + C = \frac{1}{32} - \frac{1}{32} + C$, so $C = 0$. Equating constant terms gives $1 = 8A - 8B - 4D = \frac{1}{4} + \frac{1}{4} - 4D$, so $\frac{1}{2} = -4D \quad\Leftrightarrow\quad D = -\frac{1}{8}$. Thus,

$$\begin{aligned}\int \frac{dx}{x^4-16} &= \int \left(\frac{1/32}{x-2} - \frac{1/32}{x+2} - \frac{1/8}{x^2+4}\right) dx = \frac{1}{32}\ln|x-2| - \frac{1}{32}\ln|x+2| - \frac{1}{8}\cdot\frac{1}{2}\tan^{-1}\left(\frac{x}{2}\right) + C \\ &= \frac{1}{32}\ln\left|\frac{x-2}{x+2}\right| - \frac{1}{16}\tan^{-1}\left(\frac{x}{2}\right) + C\end{aligned}$$

60. Let $2x = \sec\theta$, so that $2\,dx = \sec\theta\,\tan\theta\,d\theta$. Then

$$\begin{aligned}\int \frac{dx}{x^2\sqrt{4x^2-1}} &= \int \frac{\frac{1}{2}\sec\theta\,\tan\theta\,d\theta}{\frac{1}{4}\sec^2\theta\sqrt{\sec^2\theta-1}} = \int \frac{2\tan\theta\,d\theta}{\sec\theta\,\tan\theta} \\ &= 2\int\cos\theta\,d\theta = 2\sin\theta + C \\ &= 2\cdot\frac{\sqrt{4x^2-1}}{2x} + C = \frac{\sqrt{4x^2-1}}{x} + C\end{aligned}$$



61. $$\begin{aligned}\int \frac{d\theta}{1+\cos\theta} &= \int\left(\frac{1}{1+\cos\theta}\cdot\frac{1-\cos\theta}{1-\cos\theta}\right)d\theta = \int\frac{1-\cos\theta}{1-\cos^2\theta}\,d\theta = \int\frac{1-\cos\theta}{\sin^2\theta}\,d\theta = \int\left(\frac{1}{\sin^2\theta} - \frac{\cos\theta}{\sin^2\theta}\right)d\theta \\ &= \int(\csc^2\theta - \cot\theta\,\csc\theta)\,d\theta = -\cot\theta + \csc\theta + C\end{aligned}$$

Another method: Use the substitutions in Exercise 7.4.59.

$$\int\frac{d\theta}{1+\cos\theta} = \int\frac{2/(1+t^2)\,dt}{1+(1-t^2)/(1+t^2)} = \int\frac{2\,dt}{(1+t^2)+(1-t^2)} = \int dt = t + C = \tan\left(\frac{\theta}{2}\right) + C$$

62. $$\begin{aligned}\int\frac{d\theta}{1+\cos^2\theta} &= \int\frac{(1/\cos^2\theta)\,d\theta}{(1+\cos^2\theta)/\cos^2\theta} = \int\frac{\sec^2\theta}{\sec^2\theta+1}\,d\theta = \int\frac{\sec^2\theta}{\tan^2\theta+2}\,d\theta = \int\frac{1}{u^2+2}\,du \quad \left[\begin{matrix}u = \tan\theta, \\ du = \sec^2\theta\,d\theta\end{matrix}\right] \\ &= \int\frac{1}{u^2+\left(\sqrt{2}\right)^2}\,du = \frac{1}{\sqrt{2}}\tan^{-1}\left(\frac{u}{\sqrt{2}}\right) + C = \frac{1}{\sqrt{2}}\tan^{-1}\left(\frac{\tan\theta}{\sqrt{2}}\right) + C\end{aligned}$$

63. Let $y = \sqrt{x}$ so that $dy = \dfrac{1}{2\sqrt{x}}\,dx \quad\Rightarrow\quad dx = 2\sqrt{x}\,dy = 2y\,dy$. Then

$$\begin{aligned}\int\sqrt{x}\,e^{\sqrt{x}}\,dx &= \int ye^y(2y\,dy) = \int 2y^2e^y\,dy \quad \left[\begin{matrix}u = 2y^2, & dv = e^y\,dy, \\ du = 4y\,dy & v = e^y\end{matrix}\right] \\ &= 2y^2e^y - \int 4ye^y\,dy \quad \left[\begin{matrix}U = 4y, & dV = e^y\,dy, \\ dU = 4\,dy & V = e^y\end{matrix}\right] \\ &= 2y^2e^y - \left(4ye^y - \textstyle\int 4e^y\,dy\right) = 2y^2e^y - 4ye^y + 4e^y + C \\ &= 2(y^2 - 2y + 2)e^y + C = 2\left(x - 2\sqrt{x} + 2\right)e^{\sqrt{x}} + C\end{aligned}$$

64. Let $u = \sqrt{x} + 1$, so that $x = (u-1)^2$ and $dx = 2(u-1)\,du$. Then

$$\int \frac{1}{\sqrt{\sqrt{x}+1}}\,dx = \int \frac{2(u-1)\,du}{\sqrt{u}} = \int (2u^{1/2} - 2u^{-1/2})\,du = \frac{4}{3}u^{3/2} - 4u^{1/2} + C = \frac{4}{3}(\sqrt{x}+1)^{3/2} - 4\sqrt{\sqrt{x}+1} + C.$$

65. Let $u = \cos^2 x$, so that $du = 2\cos x\,(-\sin x)\,dx$. Then

$$\int \frac{\sin 2x}{1+\cos^4 x}\,dx = \int \frac{2\sin x\,\cos x}{1+(\cos^2 x)^2}\,dx = \int \frac{1}{1+u^2}\,(-du) = -\tan^{-1} u + C = -\tan^{-1}(\cos^2 x) + C.$$

66. Let $u = \tan x$. Then

$$\int_{\pi/4}^{\pi/3} \frac{\ln(\tan x)\,dx}{\sin x\,\cos x} = \int_{\pi/4}^{\pi/3} \frac{\ln(\tan x)}{\tan x}\sec^2 x\,dx = \int_1^{\sqrt{3}} \frac{\ln u}{u}\,du = \left[\tfrac{1}{2}(\ln u)^2\right]_1^{\sqrt{3}} = \tfrac{1}{2}\left(\ln\sqrt{3}\right)^2 = \tfrac{1}{8}(\ln 3)^2.$$

67. $$\int \frac{dx}{\sqrt{x+1}+\sqrt{x}} = \int \left(\frac{1}{\sqrt{x+1}+\sqrt{x}} \cdot \frac{\sqrt{x+1}-\sqrt{x\sqrt{x}}}{\sqrt{x+1}-\sqrt{x}}\right)dx = \int \left(\sqrt{x+1}-\sqrt{x}\right)dx$$

$$= \tfrac{2}{3}\left[(x+1)^{3/2} - x^{3/2}\right] + C$$

68. $$\int \frac{x^2}{x^6+3x^3+2}\,dx = \int \frac{x^2\,dx}{(x^3+1)(x^3+2)} = \int \frac{\frac{1}{3}\,du}{(u+1)(u+2)} \quad \begin{bmatrix} u = x^3, \\ du = 3x^2\,dx \end{bmatrix}.$$

Now $\dfrac{1}{(u+1)(u+2)} = \dfrac{A}{u+1} + \dfrac{B}{u+2} \;\Rightarrow\; 1 = A(u+2) + B(u+1)$. Setting $u = -2$ gives $B = -1$. Setting $u = -1$ gives $A = 1$. Thus,

$$\frac{1}{3}\int \frac{du}{(u+1)(u+2)} = \frac{1}{3}\int \left(\frac{1}{u+1} - \frac{1}{u+2}\right)du = \frac{1}{3}\ln|u+1| - \frac{1}{3}\ln|u+2| + C$$

$$= \tfrac{1}{3}\ln\left|x^3+1\right| - \tfrac{1}{3}\ln\left|x^3+2\right| + C$$

69. Let $x = \tan\theta$, so that $dx = \sec^2\theta\,d\theta$, $x = \sqrt{3} \;\Rightarrow\; \theta = \frac{\pi}{3}$, and $x = 1 \;\Rightarrow\; \theta = \frac{\pi}{4}$. Then

$$\int_1^{\sqrt{3}} \frac{\sqrt{1+x^2}}{x^2}\,dx = \int_{\pi/4}^{\pi/3} \frac{\sec\theta}{\tan^2\theta}\sec^2\theta\,d\theta = \int_{\pi/4}^{\pi/3} \frac{\sec\theta\,(\tan^2\theta+1)}{\tan^2\theta}\,d\theta = \int_{\pi/4}^{\pi/3} \left(\frac{\sec\theta\,\tan^2\theta}{\tan^2\theta} + \frac{\sec\theta}{\tan^2\theta}\right)d\theta$$

$$= \int_{\pi/4}^{\pi/3} (\sec\theta + \csc\theta\,\cot\theta)\,d\theta = \Big[\ln|\sec\theta+\tan\theta| - \csc\theta\Big]_{\pi/4}^{\pi/3}$$

$$= \left(\ln|2+\sqrt{3}| - \tfrac{2}{\sqrt{3}}\right) - \left(\ln|\sqrt{2}+1| - \sqrt{2}\right) = \sqrt{2} - \tfrac{2}{\sqrt{3}} + \ln(2+\sqrt{3}) - \ln(1+\sqrt{2})$$

70. Let $u = e^x$. Then $x = \ln u$, $dx = du/u \;\Rightarrow$

$$\int \frac{dx}{1+2e^x-e^{-x}} = \int \frac{du/u}{1+2u-1/u} = \int \frac{du}{2u^2+u-1} = \int \left[\frac{2/3}{2u-1} - \frac{1/3}{u+1}\right]du$$

$$= \tfrac{1}{3}\ln|2u-1| - \tfrac{1}{3}\ln|u+1| + C = \tfrac{1}{3}\ln|(2e^x-1)/(e^x+1)| + C$$

71. Let $u = e^x$. Then $x = \ln u$, $dx = du/u \quad \Rightarrow$

$$\int \frac{e^{2x}}{1+e^x}\,dx = \int \frac{u^2}{1+u}\,\frac{du}{u} = \int \frac{u}{1+u}\,du = \int \left(1 - \frac{1}{1+u}\right) du = u - \ln|1+u| + C = e^x - \ln(1+e^x) + C.$$

72. Use parts with $u = \ln(x+1)$, $dv = dx/x^2$:

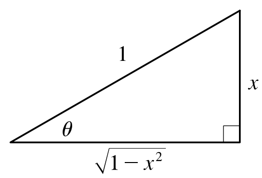
$$\int \frac{\ln(x+1)}{x^2}\,dx = -\frac{1}{x}\ln(x+1) + \int \frac{dx}{x(x+1)} = -\frac{1}{x}\ln(x+1) + \int \left[\frac{1}{x} - \frac{1}{x+1}\right] dx$$

$$= -\frac{1}{x}\ln(x+1) + \ln|x| - \ln(x+1) + C = -\left(1 + \frac{1}{x}\right)\ln(x+1) + \ln|x| + C$$

73. Let $\theta = \arcsin x$, so that $d\theta = \dfrac{1}{\sqrt{1-x^2}}\,dx$ and $x = \sin\theta$. Then

$$\int \frac{x + \arcsin x}{\sqrt{1-x^2}}\,dx = \int (\sin\theta + \theta)\,d\theta = -\cos\theta + \tfrac{1}{2}\theta^2 + C$$

$$= -\sqrt{1-x^2} + \tfrac{1}{2}(\arcsin x)^2 + C$$



74. $$\int \frac{4^x + 10^x}{2^x}\,dx = \int \left(\frac{4^x}{2^x} + \frac{10^x}{2^x}\right) dx = \int (2^x + 5^x)\,dx = \frac{2^x}{\ln 2} + \frac{5^x}{\ln 5} + C$$

75. $$\int \frac{dx}{x\ln x - x} = \int \frac{dx}{x(\ln x - 1)} = \int \frac{du}{u} \qquad \begin{bmatrix} u = \ln x - 1, \\ du = (1/x)\,dx \end{bmatrix}$$

$$= \ln|u| + C = \ln|\ln x - 1| + C$$

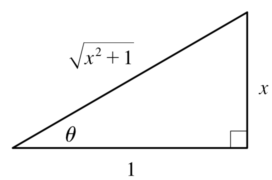
76. $$\int \frac{x^2}{\sqrt{x^2+1}}\,dx = \int \frac{\tan^2\theta}{\sec\theta}\sec^2\theta\,d\theta \qquad \begin{bmatrix} x = \tan\theta, \\ dx = \sec^2\theta\,d\theta \end{bmatrix}$$

$$= \int \tan^2\theta\,\sec\theta\,d\theta = \int (\sec^2\theta - 1)\sec\theta\,d\theta$$

$$= \int (\sec^3\theta - \sec\theta)\,d\theta$$

$$= \tfrac{1}{2}(\sec\theta\,\tan\theta + \ln|\sec\theta + \tan\theta|) - \ln|\sec\theta + \tan\theta| + C \quad \text{[by (1) and Example 7.2.8]}$$

$$= \tfrac{1}{2}(\sec\theta\,\tan\theta - \ln|\sec\theta + \tan\theta|) + C = \tfrac{1}{2}\left[x\sqrt{x^2+1} - \ln\left(\sqrt{x^2+1} + x\right)\right] + C$$



77. Let $y = \sqrt{1+e^x}$, so that $y^2 = 1 + e^x$, $2y\,dy = e^x\,dx$, $e^x = y^2 - 1$, and $x = \ln(y^2 - 1)$. Then

$$\int \frac{xe^x}{\sqrt{1+e^x}}\,dx = \int \frac{\ln(y^2-1)}{y}(2y\,dy) = 2\int [\ln(y+1) + \ln(y-1)]\,dy$$

$$= 2[(y+1)\ln(y+1) - (y+1) + (y-1)\ln(y-1) - (y-1)] + C \qquad \text{[by Example 7.1.2]}$$

$$= 2[y\ln(y+1) + \ln(y+1) - y - 1 + y\ln(y-1) - \ln(y-1) - y + 1] + C$$

$$= 2[y(\ln(y+1) + \ln(y-1)) + \ln(y+1) - \ln(y-1) - 2y] + C$$

$$= 2\left[y\ln(y^2-1) + \ln\frac{y+1}{y-1} - 2y\right] + C = 2\left[\sqrt{1+e^x}\,\ln(e^x) + \ln\frac{\sqrt{1+e^x}+1}{\sqrt{1+e^x}-1} - 2\sqrt{1+e^x}\right] + C$$

$$= 2x\sqrt{1+e^x} + 2\ln\frac{\sqrt{1+e^x}+1}{\sqrt{1+e^x}-1} - 4\sqrt{1+e^x} + C = 2(x-2)\sqrt{1+e^x} + 2\ln\frac{\sqrt{1+e^x}+1}{\sqrt{1+e^x}-1} + C$$

78. $\dfrac{1+\sin x}{1-\sin x} = \dfrac{1+\sin x}{1-\sin x}\cdot\dfrac{1+\sin x}{1+\sin x} = \dfrac{1+2\sin x+\sin^2 x}{1-\sin^2 x} = \dfrac{1+2\sin x+\sin^2 x}{\cos^2 x} = \dfrac{1}{\cos^2 x}+\dfrac{2\sin x}{\cos^2 x}+\dfrac{\sin^2 x}{\cos^2 x}$

$= \sec^2 x + 2\sec x\,\tan x + \tan^2 x = \sec^2 x + 2\sec x\,\tan x + \sec^2 x - 1 = 2\sec^2 x + 2\sec x\,\tan x - 1$

Thus, $\displaystyle\int \frac{1+\sin x}{1-\sin x}\,dx = \int (2\sec^2 x + 2\sec x\,\tan x - 1)\,dx = 2\tan x + 2\sec x - x + C$

79. Let $u = x$, $dv = \sin^2 x\cos x\,dx \quad\Rightarrow\quad du = dx$, $v = \frac{1}{3}\sin^3 x$. Then

$\int x\sin^2 x\,\cos x\,dx = \frac{1}{3}x\sin^3 x - \int \frac{1}{3}\sin^3 x\,dx = \frac{1}{3}x\sin^3 x - \frac{1}{3}\int(1-\cos^2 x)\sin x\,dx$

$\displaystyle = \frac{1}{3}x\sin^3 x + \frac{1}{3}\int(1-y^2)\,dy \qquad \begin{bmatrix} u=\cos x, \\ du=-\sin x\,dx \end{bmatrix}$

$= \frac{1}{3}x\sin^3 x + \frac{1}{3}y - \frac{1}{9}y^3 + C = \frac{1}{3}x\sin^3 x + \frac{1}{3}\cos x - \frac{1}{9}\cos^3 x + C$

80. $\displaystyle\int \frac{\sec x\,\cos 2x}{\sin x+\sec x}\,dx = \int \frac{\sec x\,\cos 2x}{\sin x+\sec x}\cdot\frac{2\cos x}{2\cos x}\,dx = \int \frac{2\cos 2x}{2\sin x\cos x+2}\,dx$

$\displaystyle = \int \frac{2\cos 2x}{\sin 2x+2}\,dx = \int \frac{1}{u}\,du \qquad \begin{bmatrix} u=\sin 2x+2, \\ du=2\cos 2x\,dx \end{bmatrix}$

$= \ln|u| + C = \ln|\sin 2x+2| + C = \ln(\sin 2x+2) + C$

81. $\displaystyle\int \sqrt{1-\sin x}\,dx = \int \sqrt{\frac{1-\sin x}{1}\cdot\frac{1+\sin x}{1+\sin x}}\,dx = \int \sqrt{\frac{1-\sin^2 x}{1+\sin x}}\,dx$

$\displaystyle = \int \sqrt{\frac{\cos^2 x}{1+\sin x}}\,dx = \int \frac{\cos x\,dx}{\sqrt{1+\sin x}} \qquad [\text{assume } \cos x > 0]$

$\displaystyle = \int \frac{du}{\sqrt{u}} \qquad \begin{bmatrix} u=1+\sin x, \\ du=\cos x\,dx \end{bmatrix}$

$= 2\sqrt{u} + C = 2\sqrt{1+\sin x} + C$

Another method: Let $u = \sin x$ so that $du = \cos x\,dx = \sqrt{1-\sin^2 x}\,dx = \sqrt{1-u^2}\,dx$. Then

$\displaystyle\int \sqrt{1-\sin x}\,dx = \int \sqrt{1-u}\left(\frac{du}{\sqrt{1-u^2}}\right) = \int \frac{1}{\sqrt{1+u}}\,du = 2\sqrt{1+u} + C = 2\sqrt{1+\sin x} + C.$

82. $\displaystyle\int \frac{\sin x\,\cos x}{\sin^4 x+\cos^4 x}\,dx = \int \frac{\sin x\,\cos x}{(\sin^2 x)^2+(\cos^2 x)^2}\,dx = \int \frac{\sin x\,\cos x}{(\sin^2 x)^2+(1-\sin^2 x)^2}\,dx$

$\displaystyle = \int \frac{1}{u^2+(1-u)^2}\left(\frac{1}{2}\,du\right) \qquad \begin{bmatrix} u=\sin^2 x, \\ du=2\sin x\,\cos x\,dx \end{bmatrix}$

$\displaystyle = \int \frac{1}{4u^2-4u+2}\,du = \int \frac{1}{(4u^2-4u+1)+1}\,du$

$\displaystyle = \int \frac{1}{(2u-1)^2+1}\,du = \frac{1}{2}\int \frac{1}{y^2+1}\,dy \qquad \begin{bmatrix} y=2u-1, \\ dy=2\,du \end{bmatrix}$

$= \frac{1}{2}\tan^{-1} y + C = \frac{1}{2}\tan^{-1}(2u-1) + C = \frac{1}{2}\tan^{-1}(2\sin^2 x - 1) + C$

Another solution:

$$\int \frac{\sin x\, \cos x}{\sin^4 x + \cos^4 x}\,dx = \int \frac{(\sin x\, \cos x)/\cos^4 x}{(\sin^4 x + \cos^4 x)/\cos^4 x}\,dx = \int \frac{\tan x\, \sec^2 x}{\tan^4 x + 1}\,dx$$

$$= \int \frac{1}{u^2+1}\left(\frac{1}{2}\,du\right) \quad \left[\begin{matrix} u = \tan^2 x, \\ du = 2\tan x\, \sec^2 x\, dx \end{matrix}\right]$$

$$= \tfrac{1}{2}\tan^{-1} u + C = \tfrac{1}{2}\tan^{-1}(\tan^2 x) + C$$

83. The function $y = 2xe^{x^2}$ *does* have an elementary antiderivative, so we'll use this fact to help evaluate the integral.

$$\int (2x^2+1)e^{x^2}\,dx = \int 2x^2 e^{x^2}\,dx + \int e^{x^2}\,dx = \int x\left(2xe^{x^2}\right)dx + \int e^{x^2}\,dx$$

$$= xe^{x^2} - \int e^{x^2}\,dx + \int e^{x^2}\,dx \quad \left[\begin{matrix} u = x, & dv = 2xe^{x^2}\,dx, \\ du = dx & v = e^{x^2} \end{matrix}\right] \quad = xe^{x^2} + C$$

84. (a) $$\int_1^2 \frac{e^x}{x}\,dx = \int_0^{\ln 2} \frac{e^{e^t}}{e^t}\,e^t\,dt \quad \left[\begin{matrix} x = e^t, \\ dx = e^t\,dt \end{matrix}\right] \quad = \int_0^{\ln 2} e^{e^t}\,dt = F(\ln 2)$$

(b) $$\int_2^3 \frac{1}{\ln x}\,dx = \int_{\ln 2}^{\ln 3} \frac{1}{u}\,(e^u\,du) \quad \left[\begin{matrix} u = \ln x, \\ du = \frac{1}{x}\,dx \end{matrix}\right] \quad = \int_{\ln\ln 2}^{\ln\ln 3} \frac{e^{e^v}}{e^v}\,e^v\,dv \quad \left[\begin{matrix} u = e^v, \\ du = e^v\,dv \end{matrix}\right]$$

$$= \int_{\ln\ln 2}^{0} e^{e^v}\,dv + \int_0^{\ln\ln 3} e^{e^v}\,dv \quad [\text{note that } \ln\ln 2 < 0]$$

$$= \int_0^{\ln\ln 3} e^{e^v}\,dv - \int_0^{\ln\ln 2} e^{e^v}\,dv = F(\ln\ln 3) - F(\ln\ln 2)$$

Another method: Substitute $x = e^{e^t}$ in the original integral.

7.6 Integration Using Tables and Computer Algebra Systems

Keep in mind that there are several ways to approach many of these exercises, and different methods can lead to different forms of the answer.

1. $$\int_0^{\pi/2} \cos 5x\, \cos 2x\,dx \overset{80}{=} \left[\frac{\sin(5-2)x}{2(5-2)} + \frac{\sin(5+2)x}{2(5+2)}\right]_0^{\pi/2} \quad \left[\begin{matrix} a = 5, \\ b = 2 \end{matrix}\right]$$

$$= \left[\frac{\sin 3x}{6} + \frac{\sin 7x}{14}\right]_0^{\pi/2} = \left(-\frac{1}{6} - \frac{1}{14}\right) - 0 = \frac{-7-3}{42} = -\frac{5}{21}$$

2. $$\int_0^1 \sqrt{x - x^2}\,dx = \int_0^1 \sqrt{2\left(\tfrac{1}{2}\right)x - x^2}\,dx \overset{113}{=} \left[\frac{x - \frac{1}{2}}{2}\sqrt{2\left(\tfrac{1}{2}\right)x - x^2} + \frac{\left(\frac{1}{2}\right)^2}{2}\cos^{-1}\left(\frac{\frac{1}{2} - x}{\frac{1}{2}}\right)\right]_0^1$$

$$= \left[\frac{2x-1}{4}\sqrt{x - x^2} + \frac{1}{8}\cos^{-1}(1-2x)\right]_0^1 = \left(0 + \frac{1}{8}\cdot\pi\right) - \left(0 + \frac{1}{8}\cdot 0\right) = \frac{1}{8}\pi$$

3. $$\int_1^2 \sqrt{4x^2 - 3}\,dx = \tfrac{1}{2}\int_2^4 \sqrt{u^2 - \left(\sqrt{3}\right)^2}\,du \qquad [u = 2x,\ du = 2\,dx]$$

$$\overset{39}{=} \frac{1}{2}\left[\frac{u}{2}\sqrt{u^2 - \left(\sqrt{3}\right)^2} - \frac{\left(\sqrt{3}\right)^2}{2}\ln\left|u + \sqrt{u^2 - \left(\sqrt{3}\right)^2}\right|\right]_2^4$$

$$= \tfrac{1}{2}\left[2\sqrt{13} - \tfrac{3}{2}\ln\left(4 + \sqrt{13}\right)\right] - \tfrac{1}{2}\left(1 - \tfrac{3}{2}\ln 3\right) = \sqrt{13} - \tfrac{3}{4}\ln\left(4 + \sqrt{13}\right) - \tfrac{1}{2} + \tfrac{3}{4}\ln 3$$

4. $\displaystyle\int_0^1 \tan^3\left(\frac{\pi}{6}x\right)dx = \frac{6}{\pi}\int_0^{\pi/6}\tan^3 u\,du \qquad [u = (\pi/6)x,\ du = (\pi/6)\,dx]$

$$\overset{69}{=} \frac{6}{\pi}\left[\frac{1}{2}\tan^2 u + \ln|\cos u|\right]_0^{\pi/6} = \frac{6}{\pi}\left[\left(\frac{1}{2}\left(\frac{1}{\sqrt{3}}\right)^2 + \ln\frac{\sqrt{3}}{2}\right) - (0 + \ln 1)\right] = \frac{1}{\pi} + \frac{6}{\pi}\ln\frac{\sqrt{3}}{2}$$

5. $\int_0^{\pi/8}\arctan 2x\,dx = \frac{1}{2}\int_0^{\pi/4}\arctan u\,du \qquad [u = 2x,\ du = 2\,dx]$

$$\overset{89}{=} \frac{1}{2}\left[u\arctan u - \frac{1}{2}\ln(1+u^2)\right]_0^{\pi/4} = \frac{1}{2}\left\{\left[\frac{\pi}{4}\arctan\frac{\pi}{4} - \frac{1}{2}\ln\left(1+\frac{\pi^2}{16}\right)\right] - 0\right\}$$

$$= \frac{\pi}{8}\arctan\frac{\pi}{4} - \frac{1}{4}\ln\left(1+\frac{\pi^2}{16}\right)$$

6. $\displaystyle\int_0^2 x^2\sqrt{4-x^2}\,dx \overset{31}{=} \left[\frac{x}{8}(2x^2-4)\sqrt{4-x^2} + \frac{16}{8}\sin^{-1}\left(\frac{x}{2}\right)\right]_0^2 = \left(0 + 2\cdot\frac{\pi}{2}\right) - 0 = \pi$

7. $\displaystyle\int\frac{\cos x}{\sin^2 x - 9}\,dx = \int\frac{1}{u^2-9}\,du \quad \begin{bmatrix} u = \sin x, \\ du = \cos x\,dx \end{bmatrix} \quad \overset{20}{=} \frac{1}{2(3)}\ln\left|\frac{u-3}{u+3}\right| + C = \frac{1}{6}\ln\left|\frac{\sin x - 3}{\sin x + 3}\right| + C$

8. $\displaystyle\int\frac{e^x}{4-e^{2x}}\,dx = \int\frac{1}{4-u^2}\,du \quad \begin{bmatrix} u = e^x, \\ du = e^x\,dx \end{bmatrix} \quad \overset{19}{=} \frac{1}{2(2)}\ln\left|\frac{u+2}{u-2}\right| + C = \frac{1}{4}\ln\left|\frac{e^x+2}{e^x-2}\right| + C$

9. $\displaystyle\int\frac{\sqrt{9x^2+4}}{x^2}\,dx = \int\frac{\sqrt{u^2+4}}{u^2/9}\left(\frac{1}{3}du\right) \qquad \begin{bmatrix} u = 3x, \\ du = 3\,dx \end{bmatrix}$

$$= 3\int\frac{\sqrt{4+u^2}}{u^2}\,du \overset{24}{=} 3\left[-\frac{\sqrt{4+u^2}}{u} + \ln(u + \sqrt{4+u^2})\right] + C$$

$$= -\frac{3\sqrt{4+9x^2}}{3x} + 3\ln(3x + \sqrt{4+9x^2}) + C = -\frac{\sqrt{9x^2+4}}{x} + 3\ln(3x + \sqrt{9x^2+4}) + C$$

10. Let $u = \sqrt{2}\,y$ and $a = \sqrt{3}$. Then $du = \sqrt{2}\,dy$ and

$$\int\frac{\sqrt{2y^2-3}}{y^2}\,dy = \int\frac{\sqrt{u^2-a^2}}{\frac{1}{2}u^2}\,\frac{du}{\sqrt{2}} = \sqrt{2}\int\frac{\sqrt{u^2-a^2}}{u^2}\,du \overset{42}{=} \sqrt{2}\left(-\frac{\sqrt{u^2-a^2}}{u} + \ln\left|u + \sqrt{u^2-a^2}\right|\right) + C$$

$$= \sqrt{2}\left(-\frac{\sqrt{2y^2-3}}{\sqrt{2}\,y} + \ln\left|\sqrt{2}\,y + \sqrt{2y^2-3}\right|\right) + C$$

$$= -\frac{\sqrt{2y^2-3}}{y} + \sqrt{2}\ln\left|\sqrt{2}\,y + \sqrt{2y^2-3}\right| + C$$

11. $\int_0^\pi\cos^6\theta\,d\theta \overset{74}{=} \left[\frac{1}{6}\cos^5\theta\,\sin\theta\right]_0^\pi + \frac{5}{6}\int_0^\pi\cos^4\theta\,d\theta \overset{74}{=} 0 + \frac{5}{6}\left\{\left[\frac{1}{4}\cos^3\theta\,\sin\theta\right]_0^\pi + \frac{3}{4}\int_0^\pi\cos^2\theta\,d\theta\right\}$

$$\overset{64}{=} \frac{5}{6}\left\{0 + \frac{3}{4}\left[\frac{1}{2}\theta + \frac{1}{4}\sin 2\theta\right]_0^\pi\right\} = \frac{5}{6}\cdot\frac{3}{4}\cdot\frac{\pi}{2} = \frac{5\pi}{16}$$

12. $\int x\sqrt{2+x^4}\,dx = \int\sqrt{2+u^2}\,\left(\frac{1}{2}\,du\right) \qquad \begin{bmatrix} u = x^2, \\ du = 2x\,dx \end{bmatrix}$

$$\overset{21}{=} \frac{1}{2}\left[\frac{u}{2}\sqrt{2+u^2} + \frac{2}{2}\ln\left(u + \sqrt{2+u^2}\right)\right] + C = \frac{x^2}{4}\sqrt{2+x^4} + \frac{1}{2}\ln(x^2 + \sqrt{2+x^4}\,) + C$$

13. $\displaystyle\int \frac{\arctan\sqrt{x}}{\sqrt{x}}\,dx = \int \arctan u\,(2\,du) \qquad \left[\begin{array}{l} u=\sqrt{x}, \\ du = 1/(2\sqrt{x})\,dx \end{array}\right]$

$\overset{89}{=} 2\left[u\arctan u - \tfrac{1}{2}\ln(1+u^2)\right] + C = 2\sqrt{x}\arctan\sqrt{x} - \ln(1+x) + C$

14. $\int_0^\pi x^3\sin x\,dx \overset{84}{=} \left[-x^3\cos x\right]_0^\pi + 3\int_0^\pi x^2\cos x\,dx \overset{85}{=} -\pi^3(-1) + 3\left\{\left[x^2\sin x\right]_0^\pi - 2\int_0^\pi x\sin x\,dx\right\}$

$= \pi^3 - 6\int_0^\pi x\sin x\,dx \overset{84}{=} \pi^3 - 6\left\{\left[-x\cos x\right]_0^\pi + \int_0^\pi \cos x\,dx\right\}$

$= \pi^3 - 6[\pi] - 6\left[\sin x\right]_0^\pi = \pi^3 - 6\pi$

15. $\displaystyle\int \frac{\coth(1/y)}{y^2}\,dy = \int \coth u\,(-du) \qquad \left[\begin{array}{l} u = 1/y, \\ du = -1/y^2\,dy \end{array}\right]$

$\overset{106}{=} -\ln|\sinh u| + C = -\ln|\sinh(1/y)| + C$

16. $\displaystyle\int \frac{e^{3t}}{\sqrt{e^{2t}-1}}\,dt = \int \frac{e^{2t}}{\sqrt{e^{2t}-1}}\,(e^t\,dt) = \int \frac{u^2}{\sqrt{u^2-1}}\,du \qquad \left[\begin{array}{l} u = e^t, \\ du = e^t\,dt \end{array}\right]$

$\displaystyle\overset{44}{=} \frac{u}{2}\sqrt{u^2-1} + \tfrac{1}{2}\ln\left|u + \sqrt{u^2-1}\right| + C = \tfrac{1}{2}e^t\sqrt{e^{2t}-1} + \tfrac{1}{2}\ln\left(e^t + \sqrt{e^{2t}-1}\right) + C$

17. Let $z = 6 + 4y - 4y^2 = 6 - (4y^2 - 4y + 1) + 1 = 7 - (2y-1)^2$, $u = 2y - 1$, and $a = \sqrt{7}$.

Then $z = a^2 - u^2$, $du = 2\,dy$, and

$\int y\sqrt{6+4y-4y^2}\,dy = \int y\sqrt{z}\,dy = \int \tfrac{1}{2}(u+1)\sqrt{a^2-u^2}\,\tfrac{1}{2}\,du = \tfrac{1}{4}\int u\sqrt{a^2-u^2}\,du + \tfrac{1}{4}\int\sqrt{a^2-u^2}\,du$

$= \tfrac{1}{4}\int\sqrt{a^2-u^2}\,du - \tfrac{1}{8}\int(-2u)\sqrt{a^2-u^2}\,du$

$\displaystyle\overset{30}{=} \frac{u}{8}\sqrt{a^2-u^2} + \frac{a^2}{8}\sin^{-1}\!\left(\frac{u}{a}\right) - \frac{1}{8}\int\sqrt{w}\,dw \qquad \left[\begin{array}{l} w = a^2 - u^2, \\ dw = -2u\,du \end{array}\right]$

$\displaystyle= \frac{2y-1}{8}\sqrt{6+4y-4y^2} + \frac{7}{8}\sin^{-1}\frac{2y-1}{\sqrt{7}} - \frac{1}{8}\cdot\frac{2}{3}w^{3/2} + C$

$\displaystyle= \frac{2y-1}{8}\sqrt{6+4y-4y^2} + \frac{7}{8}\sin^{-1}\frac{2y-1}{\sqrt{7}} - \frac{1}{12}(6+4y-4y^2)^{3/2} + C$

This can be rewritten as

$\displaystyle\sqrt{6+4y-4y^2}\left[\frac{1}{8}(2y-1) - \frac{1}{12}(6+4y-4y^2)\right] + \frac{7}{8}\sin^{-1}\frac{2y-1}{\sqrt{7}} + C$

$\displaystyle= \left(\frac{1}{3}y^2 - \frac{1}{12}y - \frac{5}{8}\right)\sqrt{6+4y-4y^2} + \frac{7}{8}\sin^{-1}\left(\frac{2y-1}{\sqrt{7}}\right) + C$

$\displaystyle= \frac{1}{24}(8y^2 - 2y - 15)\sqrt{6+4y-4y^2} + \frac{7}{8}\sin^{-1}\left(\frac{2y-1}{\sqrt{7}}\right) + C$

18. $\displaystyle\int \frac{dx}{2x^3 - 3x^2} = \int \frac{dx}{x^2(-3+2x)} \overset{50}{=} -\frac{1}{-3x} + \frac{2}{(-3)^2}\ln\left|\frac{-3+2x}{x}\right| + C = \frac{1}{3x} + \tfrac{2}{9}\ln\left|\frac{2x-3}{x}\right| + C$

19. Let $u = \sin x$. Then $du = \cos x\,dx$, so

$\displaystyle\int \sin^2 x\,\cos x\,\ln(\sin x)\,dx = \int u^2\ln u\,du \overset{101}{=} \frac{u^{2+1}}{(2+1)^2}\left[(2+1)\ln u - 1\right] + C = \tfrac{1}{9}u^3(3\ln u - 1) + C$

$= \tfrac{1}{9}\sin^3 x\,[3\ln(\sin x) - 1] + C$

20. Let $u = \sin\theta$, so that $du = \cos\theta\, d\theta$. Then

$$\int \frac{\sin 2\theta}{\sqrt{5-\sin\theta}}\,d\theta = \int \frac{2\sin\theta\,\cos\theta}{\sqrt{5-\sin\theta}}d\theta = 2\int \frac{u}{\sqrt{5-u}}\,du \overset{55}{=} 2\cdot\frac{2}{3(-1)^2}\,[-1u-2(5)]\,\sqrt{5-u}+C$$
$$= \tfrac{4}{3}(-u-10)\,\sqrt{5-u}+C = -\tfrac{4}{3}(\sin\theta+10)\,\sqrt{5-\sin\theta}+C$$

21. Let $u = e^x$ and $a = \sqrt{3}$. Then $du = e^x\,dx$ and

$$\int \frac{e^x}{3-e^{2x}}\,dx = \int \frac{du}{a^2-u^2} \overset{19}{=} \frac{1}{2a}\ln\left|\frac{u+a}{u-a}\right|+C = \frac{1}{2\sqrt{3}}\ln\left|\frac{e^x+\sqrt{3}}{e^x-\sqrt{3}}\right|+C.$$

22. Let $u = x^2$ and $a = 2$. Then $du = 2x\,dx$ and

$$\int_0^2 x^3\sqrt{4x^2-x^4}\,dx = \tfrac{1}{2}\int_0^2 x^2\,\sqrt{2\cdot 2\cdot x^2-(x^2)^2}\cdot 2x\,dx = \tfrac{1}{2}\int_0^4 u\,\sqrt{2au-u^2}\,du$$
$$\overset{114}{=} \left[\frac{2u^2-au-3a^2}{12}\sqrt{2au-u^2}+\frac{a^3}{4}\cos^{-1}\left(\frac{a-u}{a}\right)\right]_0^4$$
$$= \left[\frac{2u^2-2u-12}{12}\sqrt{4u-u^2}+\frac{8}{4}\cos^{-1}\left(\frac{2-u}{2}\right)\right]_0^4$$
$$= \left[\frac{u^2-u-6}{6}\sqrt{4u-u^2}+2\cos^{-1}\left(\frac{2-u}{2}\right)\right]_0^4$$
$$= [0+2\cos^{-1}(-1)]-(0+2\cos^{-1}1) = 2\cdot\pi-2\cdot 0 = 2\pi$$

23. $\int \sec^5 x\,dx \overset{77}{=} \frac{1}{4}\tan x\,\sec^3 x+\frac{3}{4}\int\sec^3 x\,dx \overset{77}{=} \frac{1}{4}\tan x\,\sec^3 x+\frac{3}{4}\left(\frac{1}{2}\tan x\,\sec x+\frac{1}{2}\int\sec x\,dx\right)$

$\overset{14}{=} \frac{1}{4}\tan x\,\sec^3 x+\frac{3}{8}\tan x\,\sec x+\frac{3}{8}\ln|\sec x+\tan x|+C$

24. $\int x^3\arcsin(x^2)\,dx = \int u\arcsin u\,\left(\frac{1}{2}du\right)$ $\quad\left[\begin{array}{l} u = x^2, \\ du = 2x\,dx \end{array}\right]$

$$\overset{90}{=} \frac{1}{2}\left[\frac{2u^2-1}{4}\arcsin u+\frac{u\sqrt{1-u^2}}{4}\right]+C = \frac{2x^4-1}{8}\arcsin(x^2)+\frac{x^2\sqrt{1-x^4}}{8}+C$$

25. Let $u = \ln x$ and $a = 2$. Then $du = dx/x$ and

$$\int \frac{\sqrt{4+(\ln x)^2}}{x}\,dx = \int\sqrt{a^2+u^2}\,du \overset{21}{=} \frac{u}{2}\sqrt{a^2+u^2}+\frac{a^2}{2}\ln\left(u+\sqrt{a^2+u^2}\right)+C$$
$$= \tfrac{1}{2}(\ln x)\sqrt{4+(\ln x)^2}+2\ln\left[\ln x+\sqrt{4+(\ln x)^2}\right]+C$$

26. $\int x^4e^{-x}\,dx \overset{97}{=} -x^4e^{-x}+4\int x^3e^{-x}\,dx \overset{97}{=} -x^4e^{-x}+4\left(-x^3e^{-x}+3\int x^2e^{-x}\,dx\right)$

$\overset{97}{=} -(x^4+4x^3)e^{-x}+12\left(-x^2e^{-x}+2\int xe^{-x}\,dx\right)$

$\overset{96}{=} -(x^4+4x^3+12x^2)e^{-x}+24[(-x-1)e^{-x}]+C = -(x^4+4x^3+12x^2+24x+24)e^{-x}+C$

So $\int_0^1 x^4e^{-x}\,dx = \left[-(x^4+4x^3+12x^2+24x+24)e^{-x}\right]_0^1 = -(1+4+12+24+24)e^{-1}+24e^0 = 24-65e^{-1}$.

27. $\displaystyle\int \frac{\cos^{-1}(x^{-2})}{x^3}\,dx = -\frac{1}{2}\int\cos^{-1}u\,du$ $\quad\left[\begin{array}{l} u = x^{-2}, \\ du = -2x^{-3}\,dx \end{array}\right]$

$$\overset{88}{=} -\tfrac{1}{2}\left(u\cos^{-1}u-\sqrt{1-u^2}\right)+C = -\tfrac{1}{2}x^{-2}\cos^{-1}(x^{-2})+\tfrac{1}{2}\sqrt{1-x^{-4}}+C$$

28. $$\int \frac{dx}{\sqrt{1-e^{2x}}} = \int \frac{1}{\sqrt{1-u^2}}\left(\frac{du}{u}\right) \qquad \left[\begin{array}{l} u = e^x, \\ du = e^x\,dx,\ dx = du/u \end{array}\right]$$

$$\overset{35}{=} -\frac{1}{1}\ln\left|\frac{1+\sqrt{1-u^2}}{u}\right| + C = -\ln\left|\frac{1+\sqrt{1-e^{2x}}}{e^x}\right| + C = -\ln\left(\frac{1+\sqrt{1-e^{2x}}}{e^x}\right) + C$$

29. Let $u = e^x$. Then $x = \ln u$, $dx = du/u$, so

$$\int \sqrt{e^{2x}-1}\,dx = \int \frac{\sqrt{u^2-1}}{u}\,du \overset{41}{=} \sqrt{u^2-1} - \cos^{-1}(1/u) + C = \sqrt{e^{2x}-1} - \cos^{-1}(e^{-x}) + C.$$

30. Let $u = \alpha t - 3$ and assume that $\alpha \neq 0$. Then $du = \alpha\,dt$ and

$$\int e^t \sin(\alpha t - 3)\,dt = \frac{1}{\alpha}\int e^{(u+3)/\alpha}\sin u\,du = \frac{1}{\alpha}e^{3/\alpha}\int e^{(1/\alpha)u}\sin u\,du$$

$$\overset{98}{=} \frac{1}{\alpha}e^{3/\alpha}\frac{e^{(1/\alpha)u}}{(1/\alpha)^2+1^2}\left(\frac{1}{\alpha}\sin u - \cos u\right) + C = \frac{1}{\alpha}e^{3/\alpha}e^{(1/\alpha)u}\frac{\alpha^2}{1+\alpha^2}\left(\frac{1}{\alpha}\sin u - \cos u\right) + C$$

$$= \frac{1}{1+\alpha^2}e^{(u+3)/\alpha}(\sin u - \alpha\cos u) + C = \frac{1}{1+\alpha^2}\,e^t\left[\sin(\alpha t - 3) - \alpha\cos(\alpha t - 3)\right] + C$$

31. $$\int \frac{x^4\,dx}{\sqrt{x^{10}-2}} = \int \frac{x^4\,dx}{\sqrt{(x^5)^2-2}} = \frac{1}{5}\int \frac{du}{\sqrt{u^2-2}} \qquad \left[\begin{array}{l} u = x^5, \\ du = 5x^4\,dx \end{array}\right]$$

$$\overset{43}{=} \tfrac{1}{5}\ln\left|u + \sqrt{u^2-2}\right| + C = \tfrac{1}{5}\ln\left|x^5 + \sqrt{x^{10}-2}\right| + C$$

32. Let $u = \tan\theta$ and $a = 3$. Then $du = \sec^2\theta\,d\theta$ and

$$\int \frac{\sec^2\theta\,\tan^2\theta}{\sqrt{9-\tan^2\theta}}\,d\theta = \int \frac{u^2}{\sqrt{a^2-u^2}}\,du \overset{34}{=} -\frac{u}{2}\sqrt{a^2-u^2} + \frac{a^2}{2}\sin^{-1}\left(\frac{u}{a}\right) + C$$

$$= -\frac{1}{2}\tan\theta\,\sqrt{9-\tan^2\theta} + \frac{9}{2}\sin^{-1}\left(\frac{\tan\theta}{3}\right) + C$$

33. Use disks about the x-axis:

$$V = \int_0^\pi \pi(\sin^2 x)^2\,dx = \pi\int_0^\pi \sin^4 x\,dx \overset{73}{=} \pi\left\{\left[-\tfrac{1}{4}\sin^3 x\,\cos x\right]_0^\pi + \tfrac{3}{4}\int_0^\pi \sin^2 x\,dx\right\}$$

$$\overset{63}{=} \pi\left\{0 + \tfrac{3}{4}\left[\tfrac{1}{2}x - \tfrac{1}{4}\sin 2x\right]_0^\pi\right\} = \pi\left[\tfrac{3}{4}\left(\tfrac{1}{2}\pi - 0\right)\right] = \tfrac{3}{8}\pi^2$$

34. Use shells about the y-axis:

$$V = \int_0^1 2\pi x \arcsin x\,dx \overset{90}{=} 2\pi\left[\frac{2x^2-1}{4}\sin^{-1}x + \frac{x\sqrt{1-x^2}}{4}\right]_0^1 = 2\pi\left[\left(\frac{1}{4}\cdot\frac{\pi}{2} + 0\right) - 0\right] = \frac{1}{4}\pi^2$$

35. (a) $$\frac{d}{du}\left[\frac{1}{b^3}\left(a + bu - \frac{a^2}{a+bu} - 2a\ln|a+bu|\right) + C\right] = \frac{1}{b^3}\left[b + \frac{ba^2}{(a+bu)^2} - \frac{2ab}{(a+bu)}\right]$$

$$= \frac{1}{b^3}\left[\frac{b(a+bu)^2 + ba^2 - (a+bu)2ab}{(a+bu)^2}\right]$$

$$= \frac{1}{b^3}\left[\frac{b^3u^2}{(a+bu)^2}\right] = \frac{u^2}{(a+bu)^2}$$

(b) Let $t = a + bu \quad \Rightarrow \quad dt = b\,du$. Note that $u = \dfrac{t-a}{b}$ and $du = \dfrac{1}{b}\,dt$.

$$\int \frac{u^2\,du}{(a+bu)^2} = \frac{1}{b^3}\int \frac{(t-a)^2}{t^2}\,dt = \frac{1}{b^3}\int \frac{t^2 - 2at + a^2}{t^2}\,dt = \frac{1}{b^3}\int\left(1 - \frac{2a}{t} + \frac{a^2}{t^2}\right)dt$$

$$= \frac{1}{b^3}\left(t - 2a\ln|t| - \frac{a^2}{t}\right) + C = \frac{1}{b^3}\left(a + bu - \frac{a^2}{a+bu} - 2a\ln|a+bu|\right) + C$$

36. (a) $\dfrac{d}{du}\left[\dfrac{u}{8}(2u^2 - a^2)\sqrt{a^2-u^2} + \dfrac{a^4}{8}\sin^{-1}\dfrac{u}{a} + C\right]$

$$= \frac{u}{8}(2u^2-a^2)\frac{-u}{\sqrt{a^2-u^2}} + \sqrt{a^2-u^2}\left[\frac{u}{8}(4u) + (2u^2-a^2)\,\tfrac{1}{8}\right] + \frac{a^4}{8}\frac{1/a}{\sqrt{1-u^2/a^2}}$$

$$= -\frac{u^2(2u^2-a^2)}{8\sqrt{a^2-u^2}} + \sqrt{a^2-u^2}\left[\frac{u^2}{2} + \frac{2u^2-a^2}{8}\right] + \frac{a^4}{8\sqrt{a^2-u^2}}$$

$$= \tfrac{1}{2}(a^2-u^2)^{-1/2}\left[-\frac{u^2}{4}(2u^2-a^2) + u^2(a^2-u^2) + \tfrac{1}{4}(a^2-u^2)(2u^2-a^2) + \frac{a^4}{4}\right]$$

$$= \tfrac{1}{2}(a^2-u^2)^{-1/2}[2u^2a^2 - 2u^4] = \frac{u^2(a^2-u^2)}{\sqrt{a^2-u^2}} = u^2\sqrt{a^2-u^2}$$

(b) Let $u = a\sin\theta \quad \Rightarrow \quad du = a\cos\theta\,d\theta$. Then

$$\int u^2\sqrt{a^2-u^2}\,du = \int a^2\sin^2\theta\,a\sqrt{1-\sin^2\theta}\,a\cos\theta\,d\theta = a^4\int \sin^2\theta\,\cos^2\theta\,d\theta$$

$$= a^4\int \tfrac{1}{2}(1+\cos 2\theta)\tfrac{1}{2}(1-\cos 2\theta)\,d\theta = \tfrac{1}{4}a^4\int(1-\cos^2 2\theta)\,d\theta$$

$$= \tfrac{1}{4}a^4\int\left[1 - \tfrac{1}{2}(1+\cos 4\theta)\right]d\theta = \tfrac{1}{4}a^4\left(\tfrac{1}{2}\theta - \tfrac{1}{8}\sin 4\theta\right) + C$$

$$= \tfrac{1}{4}a^4\left(\tfrac{1}{2}\theta - \tfrac{1}{8}\cdot 2\sin 2\theta\,\cos 2\theta\right) + C = \tfrac{1}{4}a^4\left[\tfrac{1}{2}\theta - \tfrac{1}{2}\sin\theta\,\cos\theta(1-2\sin^2\theta)\right] + C$$

$$= \frac{a^4}{8}\left[\sin^{-1}\frac{u}{a} - \frac{u}{a}\frac{\sqrt{a^2-u^2}}{a}\left(1 - \frac{2u^2}{a^2}\right)\right] + C = \frac{a^4}{8}\left[\sin^{-1}\frac{u}{a} - \frac{u}{a}\frac{\sqrt{a^2-u^2}}{a}\frac{a^2-2u^2}{a^2}\right] + C$$

$$= \frac{u}{8}(2u^2-a^2)\sqrt{a^2-u^2} + \frac{a^4}{8}\sin^{-1}\frac{u}{a} + C$$

37. Maple and Mathematica both give $\int \sec^4 x\,dx = \frac{2}{3}\tan x + \frac{1}{3}\tan x\,\sec^2 x$, while Derive gives the second term as $\dfrac{\sin x}{3\cos^3 x} = \dfrac{1}{3}\dfrac{\sin x}{\cos x}\dfrac{1}{\cos^2 x} = \dfrac{1}{3}\tan x\,\sec^2 x$. Using Formula 77, we get

$\int \sec^4 x\,dx = \frac{1}{3}\tan x\,\sec^2 x + \frac{2}{3}\int\sec^2 x\,dx = \frac{1}{3}\tan x\,\sec^2 x + \frac{2}{3}\tan x + C.$

38. Derive gives $\int \csc^5 x\,dx = \dfrac{3}{8}\ln\!\left(\tan\!\left(\dfrac{x}{2}\right)\right) - \cos x\left(\dfrac{3}{8\sin^2 x} + \dfrac{1}{4\sin^4 x}\right)$ and Maple gives

$-\dfrac{1}{4}\dfrac{\cos x}{\sin^4 x} - \dfrac{3}{8}\dfrac{\cos x}{\sin^2 x} + \dfrac{3}{8}\ln(\csc x - \cot x)$. Using a half-angle identity for tangent, $\tan\dfrac{x}{2} = \dfrac{1-\cos x}{\sin x}$, we have

$\ln\tan\dfrac{x}{2} = \ln\dfrac{1-\cos x}{\sin x} = \ln\!\left(\dfrac{1}{\sin x} - \dfrac{\cos x}{\sin x}\right) = \ln(\csc x - \cot x)$, so those two answers are equivalent.

Mathematica gives

$$\begin{aligned} I &= -\frac{3}{32}\csc^2\frac{x}{2} - \frac{1}{64}\csc^4\frac{x}{2} - \frac{3}{8}\log\cos\frac{x}{2} + \frac{3}{8}\log\sin\frac{x}{2} + \frac{3}{32}\sec^2\frac{x}{2} + \frac{1}{64}\sec^4\frac{x}{2} \\ &= \frac{3}{8}\left(\log\sin\frac{x}{2} - \log\cos\frac{x}{2}\right) + \frac{3}{32}\left(\sec^2\frac{x}{2} - \csc^2\frac{x}{2}\right) + \frac{1}{64}\left(\sec^4\frac{x}{2} - \csc^4\frac{x}{2}\right) \\ &= \frac{3}{8}\log\frac{\sin(x/2)}{\cos(x/2)} + \frac{3}{32}\left[\frac{1}{\cos^2(x/2)} - \frac{1}{\sin^2(x/2)}\right] + \frac{1}{64}\left[\frac{1}{\cos^4(x/2)} - \frac{1}{\sin^4(x/2)}\right] \\ &= \frac{3}{8}\log\tan\frac{x}{2} + \frac{3}{32}\left[\frac{\sin^2(x/2)-\cos^2(x/2)}{\cos^2(x/2)\,\sin^2(x/2)}\right] + \frac{1}{64}\left[\frac{\sin^4(x/2)-\cos^4(x/2)}{\cos^4(x/2)\,\sin^4(x/2)}\right] \end{aligned}$$

Now
$$\frac{\sin^2(x/2)-\cos^2(x/2)}{\cos^2(x/2)\,\sin^2(x/2)} = \frac{\dfrac{1-\cos x}{2} - \dfrac{1+\cos x}{2}}{\dfrac{1+\cos x}{2}\cdot\dfrac{1-\cos x}{2}} = \frac{-\dfrac{2\cos x}{2}}{\dfrac{1-\cos^2 x}{4}} = \frac{-4\cos x}{\sin^2 x}$$

and
$$\begin{aligned} \frac{\sin^4(x/2)-\cos^4(x/2)}{\cos^4(x/2)\,\sin^4(x/2)} &= \frac{\sin^2(x/2)-\cos^2(x/2)}{\cos^2(x/2)\,\sin^2(x/2)}\,\frac{\sin^2(x/2)+\cos^2(x/2)}{\cos^2(x/2)\,\sin^2(x/2)} \\ &= \frac{-4\cos x}{\sin^2 x}\,\frac{1}{\dfrac{1+\cos x}{2}\cdot\dfrac{1-\cos x}{2}} = -\frac{4\cos x}{\sin^2 x}\,\frac{4}{1-\cos^2 x} = -\frac{16\cos x}{\sin^4 x} \end{aligned}$$

Returning to the expression for I, we get

$$I = \frac{3}{8}\log\tan\frac{x}{2} + \frac{3}{32}\left(\frac{-4\cos x}{\sin^2 x}\right) + \frac{1}{64}\left(\frac{-16\cos x}{\sin^4 x}\right) = \frac{3}{8}\log\tan\frac{x}{2} - \frac{3}{8}\frac{\cos x}{\sin^2 x} - \frac{1}{4}\frac{\cos x}{\sin^4 x},$$

so all are equivalent.

Now use Formula 78 to get

$$\begin{aligned} \int \csc^5 x\,dx &= \frac{-1}{4}\cot x\,\csc^3 x + \frac{3}{4}\int \csc^3 x\,dx = -\frac{1}{4}\frac{\cos x}{\sin x}\frac{1}{\sin^3 x} + \frac{3}{4}\left(\frac{-1}{2}\cot x\csc x + \frac{1}{2}\int \csc x\,dx\right) \\ &= -\frac{1}{4}\frac{\cos x}{\sin^4 x} - \frac{3}{8}\frac{\cos x}{\sin x}\frac{1}{\sin x} + \frac{3}{8}\int \csc x\,dx = -\frac{1}{4}\frac{\cos x}{\sin^4 x} - \frac{3}{8}\frac{\cos x}{\sin^2 x} + \frac{3}{8}\ln|\csc x - \cot x| + C \end{aligned}$$

39. Derive gives $\int x^2\sqrt{x^2+4}\,dx = \frac{1}{4}x(x^2+2)\sqrt{x^2+4} - 2\ln\left(\sqrt{x^2+4}+x\right)$. Maple gives $\frac{1}{4}x(x^2+4)^{3/2} - \frac{1}{2}x\sqrt{x^2+4} - 2\,\mathrm{arcsinh}\left(\frac{1}{2}x\right)$. Applying the command `convert(%,ln);` yields

$$\begin{aligned} \tfrac{1}{4}x(x^2+4)^{3/2} - \tfrac{1}{2}x\sqrt{x^2+4} - 2\ln\left(\tfrac{1}{2}x + \tfrac{1}{2}\sqrt{x^2+4}\right) &= \tfrac{1}{4}x(x^2+4)^{1/2}\left[(x^2+4)-2\right] - 2\ln\left[\left(x+\sqrt{x^2+4}\right)/2\right] \\ &= \tfrac{1}{4}x(x^2+2)\sqrt{x^2+4} - 2\ln\left(\sqrt{x^2+4}+x\right) + 2\ln 2 \end{aligned}$$

Mathematica gives $\frac{1}{4}x(2+x^2)\sqrt{3+x^2} - 2\,\mathrm{arcsinh}(x/2)$. Applying the `TrigToExp` and `Simplify` commands gives $\frac{1}{4}\left[x(2+x^2)\sqrt{4+x^2} - 8\log\left(\frac{1}{2}\left(x+\sqrt{4+x^2}\right)\right)\right] = \frac{1}{4}x(x^2+2)\sqrt{x^2+4} - 2\ln\left(x+\sqrt{4+x^2}\right) + 2\ln 2$, so all are equivalent (without constant).

Now use Formula 22 to get

$$\begin{aligned} \int x^2\sqrt{2^2+x^2}\,dx &= \frac{x}{8}(2^2+2x^2)\sqrt{2^2+x^2} - \frac{2^4}{8}\ln\left(x+\sqrt{2^2+x^2}\right) + C \\ &= \frac{x}{8}(2)(2+x^2)\sqrt{4+x^2} - 2\ln\left(x+\sqrt{4+x^2}\right) + C \\ &= \tfrac{1}{4}x(x^2+2)\sqrt{x^2+4} - 2\ln\left(\sqrt{x^2+4}+x\right) + C \end{aligned}$$

40. Derive gives $\displaystyle\int \frac{dx}{e^x(3e^x+2)} = -\frac{e^{-x}}{2} + \frac{3\ln(3e^x+2)}{4} - \frac{3x}{4}$, Maple gives $\displaystyle\frac{3}{4}\ln(3e^x+2) - \frac{1}{2e^x} - \frac{3}{4}\ln(e^x)$, and Mathematica gives

$$-\frac{e^{-x}}{2} + \frac{3}{4}\log(3+2e^{-x}) = -\frac{e^{-x}}{2} + \frac{3}{4}\log\left(\frac{3e^x+2}{e^x}\right) = -\frac{e^{-x}}{2} + \frac{3}{4}\frac{\ln(3e^x+2)}{\ln e^x} = -\frac{e^{-x}}{2} + \frac{3}{4}\ln(3e^x+2) - \frac{3}{4}x,$$

so all are equivalent. Now let $u = e^x$, so $du = e^x\,dx$ and $dx = du/u$. Then

$$\int \frac{1}{e^x(3e^x+2)}\,dx = \int \frac{1}{u(3u+2)}\,\frac{du}{u} = \int \frac{1}{u^2(2+3u)}\,du \overset{50}{=} -\frac{1}{2u} + \frac{3}{2^2}\ln\left|\frac{2+3u}{u}\right| + C$$
$$= -\frac{1}{2e^x} + \frac{3}{4}\ln(2+3e^x) - \frac{3}{4}\ln e^x + C = -\frac{1}{2e^x} + \frac{3}{4}\ln(3e^x+2) - \frac{3}{4}x + C$$

41. Derive and Maple give $\displaystyle\int \cos^4 x\,dx = \frac{\sin x\,\cos^3 x}{4} + \frac{3\sin x\,\cos x}{8} + \frac{3x}{8}$, while Mathematica gives

$$\frac{3x}{8} + \frac{1}{4}\sin(2x) + \frac{1}{32}\sin(4x) = \frac{3x}{8} + \frac{1}{4}(2\sin x\,\cos x) + \frac{1}{32}(2\sin 2x\,\cos 2x)$$
$$= \frac{3x}{8} + \frac{1}{2}\sin x\,\cos x + \frac{1}{16}[2\sin x\,\cos x\,(2\cos^2 x - 1)]$$
$$= \frac{3x}{8} + \frac{1}{2}\sin x\,\cos x + \frac{1}{4}\sin x\,\cos^3 x - \frac{1}{8}\sin x\,\cos x,$$

so all are equivalent.

Using tables,

$$\int \cos^4 x\,dx \overset{74}{=} \tfrac{1}{4}\cos^3 x\,\sin x + \tfrac{3}{4}\int \cos^2 x\,dx \overset{64}{=} \tfrac{1}{4}\cos^3 x\,\sin x + \tfrac{3}{4}\left(\tfrac{1}{2}x + \tfrac{1}{4}\sin 2x\right) + C$$
$$= \tfrac{1}{4}\cos^3 x\,\sin x + \tfrac{3}{8}x + \tfrac{3}{16}(2\sin x\,\cos x) + C = \tfrac{1}{4}\cos^3 x\,\sin x + \tfrac{3}{8}x + \tfrac{3}{8}\sin x\,\cos x + C$$

42. Derive gives $\displaystyle\int x^2\sqrt{1-x^2}\,dx = \frac{\arcsin x}{8} + \frac{x\sqrt{1-x^2}(2x^2-1)}{8}$, Maple gives

$$-\frac{x}{4}(1-x^2)^{3/2} + \frac{x}{8}\sqrt{1-x^2} + \frac{1}{8}\arcsin x = \frac{x}{8}(1-x^2)^{1/2}[-2(1-x^2)+1] + \frac{1}{8}\arcsin x$$
$$= \frac{x}{8}(1-x^2)^{1/2}(2x^2-1) + \frac{1}{8}\arcsin x,$$

and Mathematica gives $\frac{1}{8}\left(x\sqrt{1-x^2}(-1+2x^2) + \arcsin x\right)$, so all are equivalent.

Now use Formula 31 to get

$$\int x^2\sqrt{1-x^2}\,dx = \frac{x}{8}(2x^2-1)\sqrt{1-x^2} + \frac{1}{8}\sin^{-1} x + C$$

43. Maple gives $\int \tan^5 x\,dx = \frac{1}{4}\tan^4 x - \frac{1}{2}\tan^2 x + \frac{1}{2}\ln(1+\tan^2 x)$, Mathematica gives $\int \tan^5 x\,dx = \frac{1}{4}[-1-2\cos(2x)]\sec^4 x - \ln(\cos x)$, and Derive gives $\int \tan^5 x\,dx = \frac{1}{4}\tan^4 x - \frac{1}{2}\tan^2 x - \ln(\cos x)$. These expressions are equivalent, and none includes absolute value bars or a constant of integration. Note that Mathematica's and Derive's expressions suggest that the integral is undefined where $\cos x < 0$, which is not the case. Using Formula 75, $\int \tan^5 x\,dx = \frac{1}{5-1}\tan^{5-1} x - \int \tan^{5-2} x\,dx = \frac{1}{4}\tan^4 x - \int \tan^3 x\,dx$. Using Formula 69, $\int \tan^3 x\,dx = \frac{1}{2}\tan^2 x + \ln|\cos x| + C$, so $\int \tan^5 x\,dx = \frac{1}{4}\tan^4 x - \frac{1}{2}\tan^2 x - \ln|\cos x| + C$.

44. Derive, Maple, and Mathematica all give $\int \frac{1}{\sqrt{1+\sqrt[3]{x}}}\,dx = \frac{2}{5}\sqrt{\sqrt[3]{x}+1}\left(3\sqrt[3]{x^2} - 4\sqrt[3]{x} + 8\right)$. [Maple adds a constant of $-\frac{16}{5}$.] We'll change the form of the integral by letting $u = \sqrt[3]{x}$, so that $u^3 = x$ and $3u^2\,du = dx$. Then

$$\int \frac{1}{\sqrt{1+\sqrt[3]{x}}}\,dx = \int \frac{3u^2\,du}{\sqrt{1+u}} \overset{56}{=} 3\left[\frac{2}{15(1)^3}\left(8(1)^2 + 3(1)^2u^2 - 4(1)(1)u\right)\sqrt{1+u}\right] + C$$

$$= \tfrac{2}{5}(8 + 3u^2 - 4u)\sqrt{1+u} + C = \tfrac{2}{5}\left(8 + 3\sqrt[3]{x^2} - 4\sqrt[3]{x}\right)\sqrt{1+\sqrt[3]{x}} + C$$

45. (a) $F(x) = \int f(x)\,dx = \int \frac{1}{x\sqrt{1-x^2}}\,dx \overset{35}{=} -\frac{1}{1}\ln\left|\frac{1+\sqrt{1-x^2}}{x}\right| + C = -\ln\left|\frac{1+\sqrt{1-x^2}}{x}\right| + C.$

f has domain $\{x \mid x \neq 0, 1 - x^2 > 0\} = \{x \mid x \neq 0,\ |x| < 1\} = (-1, 0) \cup (0, 1)$. F has the same domain.

(b) Derive gives $F(x) = \ln\left(\sqrt{1-x^2} - 1\right) - \ln x$ and Mathematica gives $F(x) = \ln x - \ln\left(1 + \sqrt{1-x^2}\right)$. Both are correct if you take absolute values of the logarithm arguments, and both would then have the same domain. Maple gives $F(x) = -\operatorname{arctanh}\left(1/\sqrt{1-x^2}\right)$. This function has domain $\left\{x \mid |x| < 1, -1 < 1/\sqrt{1-x^2} < 1\right\} = \left\{x \mid |x| < 1, 1/\sqrt{1-x^2} < 1\right\} = \left\{x \mid |x| < 1, \sqrt{1-x^2} > 1\right\} = \emptyset$, the empty set! If we apply the command `convert(%,ln);` to Maple's answer, we get $-\frac{1}{2}\ln\left(\frac{1}{\sqrt{1-x^2}} + 1\right) + \frac{1}{2}\ln\left(1 - \frac{1}{\sqrt{1-x^2}}\right)$, which has the same domain, $\emptyset$.

46. None of Maple, Mathematica and Derive is able to evaluate $\int (1 + \ln x)\sqrt{1 + (x\ln x)^2}\,dx$. However, if we let $u = x\ln x$, then $du = (1 + \ln x)\,dx$ and the integral is simply $\int \sqrt{1+u^2}\,du$, which any CAS can evaluate. The antiderivative is $\frac{1}{2}\ln\left(x\ln x + \sqrt{1 + (x\ln x)^2}\right) + \frac{1}{2}x\ln x\sqrt{1 + (x\ln x)^2} + C$.

DISCOVERY PROJECT Patterns in Integrals

1. (a) The CAS results are listed. Note that the absolute value symbols are missing, as is the familiar "$+\,C$".

(i) $\int \frac{1}{(x+2)(x+3)}\,dx = \ln(x+2) - \ln(x+3)$ (ii) $\int \frac{1}{(x+1)(x+5)}\,dx = \frac{\ln(x+1)}{4} - \frac{\ln(x+5)}{4}$

(iii) $\int \frac{1}{(x+2)(x-5)}\,dx = \frac{\ln(x-5)}{7} - \frac{\ln(x+2)}{7}$ (iv) $\int \frac{1}{(x+2)^2}\,dx = -\frac{1}{x+2}$

(b) If $a \neq b$, it appears that $\ln(x+a)$ is divided by $b - a$ and $\ln(x+b)$ is divided by $a - b$, so we guess that $\int \frac{1}{(x+a)(x+b)}\,dx = \frac{\ln(x+a)}{b-a} + \frac{\ln(x+b)}{a-b} + C$. If $a = b$, as in part (a)(iv), it appears that $\int \frac{1}{(x+a)^2}\,dx = -\frac{1}{x+a} + C$.

(c) The CAS verifies our guesses. Now $\frac{1}{(x+a)(x+b)} = \frac{A}{x+a} + \frac{B}{x+b} \quad\Rightarrow\quad 1 = A(x+b) + B(x+a)$.

Setting $x = -b$ gives $B = 1/(a-b)$ and setting $x = -a$ gives $A = 1/(b-a)$. So

$$\int \frac{1}{(x+a)(x+b)}\,dx = \int \left[\frac{1/(b-a)}{x+a} + \frac{1/(a-b)}{x+b}\right] dx = \frac{\ln|x+a|}{b-a} + \frac{\ln|x+b|}{a-b} + C$$

[continued]

and our guess for $a \neq b$ is correct. If $a = b$, then $\dfrac{1}{(x+a)(x+b)} = \dfrac{1}{(x+a)^2} = (x+a)^{-2}$. Letting $u = x + a \Rightarrow$ $du = dx$, we have $\displaystyle\int (x+a)^{-2}\,dx = \int u^{-2}\,du = -\frac{1}{u} + C = -\frac{1}{x+a} + C$, and our guess for $a = b$ is also correct.

2. (a) (i) $\displaystyle\int \sin x\, \cos 2x\, dx = \frac{\cos x}{2} - \frac{\cos 3x}{6}$ (ii) $\displaystyle\int \sin 3x\, \cos 7x\, dx = \frac{\cos 4x}{8} - \frac{\cos 10x}{20}$

(iii) $\displaystyle\int \sin 8x\, \cos 3x\, dx = -\frac{\cos 11x}{22} - \frac{\cos 5x}{10}$

(b) Looking at the sums and differences of a and b in part (a), we guess that

$$\int \sin ax\, \cos bx\, dx = \frac{\cos((a-b)x)}{2(b-a)} - \frac{\cos((a+b)x)}{2(a+b)} + C$$

Note that $\cos((a-b)x) = \cos((b-a)x)$.

(c) The CAS verifies our guess. Again, we can prove that the guess is correct by differentiating:

$$\begin{aligned}\frac{d}{dx}\left[\frac{\cos((a-b)x)}{2(b-a)} - \frac{\cos((a+b)x)}{2(a+b)}\right] &= \frac{1}{2(b-a)}\,[-\sin((a-b)x)](a-b) - \frac{1}{2(a+b)}\,[-\sin((a+b)x)](a+b)\\ &= \tfrac{1}{2}\sin(ax-bx) + \tfrac{1}{2}\sin(ax+bx)\\ &= \tfrac{1}{2}(\sin ax\, \cos bx - \cos ax\, \sin bx) + \tfrac{1}{2}(\sin ax\, \cos bx + \cos ax\, \sin bx)\\ &= \sin ax\, \cos bx\end{aligned}$$

Our formula is valid for $a \neq b$.

3. (a) (i) $\int \ln x\, dx = x\ln x - x$ (ii) $\int x\ln x\, dx = \frac{1}{2}x^2\ln x - \frac{1}{4}x^2$

(iii) $\int x^2\ln x\, dx = \frac{1}{3}x^3\ln x - \frac{1}{9}x^3$ (iv) $\int x^3\ln x\, dx = \frac{1}{4}x^4\ln x - \frac{1}{16}x^4$

(v) $\int x^7\ln x\, dx = \frac{1}{8}x^8\ln x - \frac{1}{64}x^8$

(b) We guess that $\int x^n \ln x\, dx = \dfrac{1}{n+1}x^{n+1}\ln x - \dfrac{1}{(n+1)^2}x^{n+1}$.

(c) Let $u = \ln x$, $dv = x^n\,dx \Rightarrow du = \dfrac{dx}{x}$, $v = \dfrac{1}{n+1}x^{n+1}$. Then

$$\int x^n \ln x\, dx = \frac{1}{n+1}x^{n+1}\ln x - \frac{1}{n+1}\int x^n\, dx = \frac{1}{n+1}x^{n+1}\ln x - \frac{1}{n+1}\cdot\frac{1}{n+1}x^{n+1},$$

which verifies our guess. We must have $n + 1 \neq 0 \Leftrightarrow n \neq -1$.

4. (a) (i) $\int xe^x\, dx = e^x(x-1)$ (ii) $\int x^2e^x\, dx = e^x(x^2 - 2x + 2)$

(iii) $\int x^3e^x\, dx = e^x(x^3 - 3x^2 + 6x - 6)$ (iv) $\int x^4e^x\, dx = e^x(x^4 - 4x^3 + 12x^2 - 24x + 24)$

(v) $\int x^5e^x\, dx = e^x\left(x^5 - 5x^4 + 20x^3 - 60x^2 + 120x - 120\right)$

(b) Notice from part (a) that we can write

$$\int x^4e^x\, dx = e^x(x^4 - 4x^3 + 4\cdot 3x^2 - 4\cdot 3\cdot 2x + 4\cdot 3\cdot 2\cdot 1)$$

and $$\int x^5e^x\, dx = e^x(x^5 - 5x^4 + 5\cdot 4x^3 - 5\cdot 4\cdot 3x^2 + 5\cdot 4\cdot 3\cdot 2x - 5\cdot 4\cdot 3\cdot 2\cdot 1)$$

So we guess that

$$\int x^6 e^x\,dx = e^x(x^6 - 6x^5 + 6\cdot 5x^4 - 6\cdot 5\cdot 4x^3 + 6\cdot 5\cdot 4\cdot 3x^2 - 6\cdot 5\cdot 4\cdot 3\cdot 2x + 6\cdot 5\cdot 4\cdot 3\cdot 2\cdot 1)$$
$$= e^x(x^6 - 6x^5 + 30x^4 - 120x^3 + 360x^2 - 720x + 720)$$

The CAS verifies our guess.

(c) From the results in part (a), as well as our prediction in part (b), we speculate that

$$\int x^n e^x\,dx = e^x\left[x^n - nx^{n-1} + n(n-1)x^{n-2} - n(n-1)(n-2)x^{n-3} + \cdots \pm n!x \mp n!\right] = e^x \sum_{i=0}^{n}(-1)^{n-i}\frac{n!}{i!}\,x^i.$$

(We have reversed the order of the polynomial's terms.)

(d) Let S_n be the statement that $\int x^n e^x\,dx = e^x \sum_{i=0}^{n}(-1)^{n-i}\frac{n!}{i!}\,x^i$.

S_1 is true by part (a)(i). Suppose S_k is true for some k, and consider S_{k+1}. Integrating by parts with $u = x^{k+1}$, $dv = e^x\,dx \;\Rightarrow\; du = (k+1)x^k\,dx$, $v = e^x$, we get

$$\int x^{k+1}e^x\,dx = x^{k+1}e^x - (k+1)\int x^k e^x\,dx = x^{k+1}e^x - (k+1)\left[e^x \sum_{i=0}^{k}(-1)^{k-i}\frac{k!}{i!}\,x^i\right]$$
$$= e^x\left[x^{k+1} - (k+1)\sum_{i=0}^{k}(-1)^{k-i}\frac{k!}{i!}\,x^i\right] = e^x\left[x^{k+1} + \sum_{i=0}^{k}(-1)^{k-i+1}\frac{(k+1)k!}{i!}\,x^i\right]$$
$$= e^x \sum_{i=0}^{k+1}(-1)^{(k+1)-i}\frac{(k+1)!}{i!}\,x^i$$

This verifies S_n for $n = k+1$. Thus, by mathematical induction, S_n is true for all n, where n is a positive integer.

7.7 Approximate Integration

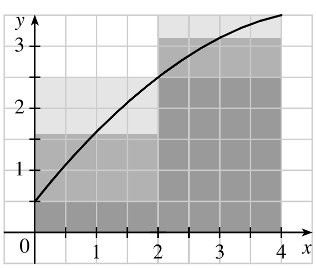
1. (a) $\Delta x = (b-a)/n = (4-0)/2 = 2$

$L_2 = \sum_{i=1}^{2} f(x_{i-1})\,\Delta x = f(x_0)\cdot 2 + f(x_1)\cdot 2 = 2\,[f(0) + f(2)] = 2(0.5 + 2.5) = 6$

$R_2 = \sum_{i=1}^{2} f(x_i)\,\Delta x = f(x_1)\cdot 2 + f(x_2)\cdot 2 = 2\,[f(2) + f(4)] = 2(2.5 + 3.5) = 12$

$M_2 = \sum_{i=1}^{2} f(\overline{x}_i)\Delta x = f(\overline{x}_1)\cdot 2 + f(\overline{x}_2)\cdot 2 = 2\,[f(1) + f(3)] \approx 2(1.6 + 3.2) = 9.6$

(b)



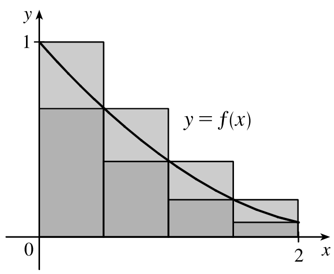
L_2 is an underestimate, since the area under the small rectangles is less than the area under the curve, and R_2 is an overestimate, since the area under the large rectangles is greater than the area under the curve. It appears that M_2 is an overestimate, though it is fairly close to I. See the solution to Exercise 47 for a proof of the fact that if f is concave down on $[a, b]$, then the Midpoint Rule is an overestimate of $\int_a^b f(x)\,dx$.

(c) $T_2 = \left(\frac{1}{2}\,\Delta x\right)[f(x_0) + 2f(x_1) + f(x_2)] = \frac{2}{2}[f(0) + 2f(2) + f(4)] = 0.5 + 2(2.5) + 3.5 = 9.$

This approximation is an underestimate, since the graph is concave down. Thus, $T_2 = 9 < I$. See the solution to Exercise 47 for a general proof of this conclusion.

(d) For any n, we will have $L_n < T_n < I < M_n < R_n$.

2.



The diagram shows that $L_4 > T_4 > \int_0^2 f(x)\,dx > R_4$, and it appears that M_4 is a bit less than $\int_0^2 f(x)\,dx$. In fact, for any function that is concave upward, it can be shown that $L_n > T_n > \int_0^2 f(x)\,dx > M_n > R_n$.

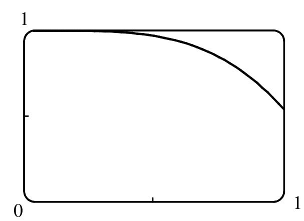
(a) Since $0.9540 > 0.8675 > 0.8632 > 0.7811$, it follows that $L_n = 0.9540$, $T_n = 0.8675$, $M_n = 0.8632$, and $R_n = 0.7811$.

(b) Since $M_n < \int_0^2 f(x)\,dx < T_n$, we have $0.8632 < \int_0^2 f(x)\,dx < 0.8675$.

3. $f(x) = \cos\left(x^2\right)$, $\Delta x = \frac{1-0}{4} = \frac{1}{4}$

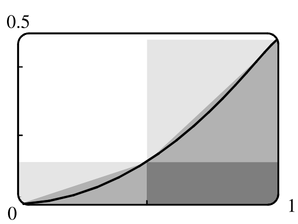
(a) $T_4 = \frac{1}{4 \cdot 2}\left[f(0) + 2f\left(\frac{1}{4}\right) + 2f\left(\frac{2}{4}\right) + 2f\left(\frac{3}{4}\right) + f(1)\right] \approx 0.895759$

(b) $M_4 = \frac{1}{4}\left[f\left(\frac{1}{8}\right) + f\left(\frac{3}{8}\right) + f\left(\frac{5}{8}\right) + f\left(\frac{7}{8}\right)\right] \approx 0.908907$



The graph shows that f is concave down on $[0, 1]$. So T_4 is an underestimate and M_4 is an overestimate. We can conclude that $0.895759 < \int_0^1 \cos\left(x^2\right) dx < 0.908907$.

4.



(a) Since f is increasing on $[0, 1]$, L_2 will underestimate I (since the area of the darkest rectangle is less than the area under the curve), and R_2 will overestimate I. Since f is concave upward on $[0, 1]$, M_2 will underestimate I and T_2 will overestimate I (the area under the straight line segments is greater than the area under the curve).

(b) For any n, we will have $L_n < M_n < I < T_n < R_n$.

(c) $L_5 = \sum\limits_{i=1}^{5} f(x_{i-1})\,\Delta x = \frac{1}{5}[f(0.0) + f(0.2) + f(0.4) + f(0.6) + f(0.8)] \approx 0.1187$

$R_5 = \sum\limits_{i=1}^{5} f(x_i)\,\Delta x = \frac{1}{5}[f(0.2) + f(0.4) + f(0.6) + f(0.8) + f(1)] \approx 0.2146$

$M_5 = \sum\limits_{i=1}^{5} f(\overline{x}_i)\,\Delta x = \frac{1}{5}[f(0.1) + f(0.3) + f(0.5) + f(0.7) + f(0.9)] \approx 0.1622$

$T_5 = \left(\frac{1}{2}\,\Delta x\right)[f(0) + 2f(0.2) + 2f(0.4) + 2f(0.6) + 2f(0.8) + f(1)] \approx 0.1666$

From the graph, it appears that the Midpoint Rule gives the best approximation. (This is in fact the case, since $I \approx 0.16371405$.)

5. (a) $f(x) = \dfrac{x}{1+x^2}$, $\quad \Delta x = \dfrac{b-a}{n} = \dfrac{2-0}{10} = \dfrac{1}{5}$

$M_{10} = \frac{1}{5}\left[f\left(\frac{1}{10}\right) + f\left(\frac{3}{10}\right) + f\left(\frac{5}{10}\right) + \cdots + f\left(\frac{19}{10}\right)\right] \approx 0.806598$

(b) $S_{10} = \frac{1}{5\cdot 3}\left[f(0) + 4f\left(\frac{1}{5}\right) + 2f\left(\frac{2}{5}\right) + 4f\left(\frac{3}{5}\right) + 2f\left(\frac{4}{5}\right) + \cdots + 4f\left(\frac{9}{5}\right) + f(2)\right] \approx 0.804779$

Actual: $I = \displaystyle\int_0^2 \frac{x}{1+x^2}\,dx = \left[\tfrac{1}{2}\ln\left|1+x^2\right|\right]_0^2 \qquad [u = 1+x^2,\ du = 2x\,dx]$

$= \frac{1}{2}\ln 5 - \frac{1}{2}\ln 1 = \frac{1}{2}\ln 5 \approx 0.804719$

Errors: $E_M =$ actual $- M_{10} = I - M_{10} \approx -0.001879$

$E_S =$ actual $- S_{10} = I - S_{10} \approx -0.000060$

6. (a) $f(x) = x\cos x$, $\quad \Delta x = \dfrac{b-a}{n} = \dfrac{\pi - 0}{4} = \dfrac{\pi}{4}$

$M_4 = \frac{\pi}{4}\left[f\left(\frac{\pi}{8}\right) + f\left(\frac{3\pi}{8}\right) + f\left(\frac{5\pi}{8}\right) + f\left(\frac{7\pi}{8}\right)\right] \approx -1.945744$

(b) $S_4 = \frac{\pi}{4\cdot 3}\left[f(0) + 4f\left(\frac{\pi}{4}\right) + 2f\left(\frac{2\pi}{4}\right) + 4f\left(\frac{3\pi}{4}\right) + f(\pi)\right] \approx -1.985611$

Actual: $I = \int_0^\pi x\cos x\,dx = \Big[x\sin x + \cos x\Big]_0^\pi \qquad$ [use parts with $u = x$ and $dv = \cos x\,dx$]

$= (0 + (-1)) - (0 + 1) = -2$

Errors: $E_M =$ actual $- M_4 = I - M_4 \approx -0.054256$

$E_S =$ actual $- S_4 = I - S_4 \approx -0.014389$

7. $f(x) = \sqrt{x^3 - 1}$, $\Delta x = \dfrac{b-a}{n} = \dfrac{2-1}{10} = \dfrac{1}{10}$

(a) $T_{10} = \frac{1}{10\cdot 2}[f(1) + 2f(1.1) + 2f(1.2) + 2f(1.3) + 2f(1.4) + 2f(1.5)$
$\qquad + 2f(1.6) + 2f(1.7) + 2f(1.8) + 2f(1.9) + f(2)]$

≈ 1.506361

(b) $M_{10} = \frac{1}{10}[f(1.05) + f(1.15) + f(1.25) + f(1.35) + f(1.45) + f(1.55) + f(1.65) + f(1.75) + f(1.85) + f(1.95)]$

≈ 1.518362

(c) $S_{10} = \frac{1}{10\cdot 3}[f(1) + 4f(1.1) + 2f(1.2) + 4f(1.3) + 2f(1.4)$
$\qquad + 4f(1.5) + 2f(1.6) + 4f(1.7) + 2f(1.8) + 4f(1.9) + f(2)]$

≈ 1.511519

8. $f(x) = \dfrac{1}{1+x^6}$, $\Delta x = \dfrac{b-a}{n} = \dfrac{2-0}{8} = \dfrac{1}{4}$

(a) $T_8 = \frac{1}{4\cdot 2}[f(0) + 2f(0.25) + 2f(0.5) + 2f(0.75) + 2f(1) + 2f(1.25) + 2f(1.5) + 2f(1.75) + f(2)] \approx 1.040756$

(b) $M_8 = \frac{1}{4}[f(0.125) + f(0.375) + f(0.625) + f(0.875) + f(1.125) + f(1.375) + f(1.625) + f(1.875)] \approx 1.041109$

(c) $S_8 = \frac{1}{4\cdot 3}[f(0) + 4f(0.25) + 2f(0.5) + 4f(0.75) + 2f(1) + 4f(1.25) + 2f(1.5) + 4f(1.75) + f(2)] \approx 1.042172$

9. $f(x) = \dfrac{e^x}{1+x^2}$, $\Delta x = \dfrac{b-a}{n} = \dfrac{2-0}{10} = \dfrac{1}{5}$

(a) $T_{10} = \frac{1}{5\cdot 2}[f(0) + 2f(0.2) + 2f(0.4) + 2f(0.6) + 2f(0.8) + 2f(1)$
$\qquad + 2f(1.2) + 2f(1.4) + 2f(1.6) + 2f(1.8) + f(2)]$

≈ 2.660833

(b) $M_{10} = \frac{1}{5}[f(0.1) + f(0.3) + f(0.5) + f(0.7) + f(0.9) + f(1.1) + f(1.3) + f(1.5) + f(1.7) + f(1.9)]$
≈ 2.664377

(c) $S_{10} = \frac{1}{5 \cdot 3}[f(0) + 4f(0.2) + 2f(0.4) + 4f(0.6) + 2f(0.8)$
$+ 4f(1) + 2f(1.2) + 4f(1.4) + 2f(1.6) + 4f(1.8) + f(2)] \approx 2.663244$

10. $f(x) = \sqrt[3]{1 + \cos x}$, $\Delta x = \frac{\pi/2 - 0}{4} = \frac{\pi}{8}$

(a) $T_4 = \frac{\pi}{8 \cdot 2}\left[f(0) + 2f\left(\frac{\pi}{8}\right) + 2f\left(\frac{2\pi}{8}\right) + 2f\left(\frac{3\pi}{8}\right) + f\left(\frac{\pi}{2}\right)\right] \approx 1.838967$

(b) $M_4 = \frac{\pi}{8}\left[f\left(\frac{\pi}{16}\right) + f\left(\frac{3\pi}{16}\right) + f\left(\frac{5\pi}{16}\right) + f\left(\frac{7\pi}{16}\right)\right] \approx 1.845390$

(c) $S_4 = \frac{\pi}{8 \cdot 3}\left[f(0) + 4f\left(\frac{\pi}{8}\right) + 2f\left(\frac{2\pi}{8}\right) + 4f\left(\frac{3\pi}{8}\right) + f\left(\frac{\pi}{2}\right)\right] \approx 1.843245$

11. $f(x) = x^3 \sin x$, $\Delta x = \frac{4 - 0}{8} = \frac{1}{2}$

(a) $T_8 = \frac{1}{2 \cdot 2}\left[f(0) + 2f\left(\frac{1}{2}\right) + 2f(1) + 2f\left(\frac{3}{2}\right) + 2f(2) + 2f\left(\frac{5}{2}\right) + 2f(3) + 2f\left(\frac{7}{2}\right) + f(4)\right] \approx -7.276910$

(b) $M_8 = \frac{1}{2}\left[f\left(\frac{1}{4}\right) + f\left(\frac{3}{4}\right) + f\left(\frac{5}{4}\right) + f\left(\frac{7}{4}\right) + f\left(\frac{9}{4}\right) + f\left(\frac{11}{4}\right) + f\left(\frac{13}{4}\right) + f\left(\frac{15}{4}\right)\right] \approx -4.818251$

(c) $S_8 = \frac{1}{2 \cdot 3}\left[f(0) + 4f\left(\frac{1}{2}\right) + 2f(1) + 4f\left(\frac{3}{2}\right) + 2f(2) + 4f\left(\frac{5}{2}\right) + 2f(3) + 4f\left(\frac{7}{2}\right) + f(4)\right] \approx -5.605350$

12. $f(x) = e^{1/x}$, $\Delta x = \frac{3 - 1}{8} = \frac{1}{4}$

(a) $T_8 = \frac{1}{4 \cdot 2}\left[f(1) + 2f\left(\frac{5}{4}\right) + 2f\left(\frac{3}{2}\right) + 2f\left(\frac{7}{4}\right) + 2f(2) + 2f\left(\frac{9}{4}\right) + 2f\left(\frac{5}{2}\right) + 2f\left(\frac{11}{4}\right) + f(3)\right] \approx 3.534934$

(b) $M_8 = \frac{1}{4}\left[f\left(\frac{9}{8}\right) + f\left(\frac{11}{8}\right) + f\left(\frac{13}{8}\right) + f\left(\frac{15}{8}\right) + f\left(\frac{17}{8}\right) + f\left(\frac{19}{8}\right) + f\left(\frac{21}{8}\right) + f\left(\frac{23}{8}\right)\right] \approx 3.515248$

(c) $S_8 = \frac{1}{4 \cdot 3}\left[f(1) + 4f\left(\frac{5}{4}\right) + 2f\left(\frac{3}{2}\right) + 4f\left(\frac{7}{4}\right) + 2f(2) + 4f\left(\frac{9}{4}\right) + 2f\left(\frac{5}{2}\right) + 4f\left(\frac{11}{4}\right) + f(3)\right] \approx 3.522375$

13. $f(y) = \sqrt{y}\cos y$, $\Delta y = \frac{4 - 0}{8} = \frac{1}{2}$

(a) $T_8 = \frac{1}{2 \cdot 2}\left[f(0) + 2f\left(\frac{1}{2}\right) + 2f(1) + 2f\left(\frac{3}{2}\right) + 2f(2) + 2f\left(\frac{5}{2}\right) + 2f(3) + 2f\left(\frac{7}{2}\right) + f(4)\right] \approx -2.364034$

(b) $M_8 = \frac{1}{2}\left[f\left(\frac{1}{4}\right) + f\left(\frac{3}{4}\right) + f\left(\frac{5}{4}\right) + f\left(\frac{7}{4}\right) + f\left(\frac{9}{4}\right) + f\left(\frac{11}{4}\right) + f\left(\frac{13}{4}\right) + f\left(\frac{15}{4}\right)\right] \approx -2.310690$

(c) $S_8 = \frac{1}{2 \cdot 3}\left[f(0) + 4f\left(\frac{1}{2}\right) + 2f(1) + 4f\left(\frac{3}{2}\right) + 2f(2) + 4f\left(\frac{5}{2}\right) + 2f(3) + 4f\left(\frac{7}{2}\right) + f(4)\right] \approx -2.346520$

14. $f(t) = \dfrac{1}{\ln t}$, $\Delta t = \dfrac{3 - 2}{10} = \dfrac{1}{10}$

(a) $T_{10} = \frac{1}{10 \cdot 2}\{f(2) + 2[f(2.1) + f(2.2) + \cdots + f(2.9)] + f(3)\} \approx 1.119061$

(b) $M_{10} = \frac{1}{10}[f(2.05) + f(2.15) + \cdots + f(2.85) + f(2.95)] \approx 1.118107$

(c) $S_{10} = \frac{1}{10 \cdot 3}[f(2) + 4f(2.1) + 2f(2.2) + 4f(2.3) + 2f(2.4) + 4f(2.5) + 2f(2.6)$
$+ 4f(2.7) + 2f(2.8) + 4f(2.9) + f(3)] \approx 1.118428$

15. $f(x) = \dfrac{x^2}{1 + x^4}$, $\Delta x = \dfrac{1 - 0}{10} = \dfrac{1}{10}$

(a) $T_{10} = \frac{1}{10 \cdot 2}\{f(0) + 2[f(0.1 + f(0.2) + \cdots + f(0.9)] + f(1)\} \approx 0.243747$

(b) $M_{10} = \frac{1}{10}[f(0.05) + f(0.15) + \cdots + f(0.85) + f(0.95)] \approx 0.243748$

(c) $S_{10} = \frac{1}{10 \cdot 3}[f(0) + 4f(0.1) + 2f(0.2) + 4f(0.3) + 2f(0.4) + 4f(0.5) + 2f(0.6)$
$+ 4f(0.7) + 2f(0.8) + 4f(0.9) + f(1)] \approx 0.243751$

Note: $\int_0^1 f(x)\,dx \approx 0.24374775$. This is a rare case where the Trapezoidal and Midpoint Rules give better approximations than Simpson's Rule.

16. $f(t) = \dfrac{\sin t}{t}$, $\Delta t = \dfrac{3-1}{4} = \dfrac{1}{2}$

(a) $T_4 = \frac{1}{2 \cdot 2}[f(1) + 2f(1.5) + 2f(2) + 2f(2.5) + f(3)] \approx 0.901645$

(b) $M_4 = \frac{1}{2}[f(1.25) + f(1.75) + f(2.25) + f(2.75)] \approx 0.903031$

(c) $S_4 = \frac{1}{2 \cdot 3}[f(1) + 4f(1.5) + 2f(2) + 4f(2.5) + f(3)] \approx 0.902558$

17. $f(x) = \ln(1 + e^x)$, $\Delta x = \frac{4-0}{8} = \frac{1}{2}$

(a) $T_8 = \frac{1}{2 \cdot 2}\{f(0) + 2[f(0.5) + f(1) + \cdots + f(3) + f(3.5)] + f(4)\} \approx 8.814278$

(b) $M_8 = \frac{1}{2}[f(0.25) + f(0.75) + \cdots + f(3.25) + f(3.75)] \approx 8.799212$

(c) $S_8 = \frac{1}{2 \cdot 3}[f(0) + 4f(0.5) + 2f(1) + 4f(1.5) + 2f(2) + 4f(2.5) + 2f(3) + 4f(3.5) + f(4)] \approx 8.804229$

18. $f(x) = \sqrt{x + x^3}$, $\Delta x = \frac{1-0}{10} = \frac{1}{10}$

(a) $T_{10} = \frac{1}{2 \cdot 2}\{f(0) + 2[f(0.1) + f(0.2) + \cdots + f(0.8) + f(0.9)] + f(1)\} \approx 0.787092$

(b) $M_{10} = \frac{1}{2}[f(0.05) + f(0.15) + \cdots + f(0.85) + f(0.95)] \approx 0.793821$

(c)
$$S_{10} = \tfrac{1}{2 \cdot 3}[f(0) + 4f(0.1) + 2f(0.2) + 4f(0.3) + 2f(0.4) + 4f(0.5) + 2f(0.6) + 4f(0.7) + 2f(0.8) + 4f(0.9) + f(1)] \approx 0.789915$$

19. $f(x) = \cos(x^2)$, $\Delta x = \frac{1-0}{8} = \frac{1}{8}$

(a) $T_8 = \frac{1}{8 \cdot 2}\{f(0) + 2\left[f\left(\frac{1}{8}\right) + f\left(\frac{2}{8}\right) + \cdots + f\left(\frac{7}{8}\right)\right] + f(1)\} \approx 0.902333$

$M_8 = \frac{1}{8}\left[f\left(\frac{1}{16}\right) + f\left(\frac{3}{16}\right) + f\left(\frac{5}{16}\right) + \cdots + f\left(\frac{15}{16}\right)\right] = 0.905620$

(b) $f(x) = \cos(x^2)$, $f'(x) = -2x\sin(x^2)$, $f''(x) = -2\sin(x^2) - 4x^2\cos(x^2)$. For $0 \le x \le 1$, sin and cos are positive, so $|f''(x)| = 2\sin(x^2) + 4x^2\cos(x^2) \le 2 \cdot 1 + 4 \cdot 1 \cdot 1 = 6$ since $\sin(x^2) \le 1$ and $\cos(x^2) \le 1$ for all x, and $x^2 \le 1$ for $0 \le x \le 1$. So for $n = 8$, we take $K = 6$, $a = 0$, and $b = 1$ in Theorem 3, to get $|E_T| \le 6 \cdot 1^3/(12 \cdot 8^2) = \frac{1}{128} = 0.0078125$ and $|E_M| \le \frac{1}{256} = 0.00390625$. [A better estimate is obtained by noting from a graph of f'' that $|f''(x)| \le 4$ for $0 \le x \le 1$.]

(c) Take $K = 6$ [as in part (b)] in Theorem 3. $|E_T| \le \dfrac{K(b-a)^3}{12n^2} \le 0.0001 \quad \Leftrightarrow \quad \dfrac{6(1-0)^3}{12n^2} \le 10^{-4} \quad \Leftrightarrow$

$\dfrac{1}{2n^2} \le \dfrac{1}{10^4} \quad \Leftrightarrow \quad 2n^2 \ge 10^4 \quad \Leftrightarrow \quad n^2 \ge 5000 \quad \Leftrightarrow \quad n \ge 71$. Take $n = 71$ for T_n. For E_M, again take $K = 6$ in Theorem 3 to get $|E_M| \le 10^{-4} \quad \Leftrightarrow \quad 4n^2 \ge 10^4 \quad \Leftrightarrow \quad n^2 \ge 2500 \quad \Leftrightarrow \quad n \ge 50$. Take $n = 50$ for M_n.

20. $f(x) = e^{1/x}$, $\Delta x = \frac{2-1}{10} = \frac{1}{10}$

(a) $T_{10} = \frac{1}{10 \cdot 2}[f(1) + 2f(1.1) + 2f(1.2) + \cdots + 2f(1.9) + f(2)] \approx 2.021976$

$M_{10} = \frac{1}{10}\,[f(1.05) + f(1.15) + f(1.25) + \cdots + f(1.95)] \approx 2.019102$

(b) $f(x) = e^{1/x}$, $f'(x) = -\dfrac{1}{x^2}e^{1/x}$, $f''(x) = \dfrac{2x+1}{x^4}\,e^{1/x}$. Now f'' is decreasing on $[1, 2]$, so let $x = 1$ to take $K = 3e$.

$|E_T| \le \dfrac{3e(2-1)^3}{12(10)^2} = \dfrac{e}{400} \approx 0.006796$. $|E_M| \le \dfrac{|E_T|}{2} = \dfrac{e}{800} \approx 0.003398$.

(c) Take $K = 3e$ [as in part (b)] in Theorem 3. $|E_T| \le \dfrac{K(b-a)^3}{12n^2} \le 0.0001 \iff \dfrac{3e(2-1)^3}{12n^2} \le 10^{-4} \iff$

$\dfrac{e}{4n^2} \le \dfrac{1}{10^4} \iff n^2 \ge \dfrac{10^4 e}{4} \iff n \ge 83$. Take $n = 83$ for T_n. For E_M, again take $K = 3e$ in Theorem 3 to get

$|E_M| \le 10^{-4} \iff n^2 \ge \dfrac{10^4 e}{8} \iff n \ge 59$. Take $n = 59$ for M_n.

21. $f(x) = \sin x$, $\Delta x = \frac{\pi - 0}{10} = \frac{\pi}{10}$

(a) $T_{10} = \frac{\pi}{10 \cdot 2}\left[f(0) + 2f\left(\frac{\pi}{10}\right) + 2f\left(\frac{2\pi}{10}\right) + \cdots + 2f\left(\frac{9\pi}{10}\right) + f(\pi)\right] \approx 1.983524$

$M_{10} = \frac{\pi}{10}\left[f\left(\frac{\pi}{20}\right) + f\left(\frac{3\pi}{20}\right) + f\left(\frac{5\pi}{20}\right) + \cdots + f\left(\frac{19\pi}{20}\right)\right] \approx 2.008248$

$S_{10} = \frac{\pi}{10 \cdot 3}\left[f(0) + 4f\left(\frac{\pi}{10}\right) + 2f\left(\frac{2\pi}{10}\right) + 4f\left(\frac{3\pi}{10}\right) + \cdots + 4f\left(\frac{9\pi}{10}\right) + f(\pi)\right] \approx 2.000110$

Since $I = \int_0^\pi \sin x\,dx = \left[-\cos x\right]_0^\pi = 1 - (-1) = 2$, $E_T = I - T_{10} \approx 0.016476$, $E_M = I - M_{10} \approx -0.008248$, and $E_S = I - S_{10} \approx -0.000110$.

(b) $f(x) = \sin x \Rightarrow \left|f^{(n)}(x)\right| \le 1$, so take $K = 1$ for all error estimates.

$|E_T| \le \dfrac{K(b-a)^3}{12n^2} = \dfrac{1(\pi-0)^3}{12(10)^2} = \dfrac{\pi^3}{1200} \approx 0.025839$. $|E_M| \le \dfrac{|E_T|}{2} = \dfrac{\pi^3}{2400} \approx 0.012919$.

$|E_S| \le \dfrac{K(b-a)^5}{180n^4} = \dfrac{1(\pi-0)^5}{180(10)^4} = \dfrac{\pi^5}{1{,}800{,}000} \approx 0.000170$.

The actual error is about 64% of the error estimate in all three cases.

(c) $|E_T| \le 0.00001 \iff \dfrac{\pi^3}{12n^2} \le \dfrac{1}{10^5} \iff n^2 \ge \dfrac{10^5\pi^3}{12} \Rightarrow n \ge 508.3$. Take $n = 509$ for T_n.

$|E_M| \le 0.00001 \iff \dfrac{\pi^3}{24n^2} \le \dfrac{1}{10^5} \iff n^2 \ge \dfrac{10^5\pi^3}{24} \Rightarrow n \ge 359.4$. Take $n = 360$ for M_n.

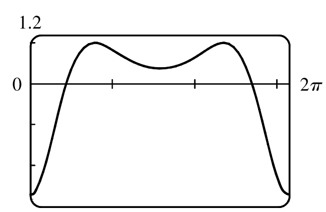
$|E_S| \le 0.00001 \iff \dfrac{\pi^5}{180n^4} \le \dfrac{1}{10^5} \iff n^4 \ge \dfrac{10^5\pi^5}{180} \Rightarrow n \ge 20.3$.

Take $n = 22$ for S_n (since n must be even).

22. From Example 7(b), we take $K = 76e$ to get $|E_S| \le \dfrac{76e(1)^5}{180n^4} \le 0.00001 \Rightarrow n^4 \ge \dfrac{76e}{180(0.00001)} \Rightarrow n \ge 18.4$.

Take $n = 20$ (since n must be even).

23. (a) Using a CAS, we differentiate $f(x) = e^{\cos x}$ twice, and find that $f''(x) = e^{\cos x}(\sin^2 x - \cos x)$. From the graph, we see that the maximum value of $|f''(x)|$ occurs at the endpoints of the interval $[0, 2\pi]$. Since $f''(0) = -e$, we can use $K = e$ or $K = 2.8$.



(b) A CAS gives $M_{10} \approx 7.954926518$. (In Maple, use `Student[Calculus1][RiemannSum]` or `Student[Calculus1][ApproximateInt]`.)

(c) Using Theorem 3 for the Midpoint Rule, with $K = e$, we get $|E_M| \le \dfrac{e(2\pi - 0)^3}{24 \cdot 10^2} \approx 0.280945995$.

With $K = 2.8$, we get $|E_M| \le \dfrac{2.8(2\pi - 0)^3}{24 \cdot 10^2} = 0.289391916$.

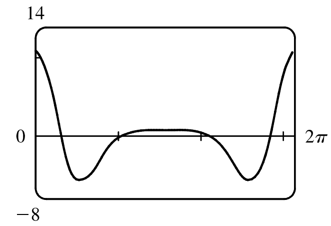
(d) A CAS gives $I \approx 7.954926521$.

(e) The actual error is only about 3×10^{-9}, much less than the estimate in part (c).

(f) We use the CAS to differentiate twice more, and then graph

$f^{(4)}(x) = e^{\cos x}(\sin^4 x - 6\sin^2 x \cos x + 3 - 7\sin^2 x + \cos x)$.

From the graph, we see that the maximum value of $\left|f^{(4)}(x)\right|$ occurs at the endpoints of the interval $[0, 2\pi]$. Since $f^{(4)}(0) = 4e$, we can use $K = 4e$ or $K = 10.9$.



(g) A CAS gives $S_{10} \approx 7.953789422$. (In Maple, use `Student[Calculus1][ApproximateInt]`.)

(h) Using Theorem 4 with $K = 4e$, we get $|E_S| \le \dfrac{4e(2\pi - 0)^5}{180 \cdot 10^4} \approx 0.059153618$.

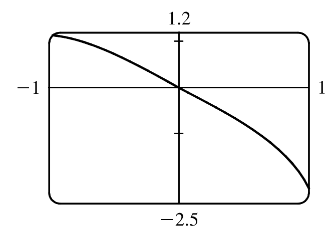
With $K = 10.9$, we get $|E_S| \le \dfrac{10.9(2\pi - 0)^5}{180 \cdot 10^4} \approx 0.059299814$.

(i) The actual error is about $7.954926521 - 7.953789422 \approx 0.00114$. This is quite a bit smaller than the estimate in part (h), though the difference is not nearly as great as it was in the case of the Midpoint Rule.

(j) To ensure that $|E_S| \le 0.0001$, we use Theorem 4: $|E_S| \le \dfrac{4e(2\pi)^5}{180 \cdot n^4} \le 0.0001 \quad \Rightarrow \quad \dfrac{4e(2\pi)^5}{180 \cdot 0.0001} \le n^4 \quad \Rightarrow$ $n^4 \ge 5{,}915{,}362 \quad \Leftrightarrow \quad n \ge 49.3$. So we must take $n \ge 50$ to ensure that $|I - S_n| \le 0.0001$. ($K = 10.9$ leads to the same value of n.)

24. (a) Using the CAS, we differentiate $f(x) = \sqrt{4 - x^3}$ twice, and find that $f''(x) = -\dfrac{9x^4}{4(4 - x^3)^{3/2}} - \dfrac{3x}{(4 - x^3)^{1/2}}$.

From the graph, we see that $|f''(x)| < 2.2$ on $[-1, 1]$.



(b) A CAS gives $M_{10} \approx 3.995804152$. (In Maple, use `Student[Calculus1][RiemannSum]` or `Student[Calculus1][ApproximateInt]`.)

(c) Using Theorem 3 for the Midpoint Rule, with $K = 2.2$, we get $|E_M| \le \dfrac{2.2\,[1 - (-1)]^3}{24 \cdot 10^2} \approx 0.00733$.

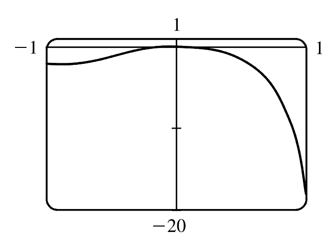
(d) A CAS gives $I \approx 3.995487677$.

(e) The actual error is about -0.0003165, much less than the estimate in part (c).

(f) We use the CAS to differentiate twice more, and then graph

$f^{(4)}(x) = \dfrac{9}{16}\dfrac{x^2(x^6 - 224x^3 - 1280)}{(4 - x^3)^{7/2}}$.

From the graph, we see that $\left|f^{(4)}(x)\right| < 18.1$ on $[-1, 1]$.



(g) A CAS gives $S_{10} \approx 3.995449790$. (In Maple, use `Student[Calculus1][ApproximateInt]`.)

(h) Using Theorem 4 with $K = 18.1$, we get $|E_S| \le \dfrac{18.1\,[1-(-1)]^5}{180 \cdot 10^4} \approx 0.000322$.

(i) The actual error is about $3.995487677 - 3.995449790 \approx 0.0000379$. This is quite a bit smaller than the estimate in part (h).

(j) To ensure that $|E_S| \le 0.0001$, we use Theorem 4: $|E_S| \le \dfrac{18.1(2)^5}{180 \cdot n^4} \le 0.0001 \quad\Rightarrow\quad \dfrac{18.1(2)^5}{180 \cdot 0.0001} \le n^4 \quad\Rightarrow$ $n^4 \ge 32{,}178 \quad\Rightarrow n \ge 13.4$. So we must take $n \ge 14$ to ensure that $|I - S_n| \le 0.0001$.

25. $I = \int_0^1 xe^x\,dx = [(x-1)e^x]_0^1 \quad$ [parts or Formula 96] $\quad = 0 - (-1) = 1$, $f(x) = xe^x$, $\Delta x = 1/n$

$n = 5$:

$$L_5 = \tfrac{1}{5}[f(0) + f(0.2) + f(0.4) + f(0.6) + f(0.8)] \approx 0.742943$$
$$R_5 = \tfrac{1}{5}[f(0.2) + f(0.4) + f(0.6) + f(0.8) + f(1)] \approx 1.286599$$
$$T_5 = \tfrac{1}{5 \cdot 2}[f(0) + 2f(0.2) + 2f(0.4) + 2f(0.6) + 2f(0.8) + f(1)] \approx 1.014771$$
$$M_5 = \tfrac{1}{5}[f(0.1) + f(0.3) + f(0.5) + f(0.7) + f(0.9)] \approx 0.992621$$

$$E_L = I - L_5 \approx 1 - 0.742943 = 0.257057$$
$$E_R \approx 1 - 1.286599 = -0.286599$$
$$E_T \approx 1 - 1.014771 = -0.014771$$
$$E_M \approx 1 - 0.992621 = 0.007379$$

$n = 10$:

$$L_{10} = \tfrac{1}{10}[f(0) + f(0.1) + f(0.2) + \cdots + f(0.9)] \approx 0.867782$$
$$R_{10} = \tfrac{1}{10}[f(0.1) + f(0.2) + \cdots + f(0.9) + f(1)] \approx 1.139610$$
$$T_{10} = \tfrac{1}{10 \cdot 2}\{f(0) + 2[f(0.1) + f(0.2) + \cdots + f(0.9)] + f(1)\} \approx 1.003696$$
$$M_{10} = \tfrac{1}{10}[f(0.05) + f(0.15) + \cdots + f(0.85) + f(0.95)] \approx 0.998152$$

$$E_L = I - L_{10} \approx 1 - 0.867782 = 0.132218$$
$$E_R \approx 1 - 1.139610 = -0.139610$$
$$E_T \approx 1 - 1.003696 = -0.003696$$
$$E_M \approx 1 - 0.998152 = 0.001848$$

$n = 20$:

$$L_{20} = \tfrac{1}{20}[f(0) + f(0.05) + f(0.10) + \cdots + f(0.95)] \approx 0.932967$$
$$R_{20} = \tfrac{1}{20}[f(0.05) + f(0.10) + \cdots + f(0.95) + f(1)] \approx 1.068881$$
$$T_{20} = \tfrac{1}{20 \cdot 2}\{f(0) + 2[f(0.05) + f(0.10) + \cdots + f(0.95)] + f(1)\} \approx 1.000924$$
$$M_{20} = \tfrac{1}{20}[f(0.025) + f(0.075) + f(0.125) + \cdots + f(0.975)] \approx 0.999538$$

$$E_L = I - L_{20} \approx 1 - 0.932967 = 0.067033$$
$$E_R \approx 1 - 1.068881 = -0.068881$$
$$E_T \approx 1 - 1.000924 = -0.000924$$
$$E_M \approx 1 - 0.999538 = 0.000462$$

n	L_n	R_n	T_n	M_n
5	0.742943	1.286599	1.014771	0.992621
10	0.867782	1.139610	1.003696	0.998152
20	0.932967	1.068881	1.000924	0.999538

n	E_L	E_R	E_T	E_M
5	0.257057	−0.286599	−0.014771	0.007379
10	0.132218	−0.139610	−0.003696	0.001848
20	0.067033	−0.068881	−0.000924	0.000462

Observations:

1. E_L and E_R are always opposite in sign, as are E_T and E_M.
2. As n is doubled, E_L and E_R are decreased by about a factor of 2, and E_T and E_M are decreased by a factor of about 4.
3. The Midpoint approximation is about twice as accurate as the Trapezoidal approximation.
4. All the approximations become more accurate as the value of n increases.
5. The Midpoint and Trapezoidal approximations are much more accurate than the endpoint approximations.

26. $I = \int_1^2 \frac{1}{x^2}\,dx = \left[-\frac{1}{x}\right]_1^2 = -\frac{1}{2} - (-1) = \frac{1}{2}, f(x) = \frac{1}{x^2}, \Delta x = \frac{1}{n}$

$n = 5$: $L_5 = \frac{1}{5}[f(1) + f(1.2) + f(1.4) + f(1.6) + f(1.8)] \approx 0.580783$

$R_5 = \frac{1}{5}[f(1.2) + f(1.4) + f(1.6) + f(1.8) + f(2)] \approx 0.430783$

$T_5 = \frac{1}{5 \cdot 2}[f(1) + 2f(1.2) + 2f(1.4) + 2f(1.6) + 2f(1.8) + f(2)] \approx 0.505783$

$M_5 = \frac{1}{5}[f(1.1) + f(1.3) + f(1.5) + f(1.7) + f(1.9)] \approx 0.497127$

$E_L = I - L_5 \approx \frac{1}{2} - 0.580783 = -0.080783$

$E_R \approx \frac{1}{2} - 0.430783 = 0.069217$

$E_T \approx \frac{1}{2} - 0.505783 = -0.005783$

$E_M \approx \frac{1}{2} - 0.497127 = 0.002873$

$n = 10$: $L_{10} = \frac{1}{10}[f(1) + f(1.1) + f(1.2) + \cdots + f(1.9)] \approx 0.538955$

$R_{10} = \frac{1}{10}[f(1.1) + f(1.2) + \cdots + f(1.9) + f(2)] \approx 0.463955$

$T_{10} = \frac{1}{10 \cdot 2}\{f(1) + 2[f(1.1) + f(1.2) + \cdots + f(1.9)] + f(2)\} \approx 0.501455$

$M_{10} = \frac{1}{10}[f(1.05) + f(1.15) + \cdots + f(1.85) + f(1.95)] \approx 0.499274$

$E_L = I - L_{10} \approx \frac{1}{2} - 0.538955 = -0.038955$

$E_R \approx \frac{1}{2} - 0.463955 = 0.036049$

$E_T \approx \frac{1}{2} - 0.501455 = -0.001455$

$E_M \approx \frac{1}{2} - 0.499274 = 0.000726$

$n = 20$: $L_{20} = \frac{1}{20}[f(1) + f(1.05) + f(1.10) + \cdots + f(1.95)] \approx 0.519114$

$R_{20} = \frac{1}{20}[f(1.05) + f(1.10) + \cdots + f(1.95) + f(2)] \approx 0.481614$

$T_{20} = \frac{1}{20 \cdot 2}\{f(1) + 2[f(1.05) + f(1.10) + \cdots + f(1.95)] + f(2)\} \approx 0.500364$

$M_{20} = \frac{1}{20}[f(1.025) + f(1.075) + f(1.125) + \cdots + f(1.975)] \approx 0.499818$

$$\begin{aligned} E_L &= I - L_{20} \approx \tfrac{1}{2} - 0.519114 = -0.019114 \\ E_R &\approx \tfrac{1}{2} - 0.481614 = 0.018386 \\ E_T &\approx \tfrac{1}{2} - 0.500364 = -0.000364 \\ E_M &\approx \tfrac{1}{2} - 0.499818 = 0.000182 \end{aligned}$$

n	L_n	R_n	T_n	M_n
5	0.580783	0.430783	0.505783	0.497127
10	0.538955	0.463955	0.501455	0.499274
20	0.519114	0.481614	0.500364	0.499818

n	E_L	E_R	E_T	E_M
5	−0.080783	0.069217	−0.005783	0.002873
10	−0.038955	0.036049	−0.001455	0.000726
20	−0.019114	0.018386	−0.000364	0.000182

Observations:

1. E_L and E_R are always opposite in sign, as are E_T and E_M.
2. As n is doubled, E_L and E_R are decreased by about a factor of 2, and E_T and E_M are decreased by a factor of about 4.
3. The Midpoint approximation is about twice as accurate as the Trapezoidal approximation.
4. All the approximations become more accurate as the value of n increases.
5. The Midpoint and Trapezoidal approximations are much more accurate than the endpoint approximations.

27. $I = \int_0^2 x^4\,dx = \left[\frac{1}{5}x^5\right]_0^2 = \frac{32}{5} - 0 = 6.4$, $f(x) = x^4$, $\Delta x = \frac{2-0}{n} = \frac{2}{n}$

$n = 6$:

$$\begin{aligned} T_6 &= \tfrac{2}{6\cdot 2}\left\{f(0) + 2\left[f\left(\tfrac{1}{3}\right) + f\left(\tfrac{2}{3}\right) + f\left(\tfrac{3}{3}\right) + f\left(\tfrac{4}{3}\right) + f\left(\tfrac{5}{3}\right)\right] + f(2)\right\} \approx 6.695473 \\ M_6 &= \tfrac{2}{6}\left[f\left(\tfrac{1}{6}\right) + f\left(\tfrac{3}{6}\right) + f\left(\tfrac{5}{6}\right) + f\left(\tfrac{7}{6}\right) + f\left(\tfrac{9}{6}\right) + f\left(\tfrac{11}{6}\right)\right] \approx 6.252572 \\ S_6 &= \tfrac{2}{6\cdot 3}\left[f(0) + 4f\left(\tfrac{1}{3}\right) + 2f\left(\tfrac{2}{3}\right) + 4f\left(\tfrac{3}{3}\right) + 2f\left(\tfrac{4}{3}\right) + 4f\left(\tfrac{5}{3}\right) + f(2)\right] \approx 6.403292 \\ E_T &= I - T_6 \approx 6.4 - 6.695473 = -0.295473 \\ E_M &\approx 6.4 - 6.252572 = 0.147428 \\ E_S &\approx 6.4 - 6.403292 = -0.003292 \end{aligned}$$

$n = 12$:

$$\begin{aligned} T_{12} &= \tfrac{2}{12\cdot 2}\left\{f(0) + 2\left[f\left(\tfrac{1}{6}\right) + f\left(\tfrac{2}{6}\right) + f\left(\tfrac{3}{6}\right) + \cdots + f\left(\tfrac{11}{6}\right)\right] + f(2)\right\} \approx 6.474023 \\ M_6 &= \tfrac{2}{12}\left[f\left(\tfrac{1}{12}\right) + f\left(\tfrac{3}{12}\right) + f\left(\tfrac{5}{12}\right) + \cdots + f\left(\tfrac{23}{12}\right)\right] \approx 6.363008 \\ S_6 &= \tfrac{2}{12\cdot 3}\left[f(0) + 4f\left(\tfrac{1}{6}\right) + 2f\left(\tfrac{2}{6}\right) + 4f\left(\tfrac{3}{6}\right) + 2f\left(\tfrac{4}{6}\right) + \cdots + 4f\left(\tfrac{11}{6}\right) + f(2)\right] \approx 6.400206 \\ E_T &= I - T_{12} \approx 6.4 - 6.474023 = -0.074023 \\ E_M &\approx 6.4 - 6.363008 = 0.036992 \\ E_S &\approx 6.4 - 6.400206 = -0.000206 \end{aligned}$$

n	T_n	M_n	S_n
6	6.695473	6.252572	6.403292
12	6.474023	6.363008	6.400206

6	−0.295473	0.147428	−0.003292
12	−0.074023	0.036992	−0.000206

Observations:

1. E_T and E_M are opposite in sign and decrease by a factor of about 4 as n is doubled.
2. The Simpson's approximation is much more accurate than the Midpoint and Trapezoidal approximations, and E_S seems to decrease by a factor of about 16 as n is doubled.

28. $I = \int_1^4 \frac{1}{\sqrt{x}}\,dx = \left[2\sqrt{x}\,\right]_1^4 = 4 - 2 = 2$, $f(x) = \frac{1}{\sqrt{x}}$, $\Delta x = \frac{4-1}{n} = \frac{3}{n}$

$n = 6$: $T_6 = \frac{3}{6 \cdot 2}\{f(1) + 2[f(\frac{3}{2}) + f(\frac{4}{2}) + f(\frac{5}{2}) + f(\frac{6}{2}) + f(\frac{7}{2})] + f(4)\} \approx 2.008966$

$M_6 = \frac{3}{6}[f(\frac{5}{4}) + f(\frac{7}{4}) + f(\frac{9}{4}) + f(\frac{11}{4}) + f(\frac{13}{4}) + f(\frac{15}{4})] \approx 1.995572$

$S_6 = \frac{3}{6 \cdot 3}[f(1) + 4f(\frac{3}{2}) + 2f(\frac{4}{2}) + 4f(\frac{5}{2}) + 2f(\frac{6}{2}) + 4f(\frac{7}{2}) + f(4)] \approx 2.000469$

$E_T = I - T_6 \approx 2 - 2.008966 = -0.008966$,

$E_M \approx 2 - 1.995572 = 0.004428$,

$E_S \approx 2 - 2.000469 = -0.000469$

$n = 12$: $T_{12} = \frac{3}{12 \cdot 2}\{f(1) + 2[f(\frac{5}{4}) + f(\frac{6}{4}) + f(\frac{7}{4}) + \cdots + f(\frac{15}{4})] + f(4)\} \approx 2.002269$

$M_{12} = \frac{3}{12}[f(\frac{9}{8}) + f(\frac{11}{8}) + f(\frac{13}{8}) + \cdots + f(\frac{31}{8})] \approx 1.998869$

$S_{12} = \frac{3}{12 \cdot 3}[f(1) + 4f(\frac{5}{4}) + 2f(\frac{6}{4}) + 4f(\frac{7}{4}) + 2f(\frac{8}{4}) + \cdots + 4f(\frac{15}{4}) + f(4)] \approx 2.000036$

$E_T = I - T_{12} \approx 2 - 2.002269 = -0.002269$

$E_M \approx 2 - 1.998869 = 0.001131$

$E_S \approx 2 - 2.000036 = -0.000036$

n	T_n	M_n	S_n
6	2.008966	1.995572	2.000469
12	2.002269	1.998869	2.000036

n	E_T	E_M	E_S
6	−0.008966	0.004428	−0.000469
12	−0.002269	0.001131	−0.000036

Observations:

1. E_T and E_M are opposite in sign and decrease by a factor of about 4 as n is doubled.
2. The Simpson's approximation is much more accurate than the Midpoint and Trapezoidal approximations, and E_S seems to decrease by a factor of about 16 as n is doubled.

29. (a) $\Delta x = (b-a)/n = (6-0)/6 = 1$

$T_6 = \frac{1}{2}[f(0) + 2f(1) + 2f(2) + 2f(3) + 2f(4) + 2f(5) + f(6)]$

$\approx \frac{1}{2}[2 + 2(1) + 2(3) + 2(5) + 2(4) + 2(3) + 4] = \frac{1}{2}(38) = 19$

(b) $M_6 = 1[f(0.5) + f(1.5) + f(2.5) + f(3.5) + f(4.5) + f(5.5)] \approx 1.3 + 1.5 + 4.6 + 4.7 + 3.3 + 3.2 = 18.6$

(c) $S_6 = \frac{1}{3}[f(0) + 4f(1) + 2f(2) + 4f(3) + 2f(4) + 4f(5) + f(6)]$

$\approx \frac{1}{3}[2 + 4(1) + 2(3) + 4(5) + 2(4) + 4(3) + 4] = \frac{1}{3}(56) = 18.\overline{6}$

30. If x = distance from left end of pool and $w = w(x)$ = width at x, then Simpson's Rule with $n = 8$ and $\Delta x = 2$ gives

Area $= \int_0^{16} w\,dx \approx \frac{2}{3}[0 + 4(6.2) + 2(7.2) + 4(6.8) + 2(5.6) + 4(5.0) + 2(4.8) + 4(4.8) + 0] \approx 84\text{ m}^2$.

31. (a) $\int_1^5 f(x)\,dx \approx M_4 = \frac{5-1}{4}[f(1.5) + f(2.5) + f(3.5) + f(4.5)] = 1(2.9 + 3.6 + 4.0 + 3.9) = 14.4$

(b) $-2 \le f''(x) \le 3 \;\Rightarrow\; |f''(x)| \le 3 \;\Rightarrow\; K = 3$, since $|f''(x)| \le K$. The error estimate for the Midpoint Rule is

$|E_M| \le \frac{K(b-a)^3}{24n^2} = \frac{3(5-1)^3}{24(4)^2} = \frac{1}{2}$.

32. (a) $\int_0^{1.6} g(x)\,dx \approx S_8 = \frac{1.6-0}{8\cdot 3}[g(0)+4g(0.2)+2g(0.4)+4g(0.6)+2g(0.8)+4g(1.0)+2g(1.2)+4g(1.4)+g(1.6)]$

$$= \tfrac{1}{15}[12.1+4(11.6)+2(11.3)+4(11.1)+2(11.7)+4(12.2)+2(12.6)+4(13.0)+13.2]$$

$$= \tfrac{1}{15}(288.1) = \tfrac{2881}{150} \approx 19.2$$

(b) $-5 \le g^{(4)}(x) \le 2 \;\Rightarrow\; \left|g^{(4)}(x)\right| \le 5 \;\Rightarrow\; K = 5$, since $\left|g^{(4)}(x)\right| \le K$. The error estimate for Simpson's Rule is

$$|E_S| \le \frac{K(b-a)^5}{180n^4} = \frac{5(1.6-0)^5}{180(8)^4} = \frac{2}{28{,}125} = 7.\overline{1}\times 10^{-5}.$$

33. We use Simpson's Rule with $n = 12$ and $\Delta t = \frac{24-0}{12} = 2$.

$$S_{12} = \tfrac{2}{3}[T(0)+4T(2)+2T(4)+4T(6)+2T(8)+4T(10)+2T(12)$$
$$+4T(14)+2T(16)+4T(18)+2T(20)+4T(22)+T(24)]$$
$$\approx \tfrac{2}{3}[66.6+4(65.4)+2(64.4)+4(61.7)+2(67.3)+4(72.1)+2(74.9)$$
$$+4(77.4)+2(79.1)+4(75.4)+2(75.6)+4(71.4)+67.5] = \tfrac{2}{3}(2550.3) = 1700.2.$$

Thus, $\int_0^{24} T(t)\,dt \approx S_{12}$ and $T_{\text{ave}} = \frac{1}{24-0}\int_0^{24} T(t)\,dt \approx 70.84^\circ\text{F}$.

34. We use Simpson's Rule with $n = 10$ and $\Delta x = \frac{1}{2}$:

$$\text{distance} = \int_0^5 v(t)\,dt \approx S_{10} = \tfrac{1}{2\cdot 3}[f(0)+4f(0.5)+2f(1)+\cdots+4f(4.5)+f(5)]$$
$$= \tfrac{1}{6}[0+4(4.67)+2(7.34)+4(8.86)+2(9.73)+4(10.22)$$
$$+2(10.51)+4(10.67)+2(10.76)+4(10.81)+10.81]$$
$$= \tfrac{1}{6}(268.41) = 44.735 \text{ m}$$

35. By the Net Change Theorem, the increase in velocity is equal to $\int_0^6 a(t)\,dt$. We use Simpson's Rule with $n = 6$ and $\Delta t = (6-0)/6 = 1$ to estimate this integral:

$$\int_0^6 a(t)\,dt \approx S_6 = \tfrac{1}{3}[a(0)+4a(1)+2a(2)+4a(3)+2a(4)+4a(5)+a(6)]$$
$$\approx \tfrac{1}{3}[0+4(0.5)+2(4.1)+4(9.8)+2(12.9)+4(9.5)+0] = \tfrac{1}{3}(113.2) = 37.7\overline{3} \text{ ft/s}$$

36. By the Net Change Theorem, the total amount of water that leaked out during the first six hours is equal to $\int_0^6 r(t)\,dt$. We use Simpson's Rule with $n = 6$ and $\Delta t = \frac{6-0}{6} = 1$ to estimate this integral:

$$\int_0^6 r(t)\,dt \approx S_6 = \tfrac{1}{3}[r(0)+4r(1)+2r(2)+4r(3)+2r(4)+4r(5)+r(6)]$$
$$\approx \tfrac{1}{3}[4+4(3)+2(2.4)+4(1.9)+2(1.4)+4(1.1)+1] = \tfrac{1}{3}(36.6) = 12.2 \text{ liters}$$

37. By the Net Change Theorem, the energy used is equal to $\int_0^6 P(t)\,dt$. We use Simpson's Rule with $n = 12$ and $\Delta t = \frac{6-0}{12} = \frac{1}{2}$ to estimate this integral:

$$\int_0^6 P(t)\,dt \approx S_{12} = \tfrac{1/2}{3}[P(0)+4P(0.5)+2P(1)+4P(1.5)+2P(2)+4P(2.5)+2P(3)$$
$$+4P(3.5)+2P(4)+4P(4.5)+2P(5)+4P(5.5)+P(6)]$$
$$= \tfrac{1}{6}[1814+4(1735)+2(1686)+4(1646)+2(1637)+4(1609)+2(1604)$$
$$+4(1611)+2(1621)+4(1666)+2(1745)+4(1886)+2052]$$
$$= \tfrac{1}{6}(61{,}064) = 10{,}177.\overline{3} \text{ megawatt-hours}$$

38. By the Net Change Theorem, the total amount of data transmitted is equal to $\int_0^8 D(t)\,dt \times 3600$ [since $D(t)$ is measured in megabits per second and t is in hours]. We use Simpson's Rule with $n = 8$ and $\Delta t = (8-0)/8 = 1$ to estimate this integral:

$$\begin{aligned}\int_0^8 D(t)\,dt \approx S_8 &= \tfrac{1}{3}[D(0) + 4D(1) + 2D(2) + 4D(3) + 2D(4) + 4D(5) + 2D(6) + 4D(7) + D(8)]\\ &\approx \tfrac{1}{3}[0.35 + 4(0.32) + 2(0.41) + 4(0.50) + 2(0.51) + 4(0.56) + 2(0.56) + 4(0.83) + 0.88]\\ &= \tfrac{1}{3}(13.03) = 4.34\overline{3}\end{aligned}$$

Now multiply by 3600 to obtain 15,636 megabits.

39. (a) Let $y = f(x)$ denote the curve. Using disks, $V = \int_2^{10} \pi[f(x)]^2\,dx = \pi\int_2^{10} g(x)\,dx = \pi I_1$.

Now use Simpson's Rule to approximate I_1:

$$\begin{aligned}I_1 \approx S_8 &= \tfrac{10-2}{3(8)}[g(2) + 4g(3) + 2g(4) + 4g(5) + 2g(6) + 4g(7) + g(8)]\\ &\approx \tfrac{1}{3}[0^2 + 4(1.5)^2 + 2(1.9)^2 + 4(2.2)^2 + 2(3.0)^2 + 4(3.8)^2 + 2(4.0)^2 + 4(3.1)^2 + 0^2]\\ &= \tfrac{1}{3}(181.78)\end{aligned}$$

Thus, $V \approx \pi \cdot \frac{1}{3}(181.78) \approx 190.4$ or 190 cubic units.

(b) Using cylindrical shells, $V = \int_2^{10} 2\pi x f(x)\,dx = 2\pi\int_2^{10} x f(x)\,dx = 2\pi I_1$.

Now use Simpson's Rule to approximate I_1:

$$\begin{aligned}I_1 \approx S_8 &= \tfrac{10-2}{3(8)}[2f(2) + 4\cdot 3f(3) + 2\cdot 4f(4) + 4\cdot 5f(5) + 2\cdot 6f(6)\\ &\qquad + 4\cdot 7f(7) + 2\cdot 8f(8) + 4\cdot 9f(9) + 10f(10)]\\ &\approx \tfrac{1}{3}[2(0) + 12(1.5) + 8(1.9) + 20(2.2) + 12(3.0) + 28(3.8) + 16(4.0) + 36(3.1) + 10(0)]\\ &= \tfrac{1}{3}(395.2)\end{aligned}$$

Thus, $V \approx 2\pi \cdot \frac{1}{3}(395.2) \approx 827.7$ or 828 cubic units.

40. $\text{Work} = \int_0^{18} f(x)\,dx \approx S_6 = \frac{18-0}{6\cdot 3}[f(0) + 4f(3) + 2f(6) + 4f(9) + 2f(12) + 4f(15) + f(18)]$

$$= 1\cdot[9.8 + 4(9.1) + 2(8.5) + 4(8.0) + 2(7.7) + 4(7.5) + 7.4] = 148 \text{ joules}$$

41. The curve is $y = f(x) = 1/(1+e^{-x})$. Using disks, $V = \int_0^{10} \pi[f(x)]^2\,dx = \pi\int_0^{10} g(x)\,dx = \pi I_1$. Now use Simpson's Rule to approximate I_1:

$$\begin{aligned}I_1 \approx S_{10} &= \tfrac{10-0}{10\cdot 3}[g(0) + 4g(1) + 2g(2) + 4g(3) + 2g(4) + 4g(5) + 2g(6) + 4g(7) + 2g(8) + 4g(9) + g(10)]\\ &\approx 8.80825\end{aligned}$$

Thus, $V \approx \pi I_1 \approx 27.7$ or 28 cubic units.

42. Using Simpson's Rule with $n = 10$, $\Delta x = \frac{\pi/2}{10}$, $L = 1$, $\theta_0 = \frac{42\pi}{180}$ radians, $g = 9.8 \text{ m/s}^2$, $k^2 = \sin^2\left(\frac{1}{2}\theta_0\right)$, and $f(x) = 1/\sqrt{1 - k^2\sin^2 x}$, we get

$$\begin{aligned}T &= 4\sqrt{\frac{L}{g}}\int_0^{\pi/2} \frac{dx}{\sqrt{1-k^2\sin^2 x}} \approx 4\sqrt{\frac{L}{g}}\,S_{10}\\ &= 4\sqrt{\tfrac{1}{9.8}}\left(\tfrac{\pi/2}{10\cdot 3}\right)\left[f(0) + 4f\left(\tfrac{\pi}{20}\right) + 2f\left(\tfrac{2\pi}{20}\right) + \cdots + 4f\left(\tfrac{9\pi}{20}\right) + f\left(\tfrac{\pi}{2}\right)\right] \approx 2.07665\end{aligned}$$

43. $I(\theta) = \dfrac{N^2 \sin^2 k}{k^2}$, where $k = \dfrac{\pi N d \sin\theta}{\lambda}$, $N = 10{,}000$, $d = 10^{-4}$, and $\lambda = 632.8 \times 10^{-9}$. So $I(\theta) = \dfrac{(10^4)^2 \sin^2 k}{k^2}$,

where $k = \dfrac{\pi(10^4)(10^{-4})\sin\theta}{632.8 \times 10^{-9}}$. Now $n = 10$ and $\Delta\theta = \dfrac{10^{-6} - (-10^{-6})}{10} = 2 \times 10^{-7}$, so

$M_{10} = 2 \times 10^{-7}[I(-0.0000009) + I(-0.0000007) + \cdots + I(0.0000009)] \approx 59.4.$

44. $f(x) = \cos(\pi x)$, $\Delta x = \frac{20-0}{10} = 2 \;\Rightarrow$

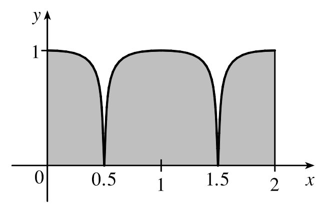
$$T_{10} = \tfrac{2}{2}\{f(0) + 2[f(2) + f(4) + \cdots + f(18)] + f(20)\} = 1[\cos 0 + 2(\cos 2\pi + \cos 4\pi + \cdots + \cos 18\pi) + \cos 20\pi]$$
$$= 1 + 2(1+1+1+1+1+1+1+1+1) + 1 = 20$$

The actual value is $\int_0^{20} \cos(\pi x)\,dx = \frac{1}{\pi}\big[\sin \pi x\big]_0^{20} = \frac{1}{\pi}(\sin 20\pi - \sin 0) = 0$. The discrepancy is due to the fact that the function is sampled only at points of the form $2n$, where its value is $f(2n) = \cos(2n\pi) = 1$.

45. Consider the function f whose graph is shown. The area $\int_0^2 f(x)\,dx$ is close to 2. The Trapezoidal Rule gives

$T_2 = \frac{2-0}{2\cdot 2}\,[f(0) + 2f(1) + f(2)] = \frac{1}{2}\,[1 + 2\cdot 1 + 1] = 2.$

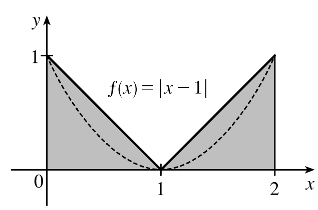
The Midpoint Rule gives $M_2 = \frac{2-0}{2}\,[f(0.5) + f(1.5)] = 1[0+0] = 0$, so the Trapezoidal Rule is more accurate.



46. Consider the function $f(x) = |x-1|$, $0 \le x \le 2$. The area $\int_0^2 f(x)\,dx$ is exactly 1. So is the right endpoint approximation:

$R_2 = f(1)\,\Delta x + f(2)\,\Delta x = 0\cdot 1 + 1\cdot 1 = 1$. But Simpson's Rule approximates f with the parabola $y = (x-1)^2$, shown dashed, and

$S_2 = \dfrac{\Delta x}{3}\,[f(0) + 4f(1) + f(2)] = \dfrac{1}{3}\,[1 + 4\cdot 0 + 1] = \dfrac{2}{3}.$



47. Since the Trapezoidal and Midpoint approximations on the interval $[a,b]$ are the sums of the Trapezoidal and Midpoint approximations on the subintervals $[x_{i-1}, x_i]$, $i = 1, 2, \ldots, n$, we can focus our attention on one such interval. The condition $f''(x) < 0$ for $a \le x \le b$ means that the graph of f is concave down as in Figure 5. In that figure, T_n is the area of the trapezoid $AQRD$, $\int_a^b f(x)\,dx$ is the area of the region $AQPRD$, and M_n is the area of the trapezoid $ABCD$, so $T_n < \int_a^b f(x)\,dx < M_n$. In general, the condition $f'' < 0$ implies that the graph of f on $[a,b]$ lies above the chord joining the points $(a, f(a))$ and $(b, f(b))$. Thus, $\int_a^b f(x)\,dx > T_n$. Since M_n is the area under a tangent to the graph, and since $f'' < 0$ implies that the tangent lies above the graph, we also have $M_n > \int_a^b f(x)\,dx$. Thus, $T_n < \int_a^b f(x)\,dx < M_n$.

48. Let f be a polynomial of degree ≤ 3; say $f(x) = Ax^3 + Bx^2 + Cx + D$. It will suffice to show that Simpson's estimate is exact when there are two subintervals ($n = 2$), because for a larger even number of subintervals the sum of exact estimates is exact. As in the derivation of Simpson's Rule, we can assume that $x_0 = -h$, $x_1 = 0$, and $x_2 = h$. Then Simpson's approximation is

$$\int_{-h}^{h} f(x)\,dx \approx \tfrac{1}{3}h[f(-h)+4f(0)+f(h)] = \tfrac{1}{3}h\big[\big(-Ah^3+Bh^2-Ch+D\big)+4D+\big(Ah^3+Bh^2+Ch+D\big)\big]$$
$$= \tfrac{1}{3}h[2Bh^2+6D] = \tfrac{2}{3}Bh^3+2Dh$$

The exact value of the integral is

$$\int_{-h}^{h}(Ax^3+Bx^2+Cx+D)\,dx = 2\int_0^h (Bx^2+D)\,dx \qquad \text{[by Theorem 5.5.7(a) and (b)]}$$
$$= 2\big[\tfrac{1}{3}Bx^3+Dx\big]_0^h = \tfrac{2}{3}Bh^3+2Dh$$

Thus, Simpson's Rule is exact.

49. $T_n = \frac{1}{2}\,\Delta x\,[f(x_0)+2f(x_1)+\cdots+2f(x_{n-1})+f(x_n)]$ and

$M_n = \Delta x\,[f(\overline{x}_1)+f(\overline{x}_2)+\cdots+f(\overline{x}_{n-1})+f(\overline{x}_n)]$, where $\overline{x}_i = \frac{1}{2}(x_{i-1}+x_i)$. Now

$T_{2n} = \frac{1}{2}\big(\frac{1}{2}\Delta x\big)[f(x_0)+2f(\overline{x}_1)+2f(x_1)+2f(\overline{x}_2)+2f(x_2)+\cdots+2f(\overline{x}_{n-1})+2f(x_{n-1})+2f(\overline{x}_n)+f(x_n)]$ so

$$\tfrac{1}{2}(T_n+M_n) = \tfrac{1}{2}T_n+\tfrac{1}{2}M_n$$
$$= \tfrac{1}{4}\Delta x[f(x_0)+2f(x_1)+\cdots+2f(x_{n-1})+f(x_n)]+\tfrac{1}{4}\Delta x[2f(\overline{x}_1)+2f(\overline{x}_2)+\cdots+2f(\overline{x}_{n-1})+2f(\overline{x}_n)]$$
$$= T_{2n}$$

50. $T_n = \dfrac{\Delta x}{2}\left[f(x_0)+2\sum\limits_{i=1}^{n-1} f(x_i)+f(x_n)\right]$ and $M_n = \Delta x \sum\limits_{i=1}^{n} f\left(x_i-\dfrac{\Delta x}{2}\right)$, so

$$\tfrac{1}{3}T_n+\tfrac{2}{3}M_n = \tfrac{1}{3}(T_n+2M_n) = \frac{\Delta x}{3\cdot 2}\left[f(x_0)+2\sum_{i=1}^{n-1} f(x_i)+f(x_n)+4\sum_{i=1}^{n} f\left(x_i-\frac{\Delta x}{2}\right)\right]$$

where $\Delta x = \dfrac{b-a}{n}$. Let $\delta x = \dfrac{b-a}{2n}$. Then $\Delta x = 2\delta x$, so

$$\tfrac{1}{3}T_n+\tfrac{2}{3}M_n = \frac{\delta x}{3}\left[f(x_0)+2\sum_{i=1}^{n-1} f(x_i)+f(x_n)+4\sum_{i=1}^{n} f(x_i-\delta x)\right]$$
$$= \tfrac{1}{3}\delta x[f(x_0)+4f(x_1-\delta x)+2f(x_1)+4f(x_2-\delta x)$$
$$+2f(x_2)+\cdots+2f(x_{n-1})+4f(x_n-\delta x)+f(x_n)]$$

Since $x_0, x_1-\delta x, x_1, x_2-\delta x, x_2, \ldots, x_{n-1}, x_n-\delta x, x_n$ are the subinterval endpoints for S_{2n}, and since $\delta x = \dfrac{b-a}{2n}$ is the width of the subintervals for S_{2n}, the last expression for $\frac{1}{3}T_n+\frac{2}{3}M_n$ is the usual expression for S_{2n}. Therefore, $\frac{1}{3}T_n+\frac{2}{3}M_n = S_{2n}$.

7.8 Improper Integrals

1. (a) Since $y = \dfrac{x}{x-1}$ has an infinite discontinuity at $x=1$, $\displaystyle\int_1^2 \frac{x}{x-1}\,dx$ is a Type 2 improper integral.

(b) Since $\displaystyle\int_0^{\infty} \frac{1}{1+x^3}\,dx$ has an infinite interval of integration, it is an improper integral of Type 1.

(c) Since $\displaystyle\int_{-\infty}^{\infty} x^2e^{-x^2}\,dx$ has an infinite interval of integration, it is an improper integral of Type 1.

(d) Since $y=\cot x$ has an infinite discontinuity at $x=0$, $\int_0^{\pi/4}\cot x\,dx$ is a Type 2 improper integral.

2. (a) Since $y = \tan x$ is defined and continuous on $\left[0, \frac{\pi}{4}\right]$, $\int_0^{\pi/4} \tan x\,dx$ is proper.

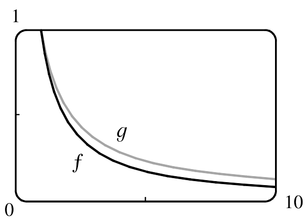
(b) Since $y = \tan x$ has an infinite discontinuity at $x = \frac{\pi}{2}$, $\int_0^{\pi} \tan x\,dx$ is a Type 2 improper integral.

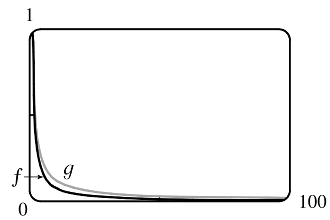
(c) Since $y = \dfrac{1}{x^2 - x - 2} = \dfrac{1}{(x-2)(x+1)}$ has an infinite discontinuity at $x = -1$, $\displaystyle\int_{-1}^{1} \frac{dx}{x^2 - x - 2}$ is a Type 2 improper integral.

(d) Since $\int_0^{\infty} e^{-x^3}\,dx$ has an infinite interval of integration, it is an improper integral of Type 1.

3. The area under the graph of $y = 1/x^3 = x^{-3}$ between $x = 1$ and $x = t$ is $A(t) = \int_1^t x^{-3}\,dx = \left[-\frac{1}{2}x^{-2}\right]_1^t = -\frac{1}{2}t^{-2} - \left(-\frac{1}{2}\right) = \frac{1}{2} - 1/(2t^2)$. So the area for $1 \le x \le 10$ is $A(10) = 0.5 - 0.005 = 0.495$, the area for $1 \le x \le 100$ is $A(100) = 0.5 - 0.00005 = 0.49995$, and the area for $1 \le x \le 1000$ is $A(1000) = 0.5 - 0.0000005 = 0.4999995$. The total area under the curve for $x \ge 1$ is $\lim_{t\to\infty} A(t) = \lim_{t\to\infty} \left[\frac{1}{2} - 1/(2t^2)\right] = \frac{1}{2}$.

4. (a)





(b) The area under the graph of f from $x = 1$ to $x = t$ is

$$F(t) = \int_1^t f(x)\,dx = \int_1^t x^{-1.1}\,dx = \left[-\frac{1}{0.1}x^{-0.1}\right]_1^t$$
$$= -10(t^{-0.1} - 1) = 10(1 - t^{-0.1})$$

and the area under the graph of g is

$$G(t) = \int_1^t g(x)\,dx = \int_1^t x^{-0.9}\,dx = \left[\frac{1}{0.1}x^{0.1}\right]_1^t = 10(t^{0.1} - 1).$$

t	$F(t)$	$G(t)$
10	2.06	2.59
100	3.69	5.85
10^4	6.02	15.12
10^6	7.49	29.81
10^{10}	9	90
10^{20}	9.9	990

(c) The total area under the graph of f is $\lim_{t\to\infty} F(t) = \lim_{t\to\infty} 10(1 - t^{-0.1}) = 10$.

The total area under the graph of g does not exist, since $\lim_{t\to\infty} G(t) = \lim_{t\to\infty} 10(t^{0.1} - 1) = \infty$.

5. $$\int_3^{\infty} \frac{1}{(x-2)^{3/2}}\,dx = \lim_{t\to\infty} \int_3^t (x-2)^{-3/2}\,dx = \lim_{t\to\infty} \left[-2\,(x-2)^{-1/2}\right]_3^t \qquad [u = x - 2,\ du = dx]$$
$$= \lim_{t\to\infty} \left(\frac{-2}{\sqrt{t-2}} + \frac{2}{\sqrt{1}}\right) = 0 + 2 = 2. \qquad \text{Convergent}$$

6. $$\int_0^{\infty} \frac{1}{\sqrt[4]{1+x}}\,dx = \lim_{t\to\infty} \int_0^t (1+x)^{-1/4}\,dx = \lim_{t\to\infty} \left[\tfrac{4}{3}(1+x)^{3/4}\right]_0^t \qquad [u = 1 + x,\ du = dx]$$
$$= \lim_{t\to\infty} \left[\tfrac{4}{3}(1+t)^{3/4} - \tfrac{4}{3}\right] = \infty. \qquad \text{Divergent}$$

7. $\displaystyle\int_{-\infty}^{0} \frac{1}{3-4x}\,dx = \lim_{t\to-\infty} \int_t^0 \frac{1}{3-4x}\,dx = \lim_{t\to-\infty}\left[-\tfrac{1}{4}\ln|3-4x|\right]_t^0 = \lim_{t\to-\infty}\left[-\tfrac{1}{4}\ln 3 + \tfrac{1}{4}\ln|3-4t|\right] = \infty.$

Divergent

8. $\displaystyle\int_1^{\infty} \frac{1}{(2x+1)^3}\,dx = \lim_{t\to\infty}\int_1^t \frac{1}{(2x+1)^3}\,dx = \lim_{t\to\infty}\left[-\frac{1}{4(2x+1)^2}\right]_1^t = \lim_{t\to\infty}\left[-\frac{1}{4(2t+1)^2} + \frac{1}{36}\right] = 0 + \frac{1}{36}.$

Convergent

9. $\int_2^{\infty} e^{-5p}\,dp = \lim_{t\to\infty}\int_2^t e^{-5p}\,dp = \lim_{t\to\infty}\left[-\tfrac{1}{5}e^{-5p}\right]_2^t = \lim_{t\to\infty}\left(-\tfrac{1}{5}e^{-5t} + \tfrac{1}{5}e^{-10}\right) = 0 + \tfrac{1}{5}e^{-10} = \tfrac{1}{5}e^{-10}.$ Convergent

10. $\displaystyle\int_{-\infty}^{0} 2^r\,dr = \lim_{t\to-\infty}\int_t^0 2^r\,dr = \lim_{t\to-\infty}\left[\frac{2^r}{\ln 2}\right]_t^0 = \lim_{t\to-\infty}\left(\frac{1}{\ln 2} - \frac{2^t}{\ln 2}\right) = \frac{1}{\ln 2} - 0 = \frac{1}{\ln 2}.$ Convergent

11. $\displaystyle\int_0^{\infty} \frac{x^2}{\sqrt{1+x^3}}\,dx = \lim_{t\to\infty}\int_0^t \frac{x^2}{\sqrt{1+x^3}}\,dx = \lim_{t\to\infty}\left[\frac{2}{3}\sqrt{1+x^3}\right]_0^t = \lim_{t\to\infty}\left(\tfrac{2}{3}\sqrt{1+t^3} - \tfrac{2}{3}\right) = \infty.$ Divergent

12. $I = \int_{-\infty}^{\infty}(y^3-3y^2)\,dy = I_1 + I_2 = \int_{-\infty}^{0}(y^3-3y^2)\,dy + \int_0^{\infty}(y^3-3y^2)\,dy$, but

$I_1 = \lim_{t\to-\infty}\left[\tfrac{1}{4}y^4 - y^3\right]_t^0 = \lim_{t\to-\infty}(t^3 - \tfrac{1}{4}t^4) = -\infty$. Since I_1 is divergent, I is divergent,

and there is no need to evaluate I_2. Divergent

13. $\int_{-\infty}^{\infty} xe^{-x^2}\,dx = \int_{-\infty}^{0} xe^{-x^2}\,dx + \int_0^{\infty} xe^{-x^2}\,dx.$

$\int_{-\infty}^{0} xe^{-x^2}\,dx = \lim_{t\to-\infty}\left(-\tfrac{1}{2}\right)\left[e^{-x^2}\right]_t^0 = \lim_{t\to-\infty}\left(-\tfrac{1}{2}\right)\left(1 - e^{-t^2}\right) = -\tfrac{1}{2}\cdot 1 = -\tfrac{1}{2}$, and

$\int_0^{\infty} xe^{-x^2}\,dx = \lim_{t\to\infty}\left(-\tfrac{1}{2}\right)\left[e^{-x^2}\right]_0^t = \lim_{t\to\infty}\left(-\tfrac{1}{2}\right)\left(e^{-t^2} - 1\right) = -\tfrac{1}{2}\cdot(-1) = \tfrac{1}{2}.$

Therefore, $\int_{-\infty}^{\infty} xe^{-x^2}\,dx = -\tfrac{1}{2} + \tfrac{1}{2} = 0.$ Convergent

14. $\displaystyle\int_1^{\infty} \frac{e^{-1/x}}{x^2}\,dx = \lim_{t\to\infty}\int_1^t \frac{e^{-1/x}}{x^2}\,dx = \lim_{t\to\infty}\left[e^{-1/x}\right]_1^t = \lim_{t\to\infty}(e^{-1/t} - e^{-1}) = 1 - \frac{1}{e}.$ Convergent

15. $\int_0^{\infty}\sin^2\alpha\,d\alpha = \lim_{t\to\infty}\int_0^t \tfrac{1}{2}(1-\cos 2\alpha)\,d\alpha = \lim_{t\to\infty}\left[\tfrac{1}{2}\left(\alpha - \tfrac{1}{2}\sin 2\alpha\right)\right]_0^t = \lim_{t\to\infty}\left[\tfrac{1}{2}\left(t - \tfrac{1}{2}\sin 2t\right) - 0\right] = \infty.$

Divergent

16. $\int_0^{\infty}\sin\theta\,e^{\cos\theta}\,d\theta = \lim_{t\to\infty}\int_0^t \sin\theta\,e^{\cos\theta}\,d\theta = \lim_{t\to\infty}\left[-e^{\cos\theta}\right]_0^t = \lim_{t\to\infty}(-e^{\cos t} + e)$

This limit does not exist since $\cos t$ oscillates in value between -1 and 1, so $e^{\cos t}$ oscillates in value between e^{-1} and e^1. Divergent

17. $\displaystyle\int_1^{\infty}\frac{1}{x^2+x}\,dx = \lim_{t\to\infty}\int_1^t \frac{1}{x(x+1)}\,dx = \lim_{t\to\infty}\int_1^t\left(\frac{1}{x} - \frac{1}{x+1}\right)dx$ [partial fractions]

$\displaystyle = \lim_{t\to\infty}\Big[\ln|x| - \ln|x+1|\Big]_1^t = \lim_{t\to\infty}\left[\ln\left|\frac{x}{x+1}\right|\right]_1^t = \lim_{t\to\infty}\left(\ln\frac{t}{t+1} - \ln\frac{1}{2}\right) = 0 - \ln\frac{1}{2} = \ln 2.$

Convergent

18. $\displaystyle\int_2^\infty \frac{dv}{v^2+2v-3} = \lim_{t\to\infty}\int_2^t \frac{dv}{(v+3)(v-1)} = \lim_{t\to\infty}\int_2^t \left(\frac{-\frac14}{v+3}+\frac{\frac14}{v-1}\right)dv = \lim_{t\to\infty}\left[-\tfrac14\ln|v+3|+\tfrac14\ln|v-1|\right]_2^t$

$\displaystyle= \frac14\lim_{t\to\infty}\left[\ln\frac{v-1}{v+3}\right]_2^t = \frac14\lim_{t\to\infty}\left(\ln\frac{t-1}{t+3}-\ln\frac15\right) = \frac14(0+\ln 5) = \frac14\ln 5.$ Convergent

19. $\int_{-\infty}^0 ze^{2z}\,dz = \lim\limits_{t\to-\infty}\int_t^0 ze^{2z}\,dz = \lim\limits_{t\to-\infty}\left[\tfrac12 ze^{2z}-\tfrac14 e^{2z}\right]_t^0$ $\left[\begin{array}{c}\text{integration by parts with}\\ u=z,\, dv=e^{2z}\,dz\end{array}\right]$

$= \lim\limits_{t\to-\infty}\left[\left(0-\tfrac14\right)-\left(\tfrac12 te^{2t}-\tfrac14 e^{2t}\right)\right] = -\tfrac14 - 0 + 0$ [by l'Hospital's Rule] $= -\tfrac14.$ Convergent

20. $\int_2^\infty ye^{-3y}\,dy = \lim\limits_{t\to\infty}\int_2^t ye^{-3y}\,dy = \lim\limits_{t\to\infty}\left[-\tfrac13 ye^{-3y}-\tfrac19 e^{-3y}\right]_2^t$ $\left[\begin{array}{c}\text{integration by parts with}\\ u=y,\, dv=e^{-3y}\,dy\end{array}\right]$

$= \lim\limits_{t\to\infty}\left[\left(-\tfrac13 te^{-3t}-\tfrac19 e^{-3t}\right)-\left(-\tfrac23 e^{-6}-\tfrac19 e^{-6}\right)\right] = 0-0+\tfrac79 e^{-6}$ [by l'Hospital's Rule] $= \tfrac79 e^{-6}.$

30. $\displaystyle\int_{-1}^2 \frac{x}{(x+1)^2}\,dx = \lim_{t\to -1^+}\int_t^2 \frac{x}{(x+1)^2}\,dx = \lim_{t\to -1^+}\int_t^2\left[\frac{1}{x+1}-\frac{1}{(x+1)^2}\right]dx$ [partial fractions]

$\displaystyle = \lim_{t\to -1^+}\left[\ln|x+1|+\frac{1}{x+1}\right]_t^2 = \lim_{t\to -1^+}\left[\ln 3+\frac{1}{3}-\left(\ln(t+1)+\frac{1}{t+1}\right)\right] = -\infty.$ Divergent

Note: To justify the last step, $\displaystyle\lim_{t\to -1^+}\left[\ln(t+1)+\frac{1}{t+1}\right] = \lim_{x\to 0^+}\left(\ln x+\frac{1}{x}\right)\ \begin{bmatrix}\text{substitute} \\ x \text{ for } t+1\end{bmatrix} = \lim_{x\to 0^+}\frac{x\ln x+1}{x} = \infty$

since $\displaystyle\lim_{x\to 0^+}(x\ln x) = \lim_{x\to 0^+}\frac{\ln x}{1/x} \overset{\text{H}}{=} \lim_{x\to 0^+}\frac{1/x}{-1/x^2} = \lim_{x\to 0^+}(-x) = 0.$

31. $\displaystyle\int_{-2}^3 \frac{dx}{x^4} = \int_{-2}^0 \frac{dx}{x^4}+\int_0^3 \frac{dx}{x^4}$, but $\displaystyle\int_{-2}^0 \frac{dx}{x^4} = \lim_{t\to 0^-}\left[-\frac{x^{-3}}{3}\right]_{-2}^t = \lim_{t\to 0^-}\left[-\frac{1}{3t^3}-\frac{1}{24}\right] = \infty.$ Divergent

32. $\displaystyle\int_0^1 \frac{dx}{\sqrt{1-x^2}} = \lim_{t\to 1^-}\int_0^t \frac{dx}{\sqrt{1-x^2}} = \lim_{t\to 1^-}\left[\sin^{-1}x\right]_0^t = \lim_{t\to 1^-}\sin^{-1}t = \frac{\pi}{2}.$ Convergent

33. There is an infinite discontinuity at $x=1$. $\displaystyle\int_0^9 \frac{1}{\sqrt[3]{x-1}}\,dx = \int_0^1 (x-1)^{-1/3}\,dx + \int_1^9 (x-1)^{-1/3}\,dx.$

Here $\int_0^1 (x-1)^{-1/3}\,dx = \lim_{t\to 1^-}\int_0^t (x-1)^{-1/3}\,dx = \lim_{t\to 1^-}\left[\frac{3}{2}(x-1)^{2/3}\right]_0^t = \lim_{t\to 1^-}\left[\frac{3}{2}(t-1)^{2/3}-\frac{3}{2}\right] = -\frac{3}{2}$

and $\int_1^9 (x-1)^{-1/3}\,dx = \lim_{t\to 1^+}\int_t^9 (x-1)^{-1/3}\,dx = \lim_{t\to 1^+}\left[\frac{3}{2}(x-1)^{2/3}\right]_t^9 = \lim_{t\to 1^+}\left[6-\frac{3}{2}(t-1)^{2/3}\right] = 6$. Thus,

$\displaystyle\int_0^9 \frac{1}{\sqrt[3]{x-1}}\,dx = -\frac{3}{2}+6 = \frac{9}{2}.$ Convergent

34. There is an infinite discontinuity at $w=2$.

$\displaystyle\int_0^2 \frac{w}{w-2}\,dw = \lim_{t\to 2^-}\int_0^t\left(1+\frac{2}{w-2}\right)dw = \lim_{t\to 2^-}\Big[w+2\ln|w-2|\Big]_0^t = \lim_{t\to 2^-}(t+2\ln|t-2|-2\ln 2) = -\infty$, so

$\displaystyle\int_0^2 \frac{w}{w-2}\,dw$ diverges, and hence, $\displaystyle\int_0^5 \frac{w}{w-2}\,dw$ diverges. Divergent

35. $\int_0^{\pi/2} \tan^2\theta\, d\theta = \lim\limits_{t\to(\pi/2)^-} \int_0^t \tan^2\theta\, d\theta = \lim\limits_{t\to(\pi/2)^-} \int_0^t (\sec^2\theta - 1)\, d\theta = \lim\limits_{t\to(\pi/2)^-} \Big[\tan\theta - \theta\Big]_0^t$

$= \lim\limits_{t\to(\pi/2)^-} (\tan t - t) = \infty$ since $\tan t \to \infty$ as $t \to \frac{\pi}{2}^-$. Divergent

36. $$\int_0^4 \frac{dx}{x^2 - x - 2} = \int_0^4 \frac{dx}{(x-2)(x+1)} = \int_0^2 \frac{dx}{(x-2)(x+1)} + \int_2^4 \frac{dx}{(x-2)(x+1)}$$

Considering only $\displaystyle\int_0^2 \frac{dx}{(x-2)(x+1)}$ and using partial fractions, we have

$$\int_0^2 \frac{dx}{(x-2)(x+1)} = \lim_{t\to 2^-} \int_0^t \left(\frac{\frac13}{x-2} - \frac{\frac13}{x+1}\right) dx = \lim_{t\to 2^-} \Big[\tfrac13 \ln|x-2| - \tfrac13 \ln|x+1|\Big]_0^t$$

$= \lim\limits_{t\to 2^-} \Big[\tfrac13 \ln|t-2| - \tfrac13 \ln|t+1| - \tfrac13 \ln 2 + 0\Big] = -\infty$ since $\ln|t-2| \to -\infty$ as $t \to 2^-$.

Thus, $\displaystyle\int_0^2 \frac{dx}{x^2-x-2}$ is divergent, and hence, $\displaystyle\int_0^4 \frac{dx}{x^2-x-2}$ is divergent as well.

37. $\int_0^1 r \ln r\, dr = \lim\limits_{t\to 0^+} \int_t^1 r \ln r\, dr = \lim\limits_{t\to 0^+} \Big[\tfrac12 r^2 \ln r - \tfrac14 r^2\Big]_t^1$ $\quad \begin{bmatrix} u = \ln r, & dv = r\,dr \\ du = (1/r)\,dr, & v = \frac12 r^2 \end{bmatrix}$

$= \lim\limits_{t\to 0^+} \Big[\big(0 - \tfrac14\big) - \big(\tfrac12 t^2 \ln t - \tfrac14 t^2\big)\Big] = -\tfrac14 - 0 = -\tfrac14$

since $\lim\limits_{t\to 0^+} t^2 \ln t = \lim\limits_{t\to 0^+} \dfrac{\ln t}{1/t^2} \overset{\text{H}}{=} \lim\limits_{t\to 0^+} \dfrac{1/t}{-2/t^3} = \lim\limits_{t\to 0^+} (-\tfrac12 t^2) = 0$. Convergent

38. $\displaystyle\int_0^{\pi/2} \frac{\cos\theta}{\sqrt{\sin\theta}}\, d\theta = \lim_{t\to 0^+} \int_t^{\pi/2} \frac{\cos\theta}{\sqrt{\sin\theta}}\, d\theta = \lim_{t\to 0^+} \Big[2\sqrt{\sin\theta}\Big]_t^{\pi/2}$ $\quad \begin{bmatrix} u = \sin\theta, \\ du = \cos\theta\, d\theta \end{bmatrix}$

$= \lim\limits_{t\to 0^+} (2 - 2\sqrt{\sin t}\,) = 2 - 0 = 2.$ Convergent

39. $\displaystyle\int_{-1}^0 \frac{e^{1/x}}{x^3}\, dx = \lim_{t\to 0^-} \int_{-1}^t \frac1x e^{1/x} \cdot \frac{1}{x^2}\, dx = \lim_{t\to 0^-} \int_{-1}^{1/t} ue^u\,(-du)$ $\quad \begin{bmatrix} u = 1/x, \\ du = -dx/x^2 \end{bmatrix}$

$= \lim\limits_{t\to 0^-} \big[(u-1)e^u\big]_{1/t}^{-1}$ $\quad$ [use parts or Formula 96] $\quad = \lim\limits_{t\to 0^-} \left[-2e^{-1} - \left(\dfrac1t - 1\right)e^{1/t}\right]$

$= -\dfrac2e - \lim\limits_{s\to -\infty} (s-1)e^s$ $\quad [s = 1/t] \quad = -\dfrac2e - \lim\limits_{s\to -\infty} \dfrac{s-1}{e^{-s}} \overset{\text{H}}{=} -\dfrac2e - \lim\limits_{s\to -\infty} \dfrac{1}{-e^{-s}}$

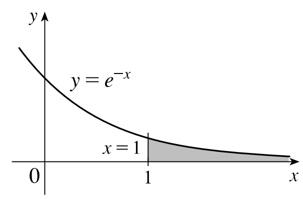
$= -\dfrac2e - 0 = -\dfrac2e.$ Convergent

40. $\displaystyle\int_0^1 \frac{e^{1/x}}{x^3}\, dx = \lim_{t\to 0^+} \int_t^1 \frac1x e^{1/x} \cdot \frac{1}{x^2}\, dx = \lim_{t\to 0^+} \int_{1/t}^1 ue^u\,(-du)$ $\quad \begin{bmatrix} u = 1/x, \\ du = -dx/x^2 \end{bmatrix}$

$= \lim\limits_{t\to 0^+} \big[(u-1)e^u\big]_1^{1/t}$ $\quad$ [use parts or Formula 96] $= \lim\limits_{t\to 0^+} \left[\left(\dfrac1t - 1\right)e^{1/t} - 0\right]$

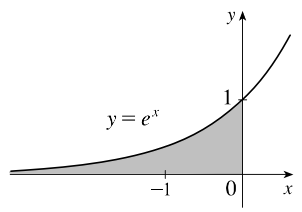
$= \lim\limits_{s\to\infty} (s-1)e^s$ $\quad [s = 1/t] \quad = \infty.$ Divergent

41.



$$\text{Area} = \int_1^\infty e^{-x}\,dx = \lim_{t\to\infty} \int_1^t e^{-x}\,dx = \lim_{t\to\infty} \Big[-e^{-x}\Big]_1^t$$
$$= \lim_{t\to\infty} (-e^{-t} + e^{-1}) = 0 + e^{-1} = 1/e$$

42.



$$\text{Area} = \int_{-\infty}^0 e^x\,dx = \lim_{t\to-\infty} \int_t^0 e^x\,dx = \lim_{t\to-\infty} \Big[e^x\Big]_t^0$$
$$= \lim_{t\to-\infty} (e^0 - e^t) = 1 - 0 = 1$$

43.

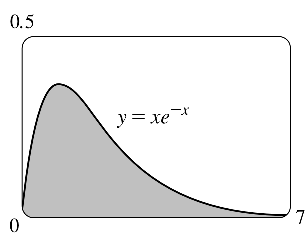
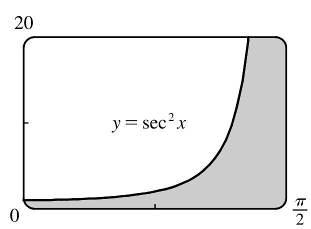
$$= \lim_{t\to\infty} \left[\ln|x| - \frac{1}{2}\ln\left|x^2+1\right|\right]_1^t = \lim_{t\to\infty} \left[\ln\frac{x}{\sqrt{x^2+1}}\right]_1^t$$
$$= \lim_{t\to\infty} \left(\ln\frac{t}{\sqrt{t^2+1}} - \ln\frac{1}{\sqrt{2}}\right) = \ln 1 - \ln 2^{-1/2} = \frac{1}{2}\ln 2$$

44.



$$\text{Area} = \int_0^\infty xe^{-x}\,dx = \lim_{t\to\infty} \int_0^t xe^{-x}\,dx$$
$$= \lim_{t\to\infty} \Big[-xe^{-x} - e^{-x}\Big]_0^t \qquad \text{[use parts wtih } u = x \text{ and } dv = e^{-x}\,dx\text{]}$$
$$= \lim_{t\to\infty} \big[(-te^{-t} - e^{-t}) - (-1)\big]$$
$$= 0 \quad \text{[use l'Hospital's Rule]} \quad - 0 + 1 = 1$$

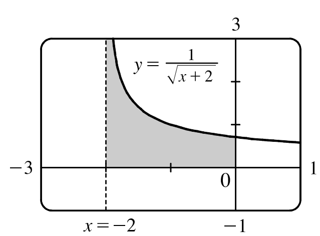
45.



$$\text{Area} = \int_0^{\pi/2} \sec^2 x\,dx = \lim_{t\to(\pi/2)^-} \int_0^t \sec^2 x\,dx = \lim_{t\to(\pi/2)^-} \Big[\tan x\Big]_0^t$$
$$= \lim_{t\to(\pi/2)^-} (\tan t - 0) = \infty$$

Infinite area

46.



$$\text{Area} = \int_{-2}^0 \frac{1}{\sqrt{x+2}}\,dx = \lim_{t\to-2^+} \int_t^0 \frac{1}{\sqrt{x+2}}\,dx = \lim_{t\to-2^+} \Big[2\sqrt{x+2}\Big]_t^0$$
$$= \lim_{t\to-2^+} \left(2\sqrt{2} - 2\sqrt{t+2}\right) = 2\sqrt{2} - 0 = 2\sqrt{2}$$

47. (a)

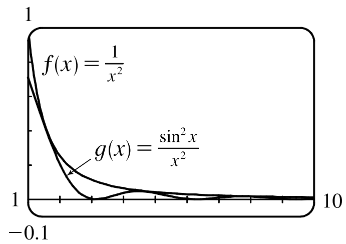
t	$\int_1^t g(x)\,dx$
2	0.447453
5	0.577101
10	0.621306
100	0.668479
1000	0.672957
10,000	0.673407

$g(x) = \dfrac{\sin^2 x}{x^2}$.

It appears that the integral is convergent.

(b) $-1 \le \sin x \le 1 \;\Rightarrow\; 0 \le \sin^2 x \le 1 \;\Rightarrow\; 0 \le \dfrac{\sin^2 x}{x^2} \le \dfrac{1}{x^2}$. Since $\displaystyle\int_1^\infty \frac{1}{x^2}\,dx$ is convergent [Equation 2 with $p = 2 > 1$], $\displaystyle\int_1^\infty \frac{\sin^2 x}{x^2}\,dx$ is convergent by the Comparison Theorem.

(c)



Since $\int_1^\infty f(x)\,dx$ is finite and the area under $g(x)$ is less than the area under $f(x)$ on any interval $[1, t]$, $\int_1^\infty g(x)\,dx$ must be finite; that is, the integral is convergent.

48. (a)

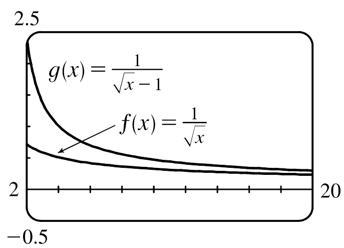
t	$\int_2^t g(x)dx$
5	3.830327
10	6.801200
100	23.328769
1000	69.023361
10,000	208.124560

$g(x) = \dfrac{1}{\sqrt{x} - 1}$.

It appears that the integral is divergent.

(b) For $x \ge 2$, $\sqrt{x} > \sqrt{x} - 1 \;\Rightarrow\; \dfrac{1}{\sqrt{x}} < \dfrac{1}{\sqrt{x} - 1}$. Since $\displaystyle\int_2^\infty \frac{1}{\sqrt{x}}\,dx$ is divergent [Equation 2 with $p = \frac{1}{2} \le 1$], $\displaystyle\int_2^\infty \frac{1}{\sqrt{x} - 1}\,dx$ is divergent by the Comparison Theorem.

(c)



Since $\int_2^\infty f(x)\,dx$ is infinite and the area under $g(x)$ is greater than the area under $f(x)$ on any interval $[2, t]$, $\int_2^\infty g(x)\,dx$ must be infinite; that is, the integral is divergent.

49. For $x > 0$, $\dfrac{x}{x^3 + 1} < \dfrac{x}{x^3} = \dfrac{1}{x^2}$. $\displaystyle\int_1^\infty \frac{1}{x^2}\,dx$ is convergent by Equation 2 with $p = 2 > 1$, so $\displaystyle\int_1^\infty \frac{x}{x^3 + 1}\,dx$ is convergent by the Comparison Theorem. $\displaystyle\int_0^1 \frac{x}{x^3 + 1}\,dx$ is a constant, so $\displaystyle\int_0^\infty \frac{x}{x^3 + 1}\,dx = \int_0^1 \frac{x}{x^3 + 1}\,dx + \int_1^\infty \frac{x}{x^3 + 1}\,dx$ is also convergent.

50. For $x \geq 1$, $\dfrac{1+\sin^2 x}{\sqrt{x}} \geq \dfrac{1}{\sqrt{x}}$. $\displaystyle\int_1^\infty \frac{1}{\sqrt{x}}\,dx$ is divergent by Equation 2 with $p = \frac{1}{2} \leq 1$, so $\displaystyle\int_1^\infty \frac{1+\sin^2 x}{\sqrt{x}}\,dx$ is divergent by the Comparison Theorem.

51. For $x > 1$, $f(x) = \dfrac{x+1}{\sqrt{x^4 - x}} > \dfrac{x+1}{\sqrt{x^4}} > \dfrac{x}{x^2} = \dfrac{1}{x}$, so $\displaystyle\int_2^\infty f(x)\,dx$ diverges by comparison with $\displaystyle\int_2^\infty \frac{1}{x}\,dx$, which diverges by Equation 2 with $p = 1 \leq 1$. Thus, $\int_1^\infty f(x)\,dx = \int_1^2 f(x)\,dx + \int_2^\infty f(x)\,dx$ also diverges.

52. For $x \geq 0$, $\arctan x < \dfrac{\pi}{2} < 2$, so $\dfrac{\arctan x}{2+e^x} < \dfrac{2}{2+e^x} < \dfrac{2}{e^x} = 2e^{-x}$. Now

$I = \displaystyle\int_0^\infty 2e^{-x}\,dx = \lim_{t\to\infty}\int_0^t 2e^{-x}\,dx = \lim_{t\to\infty}\left[-2e^{-x}\right]_0^t = \lim_{t\to\infty}\left(-\frac{2}{e^t} + 2\right) = 2$, so I is convergent, and by comparison, $\displaystyle\int_0^\infty \frac{\arctan x}{2+e^x}\,dx$ is convergent.

53. For $0 < x \leq 1$, $\dfrac{\sec^2 x}{x\sqrt{x}} > \dfrac{1}{x^{3/2}}$. Now

$I = \displaystyle\int_0^1 x^{-3/2}\,dx = \lim_{t\to 0^+}\int_t^1 x^{-3/2}\,dx = \lim_{t\to 0^+}\left[-2x^{-1/2}\right]_t^1 = \lim_{t\to 0^+}\left(-2 + \frac{2}{\sqrt{t}}\right) = \infty$, so I is divergent, and by comparison, $\displaystyle\int_0^1 \frac{\sec^2 x}{x\sqrt{x}}$ is divergent.

54. For $0 < x \leq 1$, $\dfrac{\sin^2 x}{\sqrt{x}} \leq \dfrac{1}{\sqrt{x}}$. Now

$I = \displaystyle\int_0^\pi \frac{1}{\sqrt{x}}\,dx = \lim_{t\to 0^+}\int_t^\pi x^{-1/2}\,dx = \lim_{t\to 0^+}\left[2x^{1/2}\right]_t^\pi = \lim_{t\to 0^+}\left(2\pi - 2\sqrt{t}\right) = 2\pi - 0 = 2\pi$, so I is convergent, and by comparison, $\displaystyle\int_0^\pi \frac{\sin^2 x}{\sqrt{x}}\,dx$ is convergent.

55. $\displaystyle\int_0^\infty \frac{dx}{\sqrt{x}\,(1+x)} = \int_0^1 \frac{dx}{\sqrt{x}\,(1+x)} + \int_1^\infty \frac{dx}{\sqrt{x}\,(1+x)} = \lim_{t\to 0^+}\int_t^1 \frac{dx}{\sqrt{x}\,(1+x)} + \lim_{t\to\infty}\int_1^t \frac{dx}{\sqrt{x}\,(1+x)}$. Now

$\displaystyle\int \frac{dx}{\sqrt{x}\,(1+x)} = \int \frac{2u\,du}{u(1+u^2)}\quad \begin{bmatrix} u = \sqrt{x},\ x = u^2, \\ dx = 2u\,du \end{bmatrix} \quad = 2\int \frac{du}{1+u^2} = 2\tan^{-1} u + C = 2\tan^{-1}\sqrt{x} + C$, so

$$\int_0^\infty \frac{dx}{\sqrt{x}\,(1+x)} = \lim_{t\to 0^+}\left[2\tan^{-1}\sqrt{x}\right]_t^1 + \lim_{t\to\infty}\left[2\tan^{-1}\sqrt{x}\right]_1^t$$
$$= \lim_{t\to 0^+}\left[2\left(\tfrac{\pi}{4}\right) - 2\tan^{-1}\sqrt{t}\right] + \lim_{t\to\infty}\left[2\tan^{-1}\sqrt{t} - 2\left(\tfrac{\pi}{4}\right)\right] = \tfrac{\pi}{2} - 0 + 2\left(\tfrac{\pi}{2}\right) - \tfrac{\pi}{2} = \pi.$$

56. $\displaystyle\int_2^\infty \frac{dx}{x\sqrt{x^2-4}} = \int_2^3 \frac{dx}{x\sqrt{x^2-4}} + \int_3^\infty \frac{dx}{x\sqrt{x^2-4}} = \lim_{t\to 2^+}\int_t^3 \frac{dx}{x\sqrt{x^2-4}} + \lim_{t\to\infty}\int_3^t \frac{dx}{x\sqrt{x^2-4}}$. Now

$\displaystyle\int \frac{dx}{x\sqrt{x^2-4}} = \int \frac{2\sec\theta\,\tan\theta\,d\theta}{2\sec\theta\,2\tan\theta}\quad \begin{bmatrix} x = 2\sec\theta, \text{ where} \\ 0 \leq \theta < \pi/2 \text{ or } \pi \leq \theta < 3\pi/2 \end{bmatrix} \quad = \tfrac{1}{2}\theta + C = \tfrac{1}{2}\sec^{-1}\left(\tfrac{1}{2}x\right) + C$, so

$$\int_2^\infty \frac{dx}{x\sqrt{x^2-4}} = \lim_{t\to 2^+}\left[\tfrac{1}{2}\sec^{-1}\left(\tfrac{1}{2}x\right)\right]_t^3 + \lim_{t\to\infty}\left[\tfrac{1}{2}\sec^{-1}\left(\tfrac{1}{2}x\right)\right]_3^t = \tfrac{1}{2}\sec^{-1}\left(\tfrac{3}{2}\right) - 0 + \tfrac{1}{2}\left(\tfrac{\pi}{2}\right) - \tfrac{1}{2}\sec^{-1}\left(\tfrac{3}{2}\right) = \tfrac{\pi}{4}.$$

57. If $p = 1$, then $\int_0^1 \frac{dx}{x^p} = \lim_{t\to 0^+} \int_t^1 \frac{dx}{x} = \lim_{t\to 0^+} [\ln x]_t^1 = \infty$. Divergent

If $p \neq 1$, then $\int_0^1 \frac{dx}{x^p} = \lim_{t\to 0^+} \int_t^1 \frac{dx}{x^p}$ [note that the integral is not improper if $p < 0$]

$$= \lim_{t\to 0^+} \left[\frac{x^{-p+1}}{-p+1}\right]_t^1 = \lim_{t\to 0^+} \frac{1}{1-p}\left[1 - \frac{1}{t^{p-1}}\right]$$

If $p > 1$, then $p - 1 > 0$, so $\frac{1}{t^{p-1}} \to \infty$ as $t \to 0^+$, and the integral diverges.

If $p < 1$, then $p - 1 < 0$, so $\frac{1}{t^{p-1}} \to 0$ as $t \to 0^+$ and $\int_0^1 \frac{dx}{x^p} = \frac{1}{1-p}\left[\lim_{t\to 0^+}\left(1 - t^{1-p}\right)\right] = \frac{1}{1-p}$.

Thus, the integral converges if and only if $p < 1$, and in that case its value is $\frac{1}{1-p}$.

58. Let $u = \ln x$. Then $du = dx/x \Rightarrow \int_e^\infty \frac{dx}{x(\ln x)^p} = \int_1^\infty \frac{du}{u^p}$. By Example 4, this converges to $\frac{1}{p-1}$ if $p > 1$ and diverges otherwise.

59. First suppose $p = -1$. Then

$\int_0^1 x^p \ln x\, dx = \int_0^1 \frac{\ln x}{x}\, dx = \lim_{t\to 0^+} \int_t^1 \frac{\ln x}{x}\, dx = \lim_{t\to 0^+} \left[\frac{1}{2}(\ln x)^2\right]_t^1 = -\frac{1}{2}\lim_{t\to 0^+} (\ln t)^2 = -\infty$, so the integral diverges. Now suppose $p \neq -1$. Then integration by parts gives

$\int x^p \ln x\, dx = \frac{x^{p+1}}{p+1}\ln x - \int \frac{x^p}{p+1}\, dx = \frac{x^{p+1}}{p+1}\ln x - \frac{x^{p+1}}{(p+1)^2} + C$. If $p < -1$, then $p + 1 < 0$, so

$$\int_0^1 x^p \ln x\, dx = \lim_{t\to 0^+}\left[\frac{x^{p+1}}{p+1}\ln x - \frac{x^{p+1}}{(p+1)^2}\right]_t^1 = \frac{-1}{(p+1)^2} - \left(\frac{1}{p+1}\right)\lim_{t\to 0^+}\left[t^{p+1}\left(\ln t - \frac{1}{p+1}\right)\right] = \infty.$$

If $p > -1$, then $p + 1 > 0$ and

$$\int_0^1 x^p \ln x\, dx = \frac{-1}{(p+1)^2} - \left(\frac{1}{p+1}\right)\lim_{t\to 0^+}\frac{\ln t - 1/(p+1)}{t^{-(p+1)}} \overset{\text{H}}{=} \frac{-1}{(p+1)^2} - \left(\frac{1}{p+1}\right)\lim_{t\to 0^+}\frac{1/t}{-(p+1)t^{-(p+2)}}$$

$$= \frac{-1}{(p+1)^2} + \frac{1}{(p+1)^2}\lim_{t\to 0^+} t^{p+1} = \frac{-1}{(p+1)^2}$$

Thus, the integral converges to $-\frac{1}{(p+1)^2}$ if $p > -1$ and diverges otherwise.

60. (a) $\boldsymbol{n = 0}$: $\int_0^\infty x^n e^{-x}\, dx = \lim_{t\to\infty}\int_0^t e^{-x}\, dx = \lim_{t\to\infty}\left[-e^{-x}\right]_0^t = \lim_{t\to\infty}\left[-e^{-t} + 1\right] = 0 + 1 = 1$

$\boldsymbol{n = 1}$: $\int_0^\infty x^n e^{-x}\, dx = \lim_{t\to\infty}\int_0^t xe^{-x}\, dx$. To evaluate $\int xe^{-x}\, dx$, we'll use integration by parts with $u = x$, $dv = e^{-x}\, dx \Rightarrow du = dx$, $v = -e^{-x}$.

So $\int xe^{-x}\, dx = -xe^{-x} - \int -e^{-x}\, dx = -xe^{-x} - e^{-x} + C = (-x - 1)e^{-x} + C$ and

$$\lim_{t\to\infty}\int_0^t xe^{-x}\,dx = \lim_{t\to\infty}\left[(-x-1)e^{-x}\right]_0^t = \lim_{t\to\infty}\left[(-t-1)e^{-t}+1\right] = \lim_{t\to\infty}\left[-te^{-t}-e^{-t}+1\right]$$

$$= 0 - 0 + 1 \quad [\text{use l'Hospital's Rule}] \quad = 1$$

$\boldsymbol{n=2}$: $\displaystyle\int_0^\infty x^n e^{-x}\,dx = \lim_{t\to\infty}\int_0^t x^2e^{-x}\,dx$. To evaluate $\displaystyle\int x^2e^{-x}\,dx$, we could use integration by parts again or Formula 97. Thus,

$$\lim_{t\to\infty}\int_0^t x^2e^{-x}\,dx = \lim_{t\to\infty}\left[-x^2e^{-x}\right]_0^t + 2\lim_{t\to\infty}\int_0^t xe^{-x}\,dx$$

$$= 0 + 0 + 2(1) \quad [\text{use l'Hospital's Rule and the result for } n=1] \quad = 2$$

$\boldsymbol{n=3}$: $\displaystyle\int_0^\infty x^n e^{-x}dx = \lim_{t\to\infty}\int_0^t x^3e^{-x}\,dx \overset{97}{=} \lim_{t\to\infty}\left[-x^3e^{-x}\right]_0^t + 3\lim_{t\to\infty}\int_0^t x^2e^{-x}\,dx$

$$= 0 + 0 + 3(2) \quad [\text{use l'Hospital's Rule and the result for } n=2] \quad = 6$$

(b) For $n = 1$, 2, and 3, we have $\int_0^\infty x^n e^{-x}\,dx = 1$, 2, and 6. The values for the integral are equal to the factorials for n, so we guess $\int_0^\infty x^n e^{-x}\,dx = n!$.

(c) Suppose that $\int_0^\infty x^k e^{-x}\,dx = k!$ for some positive integer k. Then $\int_0^\infty x^{k+1}e^{-x}\,dx = \lim_{t\to\infty}\int_0^t x^{k+1}e^{-x}\,dx$.

To evaluate $\int x^{k+1}e^{-x}\,dx$, we use parts with $u = x^{k+1}$, $dv = e^{-x}\,dx \quad\Rightarrow\quad du = (k+1)x^k\,dx$, $v = -e^{-x}$.

So $\int x^{k+1}e^{-x}dx = -x^{k+1}e^{-x} - \int -(k+1)x^ke^{-x}\,dx = -x^{k+1}e^{-x} + (k+1)\int x^ke^{-x}\,dx$ and

$$\lim_{t\to\infty}\int_0^t x^{k+1}e^{-x}\,dx = \lim_{t\to\infty}\left[-x^{k+1}e^{-x}\right]_0^t + (k+1)\lim_{t\to\infty}\int_0^t x^ke^{-x}\,dx$$

$$= \lim_{t\to\infty}\left[-t^{k+1}e^{-t}+0\right] + (k+1)k! = 0 + 0 + (k+1)! = (k+1)!,$$

so the formula holds for $k+1$. By induction, the formula holds for all positive integers. (Since $0! = 1$, the formula holds for $n = 0$, too.)

61. (a) $I = \int_{-\infty}^\infty x\,dx = \int_{-\infty}^0 x\,dx + \int_0^\infty x\,dx$, and $\int_0^\infty x\,dx = \lim_{t\to\infty}\int_0^t x\,dx = \lim_{t\to\infty}\left[\frac{1}{2}x^2\right]_0^t = \lim_{t\to\infty}\left[\frac{1}{2}t^2 - 0\right] = \infty$, so I is divergent.

(b) $\int_{-t}^t x\,dx = \left[\frac{1}{2}x^2\right]_{-t}^t = \frac{1}{2}t^2 - \frac{1}{2}t^2 = 0$, so $\lim_{t\to\infty}\int_{-t}^t x\,dx = 0$. Therefore, $\int_{-\infty}^\infty x\,dx \neq \lim_{t\to\infty}\int_{-t}^t x\,dx$.

62. Let $k = \dfrac{M}{2RT}$ so that $\overline{v} = \dfrac{4}{\sqrt{\pi}}k^{3/2}\displaystyle\int_0^\infty v^3e^{-kv^2}\,dv$. Let I denote the integral and use parts to integrate I. Let $\alpha = v^2$, $d\beta = ve^{-kv^2}\,dv \quad\Rightarrow\quad d\alpha = 2v\,dv$, $\beta = -\dfrac{1}{2k}e^{-kv^2}$:

$$I = \lim_{t\to\infty}\left[-\frac{1}{2k}v^2e^{-kv^2}\right]_0^t + \frac{1}{k}\int_0^\infty ve^{-kv^2}\,dv_0^t = -\frac{1}{2k}\lim_{t\to\infty}\left(t^2e^{-kt^2}\right) + \frac{1}{k}\lim_{t\to\infty}\left[-\frac{1}{2k}e^{-kv^2}\right]$$

$$\overset{\text{H}}{=} -\frac{1}{2k}\cdot 0 - \frac{1}{2k^2}(0-1) = \frac{1}{2k^2}$$

Thus, $\overline{v} = \dfrac{4}{\sqrt{\pi}}k^{3/2}\cdot\dfrac{1}{2k^2} = \dfrac{2}{(k\pi)^{1/2}} = \dfrac{2}{[\pi M/(2RT)]^{1/2}} = \dfrac{2\sqrt{2}\sqrt{RT}}{\sqrt{\pi M}} = \sqrt{\dfrac{8RT}{\pi M}}$.

63. Volume $= \int_1^\infty \pi\left(\frac{1}{x}\right)^2 dx = \pi \lim_{t\to\infty}\int_1^t \frac{dx}{x^2} = \pi \lim_{t\to\infty}\left[-\frac{1}{x}\right]_1^t = \pi \lim_{t\to\infty}\left(1-\frac{1}{t}\right) = \pi < \infty.$

64. Work $= \int_R^\infty \frac{GMm}{r^2}\,dr = \lim_{t\to\infty}\int_R^t \frac{GMm}{r^2}\,dr = \lim_{t\to\infty} GMm\left[\frac{-1}{r}\right]_R^t = GMm \lim_{t\to\infty}\left(\frac{-1}{t}+\frac{1}{R}\right) = \frac{GMm}{R}$, where

M = mass of the earth $= 5.98\times 10^{24}$ kg, m = mass of satellite $= 10^3$ kg, R = radius of the earth $= 6.37\times 10^6$ m, and

G = gravitational constant $= 6.67\times 10^{-11}$ N·m²/kg.

Therefore, Work $= \frac{6.67\times 10^{-11}\cdot 5.98\times 10^{24}\cdot 10^3}{6.37\times 10^6} \approx 6.26\times 10^{10}$ J.

65. Work $= \int_R^\infty F\,dr = \lim_{t\to\infty}\int_R^t \frac{GmM}{r^2}\,dr = \lim_{t\to\infty} GmM\left(\frac{1}{R}-\frac{1}{t}\right) = \frac{GmM}{R}$. The initial kinetic energy provides the work,

so $\frac{1}{2}mv_0^2 = \frac{GmM}{R} \quad\Rightarrow\quad v_0 = \sqrt{\frac{2GM}{R}}$.

66. $y(s) = \int_s^R \frac{2r}{\sqrt{r^2-s^2}}\,x(r)\,dr$ and $x(r) = \frac{1}{2}(R-r)^2 \quad\Rightarrow$

$$\begin{aligned} y(s) &= \lim_{t\to s^+}\int_t^R \frac{r(R-r)^2}{\sqrt{r^2-s^2}}\,dr = \lim_{t\to s^+}\int_t^R \frac{r^3-2Rr^2+R^2r}{\sqrt{r^2-s^2}}\,dr \\ &= \lim_{t\to s^+}\left[\int_t^R \frac{r^3\,dr}{\sqrt{r^2-s^2}} - 2R\int_t^R \frac{r^2\,dr}{\sqrt{r^2-s^2}} + R^2\int_t^R \frac{r\,dr}{\sqrt{r^2-s^2}}\right] = \lim_{t\to s^+}\left(I_1 - 2RI_2 + R^2 I_3\right) = L \end{aligned}$$

For I_1: Let $u = \sqrt{r^2-s^2} \quad\Rightarrow\quad u^2 = r^2-s^2$, $r^2 = u^2+s^2$, $2r\,dr = 2u\,du$, so, omitting limits and constant of integration,

$$\begin{aligned} I_1 &= \int \frac{(u^2+s^2)u}{u}\,du = \int (u^2+s^2)\,du = \tfrac{1}{3}u^3 + s^2u = \tfrac{1}{3}u(u^2+3s^2) \\ &= \tfrac{1}{3}\sqrt{r^2-s^2}\,(r^2-s^2+3s^2) = \tfrac{1}{3}\sqrt{r^2-s^2}\,(r^2+2s^2) \end{aligned}$$

For I_2: Using Formula 44, $I_2 = \frac{r}{2}\sqrt{r^2-s^2} + \frac{s^2}{2}\ln\left|r+\sqrt{r^2-s^2}\right|$.

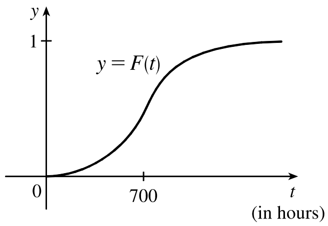
For I_3: Let $u = r^2-s^2 \quad\Rightarrow\quad du = 2r\,dr$. Then $I_3 = \frac{1}{2}\int\frac{du}{\sqrt{u}} = \frac{1}{2}\cdot 2\sqrt{u} = \sqrt{r^2-s^2}$.

Thus,

$$\begin{aligned} L &= \lim_{t\to s^+}\left[\tfrac{1}{3}\sqrt{r^2-s^2}\,(r^2+2s^2) - 2R\left(\frac{r}{2}\sqrt{r^2-s^2}+\frac{s^2}{2}\ln\left|r+\sqrt{r^2-s^2}\right|\right) + R^2\sqrt{r^2-s^2}\right]_t^R \\ &= \lim_{t\to s^+}\left[\tfrac{1}{3}\sqrt{R^2-s^2}(R^2+2s^2) - 2R\left(\frac{R}{2}\sqrt{R^2-s^2}+\frac{s^2}{2}\ln\left|R+\sqrt{R^2-s^2}\right|\right) + R^2\sqrt{R^2-s^2}\right] \\ &\qquad - \lim_{t\to s^+}\left[\tfrac{1}{3}\sqrt{t^2-s^2}\,(t^2+2s^2) - 2R\left(\frac{t}{2}\sqrt{t^2-s^2}+\frac{s^2}{2}\ln\left|t+\sqrt{t^2-s^2}\right|\right) + R^2\sqrt{t^2-s^2}\right] \\ &= \left[\tfrac{1}{3}\sqrt{R^2-s^2}\,(R^2+2s^2) - Rs^2\ln\left|R+\sqrt{R^2-s^2}\right|\right] - \left[-Rs^2\ln|s|\right] \\ &= \tfrac{1}{3}\sqrt{R^2-s^2}\,(R^2+2s^2) - Rs^2\ln\left(\frac{R+\sqrt{R^2-s^2}}{s}\right) \end{aligned}$$

67. We would expect a small percentage of bulbs to burn out in the first few hundred hours, most of the bulbs to burn out after close to 700 hours, and a few overachievers to burn on and on.

(a)



(b) $r(t) = F'(t)$ is the rate at which the fraction $F(t)$ of burnt-out bulbs increases as t increases. This could be interpreted as a fractional burnout rate.

(c) $\int_0^\infty r(t)\,dt = \lim\limits_{x\to\infty} F(x) = 1$, since all of the bulbs will eventually burn out.

68. $I = \int_0^\infty te^{kt}\,dt = \lim\limits_{s\to\infty}\left[\frac{1}{k^2}(kt-1)\,e^{kt}\right]_0^s$ [Formula 96, or parts] $= \lim\limits_{s\to\infty}\left[\left(\frac{1}{k}se^{ks} - \frac{1}{k^2}e^{ks}\right) - \left(-\frac{1}{k^2}\right)\right]$.

Since $k < 0$ the first two terms approach 0 (you can verify that the first term does so with l'Hospital's Rule), so the limit is equal to $1/k^2$. Thus, $M = -kI = -k(1/k^2) = -1/k = -1/(-0.000121) \approx 8264.5$ years.

69. $\gamma = \int_0^\infty \frac{cN(1-e^{-kt})}{k}\,e^{-\lambda t}\,dt = \frac{cN}{k}\lim\limits_{x\to\infty}\int_0^x \left[e^{-\lambda t} - e^{(-k-\lambda)t}\right]dt$

$$= \frac{cN}{k}\lim_{x\to\infty}\left[\frac{1}{-\lambda}e^{-\lambda t} - \frac{1}{-k-\lambda}e^{(-k-\lambda)t}\right]_0^x = \frac{cN}{k}\lim_{x\to\infty}\left[\frac{1}{-\lambda e^{\lambda x}} + \frac{1}{(k+\lambda)e^{(k+\lambda)x}} - \left(\frac{1}{-\lambda} + \frac{1}{k+\lambda}\right)\right]$$

$$= \frac{cN}{k}\left(\frac{1}{\lambda} - \frac{1}{k+\lambda}\right) = \frac{cN}{k}\left(\frac{k+\lambda-\lambda}{\lambda(k+\lambda)}\right) = \frac{cN}{\lambda(k+\lambda)}$$

70. $\int_0^\infty u(t)\,dt = \lim\limits_{x\to\infty}\int_0^x \frac{r}{V}C_0\,e^{-rt/V}\,dt = \frac{r}{V}C_0\lim\limits_{x\to\infty}\left[\frac{e^{-rt/V}}{-r/V}\right]_0^x = \frac{r}{V}C_0\left(-\frac{V}{r}\right)\lim\limits_{x\to\infty}\left(e^{-rx/V} - 1\right)$

$$= -C_0(0-1) = C_0.$$

$\int_0^\infty u(t)\,dt$ represents the total amount of urea removed from the blood if dialysis is continued indefinitely. The fact that $\int_0^\infty u(t)\,dt = C_0$ means that, in the limit, as $t \to \infty$, all the urea in the blood at time $t = 0$ is removed. The calculation says nothing about how rapidly that limit is approached.

71. $I = \int_a^\infty \frac{1}{x^2+1}\,dx = \lim\limits_{t\to\infty}\int_a^t \frac{1}{x^2+1}\,dx = \lim\limits_{t\to\infty}\left[\tan^{-1}x\right]_a^t = \lim\limits_{t\to\infty}\left(\tan^{-1}t - \tan^{-1}a\right) = \frac{\pi}{2} - \tan^{-1}a.$

$I < 0.001 \;\Rightarrow\; \frac{\pi}{2} - \tan^{-1}a < 0.001 \;\Rightarrow\; \tan^{-1}a > \frac{\pi}{2} - 0.001 \;\Rightarrow\; a > \tan\left(\frac{\pi}{2} - 0.001\right) \approx 1000.$

72. $f(x) = e^{-x^2}$ and $\Delta x = \frac{4-0}{8} = \frac{1}{2}$.

$\int_0^4 f(x)\,dx \approx S_8 = \frac{1}{2\cdot 3}[f(0) + 4f(0.5) + 2f(1) + \cdots + 2f(3) + 4f(3.5) + f(4)] \approx \frac{1}{6}(5.31717808) \approx 0.8862$

Now $x > 4 \;\Rightarrow\; -x\cdot x < -x\cdot 4 \;\Rightarrow\; e^{-x^2} < e^{-4x} \;\Rightarrow\; \int_4^\infty e^{-x^2}\,dx < \int_4^\infty e^{-4x}\,dx.$

$\int_4^\infty e^{-4x}\,dx = \lim\limits_{t\to\infty}\left[-\frac{1}{4}e^{-4x}\right]_4^t = -\frac{1}{4}\left(0 - e^{-16}\right) = 1/(4e^{16}) \approx 0.0000000281 < 0.0000001$, as desired.

73. (a) $F(s) = \int_0^\infty f(t)e^{-st}\,dt = \int_0^\infty e^{-st}\,dt = \lim\limits_{n\to\infty}\left[-\frac{e^{-st}}{s}\right]_0^n = \lim\limits_{n\to\infty}\left(\frac{e^{-sn}}{-s} + \frac{1}{s}\right)$. This converges to $\frac{1}{s}$ only if $s > 0$.

Therefore $F(s) = \frac{1}{s}$ with domain $\{s \mid s > 0\}$.

(b) $F(s) = \int_0^\infty f(t)e^{-st}\,dt = \int_0^\infty e^t e^{-st}\,dt = \lim_{n\to\infty} \int_0^n e^{t(1-s)}\,dt = \lim_{n\to\infty} \left[\frac{1}{1-s}e^{t(1-s)}\right]_0^n$

$= \lim_{n\to\infty} \left(\frac{e^{(1-s)n}}{1-s} - \frac{1}{1-s}\right)$

This converges only if $1 - s < 0 \Rightarrow s > 1$, in which case $F(s) = \frac{1}{s-1}$ with domain $\{s \mid s > 1\}$.

(c) $F(s) = \int_0^\infty f(t)e^{-st}\,dt = \lim_{n\to\infty} \int_0^n te^{-st}\,dt$. Use integration by parts: let $u = t$, $dv = e^{-st}\,dt \Rightarrow du = dt$, $v = -\frac{e^{-st}}{s}$. Then $F(s) = \lim_{n\to\infty} \left[-\frac{t}{s}e^{-st} - \frac{1}{s^2}e^{-st}\right]_0^n = \lim_{n\to\infty} \left(\frac{-n}{se^{sn}} - \frac{1}{s^2e^{sn}} + 0 + \frac{1}{s^2}\right) = \frac{1}{s^2}$ only if $s > 0$.

Therefore, $F(s) = \frac{1}{s^2}$ and the domain of F is $\{s \mid s > 0\}$.

74. $0 \le f(t) \le Me^{at} \Rightarrow 0 \le f(t)e^{-st} \le Me^{at}e^{-st}$ for $t \ge 0$. Now use the Comparison Theorem:

$$\int_0^\infty Me^{at}e^{-st}\,dt = \lim_{n\to\infty} M \int_0^n e^{t(a-s)}\,dt = M \cdot \lim_{n\to\infty} \left[\frac{1}{a-s}e^{t(a-s)}\right]_0^n = M \cdot \lim_{n\to\infty} \frac{1}{a-s}\left[e^{n(a-s)} - 1\right]$$

This is convergent only when $a - s < 0 \Rightarrow s > a$. Therefore, by the Comparison Theorem, $F(s) = \int_0^\infty f(t)\,e^{-st}\,dt$ is also convergent for $s > a$.

75. $G(s) = \int_0^\infty f'(t)e^{-st}\,dt$. Integrate by parts with $u = e^{-st}$, $dv = f'(t)\,dt \Rightarrow du = -se^{-st}$, $v = f(t)$:

$$G(s) = \lim_{n\to\infty} \left[f(t)e^{-st}\right]_0^n + s\int_0^\infty f(t)e^{-st}\,dt = \lim_{n\to\infty} f(n)e^{-sn} - f(0) + sF(s)$$

But $0 \le f(t) \le Me^{at} \Rightarrow 0 \le f(t)e^{-st} \le Me^{at}e^{-st}$ and $\lim_{t\to\infty} Me^{t(a-s)} = 0$ for $s > a$. So by the Squeeze Theorem, $\lim_{t\to\infty} f(t)e^{-st} = 0$ for $s > a \Rightarrow G(s) = 0 - f(0) + sF(s) = sF(s) - f(0)$ for $s > a$.

76. Assume without loss of generality that $a < b$. Then

$$\begin{aligned}\int_{-\infty}^a f(x)\,dx + \int_a^\infty f(x)\,dx &= \lim_{t\to-\infty} \int_t^a f(x)\,dx + \lim_{u\to\infty} \int_a^u f(x)\,dx \\ &= \lim_{t\to-\infty} \int_t^a f(x)\,dx + \lim_{u\to\infty} \left[\int_a^b f(x)\,dx + \int_b^u f(x)\,dx\right] \\ &= \lim_{t\to-\infty} \int_t^a f(x)\,dx + \int_a^b f(x)\,dx + \lim_{u\to\infty} \int_b^u f(x)\,dx \\ &= \lim_{t\to-\infty} \left[\int_t^a f(x)\,dx + \int_a^b f(x)\,dx\right] + \int_b^\infty f(x)\,dx \\ &= \lim_{t\to-\infty} \int_t^b f(x)\,dx + \int_b^\infty f(x)\,dx = \int_{-\infty}^b f(x)\,dx + \int_b^\infty f(x)\,dx\end{aligned}$$

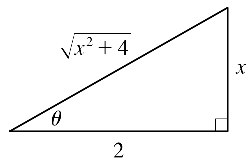
77. We use integration by parts: let $u = x$, $dv = xe^{-x^2}\,dx \Rightarrow du = dx$, $v = -\frac{1}{2}e^{-x^2}$. So

$$\int_0^\infty x^2e^{-x^2}\,dx = \lim_{t\to\infty} \left[-\frac{1}{2}xe^{-x^2}\right]_0^t + \frac{1}{2}\int_0^\infty e^{-x^2}\,dx = \lim_{t\to\infty} \left[-\frac{t}{2e^{t^2}}\right] + \frac{1}{2}\int_0^\infty e^{-x^2}\,dx = \frac{1}{2}\int_0^\infty e^{-x^2}\,dx$$

(The limit is 0 by l'Hospital's Rule.)

78. $\int_0^\infty e^{-x^2}\,dx$ is the area under the curve $y = e^{-x^2}$ for $0 \le x < \infty$ and $0 < y \le 1$. Solving $y = e^{-x^2}$ for x, we get $y = e^{-x^2} \;\Rightarrow\; \ln y = -x^2 \;\Rightarrow\; -\ln y = x^2 \;\Rightarrow\; x = \pm\sqrt{-\ln y}$. Since x is positive, choose $x = \sqrt{-\ln y}$, and the area is represented by $\int_0^1 \sqrt{-\ln y}\,dy$. Therefore, each integral represents the same area, so the integrals are equal.

79. For the first part of the integral, let $x = 2\tan\theta \;\Rightarrow\; dx = 2\sec^2\theta\,d\theta$.



$$\int \frac{1}{\sqrt{x^2+4}}\,dx = \int \frac{2\sec^2\theta}{2\sec\theta}\,d\theta = \int \sec\theta\,d\theta = \ln|\sec\theta + \tan\theta|.$$

From the figure, $\tan\theta = \dfrac{x}{2}$, and $\sec\theta = \dfrac{\sqrt{x^2+4}}{2}$. So

$$\begin{aligned} I = \int_0^\infty \left(\frac{1}{\sqrt{x^2+4}} - \frac{C}{x+2}\right) dx &= \lim_{t\to\infty}\left[\ln\left|\frac{\sqrt{x^2+4}}{2} + \frac{x}{2}\right| - C\ln|x+2|\right]_0^t \\ &= \lim_{t\to\infty}\left[\ln\frac{\sqrt{t^2+4}+t}{2} - C\ln(t+2) - (\ln 1 - C\ln 2)\right] \\ &= \lim_{t\to\infty}\left[\ln\left(\frac{\sqrt{t^2+4}+t}{2\,(t+2)^C}\right) + \ln 2^C\right] = \ln\left(\lim_{t\to\infty}\frac{t+\sqrt{t^2+4}}{(t+2)^C}\right) + \ln 2^{C-1} \end{aligned}$$

Now $L = \lim\limits_{t\to\infty}\dfrac{t+\sqrt{t^2+4}}{(t+2)^C} \overset{\text{H}}{=} \lim\limits_{t\to\infty}\dfrac{1+t/\sqrt{t^2+4}}{C\,(t+2)^{C-1}} = \dfrac{2}{C\lim\limits_{t\to\infty}(t+2)^{C-1}}$.

If $C < 1$, $L = \infty$ and I diverges.

If $C = 1$, $L = 2$ and I converges to $\ln 2 + \ln 2^0 = \ln 2$.

If $C > 1$, $L = 0$ and I diverges to $-\infty$.

80. $$\begin{aligned} I = \int_0^\infty \left(\frac{x}{x^2+1} - \frac{C}{3x+1}\right) dx &= \lim_{t\to\infty}\left[\tfrac{1}{2}\ln(x^2+1) - \tfrac{1}{3}C\ln(3x+1)\right]_0^t = \lim_{t\to\infty}\left[\ln(t^2+1)^{1/2} - \ln(3t+1)^{C/3}\right] \\ &= \lim_{t\to\infty}\left(\ln\frac{(t^2+1)^{1/2}}{(3t+1)^{C/3}}\right) = \ln\left(\lim_{t\to\infty}\frac{\sqrt{t^2+1}}{(3t+1)^{C/3}}\right) \end{aligned}$$

For $C \le 0$, the integral diverges. For $C > 0$, we have

$$L = \lim_{t\to\infty}\frac{\sqrt{t^2+1}}{(3t+1)^{C/3}} \overset{\text{H}}{=} \lim_{t\to\infty}\frac{t\big/\sqrt{t^2+1}}{C(3t+1)^{(C/3)-1}} = \frac{1}{C}\lim_{t\to\infty}\frac{1}{(3t+1)^{(C/3)-1}}$$

For $C/3 < 1 \;\Leftrightarrow\; C < 3$, $L = \infty$ and I diverges.

For $C = 3$, $L = \frac{1}{3}$ and $I = \ln\frac{1}{3}$.

For $C > 3$, $L = 0$ and I diverges to $-\infty$.

81. No, $I = \int_0^\infty f(x)\,dx$ must be *divergent*. Since $\lim\limits_{x\to\infty} f(x) = 1$, there must exist an N such that if $x \ge N$, then $f(x) \ge \frac{1}{2}$. Thus, $I = I_1 + I_2 = \int_0^N f(x)\,dx + \int_N^\infty f(x)\,dx$, where I_1 is an ordinary definite integral that has a finite value, and I_2 is improper and diverges by comparison with the divergent integral $\int_N^\infty \frac{1}{2}\,dx$.

82. As in Exercise 55, we let $I = \displaystyle\int_0^\infty \frac{x^a}{1+x^b}\,dx = I_1 + I_2$, where $I_1 = \displaystyle\int_0^1 \frac{x^a}{1+x^b}\,dx$ and $I_2 = \displaystyle\int_1^\infty \frac{x^a}{1+x^b}\,dx$. We will show that I_1 converges for $a > -1$ and I_2 converges for $b > a + 1$, so that I converges when $a > -1$ and $b > a + 1$.

[continued]

I_1 is improper only when $a < 0$. When $0 \le x \le 1$, we have $\dfrac{1}{1+x^b} \le 1 \quad\Rightarrow\quad \dfrac{1}{x^{-a}(1+x^b)} \le \dfrac{1}{x^{-a}}$. The integral $\displaystyle\int_0^1 \frac{1}{x^{-a}}\,dx$ converges for $-a < 1$ [or $a > -1$] by Exercise 57, so by the Comparison Theorem, $\displaystyle\int_0^1 \frac{1}{x^{-a}(1+x^b)}\,dx$ converges for $-1 < a < 0$. I_1 is not improper when $a \ge 0$, so it has a finite real value in that case. Therefore, I_1 has a finite real value (converges) when $a > -1$.

I_2 is always improper. When $x \ge 1$, $\dfrac{x^a}{1+x^b} = \dfrac{1}{x^{-a}(1+x^b)} = \dfrac{1}{x^{-a}+x^{b-a}} < \dfrac{1}{x^{b-a}}$. By (2), $\displaystyle\int_1^\infty \frac{1}{x^{b-a}}\,dx$ converges for $b - a > 1$ (or $b > a + 1$), so by the Comparison Theorem, $\displaystyle\int_1^\infty \frac{x^a}{1+x^b}\,dx$ converges for $b > a + 1$.

Thus, I converges if $a > -1$ and $b > a + 1$.

TRUE-FALSE QUIZ

1. False. Since the numerator has a higher degree than the denominator, $\dfrac{x(x^2+4)}{x^2-4} = x + \dfrac{8x}{x^2-4} = x + \dfrac{A}{x+2} + \dfrac{B}{x-2}$.

2. True. In fact, $A = -1$, $B = C = 1$.

3. False. It can be put in the form $\dfrac{A}{x} + \dfrac{B}{x^2} + \dfrac{C}{x-4}$.

4. False. The form is $\dfrac{A}{x} + \dfrac{Bx+C}{x^2+4}$.

5. False. This is an improper integral, since the denominator vanishes at $x = 1$.

$$\int_0^4 \frac{x}{x^2-1}\,dx = \int_0^1 \frac{x}{x^2-1}\,dx + \int_1^4 \frac{x}{x^2-1}\,dx \text{ and}$$

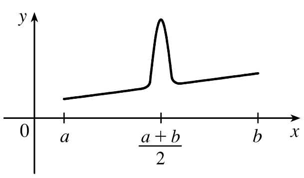
$$\int_0^1 \frac{x}{x^2-1}\,dx = \lim_{t\to 1^-} \int_0^t \frac{x}{x^2-1}\,dx = \lim_{t\to 1^-} \left[\tfrac{1}{2}\ln\left|x^2-1\right|\right]_0^t = \lim_{t\to 1^-} \tfrac{1}{2}\ln\left|t^2-1\right| = \infty$$

So the integral diverges.

6. True by Theorem 7.8.2 with $p = \sqrt{2} > 1$.

7. False. See Exercise 61 in Section 7.8.

8. False. For example, with $n = 1$ the Trapezoidal Rule is much more accurate than the Midpoint Rule for the function in the diagram.



9. (a) True. See the end of Section 7.5.

(b) False. Examples include the functions $f(x) = e^{x^2}$, $g(x) = \sin(x^2)$, and $h(x) = \dfrac{\sin x}{x}$.

10. True. If f is continuous on $[0,\infty)$, then $\int_0^1 f(x)\,dx$ is finite. Since $\int_1^\infty f(x)\,dx$ is finite, so is $\int_0^\infty f(x)\,dx = \int_0^1 f(x)\,dx + \int_1^\infty f(x)\,dx$.

11. False. If $f(x)=1/x$, then f is continuous and decreasing on $[1,\infty)$ with $\lim\limits_{x\to\infty} f(x)=0$, but $\int_1^\infty f(x)\,dx$ is divergent.

12. True.
$$\int_a^\infty [f(x)+g(x)]\,dx = \lim_{t\to\infty}\int_a^t [f(x)+g(x)]\,dx = \lim_{t\to\infty}\left(\int_a^t f(x)\,dx + \int_a^t g(x)\,dx\right)$$
$$= \lim_{t\to\infty}\int_a^t f(x)\,dx + \lim_{t\to\infty}\int_a^t g(x)\,dx \quad \left[\text{since both limits in the sum exist}\right]$$
$$= \int_a^\infty f(x)\,dx + \int_a^\infty g(x)\,dx$$
Since the two integrals are finite, so is their sum.

13. False. Take $f(x)=1$ for all x and $g(x)=-1$ for all x. Then $\int_a^\infty f(x)\,dx=\infty$ [divergent] and $\int_a^\infty g(x)\,dx=-\infty$ [divergent], but $\int_a^\infty [f(x)+g(x)]\,dx = 0$ [convergent].

14. False. $\int_0^\infty f(x)\,dx$ could converge or diverge. For example, if $g(x)=1$, then $\int_0^\infty f(x)\,dx$ diverges if $f(x)=1$ and converges if $f(x)=0$.

EXERCISES

1.
$$\int_1^2 \frac{(x+1)^2}{x}\,dx = \int_1^2 \frac{x^2+2x+1}{x}\,dx = \int_1^2 \left(x+2+\frac{1}{x}\right)dx = \left[\frac{1}{2}x^2+2x+\ln|x|\right]_1^2$$
$$= (2+4+\ln 2) - \left(\tfrac{1}{2}+2+0\right) = \tfrac{7}{2}+\ln 2$$

2.
$$\int_1^2 \frac{x}{(x+1)^2}\,dx = \int_2^3 \frac{u-1}{u^2}\,du \quad \left[\begin{matrix} u=x+1, \\ du=dx \end{matrix}\right]$$
$$= \int_2^3 \left(\frac{1}{u}-\frac{1}{u^2}\right)du = \left[\ln|u|+\frac{1}{u}\right]_2^3 = \left(\ln 3+\frac{1}{3}\right) - \left(\ln 2+\frac{1}{2}\right) = \ln\frac{3}{2}-\frac{1}{6}$$

3.
$$\int \frac{e^{\sin x}}{\sec x}\,dx = \int \cos x\, e^{\sin x}\,dx = \int e^u\,du \quad \left[\begin{matrix} u=\sin x, \\ du=\cos x\,dx \end{matrix}\right]$$
$$= e^u + C = e^{\sin x}+C$$

$$= \left(-\tfrac{\pi}{12}\cdot\tfrac{1}{2}\right) - (0) + \left[\tfrac{1}{4}\sin 2t\right]_0^{\pi/6} = -\tfrac{\pi}{24}+\tfrac{1}{8}\sqrt{3}$$

5.
$$\int \frac{dt}{2t^2+3t+1} = \int \frac{1}{(2t+1)(t+1)}\,dt = \int\left(\frac{2}{2t+1}-\frac{1}{t+1}\right)dt \quad [\text{partial fractions}] \quad = \ln|2t+1| - \ln|t+1| + C$$

6.
$$\int_1^2 x^5\ln x\,dx = \left[\tfrac{1}{6}x^6\ln x\right]_1^2 - \int_1^2 \tfrac{1}{6}x^5\,dx \quad \left[\begin{matrix} u=\ln x, & dv=x^5\,dx \\ du=\frac{1}{x}\,dx, & v=\frac{1}{6}x^6 \end{matrix}\right]$$
$$= \tfrac{64}{6}\ln 2 - 0 - \left[\tfrac{1}{36}x^6\right]_1^2 = \tfrac{32}{3}\ln 2 - \left(\tfrac{64}{36}-\tfrac{1}{36}\right) = \tfrac{32}{3}\ln 2 - \tfrac{7}{4}$$

7.
$$\int_0^{\pi/2}\sin^3\theta\,\cos^2\theta\,d\theta = \int_0^{\pi/2}(1-\cos^2\theta)\cos^2\theta\,\sin\theta\,d\theta = \int_1^0 (1-u^2)u^2\,(-du) \quad \left[\begin{matrix} u=\cos\theta, \\ du=-\sin\theta\,d\theta \end{matrix}\right]$$
$$= \int_0^1 (u^2-u^4)\,du = \left[\tfrac{1}{3}u^3-\tfrac{1}{5}u^5\right]_0^1 = \left(\tfrac{1}{3}-\tfrac{1}{5}\right) - 0 = \tfrac{2}{15}$$

8. Let $u = \sqrt{e^x - 1}$, so that $u^2 = e^x - 1$, $2u\,du = e^x\,dx$, and $e^x = u^2 + 1$. Then

$$\int \frac{1}{\sqrt{e^x - 1}}\,dx = \int \frac{1}{u}\frac{2u\,du}{u^2+1} = 2\int \frac{1}{u^2+1}\,du = 2\tan^{-1} u + C = 2\tan^{-1}\sqrt{e^x - 1} + C.$$

9. Let $u = \ln t$, $du = dt/t$. Then $\displaystyle\int \frac{\sin(\ln t)}{t}\,dt = \int \sin u\,du = -\cos u + C = -\cos(\ln t) + C.$

10. Let $u = \arctan x$, $du = dx/(1+x^2)$. Then

$$\int_0^1 \frac{\sqrt{\arctan x}}{1+x^2}\,dx = \int_0^{\pi/4} \sqrt{u}\,du = \frac{2}{3}\Big[u^{3/2}\Big]_0^{\pi/4} = \frac{2}{3}\left[\frac{\pi^{3/2}}{4^{3/2}} - 0\right] = \frac{2}{3}\cdot\frac{1}{8}\pi^{3/2} = \frac{1}{12}\pi^{3/2}.$$

11. Let $x = \sec\theta$. Then

$$\int_1^2 \frac{\sqrt{x^2-1}}{x}\,dx = \int_0^{\pi/3} \frac{\tan\theta}{\sec\theta}\,\sec\theta\,\tan\theta\,d\theta = \int_0^{\pi/3} \tan^2\theta\,d\theta = \int_0^{\pi/3}(\sec^2\theta - 1)\,d\theta = \big[\tan\theta - \theta\big]_0^{\pi/3} = \sqrt{3} - \tfrac{\pi}{3}.$$

12. $$\int \frac{e^{2x}}{1+e^{4x}}\,dx = \int \frac{1}{1+u^2}\left(\tfrac{1}{2}\,du\right) \qquad \left[\begin{matrix} u = e^{2x}, \\ du = 2e^{2x}\,dx \end{matrix}\right]$$
$$= \tfrac{1}{2}\tan^{-1} u + C = \tfrac{1}{2}\tan^{-1} e^{2x} + C$$

13. Let $w = \sqrt[3]{x}$. Then $w^3 = x$ and $3w^2\,dw = dx$, so $\int e^{\sqrt[3]{x}}\,dx = \int e^w \cdot 3w^2\,dw = 3I$. To evaluate I, let $u = w^2$, $dv = e^w\,dw \;\Rightarrow\; du = 2w\,dw$, $v = e^w$, so $I = \int w^2 e^w\,dw = w^2 e^w - \int 2we^w\,dw$. Now let $U = w$, $dV = e^w\,dw \;\Rightarrow$ $dU = dw$, $V = e^w$. Thus, $I = w^2e^w - 2\big[we^w - \int e^w\,dw\big] = w^2e^w - 2we^w + 2e^w + C_1$, and hence

$3I = 3e^w(w^2 - 2w + 2) + C = 3e^{\sqrt[3]{x}}(x^{2/3} - 2x^{1/3} + 2) + C.$

14. $$\int \frac{x^2+2}{x+2}\,dx = \int \left(x - 2 + \frac{6}{x+2}\right)dx = \tfrac{1}{2}x^2 - 2x + 6\ln|x+2| + C$$

15. $\dfrac{x-1}{x^2+2x} = \dfrac{x-1}{x(x+2)} = \dfrac{A}{x} + \dfrac{B}{x+2} \;\Rightarrow\; x - 1 = A(x+2) + Bx$. Set $x = -2$ to get $-3 = -2B$, so $B = \frac{3}{2}$. Set $x = 0$ to get $-1 = 2A$, so $A = -\frac{1}{2}$. Thus, $\displaystyle\int \frac{x-1}{x^2+2x}\,dx = \int\left(\frac{-\frac{1}{2}}{x} + \frac{\frac{3}{2}}{x+2}\right)dx = -\tfrac{1}{2}\ln|x| + \tfrac{3}{2}\ln|x+2| + C.$

16. $$\int \frac{\sec^6\theta}{\tan^2\theta}\,d\theta = \int \frac{(\tan^2\theta+1)^2\sec^2\theta}{\tan^2\theta}\,d\theta \quad \left[\begin{matrix} u = \tan\theta, \\ du = -\sec^2\theta\,d\theta \end{matrix}\right] \quad = \int \frac{(u^2+1)^2}{u^2}\,du = \int \frac{u^4+2u^2+1}{u^2}\,du$$
$$= \int\left(u^2 + 2 + \frac{1}{u^2}\right)du = \frac{u^3}{3} + 2u - \frac{1}{u} + C = \tfrac{1}{3}\tan^3\theta + 2\tan\theta - \cot\theta + C$$

17. $$\int x\cosh x\,dx = x\sinh x - \int \sinh x\,dx \qquad \left[\begin{matrix} u = x, & dv = \cosh x\,dx \\ du = dx, & v = \sinh x \end{matrix}\right]$$
$$= x\sinh x - \cosh x + C$$

18. $\dfrac{x^2+8x-3}{x^3+3x^2} = \dfrac{x^2+8x-3}{x^2(x+3)} = \dfrac{A}{x} + \dfrac{B}{x^2} + \dfrac{C}{x+3} \;\Rightarrow\; x^2 + 8x - 3 = Ax(x+3) + B(x+3) + Cx^2.$

Taking $x = 0$, we get $-3 = 3B$, so $B = -1$. Taking $x = -3$, we get $-18 = 9C$, so $C = -2$.

Taking $x = 1$, we get $6 = 4A + 4B + C = 4A - 4 - 2$, so $4A = 12$ and $A = 3$. Now

$$\int \frac{x^2 + 8x - 3}{x^3 + 3x^2}\,dx = \int \left(\frac{3}{x} - \frac{1}{x^2} - \frac{2}{x+3}\right) dx = 3\ln|x| + \frac{1}{x} - 2\ln|x+3| + C.$$

19. $$\int \frac{x+1}{9x^2+6x+5}\,dx = \int \frac{x+1}{(9x^2+6x+1)+4}\,dx = \int \frac{x+1}{(3x+1)^2+4}\,dx \qquad \begin{bmatrix} u = 3x+1, \\ du = 3\,dx \end{bmatrix}$$

$$= \int \frac{\left[\frac{1}{3}(u-1)\right]+1}{u^2+4}\left(\frac{1}{3}\,du\right) = \frac{1}{3}\cdot\frac{1}{3}\int \frac{(u-1)+3}{u^2+4}\,du$$

$$= \frac{1}{9}\int \frac{u}{u^2+4}\,du + \frac{1}{9}\int \frac{2}{u^2+2^2}\,du = \frac{1}{9}\cdot\frac{1}{2}\ln(u^2+4) + \frac{2}{9}\cdot\frac{1}{2}\tan^{-1}\left(\frac{1}{2}u\right) + C$$

$$= \tfrac{1}{18}\ln(9x^2+6x+5) + \tfrac{1}{9}\tan^{-1}\left[\tfrac{1}{2}(3x+1)\right] + C$$

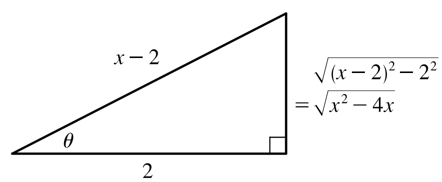
20. $$\int \tan^5\theta\,\sec^3\theta\,d\theta = \int \tan^4\theta\,\sec^2\theta\,\sec\theta\,\tan\theta\,d\theta = \int(\sec^2\theta - 1)^2\sec^2\theta\,\sec\theta\,\tan\theta\,d\theta \qquad \begin{bmatrix} u = \sec\theta, \\ du = \sec\theta\,\tan\theta\,d\theta \end{bmatrix}$$

$$= \int (u^2-1)^2u^2\,du = \int(u^6 - 2u^4 + u^2)\,du$$

$$= \tfrac{1}{7}u^7 - \tfrac{2}{5}u^5 + \tfrac{1}{3}u^3 + C = \tfrac{1}{7}\sec^7\theta - \tfrac{2}{5}\sec^5\theta + \tfrac{1}{3}\sec^3\theta + C$$

21. $$\int \frac{dx}{\sqrt{x^2-4x}} = \int \frac{dx}{\sqrt{(x^2-4x+4)-4}} = \int \frac{dx}{\sqrt{(x-2)^2-2^2}}$$

$$= \int \frac{2\sec\theta\,\tan\theta\,d\theta}{2\tan\theta} \qquad \begin{bmatrix} x - 2 = 2\sec\theta, \\ dx = 2\sec\theta\,\tan\theta\,d\theta \end{bmatrix}$$



$$= \int \sec\theta\,d\theta = \ln|\sec\theta + \tan\theta| + C_1$$

$$= \ln\left|\frac{x-2}{2} + \frac{\sqrt{x^2-4x}}{2}\right| + C_1$$

$$= \ln\left|x - 2 + \sqrt{x^2-4x}\,\right| + C, \text{ where } C = C_1 - \ln 2$$

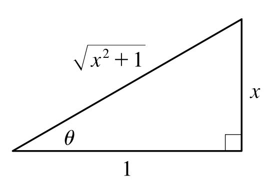
22. $$\int \cos\sqrt{t}\,dt = \int 2x\,\cos x\,dx \qquad \begin{bmatrix} x = \sqrt{t}, \\ x^2 = t,\quad 2x\,dx = dt \end{bmatrix}$$

$$= 2x\,\sin x - \int 2\sin x\,dx \qquad \begin{bmatrix} u = x, & dv = \cos x\,dx \\ du = dx, & v = \sin x \end{bmatrix}$$

$$= 2x\,\sin x + 2\cos x + C = 2\sqrt{t}\,\sin\sqrt{t} + 2\cos\sqrt{t} + C$$

23. Let $x = \tan\theta$, so that $dx = \sec^2\theta\,d\theta$. Then

$$\int \frac{dx}{x\sqrt{x^2+1}} = \int \frac{\sec^2\theta\,d\theta}{\tan\theta\,\sec\theta} = \int \frac{\sec\theta}{\tan\theta}\,d\theta$$



$$= \int \csc\theta\,d\theta = \ln|\csc\theta - \cot\theta| + C$$

$$= \ln\left|\frac{\sqrt{x^2+1}}{x} - \frac{1}{x}\right| + C = \ln\left|\frac{\sqrt{x^2+1}-1}{x}\right| + C$$

24. Let $u = \cos x$, $dv = e^x\,dx \;\Rightarrow\; du = -\sin x\,dx$, $v = e^x$: $(*)\; I = \int e^x \cos x\,dx = e^x \cos x + \int e^x \sin x\,dx$.

To integrate $\int e^x \sin x\,dx$, let $U = \sin x$, $dV = e^x\,dx \;\Rightarrow\; dU = \cos x\,dx$, $V = e^x$. Then

$\int e^x \sin x\,dx = e^x \sin x - \int e^x \cos x\,dx = e^x \sin x - I$. By substitution in $(*)$, $I = e^x \cos x + e^x \sin x - I \;\Rightarrow$

$2I = e^x(\cos x + \sin x) \;\Rightarrow\; I = \frac{1}{2}e^x(\cos x + \sin x) + C$.

25. $\dfrac{3x^3 - x^2 + 6x - 4}{(x^2+1)(x^2+2)} = \dfrac{Ax+B}{x^2+1} + \dfrac{Cx+D}{x^2+2} \;\Rightarrow\; 3x^3 - x^2 + 6x - 4 = (Ax+B)(x^2+2) + (Cx+D)(x^2+1)$.

Equating the coefficients gives $A + C = 3$, $B + D = -1$, $2A + C = 6$, and $2B + D = -4 \;\Rightarrow$

$A = 3$, $C = 0$, $B = -3$, and $D = 2$. Now

$$\int \frac{3x^3 - x^2 + 6x - 4}{(x^2+1)(x^2+2)}\,dx = 3\int \frac{x-1}{x^2+1}\,dx + 2\int \frac{dx}{x^2+2} = \frac{3}{2}\ln(x^2+1) - 3\tan^{-1}x + \sqrt{2}\tan^{-1}\left(\frac{x}{\sqrt{2}}\right) + C.$$

26. $\int x \sin x\,\cos x\,dx = \int \frac{1}{2}x \sin 2x\,dx \quad \begin{bmatrix} u = \frac{1}{2}x, & dv = \sin 2x\,dx, \\ du = \frac{1}{2}\,dx & v = -\frac{1}{2}\cos 2x \end{bmatrix}$

$$= -\tfrac{1}{4}x\cos 2x + \int \tfrac{1}{4}\cos 2x\,dx = -\tfrac{1}{4}x\cos 2x + \tfrac{1}{8}\sin 2x + C$$

27. $\int_0^{\pi/2} \cos^3 x\,\sin 2x\,dx = \int_0^{\pi/2} \cos^3 x\,(2\sin x\,\cos x)\,dx = \int_0^{\pi/2} 2\cos^4 x\,\sin x\,dx = \left[-\frac{2}{5}\cos^5 x\right]_0^{\pi/2} = \frac{2}{5}$

28. Let $u = \sqrt[3]{x}$. Then $x = u^3$, $dx = 3u^2 du \;\Rightarrow$

$$\int \frac{\sqrt[3]{x}+1}{\sqrt[3]{x}-1}\,dx = \int \frac{u+1}{u-1}\,3u^2 du = 3\int \left(u^2 + 2u + 2 + \frac{2}{u-1}\right) du$$

$$= u^3 + 3u^2 + 6u + 6\ln|u-1| + C = x + 3x^{2/3} + 6\sqrt[3]{x} + 6\ln|\sqrt[3]{x} - 1| + C$$

29. The integrand is an odd function, so $\displaystyle\int_{-3}^{3} \frac{x}{1+|x|}\,dx = 0$ [by 5.5.7(b)].

30. Let $u = e^{-x}$, $du = -e^{-x}\,dx$. Then

$$\int \frac{dx}{e^x\sqrt{1-e^{-2x}}} = \int \frac{e^{-x}\,dx}{\sqrt{1-(e^{-x})^2}} = \int \frac{-du}{\sqrt{1-u^2}} = -\sin^{-1}u + C = -\sin^{-1}(e^{-x}) + C.$$

31. Let $u = \sqrt{e^x - 1}$. Then $u^2 = e^x - 1$ and $2u\,du = e^x\,dx$. Also, $e^x + 8 = u^2 + 9$. Thus,

$$\int_0^{\ln 10} \frac{e^x\sqrt{e^x-1}}{e^x+8}\,dx = \int_0^3 \frac{u \cdot 2u\,du}{u^2+9} = 2\int_0^3 \frac{u^2}{u^2+9}\,du = 2\int_0^3 \left(1 - \frac{9}{u^2+9}\right) du$$

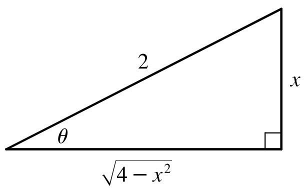
$$= 2\left[u - \frac{9}{3}\tan^{-1}\left(\frac{u}{3}\right)\right]_0^3 = 2\left[(3 - 3\tan^{-1}1) - 0\right] = 2\left(3 - 3\cdot\frac{\pi}{4}\right) = 6 - \frac{3\pi}{2}$$

32. $\displaystyle\int_0^{\pi/4} \frac{x\sin x}{\cos^3 x}\,dx = \int_0^{\pi/4} x\tan x\,\sec^2 x\,dx \quad \begin{bmatrix} u = x, & dv = \tan x\,\sec^2 x\,dx, \\ du = dx & v = \frac{1}{2}\tan^2 x \end{bmatrix}$

$$= \left[\frac{x}{2}\tan^2 x\right]_0^{\pi/4} - \frac{1}{2}\int_0^{\pi/4} \tan^2 x\,dx = \frac{\pi}{8}\cdot 1^2 - 0 - \frac{1}{2}\int_0^{\pi/4} (\sec^2 x - 1)\,dx$$

$$= \frac{\pi}{8} - \frac{1}{2}\left[\tan x - x\right]_0^{\pi/4} = \frac{\pi}{8} - \frac{1}{2}\left(1 - \frac{\pi}{4}\right) = \frac{\pi}{4} - \frac{1}{2}$$

33. Let $x = 2\sin\theta \Rightarrow (4-x^2)^{3/2} = (2\cos\theta)^3$, $dx = 2\cos\theta\,d\theta$, so



$$\int \frac{x^2}{(4-x^2)^{3/2}}\,dx = \int \frac{4\sin^2\theta}{8\cos^3\theta}\,2\cos\theta\,d\theta = \int \tan^2\theta\,d\theta = \int (\sec^2\theta - 1)\,d\theta$$

$$= \tan\theta - \theta + C = \frac{x}{\sqrt{4-x^2}} - \sin^{-1}\left(\frac{x}{2}\right) + C$$

34. Integrate by parts twice, first with $u = (\arcsin x)^2$, $dv = dx$:

$$I = \int (\arcsin x)^2\,dx = x(\arcsin x)^2 - \int 2x\arcsin x\left(\frac{dx}{\sqrt{1-x^2}}\right)$$

Now let $U = \arcsin x$, $dV = \dfrac{x}{\sqrt{1-x^2}}\,dx \Rightarrow dU = \dfrac{1}{\sqrt{1-x^2}}\,dx$, $V = -\sqrt{1-x^2}$. So

$$I = x(\arcsin x)^2 - 2\left[\arcsin x\left(-\sqrt{1-x^2}\right) + \textstyle\int dx\right] = x(\arcsin x)^2 + 2\sqrt{1-x^2}\arcsin x - 2x + C$$

35. $$\int \frac{1}{\sqrt{x+x^{3/2}}}\,dx = \int \frac{dx}{\sqrt{x(1+\sqrt{x})}} = \int \frac{dx}{\sqrt{x}\sqrt{1+\sqrt{x}}} \quad \begin{bmatrix} u = 1+\sqrt{x}, \\ du = \dfrac{dx}{2\sqrt{x}} \end{bmatrix} \quad = \int \frac{2\,du}{\sqrt{u}} = \int 2u^{-1/2}\,du$$

$$= 4\sqrt{u} + C = 4\sqrt{1+\sqrt{x}} + C$$

36. $$\int \frac{1-\tan\theta}{1+\tan\theta}\,d\theta = \int \frac{\dfrac{\cos\theta}{\cos\theta} - \dfrac{\sin\theta}{\cos\theta}}{\dfrac{\cos\theta}{\cos\theta} + \dfrac{\sin\theta}{\cos\theta}}\,d\theta = \int \frac{\cos\theta - \sin\theta}{\cos\theta + \sin\theta}\,d\theta = \ln|\cos\theta + \sin\theta| + C$$

37. $$\textstyle\int (\cos x + \sin x)^2 \cos 2x\,dx = \int (\cos^2 x + 2\sin x\cos x + \sin^2 x)\cos 2x\,dx = \int (1 + \sin 2x)\cos 2x\,dx$$

$$= \textstyle\int \cos 2x\,dx + \frac{1}{2}\int \sin 4x\,dx = \frac{1}{2}\sin 2x - \frac{1}{8}\cos 4x + C$$

Or: $\int (\cos x + \sin x)^2 \cos 2x\,dx = \int (\cos x + \sin x)^2(\cos^2 x - \sin^2 x)\,dx$

$$= \textstyle\int (\cos x + \sin x)^3(\cos x - \sin x)\,dx = \frac{1}{4}(\cos x + \sin x)^4 + C_1$$

38. $$\int \frac{2^{\sqrt{x}}}{\sqrt{x}}\,dx = \textstyle\int 2^u\,(2\,du) \qquad \begin{bmatrix} u = \sqrt{x}, \\ du = 1/(2\sqrt{x})\,dx \end{bmatrix}$$

$$= 2\cdot\frac{2^u}{\ln 2} + C = \frac{2^{\sqrt{x}+1}}{\ln 2} + C$$

39. We'll integrate $I = \displaystyle\int \frac{xe^{2x}}{(1+2x)^2}\,dx$ by parts with $u = xe^{2x}$ and $dv = \dfrac{dx}{(1+2x)^2}$. Then $du = (x\cdot 2e^{2x} + e^{2x}\cdot 1)\,dx$

and $v = -\dfrac{1}{2}\cdot\dfrac{1}{1+2x}$, so

$$I = -\frac{1}{2}\cdot\frac{xe^{2x}}{1+2x} - \int\left[-\frac{1}{2}\cdot\frac{e^{2x}(2x+1)}{1+2x}\right]dx = -\frac{xe^{2x}}{4x+2} + \frac{1}{2}\cdot\frac{1}{2}e^{2x} + C = e^{2x}\left(\frac{1}{4} - \frac{x}{4x+2}\right) + C$$

Thus, $\displaystyle\int_0^{1/2} \frac{xe^{2x}}{(1+2x)^2}\,dx = \left[e^{2x}\left(\frac{1}{4} - \frac{x}{4x+2}\right)\right]_0^{1/2} = e\left(\frac{1}{4} - \frac{1}{8}\right) - 1\left(\frac{1}{4} - 0\right) = \frac{1}{8}e - \frac{1}{4}.$

40. $\displaystyle\int_{\pi/4}^{\pi/3} \frac{\sqrt{\tan\theta}}{\sin 2\theta}\,d\theta = \int_{\pi/4}^{\pi/3} \frac{\sqrt{\frac{\sin\theta}{\cos\theta}}}{2\sin\theta\cos\theta}\,d\theta = \int_{\pi/4}^{\pi/3} \frac{1}{2}(\sin\theta)^{-1/2}(\cos\theta)^{-3/2}\,d\theta = \int_{\pi/4}^{\pi/3} \frac{1}{2}\left(\frac{\sin\theta}{\cos\theta}\right)^{-1/2}(\cos\theta)^{-2}d\theta$

$$= \int_{\pi/4}^{\pi/3} \frac{1}{2}(\tan\theta)^{-1/2}\sec^2\theta\,d\theta = \Big[\sqrt{\tan\theta}\Big]_{\pi/4}^{\pi/3} = \sqrt{\sqrt{3}} - \sqrt{1} = \sqrt[4]{3} - 1$$

41. $\displaystyle\int_1^\infty \frac{1}{(2x+1)^3}\,dx = \lim_{t\to\infty}\int_1^t \frac{1}{(2x+1)^3}\,dx = \lim_{t\to\infty}\int_1^t \tfrac{1}{2}(2x+1)^{-3}\,2\,dx = \lim_{t\to\infty}\left[-\frac{1}{4(2x+1)^2}\right]_1^t$

$$= -\frac{1}{4}\lim_{t\to\infty}\left[\frac{1}{(2t+1)^2} - \frac{1}{9}\right] = -\frac{1}{4}\left(0 - \frac{1}{9}\right) = \frac{1}{36}$$

42. $\displaystyle\int_1^\infty \frac{\ln x}{x^4}\,dx = \lim_{t\to\infty}\int_1^t \frac{\ln x}{x^4}\,dx \qquad \begin{bmatrix} u = \ln x, & dv = dx/x^4, \\ du = dx/x & v = -1/(3x^3) \end{bmatrix}$

$$= \lim_{t\to\infty}\left[-\frac{\ln x}{3x^3}\right]_1^t + \int_1^t \frac{1}{3x^4}\,dx = \lim_{t\to\infty}\left(-\frac{\ln t}{3t^3} + 0 + \left[\frac{-1}{9x^3}\right]_1^t\right) \overset{\text{H}}{=} \lim_{t\to\infty}\left(-\frac{1}{9t^3} + \left[\frac{-1}{9t^3} + \frac{1}{9}\right]\right)$$

$$= 0 + 0 + \tfrac{1}{9} = \tfrac{1}{9}$$

43. $\displaystyle\int \frac{dx}{x\ln x} \quad \begin{bmatrix} u = \ln x, \\ du = dx/x \end{bmatrix} \quad = \int \frac{du}{u} = \ln|u| + C = \ln|\ln x| + C$, so

$\displaystyle\int_2^\infty \frac{dx}{x\ln x} = \lim_{t\to\infty}\int_2^t \frac{dx}{x\ln x} = \lim_{t\to\infty}\Big[\ln|\ln x|\Big]_2^t = \lim_{t\to\infty}[\ln(\ln t) - \ln(\ln 2)] = \infty$, so the integral is divergent.

44. Let $u = \sqrt{y-2}$. Then $y = u^2 + 2$ and $dy = 2u\,du$, so

$$\int \frac{y\,dy}{\sqrt{y-2}} = \int \frac{(u^2+2)2u\,du}{u} = 2\int (u^2+2)\,du = 2\left[\tfrac{1}{3}u^3 + 2u\right] + C$$

Thus, $\displaystyle\int_2^6 \frac{y\,dy}{\sqrt{y-2}} = \lim_{t\to 2^+}\int_t^6 \frac{y\,dy}{\sqrt{y-2}} = \lim_{t\to 2^+}\left[\tfrac{2}{3}(y-2)^{3/2} + 4\sqrt{y-2}\right]_t^6$

$$= \lim_{t\to 2^+}\left[\tfrac{16}{3} + 8 - \tfrac{2}{3}(t-2)^{3/2} - 4\sqrt{t-2}\right] = \tfrac{40}{3}.$$

45. $\displaystyle\int_0^4 \frac{\ln x}{\sqrt{x}}\,dx = \lim_{t\to 0^+}\int_t^4 \frac{\ln x}{\sqrt{x}}\,dx \overset{\star}{=} \lim_{t\to 0^+}\Big[2\sqrt{x}\,\ln x - 4\sqrt{x}\Big]_t^4$

$$= \lim_{t\to 0^+}\left[(2\cdot 2\ln 4 - 4\cdot 2) - \left(2\sqrt{t}\,\ln t - 4\sqrt{t}\right)\right] \overset{\star\star}{=} (4\ln 4 - 8) - (0 - 0) = 4\ln 4 - 8$$

($\star$) Let $u = \ln x$, $dv = \dfrac{1}{\sqrt{x}}\,dx \;\Rightarrow\; du = \dfrac{1}{x}\,dx$, $v = 2\sqrt{x}$. Then

$$\int \frac{\ln x}{\sqrt{x}}\,dx = 2\sqrt{x}\,\ln x - 2\int \frac{dx}{\sqrt{x}} = 2\sqrt{x}\,\ln x - 4\sqrt{x} + C$$

($\star\star$) $\displaystyle\lim_{t\to 0^+}\left(2\sqrt{t}\,\ln t\right) = \lim_{t\to 0^+}\frac{2\ln t}{t^{-1/2}} \overset{\text{H}}{=} \lim_{t\to 0^+}\frac{2/t}{-\frac{1}{2}t^{-3/2}} = \lim_{t\to 0^+}\left(-4\sqrt{t}\right) = 0$

46. Note that $f(x) = 1/(2-3x)$ has an infinite discontinuity at $x = \frac{2}{3}$. Now

$$\int_0^{2/3} \frac{1}{2-3x}\,dx = \lim_{t\to(2/3)^-} \int_0^t \frac{1}{2-3x}\,dx = \lim_{t\to(2/3)^-} \Big[-\tfrac{1}{3}\ln|2-3x|\Big]_0^t = -\tfrac{1}{3} \lim_{t\to(2/3)^-} \Big[\ln|2-3t| - \ln 2\Big] = \infty$$

Since $\displaystyle\int_0^{2/3} \frac{1}{2-3x}\,dx$ diverges, so does $\displaystyle\int_0^1 \frac{1}{2-3x}\,dx$.

47. $$\int_0^1 \frac{x-1}{\sqrt{x}}\,dx = \lim_{t\to0^+} \int_t^1 \left(\frac{x}{\sqrt{x}} - \frac{1}{\sqrt{x}}\right)dx = \lim_{t\to0^+} \int_t^1 (x^{1/2} - x^{-1/2})\,dx = \lim_{t\to0^+} \Big[\tfrac{2}{3}x^{3/2} - 2x^{1/2}\Big]_t^1$$
$$= \lim_{t\to0^+} \Big[\big(\tfrac{2}{3} - 2\big) - \big(\tfrac{2}{3}t^{3/2} - 2t^{1/2}\big)\Big] = -\tfrac{4}{3} - 0 = -\tfrac{4}{3}$$

48. $$I = \int_{-1}^1 \frac{dx}{x^2-2x} = \int_{-1}^1 \frac{dx}{x(x-2)} = \int_{-1}^0 \frac{dx}{x(x-2)} + \int_0^1 \frac{dx}{x(x-2)} = I_1 + I_2. \text{ Now}$$

$\dfrac{1}{x(x-2)} = \dfrac{A}{x} + \dfrac{B}{x-2} \quad\Rightarrow\quad 1 = A(x-2) + Bx$. Set $x = 2$ to get $1 = 2B$, so $B = \frac{1}{2}$. Set $x = 0$ to get $1 = -2A$,

$A = -\frac{1}{2}$. Thus,

$$I_2 = \lim_{t\to0^+} \int_t^1 \left(\frac{-\frac{1}{2}}{x} + \frac{\frac{1}{2}}{x-2}\right)dx = \lim_{t\to0^+} \big[-\tfrac{1}{2}\ln|x| + \tfrac{1}{2}\ln|x-2|\big]_t^1 = \lim_{t\to0^+} \big[(0+0) - \big(-\tfrac{1}{2}\ln t + \tfrac{1}{2}\ln|t-2|\big)\big]$$
$$= -\tfrac{1}{2}\ln 2 + \tfrac{1}{2}\lim_{t\to0^+} \ln t = -\infty.$$

Since I_2 diverges, I is divergent.

49. Let $u = 2x+1$. Then

$$\int_{-\infty}^{\infty} \frac{dx}{4x^2+4x+5} = \int_{-\infty}^{\infty} \frac{\frac{1}{2}\,du}{u^2+4} = \tfrac{1}{2}\int_{-\infty}^0 \frac{du}{u^2+4} + \tfrac{1}{2}\int_0^{\infty} \frac{du}{u^2+4}$$
$$= \tfrac{1}{2}\lim_{t\to-\infty} \big[\tfrac{1}{2}\tan^{-1}\big(\tfrac{1}{2}u\big)\big]_t^0 + \tfrac{1}{2}\lim_{t\to\infty} \big[\tfrac{1}{2}\tan^{-1}\big(\tfrac{1}{2}u\big)\big]_0^t = \tfrac{1}{4}\big[0 - \big(-\tfrac{\pi}{2}\big)\big] + \tfrac{1}{4}\big[\tfrac{\pi}{2} - 0\big] = \tfrac{\pi}{4}.$$

50. $\displaystyle\int_1^{\infty} \frac{\tan^{-1}x}{x^2}\,dx = \lim_{t\to\infty} \int_1^t \frac{\tan^{-1}x}{x^2}\,dx$. Integrate by parts:

$$\int \frac{\tan^{-1}x}{x^2}\,dx = \frac{-\tan^{-1}x}{x} + \int \frac{1}{x}\frac{dx}{1+x^2} = \frac{-\tan^{-1}x}{x} + \int \left[\frac{1}{x} - \frac{x}{x^2+1}\right]dx$$
$$= \frac{-\tan^{-1}x}{x} + \ln|x| - \tfrac{1}{2}\ln(x^2+1) + C = \frac{-\tan^{-1}x}{x} + \frac{1}{2}\ln\frac{x^2}{x^2+1} + C$$

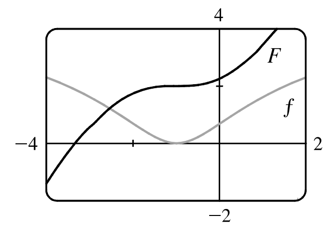
Thus,

$$\int_1^{\infty} \frac{\tan^{-1}x}{x^2}\,dx = \lim_{t\to\infty} \left[-\frac{\tan^{-1}x}{x} + \frac{1}{2}\ln\frac{x^2}{x^2+1}\right]_1^t = \lim_{t\to\infty} \left[-\frac{\tan^{-1}t}{t} + \frac{1}{2}\ln\frac{t^2}{t^2+1} + \frac{\pi}{4} - \frac{1}{2}\ln\frac{1}{2}\right]$$
$$= 0 + \tfrac{1}{2}\ln 1 + \tfrac{\pi}{4} + \tfrac{1}{2}\ln 2 = \tfrac{\pi}{4} + \tfrac{1}{2}\ln 2$$

51. We first make the substitution $t = x + 1$, so $\ln(x^2 + 2x + 2) = \ln\left[(x+1)^2 + 1\right] = \ln(t^2 + 1)$. Then we use parts with $u = \ln(t^2 + 1)$, $dv = dt$:

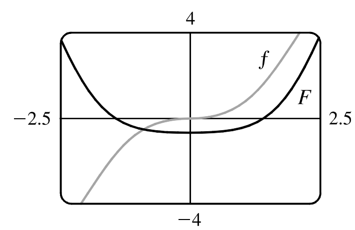
$$\begin{aligned}\int \ln(t^2+1)\,dt &= t\,\ln(t^2+1) - \int \frac{t(2t)\,dt}{t^2+1} = t\,\ln(t^2+1) - 2\int \frac{t^2\,dt}{t^2+1} = t\,\ln(t^2+1) - 2\int \left(1 - \frac{1}{t^2+1}\right)dt \\ &= t\,\ln(t^2+1) - 2t + 2\arctan t + C \\ &= (x+1)\,\ln(x^2+2x+2) - 2x + 2\arctan(x+1) + K, \text{ where } K = C - 2\end{aligned}$$

[Alternatively, we could have integrated by parts immediately with $u = \ln(x^2 + 2x + 2)$.] Notice from the graph that $f = 0$ where F has a horizontal tangent. Also, F is always increasing, and $f \geq 0$.

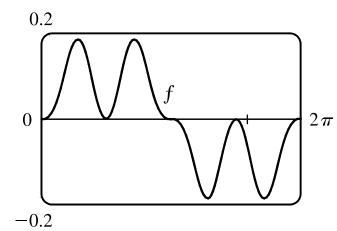


52. Let $u = x^2 + 1$. Then $x^2 = u - 1$ and $x\,dx = \frac{1}{2}\,du$, so

$$\begin{aligned}\int \frac{x^3}{\sqrt{x^2+1}}\,dx &= \int \frac{(u-1)}{\sqrt{u}}\left(\tfrac{1}{2}\,du\right) = \frac{1}{2}\int \left(u^{1/2} - u^{-1/2}\right)du \\ &= \tfrac{1}{2}\left(\tfrac{2}{3}u^{3/2} - 2u^{1/2}\right) + C = \tfrac{1}{3}(x^2+1)^{3/2} - (x^2+1)^{1/2} + C \\ &= \tfrac{1}{3}(x^2+1)^{1/2}\left[(x^2+1) - 3\right] + C = \tfrac{1}{3}\sqrt{x^2+1}\,(x^2-2) + C\end{aligned}$$



53. From the graph, it seems as though $\int_0^{2\pi} \cos^2 x\,\sin^3 x\,dx$ is equal to 0. To evaluate the integral, we write the integral as $I = \int_0^{2\pi} \cos^2 x\,(1 - \cos^2 x)\,\sin x\,dx$ and let $u = \cos x \quad\Rightarrow$ $du = -\sin x\,dx$. Thus, $I = \int_1^1 u^2(1-u^2)(-du) = 0$.

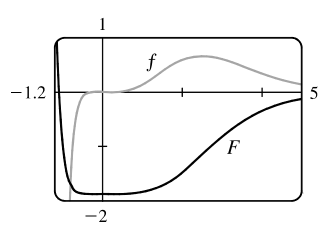


54. (a) To evaluate $\int x^5 e^{-2x}\,dx$ by hand, we would integrate by parts repeatedly, always taking $dv = e^{-2x}$ and starting with $u = x^5$. Each time we would reduce the degree of the x-factor by 1.

(b) To evaluate the integral using tables, we would use Formula 97 (which is proved using integration by parts) until the exponent of x was reduced to 1, and then we would use Formula 96.

(c) $\int x^5 e^{-2x}\,dx = -\frac{1}{8}e^{-2x}\left(4x^5 + 10x^4 + 20x^3 + 30x^2 + 30x + 15\right) + C$

(d)



55. $\int \sqrt{4x^2 - 4x - 3}\,dx = \int \sqrt{(2x-1)^2 - 4}\,dx \quad \begin{bmatrix} u = 2x - 1, \\ du = 2\,dx \end{bmatrix} \quad = \int \sqrt{u^2 - 2^2}\left(\tfrac{1}{2}\,du\right)$

$$\begin{aligned}&\overset{39}{=} \frac{1}{2}\left(\frac{u}{2}\sqrt{u^2-2^2} - \frac{2^2}{2}\ln\left|u + \sqrt{u^2-2^2}\right|\right) + C = \tfrac{1}{4}u\sqrt{u^2-4} - \ln\left|u + \sqrt{u^2-4}\right| + C \\ &= \tfrac{1}{4}(2x-1)\sqrt{4x^2-4x-3} - \ln\left|2x - 1 + \sqrt{4x^2-4x-3}\right| + C\end{aligned}$$

56. $\int \csc^5 t\,dt \overset{78}{=} -\frac{1}{4}\cot t\,\csc^3 t + \frac{3}{4}\int \csc^3 t\,dt \overset{72}{=} -\frac{1}{4}\cot t\,\csc^3 t + \frac{3}{4}\left[-\frac{1}{2}\csc t\,\cot t + \frac{1}{2}\ln|\csc t - \cot t|\right] + C$

$$= -\tfrac{1}{4}\cot t\,\csc^3 t - \tfrac{3}{8}\csc t\,\cot t + \tfrac{3}{8}\ln|\csc t - \cot t| + C$$

57. Let $u = \sin x$, so that $du = \cos x\,dx$. Then

$$\int \cos x\sqrt{4+\sin^2 x}\,dx = \int \sqrt{2^2+u^2}\,du \overset{21}{=} \frac{u}{2}\sqrt{2^2+u^2} + \frac{2^2}{2}\ln\left(u+\sqrt{2^2+u^2}\right) + C$$
$$= \tfrac{1}{2}\sin x\sqrt{4+\sin^2 x} + 2\ln\left(\sin x + \sqrt{4+\sin^2 x}\right) + C$$

58. Let $u = \sin x$. Then $du = \cos x\,dx$, so

$$\int \frac{\cot x\,dx}{\sqrt{1+2\sin x}} = \int \frac{du}{u\sqrt{1+2u}} \overset{\substack{57\text{ with}\\ a=1,\,b=2}}{=} \ln\left|\frac{\sqrt{1+2u}-1}{\sqrt{1+2u}+1}\right| + C = \ln\left|\frac{\sqrt{1+2\sin x}-1}{\sqrt{1+2\sin x}+1}\right| + C$$

59. (a) $\frac{d}{du}\left[-\frac{1}{u}\sqrt{a^2-u^2} - \sin^{-1}\left(\frac{u}{a}\right) + C\right] = \frac{1}{u^2}\sqrt{a^2-u^2} + \frac{1}{\sqrt{a^2-u^2}} - \frac{1}{\sqrt{1-u^2/a^2}}\cdot\frac{1}{a}$

$$= \left(a^2-u^2\right)^{-1/2}\left[\frac{1}{u^2}\left(a^2-u^2\right) + 1 - 1\right] = \frac{\sqrt{a^2-u^2}}{u^2}$$

(b) Let $u = a\sin\theta \quad\Rightarrow\quad du = a\cos\theta\,d\theta$, $a^2-u^2 = a^2\left(1-\sin^2\theta\right) = a^2\cos^2\theta$.

$$\int \frac{\sqrt{a^2-u^2}}{u^2}\,du = \int \frac{a^2\cos^2\theta}{a^2\sin^2\theta}\,d\theta = \int \frac{1-\sin^2\theta}{\sin^2\theta}\,d\theta = \int (\csc^2\theta - 1)\,d\theta = -\cot\theta - \theta + C$$
$$= -\frac{\sqrt{a^2-u^2}}{u} - \sin^{-1}\left(\frac{u}{a}\right) + C$$

60. Work backward, and use integration by parts with $U = u^{-(n-1)}$ and $dV = (a+bu)^{-1/2}\,du \quad\Rightarrow$

$dU = \frac{-(n-1)\,du}{u^n}$ and $V = \frac{2}{b}\sqrt{a+bu}$, to get

$$\int \frac{du}{u^{n-1}\sqrt{a+bu}} = \int U\,dV = UV - \int V\,dU = \frac{2\sqrt{a+bu}}{bu^{n-1}} + \frac{2(n-1)}{b}\int \frac{\sqrt{a+bu}}{u^n}\,du$$
$$= \frac{2\sqrt{a+bu}}{bu^{n-1}} + \frac{2(n-1)}{b}\int \frac{a+bu}{u^n\sqrt{a+bu}}\,du$$
$$= \frac{2\sqrt{a+bu}}{bu^{n-1}} + 2(n-1)\int \frac{du}{u^{n-1}\sqrt{a+bu}} + \frac{2a(n-1)}{b}\int \frac{du}{u^n\sqrt{a+bu}}$$

Rearranging the equation gives $\frac{2a(n-1)}{b}\int \frac{du}{u^n\sqrt{a+bu}} = -\frac{2\sqrt{a+bu}}{bu^{n-1}} - (2n-3)\int \frac{du}{u^{n-1}\sqrt{a+bu}} \quad\Rightarrow$

$$\int \frac{du}{u^n\sqrt{a+bu}} = \frac{-\sqrt{a+bu}}{a(n-1)u^{n-1}} - \frac{b(2n-3)}{2a(n-1)}\int \frac{du}{u^{n-1}\sqrt{a+bu}}$$

61. For $n \geq 0$, $\int_0^\infty x^n\,dx = \lim_{t\to\infty}\left[x^{n+1}/(n+1)\right]_0^t = \infty$. For $n < 0$, $\int_0^\infty x^n\,dx = \int_0^1 x^n\,dx + \int_1^\infty x^n\,dx$. Both integrals are improper. By (7.8.2), the second integral diverges if $-1 \leq n < 0$. By Exercise 7.8.57, the first integral diverges if $n \leq -1$. Thus, $\int_0^\infty x^n\,dx$ is divergent for all values of n.

62. $I = \int_0^\infty e^{ax}\cos x\,dx = \lim\limits_{t\to\infty}\int_0^t e^{ax}\cos x\,dx \overset{\substack{99\text{ with}\\ b=1}}{=} \lim\limits_{t\to\infty}\left[\dfrac{e^{ax}}{a^2+1}(a\cos x+\sin x)\right]_0^t$

$= \lim\limits_{t\to\infty}\left[\dfrac{e^{at}}{a^2+1}(a\cos t+\sin t) - \dfrac{1}{a^2+1}(a)\right] = \dfrac{1}{a^2+1}\lim\limits_{t\to\infty}\left[e^{at}(a\cos t+\sin t)-a\right].$

For $a \geq 0$, the limit does not exist due to oscillation. For $a < 0$, $\lim\limits_{t\to\infty}\left[e^{at}(a\cos t+\sin t)\right] = 0$ by the Squeeze Theorem, because $\left|e^{at}(a\cos t+\sin t)\right| \leq e^{at}(|a|+1)$, so $I = \dfrac{1}{a^2+1}(-a) = -\dfrac{a}{a^2+1}$.

63. $f(x) = \dfrac{1}{\ln x}$, $\Delta x = \dfrac{b-a}{n} = \dfrac{4-2}{10} = \dfrac{1}{5}$

(a) $T_{10} = \frac{1}{5\cdot 2}\{f(2) + 2[f(2.2)+f(2.4)+\cdots+f(3.8)] + f(4)\} \approx 1.925444$

(b) $M_{10} = \frac{1}{5}[f(2.1)+f(2.3)+f(2.5)+\cdots+f(3.9)] \approx 1.920915$

(c) $S_{10} = \frac{1}{5\cdot 3}[f(2)+4f(2.2)+2f(2.4)+\cdots+2f(3.6)+4f(3.8)+f(4)] \approx 1.922470$

64. $f(x) = \sqrt{x}\cos x$, $\Delta x = \dfrac{b-a}{n} = \dfrac{4-1}{10} = \dfrac{3}{10}$

(a) $T_{10} = \frac{3}{10\cdot 2}\{f(1) + 2[f(1.3)+f(1.6)+\cdots+f(3.7)] + f(4)\} \approx -2.835151$

(b) $M_{10} = \frac{3}{10}[f(1.15)+f(1.45)+f(1.75)+\cdots+f(3.85)] \approx -2.856809$

(c) $S_{10} = \frac{3}{10\cdot 3}[f(1)+4f(1.3)+2f(1.6)+\cdots+2f(3.4)+4f(3.7)+f(4)] \approx -2.849672$

65. $f(x) = \dfrac{1}{\ln x} \quad\Rightarrow\quad f'(x) = -\dfrac{1}{x(\ln x)^2} \quad\Rightarrow\quad f''(x) = \dfrac{2+\ln x}{x^2(\ln x)^3} = \dfrac{2}{x^2(\ln x)^3} + \dfrac{1}{x^2(\ln x)^2}$. Note that each term of $f''(x)$ decreases on $[2,4]$, so we'll take $K = f''(2) \approx 2.022$. $|E_T| \leq \dfrac{K(b-a)^3}{12n^2} \approx \dfrac{2.022(4-2)^3}{12(10)^2} = 0.01348$ and $|E_M| \leq \dfrac{K(b-a)^3}{24n^2} = 0.00674$. $|E_T| \leq 0.00001 \quad\Leftrightarrow\quad \dfrac{2.022(8)}{12n^2} \leq \dfrac{1}{10^5} \quad\Leftrightarrow\quad n^2 \geq \dfrac{10^5(2.022)(8)}{12} \quad\Rightarrow\quad n \geq 367.2.$ Take $n = 368$ for T_n. $|E_M| \leq 0.00001 \quad\Leftrightarrow\quad n^2 \geq \dfrac{10^5(2.022)(8)}{24} \quad\Rightarrow\quad n \geq 259.6$. Take $n = 260$ for M_n.

66. $\displaystyle\int_1^4 \frac{e^x}{x}\,dx \approx S_6 = \frac{(4-1)/6}{3}[f(1)+4f(1.5)+2f(2)+4f(2.5)+2f(3)+4f(3.5)+f(4)] \approx 17.739438$

67. $\Delta t = \left(\frac{10}{60}-0\right)/\,10 = \frac{1}{60}$.

Distance traveled $= \int_0^{10} v\,dt \approx S_{10}$

$= \frac{1}{60\cdot 3}[40+4(42)+2(45)+4(49)+2(52)+4(54)+2(56)+4(57)+2(57)+4(55)+56]$

$= \frac{1}{180}(1544) = 8.5\overline{7}$ mi

68. We use Simpson's Rule with $n = 6$ and $\Delta t = \frac{24-0}{6} = 4$:

Increase in bee population $= \int_0^{24} r(t)\,dt \approx S_6$

$= \frac{4}{3}[r(0)+4r(4)+2r(8)+4r(12)+2r(16)+4r(20)+r(24)]$

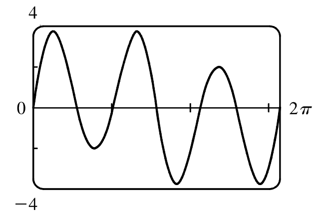
$= \frac{4}{3}[0+4(300)+2(3000)+4(11{,}000)+2(4000)+4(400)+0]$

$= \frac{4}{3}(60{,}800) \approx 81{,}067$ bees

69. (a) $f(x) = \sin(\sin x)$. A CAS gives

$$f^{(4)}(x) = \sin(\sin x)[\cos^4 x + 7\cos^2 x - 3] + \cos(\sin x)\left[6\cos^2 x \sin x + \sin x\right]$$

From the graph, we see that $\left|f^{(4)}(x)\right| < 3.8$ for $x \in [0, \pi]$.



(b) We use Simpson's Rule with $f(x) = \sin(\sin x)$ and $\Delta x = \frac{\pi}{10}$:

$$\int_0^\pi f(x)\,dx \approx \frac{\pi}{10 \cdot 3}\left[f(0) + 4f\left(\frac{\pi}{10}\right) + 2f\left(\frac{2\pi}{10}\right) + \cdots + 4f\left(\frac{9\pi}{10}\right) + f(\pi)\right] \approx 1.786721$$

From part (a), we know that $\left|f^{(4)}(x)\right| < 3.8$ on $[0, \pi]$, so we use Theorem 7.7.4 with $K = 3.8$, and estimate the error as $|E_S| \le \dfrac{3.8(\pi - 0)^5}{180(10)^4} \approx 0.000646$.

(c) If we want the error to be less than 0.00001, we must have $|E_S| \le \dfrac{3.8\pi^5}{180n^4} \le 0.00001$, so $n^4 \ge \dfrac{3.8\pi^5}{180(0.00001)} \approx 646{,}041.6 \quad \Rightarrow \quad n \ge 28.35$. Since n must be even for Simpson's Rule, we must have $n \ge 30$ to ensure the desired accuracy.

70. With an x-axis in the normal position, at $x = 7$ we have $C = 2\pi r = 45 \quad \Rightarrow \quad r(7) = \frac{2\pi}{45}$.

Using Simpson's Rule with $n = 4$ and $\Delta x = 7$, we have

$$V = \int_0^{28} \pi[r(x)]^2\,dx \approx S_4 = \frac{7}{3}\left[0 + 4\pi\left(\frac{45}{2\pi}\right)^2 + 2\pi\left(\frac{53}{2\pi}\right)^2 + 4\pi\left(\frac{45}{2\pi}\right)^2 + 0\right] = \frac{7}{3}\left(\frac{21{,}818}{4\pi}\right) \approx 4051 \text{ cm}^3.$$

71. (a) $\dfrac{2 + \sin x}{\sqrt{x}} \ge \dfrac{1}{\sqrt{x}}$ for x in $[1, \infty)$. $\displaystyle\int_1^\infty \frac{1}{\sqrt{x}}\,dx$ is divergent by (7.8.2) with $p = \dfrac{1}{2} \le 1$. Therefore, $\displaystyle\int_1^\infty \frac{2 + \sin x}{\sqrt{x}}\,dx$ is divergent by the Comparison Theorem.

(b) $\dfrac{1}{\sqrt{1 + x^4}} < \dfrac{1}{\sqrt{x^4}} = \dfrac{1}{x^2}$ for x in $[1, \infty)$. $\displaystyle\int_1^\infty \frac{1}{x^2}\,dx$ is convergent by (7.8.2) with $p = 2 > 1$. Therefore, $\displaystyle\int_1^\infty \frac{1}{\sqrt{1 + x^4}}\,dx$ is convergent by the Comparison Theorem.

72. The line $y = 3$ intersects the hyperbola $y^2 - x^2 = 1$ at two points on its upper branch, namely $\left(-2\sqrt{2}, 3\right)$ and $\left(2\sqrt{2}, 3\right)$. The desired area is

$$A = \int_{-2\sqrt{2}}^{2\sqrt{2}} \left(3 - \sqrt{x^2 + 1}\right) dx = 2\int_0^{2\sqrt{2}} \left(3 - \sqrt{x^2 + 1}\right) dx \overset{21}{=} 2\left[3x - \tfrac{1}{2}x\sqrt{x^2 + 1} - \tfrac{1}{2}\ln\left(x + \sqrt{x^2 + 1}\right)\right]_0^{2\sqrt{2}}$$

$$= \left[6x - x\sqrt{x^2 + 1} - \ln\left(x + \sqrt{x^2 + 1}\right)\right]_0^{2\sqrt{2}} = 12\sqrt{2} - 2\sqrt{2}\cdot 3 - \ln\left(2\sqrt{2} + 3\right) = 6\sqrt{2} - \ln\left(3 + 2\sqrt{2}\right)$$

Another method: $A = 2\int_1^3 \sqrt{y^2 - 1}\,dy$ and use Formula 39.

73. For x in $\left[0, \frac{\pi}{2}\right]$, $0 \le \cos^2 x \le \cos x$. For x in $\left[\frac{\pi}{2}, \pi\right]$, $\cos x \le 0 \le \cos^2 x$. Thus,

$$\text{area} = \int_0^{\pi/2} (\cos x - \cos^2 x)\,dx + \int_{\pi/2}^\pi (\cos^2 x - \cos x)\,dx$$

$$= \left[\sin x - \tfrac{1}{2}x - \tfrac{1}{4}\sin 2x\right]_0^{\pi/2} + \left[\tfrac{1}{2}x + \tfrac{1}{4}\sin 2x - \sin x\right]_{\pi/2}^\pi = \left[\left(1 - \tfrac{\pi}{4}\right) - 0\right] + \left[\tfrac{\pi}{2} - \left(\tfrac{\pi}{4} - 1\right)\right] = 2$$

74. The curves $y = \dfrac{1}{2 \pm \sqrt{x}}$ are defined for $x \geq 0$. For $x > 0$, $\dfrac{1}{2-\sqrt{x}} > \dfrac{1}{2+\sqrt{x}}$. Thus, the required area is

$$\int_0^1 \left(\frac{1}{2-\sqrt{x}} - \frac{1}{2+\sqrt{x}} \right) dx = \int_0^1 \left(\frac{1}{2-u} - \frac{1}{2+u} \right) 2u\,du \quad [u = \sqrt{x}] \quad = 2\int_0^1 \left(-\frac{u}{u-2} - \frac{u}{u+2} \right) du$$

$$= 2\int_0^1 \left(-1 - \frac{2}{u-2} - 1 + \frac{2}{u+2} \right) du = 2\left[2\ln\left|\frac{u+2}{u-2}\right| - 2u \right]_0^1 = 4\ln 3 - 4.$$

75. Using the formula for disks, the volume is

$$\begin{aligned} V &= \textstyle\int_0^{\pi/2} \pi\,[f(x)]^2\,dx = \pi \int_0^{\pi/2} (\cos^2 x)^2\,dx = \pi \int_0^{\pi/2} \left[\frac{1}{2}(1+\cos 2x)\right]^2 dx \\ &= \textstyle\frac{\pi}{4}\int_0^{\pi/2} (1 + \cos^2 2x + 2\cos 2x)\,dx = \frac{\pi}{4}\int_0^{\pi/2} \left[1 + \frac{1}{2}(1+\cos 4x) + 2\cos 2x\right] dx \\ &= \textstyle\frac{\pi}{4}\left[\frac{3}{2}x + \frac{1}{2}\left(\frac{1}{4}\sin 4x\right) + 2\left(\frac{1}{2}\sin 2x\right)\right]_0^{\pi/2} = \frac{\pi}{4}\left[\left(\frac{3\pi}{4} + \frac{1}{8}\cdot 0 + 0\right) - 0\right] = \frac{3}{16}\pi^2 \end{aligned}$$

76. Using the formula for cylindrical shells, the volume is

$$\begin{aligned} V &= \textstyle\int_0^{\pi/2} 2\pi x f(x)\,dx = 2\pi\int_0^{\pi/2} x\cos^2 x\,dx = 2\pi\int_0^{\pi/2} x\left[\frac{1}{2}(1+\cos 2x)\right] dx = 2\left(\frac{1}{2}\right)\pi\int_0^{\pi/2}(x + x\cos 2x)\,dx \\ &= \textstyle\pi\left(\left[\frac{1}{2}x^2\right]_0^{\pi/2} + \left[x\left(\frac{1}{2}\sin 2x\right)\right]_0^{\pi/2} - \int_0^{\pi/2}\frac{1}{2}\sin 2x\,dx\right) \quad \left[\begin{matrix}\text{parts with } u = x, \\ dv = \cos 2x\,dx\end{matrix}\right] \\ &= \textstyle\pi\left[\frac{1}{2}\left(\frac{\pi}{2}\right)^2 + 0 - \frac{1}{2}\left[-\frac{1}{2}\cos 2x\right]_0^{\pi/2}\right] = \frac{\pi^3}{8} + \frac{\pi}{4}(-1-1) = \frac{1}{8}(\pi^3 - 4\pi) \end{aligned}$$

77. By the Fundamental Theorem of Calculus,

$$\textstyle\int_0^\infty f'(x)\,dx = \lim\limits_{t\to\infty}\int_0^t f'(x)\,dx = \lim\limits_{t\to\infty}[f(t) - f(0)] = \lim\limits_{t\to\infty} f(t) - f(0) = 0 - f(0) = -f(0).$$

78. (a) $(\tan^{-1} x)_{\text{ave}} = \displaystyle\lim_{t\to\infty}\frac{1}{t-0}\int_0^t \tan^{-1} x\,dx \overset{89}{=} \lim_{t\to\infty}\left\{\frac{1}{t}\left[x\tan^{-1} x - \tfrac{1}{2}\ln(1+x^2)\right]_0^t\right\}$

$$= \lim_{t\to\infty}\left[\frac{1}{t}\left(t\tan^{-1} t - \tfrac{1}{2}\ln(1+t^2)\right)\right] = \lim_{t\to\infty}\left[\tan^{-1} t - \frac{\ln(1+t^2)}{2t}\right]$$

$$\overset{\text{H}}{=} \frac{\pi}{2} - \lim_{t\to\infty}\frac{2t/(1+t^2)}{2} = \frac{\pi}{2} - 0 = \frac{\pi}{2}$$

(b) $f(x) \geq 0$ and $\int_a^\infty f(x)\,dx$ is divergent $\Rightarrow$ $\lim\limits_{t\to\infty}\int_a^t f(x)\,dx = \infty$.

$$f_{\text{ave}} = \lim_{t\to\infty}\frac{\int_a^t f(x)\,dx}{t-a}\,dx \overset{\text{H}}{=} \lim_{t\to\infty}\frac{f(t)}{1} \quad [\text{by FTC1}] \quad = \lim_{x\to\infty} f(x), \text{ if this limit exists.}$$

(c) Suppose $\int_a^\infty f(x)\,dx$ converges; that is, $\lim\limits_{t\to\infty}\int_a^t f(x)\,dx = L < \infty$. Then

$$f_{\text{ave}} = \lim_{t\to\infty}\left[\frac{1}{t-a}\int_a^t f(x)\,dx\right] = \lim_{t\to\infty}\frac{1}{t-a}\cdot\lim_{t\to\infty}\int_a^t f(x)\,dx = 0\cdot L = 0.$$

(d) $(\sin x)_{\text{ave}} = \displaystyle\lim_{t\to\infty}\frac{1}{t}\int_0^t \sin x\,dx = \lim_{t\to\infty}\left(\frac{1}{t}\left[-\cos x\right]_0^t\right) = \lim_{t\to\infty}\left(-\frac{\cos t}{t} + \frac{1}{t}\right) = \lim_{t\to\infty}\frac{1-\cos t}{t} = 0$

79. Let $u = 1/x \quad \Rightarrow \quad x = 1/u \quad \Rightarrow \quad dx = -(1/u^2)\,du$.

$$\int_0^\infty \frac{\ln x}{1+x^2}\,dx = \int_\infty^0 \frac{\ln(1/u)}{1+1/u^2}\left(-\frac{du}{u^2}\right) = \int_\infty^0 \frac{-\ln u}{u^2+1}\,(-du) = \int_\infty^0 \frac{\ln u}{1+u^2}\,du = -\int_0^\infty \frac{\ln u}{1+u^2}\,du$$

Therefore, $\displaystyle\int_0^\infty \frac{\ln x}{1+x^2}\,dx = -\int_0^\infty \frac{\ln x}{1+x^2}\,dx = 0$.

80. If the distance between P and the point charge is d, then the potential V at P is

$$V = W = \int_\infty^d F\,dr = \int_\infty^d \frac{q}{4\pi\varepsilon_0 r^2}\,dr = \lim_{t\to\infty} \frac{q}{4\pi\varepsilon_0}\left[-\frac{1}{r}\right]_t^d = \frac{q}{4\pi\varepsilon_0}\lim_{t\to\infty}\left(-\frac{1}{d}+\frac{1}{t}\right) = -\frac{q}{4\pi\varepsilon_0 d}.$$

8 ☐ FURTHER APPLICATIONS OF INTEGRATION

8.1 Arc Length

1. $y = 2x - 5 \quad \Rightarrow \quad L = \int_{-1}^{3} \sqrt{1 + (dy/dx)^2}\, dx = \int_{-1}^{3} \sqrt{1 + (2)^2}\, dx = \sqrt{5}\,[3 - (-1)] = 4\sqrt{5}.$

The arc length can be calculated using the distance formula, since the curve is a line segment, so

$L = [\text{distance from } (-1, -7) \text{ to } (3, 1)] = \sqrt{[3 - (-1)]^2 + [1 - (-7)]^2} = \sqrt{80} = 4\sqrt{5}$

2. Using the arc length formula with $y = \sqrt{2 - x^2} \quad \Rightarrow \quad \dfrac{dy}{dx} = -\dfrac{x}{\sqrt{2 - x^2}}$, we get

$$L = \int_0^1 \sqrt{1 + \left(\frac{dy}{dx}\right)^2}\, dx = \int_0^1 \sqrt{1 + \frac{x^2}{2 - x^2}}\, dx = \int_0^1 \frac{\sqrt{2}\, dx}{\sqrt{2 - x^2}} = \sqrt{2} \int_0^1 \frac{dx}{\sqrt{\left(\sqrt{2}\right)^2 - x^2}}$$

$$= \sqrt{2}\left[\sin^{-1}\left(\frac{x}{\sqrt{2}}\right)\right]_0^1 = \sqrt{2}\left[\sin^{-1}\left(\frac{1}{\sqrt{2}}\right) - \sin^{-1} 0\right] = \sqrt{2}\left[\tfrac{\pi}{4} - 0\right] = \sqrt{2}\,\tfrac{\pi}{4}$$

The curve is a one-eighth of a circle with radius $\sqrt{2}$, so the length of the arc is $\frac{1}{8}\left(2\pi \cdot \sqrt{2}\right) = \sqrt{2}\,\frac{\pi}{4}$, as above.

3. $y = \sin x \quad \Rightarrow \quad dy/dx = \cos x \quad \Rightarrow \quad 1 + (dy/dx)^2 = 1 + \cos^2 x$. So $L = \int_0^{\pi} \sqrt{1 + \cos^2 x}\, dx \approx 3.8202$.

4. $y = xe^{-x} \quad \Rightarrow \quad dy/dx = x(-e^{-x}) + e^{-x}(1) = e^{-x}(1 - x) \quad \Rightarrow \quad 1 + (dy/dx)^2 = 1 + [e^{-x}(1 - x)]^2$.

So $L = \int_0^2 \sqrt{1 + e^{-2x}(1 - x)^2}\, dx \approx 2.1024$.

5. $y = x - \ln x \quad \Rightarrow \quad dy/dx = 1 - 1/x \quad \Rightarrow \quad 1 + (dy/dx)^2 = 1 + (1 - 1/x)^2$. So $L = \int_1^4 \sqrt{1 + (1 - 1/x)^2}\, dx \approx 3.4467$.

6. $x = y^2 - 2y \quad \Rightarrow \quad dx/dy = 2y - 2 \quad \Rightarrow \quad 1 + (dx/dy)^2 = 1 + (2y - 2)^2$. So $L = \int_0^2 \sqrt{1 + (2y - 2)^2}\, dy \approx 2.9579$.

7. $x = \sqrt{y} - y \quad \Rightarrow \quad dx/dy = 1/\left(2\sqrt{y}\right) - 1 \quad \Rightarrow \quad 1 + (dx/dy)^2 = 1 + \left(\dfrac{1}{2\sqrt{y}} - 1\right)^2$.

So $L = \displaystyle\int_1^4 \sqrt{1 + \left(\frac{1}{2\sqrt{y}} - 1\right)^2}\, dy \approx 3.6095$.

8. $y^2 = \ln x \quad \Leftrightarrow \quad x = e^{y^2} \quad \Rightarrow \quad dx/dy = 2ye^{y^2} \quad \Rightarrow \quad 1 + (dx/dy)^2 = 1 + 4y^2 e^{2y^2}$.

So $L = \int_{-1}^{1} \sqrt{1 + 4y^2 e^{2y^2}}\, dy \approx 4.2552$.

9. $y = 1 + 6x^{3/2} \quad \Rightarrow \quad dy/dx = 9x^{1/2} \quad \Rightarrow \quad 1 + (dy/dx)^2 = 1 + 81x$.

So $L = \displaystyle\int_0^1 \sqrt{1 + 81x}\, dx = \int_1^{82} u^{1/2}\left(\tfrac{1}{81}\, du\right) \quad \begin{bmatrix} u = 1 + 81x, \\ du = 81\, dx \end{bmatrix} = \tfrac{1}{81} \cdot \tfrac{2}{3}\left[u^{3/2}\right]_1^{82} = \tfrac{2}{243}\left(82\sqrt{82} - 1\right)$.

10. $36y^2 = (x^2 - 4)^3,\ y \geq 0 \quad \Rightarrow \quad y = \frac{1}{6}(x^2 - 4)^{3/2} \quad \Rightarrow \quad dy/dx = \frac{1}{6} \cdot \frac{3}{2}(x^2 - 4)^{1/2}(2x) = \frac{1}{2}x(x^2 - 4)^{1/2} \quad \Rightarrow$

$1 + (dy/dx)^2 = 1 + \frac{1}{4}x^2(x^2 - 4) = \frac{1}{4}x^4 - x^2 + 1 = \frac{1}{4}(x^4 - 4x^2 + 4) = \left[\frac{1}{2}(x^2 - 2)\right]^2$. So

$L = \int_2^3 \sqrt{\left[\frac{1}{2}(x^2 - 2)\right]^2}\, dx = \int_2^3 \frac{1}{2}(x^2 - 2)\, dx = \frac{1}{2}\left[\frac{1}{3}x^3 - 2x\right]_2^3 = \frac{1}{2}\left[(9 - 6) - \left(\frac{8}{3} - 4\right)\right] = \frac{1}{2}\left(\frac{13}{3}\right) = \frac{13}{6}$.

11. 
$y = \dfrac{x^3}{3} + \dfrac{1}{4x} \quad \Rightarrow \quad y' = x^2 - \dfrac{1}{4x^2} \quad \Rightarrow$

$1 + (y')^2 = 1 + \left(x^4 - \dfrac{1}{2} + \dfrac{1}{16x^4}\right) = x^4 + \dfrac{1}{2} + \dfrac{1}{16x^4} = \left(x^2 + \dfrac{1}{4x^2}\right)^2$. So

$$L = \int_1^2 \sqrt{1 + (y')^2}\, dx = \int_1^2 \left| x^2 + \frac{1}{4x^2} \right| dx = \int_1^2 \left(x^2 + \frac{1}{4x^2}\right) dx$$

$$= \left[\frac{1}{3}x^3 - \frac{1}{4x}\right]_1^2 = \left(\frac{8}{3} - \frac{1}{8}\right) - \left(\frac{1}{3} - \frac{1}{4}\right) = \frac{7}{3} + \frac{1}{8} = \frac{59}{24}$$

12. $x = \dfrac{y^4}{8} + \dfrac{1}{4y^2} \quad \Rightarrow \quad \dfrac{dx}{dy} = \frac{1}{2}y^3 - \frac{1}{2}y^{-3} \quad \Rightarrow$

$1 + (dx/dy)^2 = 1 + \frac{1}{4}y^6 - \frac{1}{2} + \frac{1}{4}y^{-6} = \frac{1}{4}y^6 + \frac{1}{2} + \frac{1}{4}y^{-6} = \left(\frac{1}{2}y^3 + \frac{1}{2}y^{-3}\right)^2$. So

$L = \int_1^2 \sqrt{\left(\frac{1}{2}y^3 + \frac{1}{2}y^{-3}\right)^2}\, dy = \int_1^2 \left(\frac{1}{2}y^3 + \frac{1}{2}y^{-3}\right) dy = \left[\frac{1}{8}y^4 - \frac{1}{4}y^{-2}\right]_1^2 = \left(2 - \frac{1}{16}\right) - \left(\frac{1}{8} - \frac{1}{4}\right)$

$= 2 + \frac{1}{16} = \frac{33}{16}$.

13. $x = \frac{1}{3}\sqrt{y}\,(y - 3) = \frac{1}{3}y^{3/2} - y^{1/2} \quad \Rightarrow \quad dx/dy = \frac{1}{2}y^{1/2} - \frac{1}{2}y^{-1/2} \quad \Rightarrow$

$1 + (dx/dy)^2 = 1 + \frac{1}{4}y - \frac{1}{2} + \frac{1}{4}y^{-1} = \frac{1}{4}y + \frac{1}{2} + \frac{1}{4}y^{-1} = \left(\frac{1}{2}y^{1/2} + \frac{1}{2}y^{-1/2}\right)^2$. So

$L = \int_1^9 \left(\frac{1}{2}y^{1/2} + \frac{1}{2}y^{-1/2}\right) dy = \frac{1}{2}\left[\frac{2}{3}y^{3/2} + 2y^{1/2}\right]_1^9 = \frac{1}{2}\left[\left(\frac{2}{3} \cdot 27 + 2 \cdot 3\right) - \left(\frac{2}{3} \cdot 1 + 2 \cdot 1\right)\right]$

$= \frac{1}{2}\left(24 - \frac{8}{3}\right) = \frac{1}{2}\left(\frac{64}{3}\right) = \frac{32}{3}$.

14. $y = \ln(\cos x) \quad \Rightarrow \quad dy/dx = -\tan x \quad \Rightarrow \quad 1 + (dy/dx)^2 = 1 + \tan^2 x = \sec^2 x$. So

$L = \int_0^{\pi/3} \sqrt{\sec^2 x}\, dx = \int_0^{\pi/3} \sec x\, dx = \left[\ln|\sec x + \tan x|\right]_0^{\pi/3} = \ln\left(2 + \sqrt{3}\right) - \ln(1 + 0) = \ln\left(2 + \sqrt{3}\right)$.

15. $y = \ln(\sec x) \quad \Rightarrow \quad \dfrac{dy}{dx} = \dfrac{\sec x \tan x}{\sec x} = \tan x \quad \Rightarrow \quad 1 + \left(\dfrac{dy}{dx}\right)^2 = 1 + \tan^2 x = \sec^2 x$, so

$L = \int_0^{\pi/4} \sqrt{\sec^2 x}\, dx = \int_0^{\pi/4} |\sec x|\, dx = \int_0^{\pi/4} \sec x\, dx = \Big[\ln(\sec x + \tan x)\Big]_0^{\pi/4}$

$= \ln\left(\sqrt{2} + 1\right) - \ln(1 + 0) = \ln\left(\sqrt{2} + 1\right)$

16. $y = 3 + \frac{1}{2}\cosh 2x \quad \Rightarrow \quad y' = \sinh 2x \quad \Rightarrow \quad 1 + (dy/dx)^2 = 1 + \sinh^2(2x) = \cosh^2(2x)$. So

$L = \int_0^1 \sqrt{\cosh^2(2x)}\, dx = \int_0^1 \cosh 2x\, dx = \left[\frac{1}{2}\sinh 2x\right]_0^1 = \frac{1}{2}\sinh 2 - 0 = \frac{1}{2}\sinh 2$.

17. $y = \dfrac{1}{4}x^2 - \dfrac{1}{2}\ln x \quad \Rightarrow \quad y' = \dfrac{1}{2}x - \dfrac{1}{2x} \quad \Rightarrow \quad 1 + (y')^2 = 1 + \left(\dfrac{1}{4}x^2 - \dfrac{1}{2} + \dfrac{1}{4x^2}\right) = \dfrac{1}{4}x^2 + \dfrac{1}{2} + \dfrac{1}{4x^2} = \left(\dfrac{1}{2}x + \dfrac{1}{2x}\right)^2$.

So

$$L = \int_1^2 \sqrt{1 + (y')^2}\, dx = \int_1^2 \left| \frac{1}{2}x + \frac{1}{2x} \right| dx = \int_1^2 \left(\frac{1}{2}x + \frac{1}{2x}\right) dx$$

$$= \left[\frac{1}{4}x^2 + \frac{1}{2}\ln|x|\right]_1^2 = \left(1 + \frac{1}{2}\ln 2\right) - \left(\frac{1}{4} + 0\right) = \frac{3}{4} + \frac{1}{2}\ln 2$$

18. $y = \sqrt{x - x^2} + \sin^{-1}\left(\sqrt{x}\right) \quad \Rightarrow \quad \dfrac{dy}{dx} = \dfrac{1 - 2x}{2\sqrt{x - x^2}} + \dfrac{1}{2\sqrt{x}\sqrt{1 - x}} = \dfrac{2 - 2x}{2\sqrt{x}\sqrt{1 - x}} = \sqrt{\dfrac{1 - x}{x}} \quad \Rightarrow$

$1 + \left(\dfrac{dy}{dx}\right)^2 = 1 + \dfrac{1 - x}{x} = \dfrac{1}{x}$. The curve has endpoints $(0, 0)$ and $\left(1, \frac{\pi}{2}\right)$,

so $L = \int_0^1 \sqrt{1/x}\, dx = \lim\limits_{t \to 0^+} \int_t^1 \sqrt{1/x}\, dx = \lim\limits_{t \to 0^+} \left[2\sqrt{x}\right]_t^1 = \lim\limits_{t \to 0^+} \left[2\sqrt{1} - 2\sqrt{t}\right] = 2 - 0 = 2$.

19. $y = \ln(1 - x^2) \quad \Rightarrow \quad y' = \dfrac{1}{1 - x^2} \cdot (-2x) \quad \Rightarrow$

$1 + \left(\dfrac{dy}{dx}\right)^2 = 1 + \dfrac{4x^2}{(1 - x^2)^2} = \dfrac{1 - 2x^2 + x^4 + 4x^2}{(1 - x^2)^2} = \dfrac{1 + 2x^2 + x^4}{(1 - x^2)^2} = \dfrac{(1 + x^2)^2}{(1 - x^2)^2} \quad \Rightarrow$

$\sqrt{1 + \left(\dfrac{dy}{dx}\right)^2} = \sqrt{\left(\dfrac{1 + x^2}{1 - x^2}\right)^2} = \dfrac{1 + x^2}{1 - x^2} = -1 + \dfrac{2}{1 - x^2}$ [by division] $= -1 + \dfrac{1}{1 + x} + \dfrac{1}{1 - x}$ [partial fractions].

So $L = \displaystyle\int_0^{1/2} \left(-1 + \frac{1}{1 + x} + \frac{1}{1 - x}\right) dx = \Big[-x + \ln|1 + x| - \ln|1 - x|\Big]_0^{1/2} = \left(-\tfrac{1}{2} + \ln\tfrac{3}{2} - \ln\tfrac{1}{2}\right) - 0 = \ln 3 - \tfrac{1}{2}$.

20. $y = 1 - e^{-x} \quad \Rightarrow \quad y' = -(-e^{-x}) = e^{-x} \quad \Rightarrow \quad 1 + (dy/dx)^2 = 1 + e^{-2x}$. So

$$\begin{aligned} L &= \int_0^2 \sqrt{1 + e^{-2x}}\, dx = \int_1^{e^{-2}} \sqrt{1 + u^2}\left(-\frac{1}{u}\, du\right) \qquad [u = e^{-x}] \\ &\overset{23}{=} \left[\ln\left|\frac{1 + \sqrt{1 + u^2}}{u}\right| - \sqrt{1 + u^2}\right]_1^{e^{-2}} \qquad [\text{or substitute } u = \tan\theta] \\ &= \ln\left|\frac{1 + \sqrt{1 + e^{-4}}}{e^{-2}}\right| - \sqrt{1 + e^{-4}} - \ln\left|\frac{1 + \sqrt{2}}{1}\right| + \sqrt{2} \\ &= \ln\left(1 + \sqrt{1 + e^{-4}}\right) - \ln e^{-2} - \sqrt{1 + e^{-4}} - \ln\left(1 + \sqrt{2}\right) + \sqrt{2} \\ &= \ln\left(1 + \sqrt{1 + e^{-4}}\right) + 2 - \sqrt{1 + e^{-4}} - \ln\left(1 + \sqrt{2}\right) + \sqrt{2} \end{aligned}$$

21. $y = \frac{1}{2}x^2 \quad \Rightarrow \quad dy/dx = x \quad \Rightarrow \quad 1 + (dy/dx)^2 = 1 + x^2$. So

$L = \int_{-1}^1 \sqrt{1 + x^2}\, dx = 2\int_0^1 \sqrt{1 + x^2}\, dx$ [by symmetry] $\overset{21}{=} 2\left[\frac{x}{2}\sqrt{1 + x^2} + \frac{1}{2}\ln\left(x + \sqrt{1 + x^2}\right)\right]_0^1$ $\left[\begin{matrix}\text{or substitute} \\ x = \tan\theta\end{matrix}\right]$

$= 2\left[\left(\frac{1}{2}\sqrt{2} + \frac{1}{2}\ln\left(1 + \sqrt{2}\right)\right) - \left(0 + \frac{1}{2}\ln 1\right)\right] = \sqrt{2} + \ln\left(1 + \sqrt{2}\right)$

22. $x^2 = (y - 4)^3 \quad \Rightarrow \quad x = (y - 4)^{3/2}$ [for $x > 0$] $\Rightarrow \quad dx/dy = \frac{3}{2}(y - 4)^{1/2} \quad \Rightarrow$

$1 + (dx/dy)^2 = 1 + \frac{9}{4}(y - 4) = \frac{9}{4}y - 8$. So

$$L = \int_5^8 \sqrt{\tfrac{9}{4}y - 8}\, dy = \int_{13/4}^{10} \sqrt{u}\,\left(\tfrac{4}{9}\, du\right) \quad \left[\begin{matrix} u = \frac{9}{4}y - 8, \\ du = \frac{9}{4}\, dy \end{matrix}\right] \quad = \tfrac{4}{9}\left[\tfrac{2}{3}u^{3/2}\right]_{13/4}^{10}$$

$$= \tfrac{8}{27}\left[10^{3/2} - \left(\tfrac{13}{4}\right)^{3/2}\right] \quad \left[\text{or } \tfrac{1}{27}\left(80\sqrt{10} - 13\sqrt{13}\right)\right]$$

23. 
From the figure, the length of the curve is slightly larger than the hypotenuse of the triangle formed by the points $(1, 2)$, $(1, 12)$, and $(2, 12)$. This length is about $\sqrt{10^2 + 1^2} \approx 10$, so we might estimate the length to be 10.

$y = x^2 + x^3 \quad \Rightarrow \quad y' = 2x + 3x^2 \quad \Rightarrow \quad 1 + (y')^2 = 1 + (2x + 3x^2)^2$.

So $L = \int_1^2 \sqrt{1 + (2x + 3x^2)^2}\, dx \approx 10.0556$.

24. 
From the figure, the length of the curve is slightly larger than the hypotenuse of the triangle formed by the points $(1,1)$, $\left(\frac{\pi}{2},1\right)$, and $\left(\frac{\pi}{2},\frac{\pi}{2}\right)$. This length is about $\sqrt{\left(\frac{\pi}{2}\right)^2+\left(\frac{\pi}{2}-1\right)^2}\approx 1.7$, so we might estimate the length to be 1.7. $\quad y=x+\cos x \quad\Rightarrow\quad y'=1-\sin x \quad\Rightarrow$ $1+(y')^2=1+(1-\sin x)^2$. So $L=\int_0^{\pi/2}\sqrt{1+(1-\sin x)^2}\,dx\approx 1.7294$.

25. $y=x\sin x \quad\Rightarrow\quad dy/dx=x\cos x+(\sin x)(1) \quad\Rightarrow\quad 1+(dy/dx)^2=1+(x\cos x+\sin x)^2$. Let $f(x)=\sqrt{1+(dy/dx)^2}=\sqrt{1+(x\cos x+\sin x)^2}$. Then $L=\int_0^{2\pi}f(x)\,dx$. Since $n=10$, $\Delta x=\frac{2\pi-0}{10}=\frac{\pi}{5}$. Now

$$\begin{aligned}L\approx S_{10}&=\tfrac{\pi/5}{3}\left[f(0)+4f\left(\tfrac{\pi}{5}\right)+2f\left(\tfrac{2\pi}{5}\right)+4f\left(\tfrac{3\pi}{5}\right)+2f\left(\tfrac{4\pi}{5}\right)+4f\left(\tfrac{5\pi}{5}\right)+2f\left(\tfrac{6\pi}{5}\right)\right.\\&\qquad\left.+4f\left(\tfrac{7\pi}{5}\right)+2f\left(\tfrac{8\pi}{5}\right)+4f\left(\tfrac{9\pi}{5}\right)+f(2\pi)\right]\\&\approx 15.498085\end{aligned}$$

The value of the integral produced by a calculator is 15.374568 (to six decimal places).

26. $y=\sqrt[3]{x} \quad\Rightarrow\quad dy/dx=\frac{1}{3}x^{-2/3} \quad\Rightarrow\quad L=\int_1^6 f(x)\,dx$, where $f(x)=\sqrt{1+\frac{1}{9}x^{-4/3}}$.

Since $n=10$, $\Delta x=\frac{6-1}{10}=\frac{1}{2}$. Now

$$\begin{aligned}L\approx S_{10}&=\tfrac{1/2}{3}[f(1)+4f(1.5)+2f(2)+4f(2.5)+2f(3)+4f(3.5)+2f(4)\\&\qquad+4f(4.5)+2f(5)+4f(5.5)+f(6)]\\&\approx 5.074212\end{aligned}$$

The value of the integral produced by a calculator is 5.074094 (to six decimal places).

27. $y=\ln(1+x^3) \quad\Rightarrow\quad dy/dx=\dfrac{1}{1+x^3}\cdot 3x^2 \quad\Rightarrow\quad L=\int_0^5 f(x)\,dx$, where $f(x)=\sqrt{1+9x^4/(1+x^3)^2}$.

Since $n=10$, $\Delta x=\frac{5-0}{10}=\frac{1}{2}$. Now

$$\begin{aligned}L\approx S_{10}&=\tfrac{1/2}{3}[f(0)+4f(0.5)+2f(1)+4f(1.5)+2f(2)+4f(2.5)+2f(3)\\&\qquad+4f(3.5)+2f(4)+4f(4.5)+f(5)]\\&\approx 7.094570\end{aligned}$$

The value of the integral produced by a calculator is 7.118819 (to six decimal places).

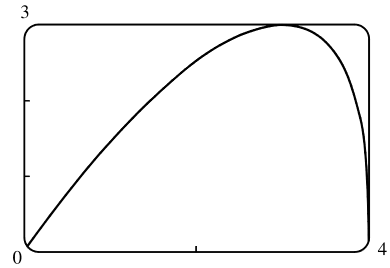
28. $y=e^{-x^2} \quad\Rightarrow\quad dy/dx=e^{-x^2}(-2x) \quad\Rightarrow\quad L=\int_0^2 f(x)\,dx$, where $f(x)=\sqrt{1+4x^2e^{-2x^2}}$.

Since $n=10$, $\Delta x=\frac{2-0}{10}=\frac{1}{5}$. Now

$$\begin{aligned}L\approx S_{10}&=\tfrac{1/5}{3}[f(0)+4f(0.2)+2f(0.4)+4f(0.6)+2f(0.8)+4f(1)+2f(1.2)\\&\qquad+4f(1.4)+2f(1.6)+4f(1.8)+f(2)]\\&\approx 2.280559\end{aligned}$$

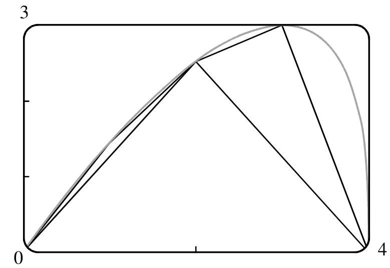
The value of the integral produced by a calculator is 2.280526 (to six decimal places).

29. (a) Let $f(x) = y = x\sqrt[3]{4-x}$ with $0 \le x \le 4$.



(b) The polygon with one side is just the line segment joining the points $(0, f(0)) = (0, 0)$ and $(4, f(4)) = (4, 0)$, and its length $L_1 = 4$.

The polygon with two sides joins the points $(0, 0)$, $(2, f(2)) = \left(2, 2\sqrt[3]{2}\right)$ and $(4, 0)$. Its length



$$L_2 = \sqrt{(2-0)^2 + \left(2\sqrt[3]{2} - 0\right)^2} + \sqrt{(4-2)^2 + \left(0 - 2\sqrt[3]{2}\right)^2} = 2\sqrt{4 + 2^{8/3}} \approx 6.43$$

Similarly, the inscribed polygon with four sides joins the points $(0, 0)$, $\left(1, \sqrt[3]{3}\right)$, $\left(2, 2\sqrt[3]{2}\right)$, $(3, 3)$, and $(4, 0)$, so its length

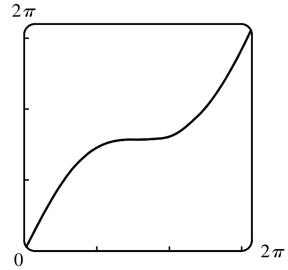
$$L_4 = \sqrt{1 + \left(\sqrt[3]{3}\right)^2} + \sqrt{1 + \left(2\sqrt[3]{2} - \sqrt[3]{3}\right)^2} + \sqrt{1 + \left(3 - 2\sqrt[3]{2}\right)^2} + \sqrt{1+9} \approx 7.50$$

(c) Using the arc length formula with $\dfrac{dy}{dx} = x\left[\frac{1}{3}(4-x)^{-2/3}(-1)\right] + \sqrt[3]{4-x} = \dfrac{12-4x}{3(4-x)^{2/3}}$, the length of the curve is

$$L = \int_0^4 \sqrt{1 + \left(\frac{dy}{dx}\right)^2}\,dx = \int_0^4 \sqrt{1 + \left[\frac{12-4x}{3(4-x)^{2/3}}\right]^2}\,dx.$$

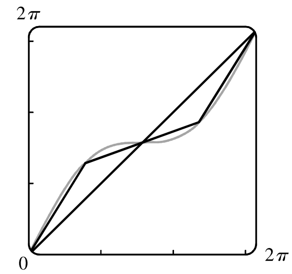
(d) According to a calculator, the length of the curve is $L \approx 7.7988$. The actual value is larger than any of the approximations in part (b). This is always true, since any approximating straight line between two points on the curve is shorter than the length of the curve between the two points.

30. (a) Let $f(x) = y = x + \sin x$ with $0 \le x \le 2\pi$.



(b) The polygon with one side is just the line segment joining the points $(0, f(0)) = (0, 0)$ and $(2\pi, f(2\pi)) = (2\pi, 2\pi)$, and its length is $\sqrt{(2\pi - 0)^2 + (2\pi - 0)^2} = 2\sqrt{2}\,\pi \approx 8.9$.

[continued]



The polygon with two sides joins the points $(0,0)$, $(\pi, f(\pi)) = (\pi, \pi)$, and $(2\pi, 2\pi)$. Its length is

$$\sqrt{(\pi-0)^2+(\pi-0)^2}+\sqrt{(2\pi-\pi)^2+(2\pi-\pi)^2}=\sqrt{2}\,\pi+\sqrt{2}\,\pi$$
$$=2\sqrt{2}\,\pi\approx 8.9$$

Note from the diagram that the two approximations are the same because the sides of the two-sided polygon are in fact on the same line, since $f(\pi)=\pi=\frac{1}{2}f(2\pi)$.

The four-sided polygon joins the points $(0,0)$, $\left(\frac{\pi}{2},\frac{\pi}{2}+1\right)$, (π,π), $\left(\frac{3\pi}{2},\frac{3\pi}{2}-1\right)$, and $(2\pi,2\pi)$, so its length is

$$\sqrt{\left(\tfrac{\pi}{2}\right)^2+\left(\tfrac{\pi}{2}+1\right)^2}+\sqrt{\left(\tfrac{\pi}{2}\right)^2+\left(\tfrac{\pi}{2}-1\right)^2}+\sqrt{\left(\tfrac{\pi}{2}\right)^2+\left(\tfrac{\pi}{2}-1\right)^2}+\sqrt{\left(\tfrac{\pi}{2}\right)^2+\left(\tfrac{\pi}{2}+1\right)^2}\approx 9.4$$

(c) Using the arc length formula with $dy/dx = 1+\cos x$, the length of the curve is

$$L=\int_0^{2\pi}\sqrt{1+(1+\cos x)^2}\,dx=\int_0^{2\pi}\sqrt{2+2\cos x+\cos^2 x}\,dx$$

(d) The calculator approximates the integral as 9.5076. The actual length is larger than the approximations in part (b).

31. $y=e^x \;\Rightarrow\; dy/dx=e^x \;\Rightarrow\; 1+(dy/dx)^2 \;\Rightarrow\; 1+e^{2x} \;\Rightarrow$

$$L=\int_0^2\sqrt{1+e^{2x}}\,dx=\int_1^{e^2}\sqrt{1+u^2}\left(\frac{1}{u}\,du\right)\qquad\begin{bmatrix}u=e^x,\\ du=e^x\,dx\end{bmatrix}$$

$$\overset{23}{=}\left[\sqrt{1+u^2}-\ln\left|\frac{1+\sqrt{1+u^2}}{u}\right|\right]_1^{e^2}=\left(\sqrt{1+e^4}-\ln\frac{1+\sqrt{1+e^4}}{e^2}\right)-\left(\sqrt{2}-\ln\frac{1+\sqrt{2}}{1}\right)$$

$$=\sqrt{1+e^4}-\ln(1+\sqrt{1+e^4})+2-\sqrt{2}+\ln(1+\sqrt{2})\approx 6.788651$$

An equivalent answer from a CAS is

$$-\sqrt{2}+\operatorname{arctanh}(\sqrt{2}/2)+\sqrt{e^4+1}-\operatorname{arctanh}(1/\sqrt{e^4+1}).$$

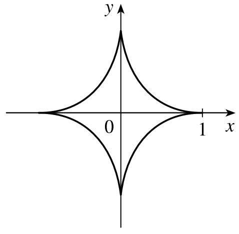
32. $y=x^{4/3} \;\Rightarrow\; dy/dx=\frac{4}{3}x^{1/3} \;\Rightarrow\; 1+(dy/dx)^2=1+\frac{16}{9}x^{2/3} \;\Rightarrow$

$$L=\int_0^1\sqrt{1+\tfrac{16}{9}x^{2/3}}\,dx=\int_0^{4/3}\sqrt{1+u^2}\,\tfrac{81}{64}u^2\,du\qquad\begin{bmatrix}u=\frac{4}{3}x^{1/3},\ du=\frac{4}{9}x^{-2/3}\,dx,\\ dx=\frac{9}{4}x^{2/3}\,du=\frac{9}{4}\cdot\frac{9}{16}u^2\,du=\frac{81}{64}u^2\,du\end{bmatrix}$$

$$\overset{22}{=}\tfrac{81}{64}\left[\tfrac{1}{8}u(1+2u^2)\sqrt{1+u^2}-\tfrac{1}{8}\ln\left(u+\sqrt{1+u^2}\right)\right]_0^{4/3}=\tfrac{81}{64}\left[\tfrac{1}{6}\left(1+\tfrac{32}{9}\right)\sqrt{\tfrac{25}{9}}-\tfrac{1}{8}\ln\left(\tfrac{4}{3}+\sqrt{\tfrac{25}{9}}\right)\right]$$

$$=\tfrac{81}{64}\left(\tfrac{1}{6}\cdot\tfrac{41}{9}\cdot\tfrac{5}{3}-\tfrac{1}{8}\ln 3\right)=\tfrac{205}{128}-\tfrac{81}{512}\ln 3\approx 1.4277586$$

33. $y^{2/3}=1-x^{2/3} \;\Rightarrow\; y=(1-x^{2/3})^{3/2} \;\Rightarrow$

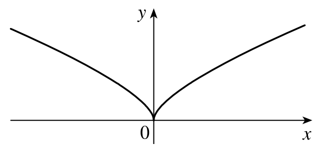


$$\frac{dy}{dx}=\tfrac{3}{2}(1-x^{2/3})^{1/2}\left(-\tfrac{2}{3}x^{-1/3}\right)=-x^{-1/3}(1-x^{2/3})^{1/2}\;\Rightarrow$$

$$\left(\frac{dy}{dx}\right)^2=x^{-2/3}(1-x^{2/3})=x^{-2/3}-1.\text{ Thus}$$

$$L=4\int_0^1\sqrt{1+(x^{-2/3}-1)}\,dx=4\int_0^1 x^{-1/3}\,dx=4\lim_{t\to 0^+}\left[\tfrac{3}{2}x^{2/3}\right]_t^1=6.$$

34. (a)



(b) $y = x^{2/3} \quad \Rightarrow \quad 1 + \left(\dfrac{dy}{dx}\right)^2 = 1 + \left(\frac{2}{3}x^{-1/3}\right)^2 = 1 + \frac{4}{9}x^{-2/3}$. So $L = \int_0^1 \sqrt{1 + \frac{4}{9}x^{-2/3}}\,dx$ [an improper integral].

$x = y^{3/2} \quad \Rightarrow \quad 1 + \left(\dfrac{dx}{dy}\right)^2 = 1 + \left(\frac{3}{2}y^{1/2}\right)^2 = 1 + \frac{9}{4}y$. So $L = \int_0^1 \sqrt{1 + \frac{9}{4}y}\,dy$.

The second integral equals $\frac{4}{9} \cdot \frac{2}{3}\left[\left(1 + \frac{9}{4}y\right)^{3/2}\right]_0^1 = \frac{8}{27}\left(\frac{13\sqrt{13}}{8} - 1\right) = \frac{13\sqrt{13} - 8}{27}$.

The first integral can be evaluated as follows:

$$\int_0^1 \sqrt{1 + \tfrac{4}{9}x^{-2/3}}\,dx = \lim_{t\to 0^+} \int_t^1 \frac{\sqrt{9x^{2/3} + 4}}{3x^{1/3}}\,dx = \lim_{t\to 0^+} \int_{9t^{2/3}}^9 \frac{\sqrt{u+4}}{18}\,du \qquad \begin{bmatrix} u = 9x^{2/3}, \\ du = 6x^{-1/3}\,dx \end{bmatrix}$$

$$= \int_0^9 \frac{\sqrt{u+4}}{18}\,du = \frac{1}{18} \cdot \left[\frac{2}{3}(u+4)^{3/2}\right]_0^9 = \frac{1}{27}(13^{3/2} - 4^{3/2}) = \frac{13\sqrt{13} - 8}{27}$$

(c) $L =$ length of the arc of this curve from $(-1, 1)$ to $(8, 4)$

$$= \int_0^1 \sqrt{1 + \frac{9}{4}y}\,dy + \int_0^4 \sqrt{1 + \frac{9}{4}y}\,dy = \frac{13\sqrt{13} - 8}{27} + \frac{8}{27}\left[\left(1 + \frac{9}{4}y\right)^{3/2}\right]_0^4 \qquad \text{[from part (b)]}$$

$$= \frac{13\sqrt{13} - 8}{27} + \frac{8}{27}\left(10\sqrt{10} - 1\right) = \frac{13\sqrt{13} + 80\sqrt{10} - 16}{27}$$

35. $y = 2x^{3/2} \quad \Rightarrow \quad y' = 3x^{1/2} \quad \Rightarrow \quad 1 + (y')^2 = 1 + 9x$. The arc length function with starting point $P_0(1, 2)$ is

$s(x) = \int_1^x \sqrt{1 + 9t}\,dt = \left[\frac{2}{27}(1 + 9t)^{3/2}\right]_1^x = \frac{2}{27}\left[(1 + 9x)^{3/2} - 10\sqrt{10}\right]$.

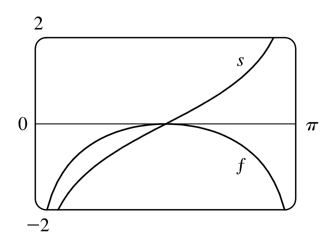
36. (a) $y = f(x) = \ln(\sin x) \quad \Rightarrow \quad y' = \dfrac{1}{\sin x} \cdot \cos x = \cot x \quad \Rightarrow \quad 1 + (y')^2 = 1 + \cot^2 x = \csc^2 x \quad \Rightarrow$

$\sqrt{1 + (y')^2} = \sqrt{\csc^2 x} = |\csc x|$. Therefore,

$$s(x) = \int_{\pi/2}^x \sqrt{1 + [f'(t)]^2}\,dt = \int_{\pi/2}^x \csc t\,dt = \Big[\ln|\csc t - \cos t|\Big]_{\pi/2}^x$$

$$= \ln|\csc x - \cot x| - \ln|1 - 0| = \ln(\csc x - \cot x)$$

(b) Note that s is increasing on $(0, \pi)$ and that $x = 0$ and $x = \pi$ are vertical asymptotes for both f and s.



37. $y = \sin^{-1} x + \sqrt{1 - x^2} \quad \Rightarrow \quad y' = \dfrac{1}{\sqrt{1 - x^2}} - \dfrac{x}{\sqrt{1 - x^2}} = \dfrac{1 - x}{\sqrt{1 - x^2}} \quad \Rightarrow$

$1 + (y')^2 = 1 + \dfrac{(1 - x)^2}{1 - x^2} = \dfrac{1 - x^2 + 1 - 2x + x^2}{1 - x^2} = \dfrac{2 - 2x}{1 - x^2} = \dfrac{2(1 - x)}{(1 + x)(1 - x)} = \dfrac{2}{1 + x} \quad \Rightarrow$

$\sqrt{1+(y')^2} = \sqrt{\dfrac{2}{1+x}}$. Thus, the arc length function with starting point $(0,1)$ is given by

$$s(x) = \int_0^x \sqrt{1+[f'(t)]^2}\,dt = \int_0^x \sqrt{\frac{2}{1+t}}\,dt = \sqrt{2}\left[2\sqrt{1+t}\,\right]_0^x = 2\sqrt{2}\left(\sqrt{1+x}-1\right).$$

38. (a) $s(x) = \int_a^x \sqrt{1+[f'(t)]^2}\,dt$ and $s(x) = \int_0^x \sqrt{3t+5}\,dt \quad\Rightarrow\quad 1+[f'(t)]^2 = 3t+5 \quad\Rightarrow\quad [f'(t)]^2 = 3t+4 \quad\Rightarrow$

$f'(t) = \sqrt{3t+4}$ [since f is increasing]. So $f(t) = \int (3t+4)^{1/2}\,dt = \frac{2}{3}\cdot\frac{1}{3}(3t+4)^{3/2} + C$ and since f has

y-intercept 2, $f(0) = \frac{2}{9}\cdot 8 + C$ and $f(0) = 2 \quad\Rightarrow\quad C = 2 - \frac{16}{9} = \frac{2}{9}$. Thus, $f(t) = \frac{2}{9}(3t+4)^{3/2} + \frac{2}{9}$.

(b) $s(x) = \displaystyle\int_0^x \sqrt{3t+5}\,dt = \left[\tfrac{2}{9}(3t+5)^{3/2}\right]_0^x = \tfrac{2}{9}(3x+5)^{3/2} - \tfrac{2}{9}(5)^{3/2}$.

$s(x) = 3 \quad\Leftrightarrow\quad \frac{2}{9}(3x+5)^{3/2} = 3 + \frac{2}{9}(5\sqrt{5}\,) \quad\Leftrightarrow\quad (3x+5)^{3/2} = \frac{27}{2} + 5\sqrt{5} \quad\Leftrightarrow\quad 3x+5 = \left(\frac{27}{2}+5\sqrt{5}\,\right)^{2/3} \quad\Rightarrow$

$x_1 = \frac{1}{3}\left[\left(\frac{27}{2}+5\sqrt{5}\,\right)^{2/3} - 5\right]$. Thus, the point on the graph of f that is 3 units along the curve from the y-intercept

is $(x_1, f(x_1)) \approx (1.159, 4.765)$.

39. $f(x) = \frac{1}{4}e^x + e^{-x} \quad\Rightarrow\quad f'(x) = \frac{1}{4}e^x - e^{-x} \quad\Rightarrow$

$1+[f'(x)]^2 = 1 + \left(\frac{1}{4}e^x - e^{-x}\right)^2 = 1 + \frac{1}{16}e^{2x} - \frac{1}{2} + e^{-2x} = \frac{1}{16}e^{2x} + \frac{1}{2} + e^{-2x} = \left(\frac{1}{4}e^x + e^{-x}\right)^2 = [f(x)]^2$. The arc

length of the curve $y = f(x)$ on the interval $[a,b]$ is $L = \int_a^b \sqrt{1+[f'(x)]^2}\,dx = \int_a^b \sqrt{[f(x)]^2}\,dx = \int_a^b f(x)\,dx$, which is

the area under the curve $y = f(x)$ on the interval $[a,b]$.

40. $y = 150 - \frac{1}{40}(x-50)^2 \quad\Rightarrow\quad y' = -\frac{1}{20}(x-50) \quad\Rightarrow\quad 1+(y')^2 = 1 + \frac{1}{20^2}(x-50)^2$, so the distance traveled by

the kite is

$$L = \int_0^{80} \sqrt{1+\frac{1}{20^2}(x-50)^2}\,dx = \int_{-5/2}^{3/2} \sqrt{1+u^2}\,(20\,du) \qquad \left[\begin{matrix} u = \frac{1}{20}(x-50), \\ du = \frac{1}{20}\,dx \end{matrix}\right]$$

$$\overset{21}{=} 20\left[\tfrac{1}{2}u\sqrt{1+u^2} + \tfrac{1}{2}\ln\!\left(u+\sqrt{1+u^2}\,\right)\right]_{-5/2}^{3/2} = 10\left[\tfrac{3}{2}\sqrt{\tfrac{13}{4}} + \ln\!\left(\tfrac{3}{2}+\sqrt{\tfrac{13}{4}}\right) + \tfrac{5}{2}\sqrt{\tfrac{29}{4}} - \ln\!\left(-\tfrac{5}{2}+\sqrt{\tfrac{29}{4}}\right)\right]$$

$$= \tfrac{15}{2}\sqrt{13} + \tfrac{25}{2}\sqrt{29} + 10\ln\!\left(\frac{3+\sqrt{13}}{-5+\sqrt{29}}\right) \approx 122.8 \text{ ft}$$

41. The prey hits the ground when $y = 0 \quad\Leftrightarrow\quad 180 - \frac{1}{45}x^2 = 0 \quad\Leftrightarrow\quad x^2 = 45\cdot 180 \quad\Rightarrow\quad x = \sqrt{8100} = 90$,

since x must be positive. $y' = -\frac{2}{45}x \quad\Rightarrow\quad 1+(y')^2 = 1 + \frac{4}{45^2}x^2$, so the distance traveled by the prey is

$$L = \int_0^{90} \sqrt{1+\frac{4}{45^2}x^2}\,dx = \int_0^4 \sqrt{1+u^2}\left(\tfrac{45}{2}\,du\right) \qquad \left[\begin{matrix} u = \frac{2}{45}x, \\ du = \frac{2}{45}\,dx \end{matrix}\right]$$

$$\overset{21}{=} \tfrac{45}{2}\left[\tfrac{1}{2}u\sqrt{1+u^2} + \tfrac{1}{2}\ln\!\left(u+\sqrt{1+u^2}\,\right)\right]_0^4 = \tfrac{45}{2}\left[2\sqrt{17} + \tfrac{1}{2}\ln\!\left(4+\sqrt{17}\,\right)\right] = 45\sqrt{17} + \tfrac{45}{4}\ln\!\left(4+\sqrt{17}\,\right) \approx 209.1 \text{ m}$$

42. Let $y = a - b\cosh cx$, where $a = 211.49$, $b = 20.96$, and $c = 0.03291765$. Then $y' = -bc\sinh cx \quad\Rightarrow$

$1+(y')^2 = 1 + b^2c^2\sinh^2(cx)$. So $L = \int_{-91.2}^{91.2} \sqrt{1+b^2c^2\sinh^2(cx)}\,dx \approx 451.137 \approx 451$, to the nearest meter.

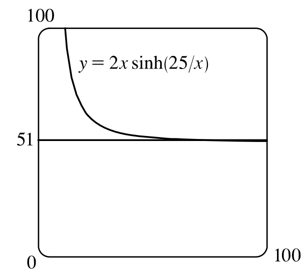
43. The sine wave has amplitude 1 and period 14, since it goes through two periods in a distance of 28 in., so its equation is $y = 1\sin\left(\frac{2\pi}{14}x\right) = \sin\left(\frac{\pi}{7}x\right)$. The width w of the flat metal sheet needed to make the panel is the arc length of the sine curve from $x = 0$ to $x = 28$. We set up the integral to evaluate w using the arc length formula with $\frac{dy}{dx} = \frac{\pi}{7}\cos\left(\frac{\pi}{7}x\right)$:

$L = \int_0^{28}\sqrt{1 + \left[\frac{\pi}{7}\cos\left(\frac{\pi}{7}x\right)\right]^2}\,dx = 2\int_0^{14}\sqrt{1 + \left[\frac{\pi}{7}\cos\left(\frac{\pi}{7}x\right)\right]^2}\,dx$. This integral would be very difficult to evaluate exactly, so we use a CAS, and find that $L \approx 29.36$ inches.

44. (a) $y = c + a\cosh\left(\frac{x}{a}\right) \quad\Rightarrow\quad y' = \sinh\left(\frac{x}{a}\right) \quad\Rightarrow\quad 1 + (y')^2 = 1 + \sinh^2\left(\frac{x}{a}\right) = \cosh^2\left(\frac{x}{a}\right)$. So

$L = \int_{-b}^{b}\sqrt{\cosh^2\left(\frac{x}{a}\right)}\,dx = 2\int_0^b \cosh\left(\frac{x}{a}\right)dx = 2\left[a\sinh\left(\frac{x}{a}\right)\right]_0^b = 2a\sinh\left(\frac{b}{a}\right).$

(b) At $x = 0$, $y = c + a$, so $c + a = 20$. The poles are 50 ft apart, so $b = 25$, and $L = 51 \quad\Rightarrow\quad 51 = 2a\sinh(b/a)$ [from part (a)]. From the figure, we see that $y = 51$ intersects $y = 2x\sinh(25/x)$ at $x \approx 72.3843$ for $x > 0$. So $a \approx 72.3843$ and the wire should be attached at a distance of $y = c + a\cosh(25/a) = 20 - a + a\cosh(25/a) \approx 24.36$ ft above the ground.



45. $y = \int_1^x \sqrt{t^3 - 1}\,dt \quad\Rightarrow\quad dy/dx = \sqrt{x^3 - 1}$ [by FTC1] $\quad\Rightarrow\quad 1 + (dy/dx)^2 = 1 + \left(\sqrt{x^3 - 1}\right)^2 = x^3 \quad\Rightarrow$

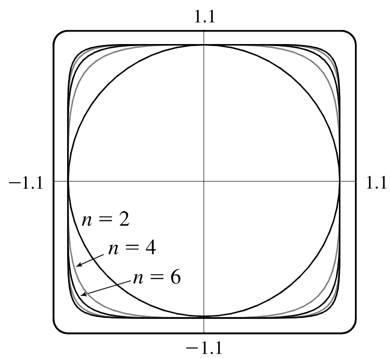
$L = \int_1^4 \sqrt{x^3}\,dx = \int_1^4 x^{3/2}\,dx = \frac{2}{5}\left[x^{5/2}\right]_1^4 = \frac{2}{5}(32 - 1) = \frac{62}{5} = 12.4$

46. By symmetry, the length of the curve in each quadrant is the same, so we'll find the length in the first quadrant and multiply by 4.

$x^{2k} + y^{2k} = 1 \quad\Rightarrow\quad y^{2k} = 1 - x^{2k} \quad\Rightarrow\quad y = (1 - x^{2k})^{1/(2k)}$

(in the first quadrant), so we use the arc length formula with

$\frac{dy}{dx} = \frac{1}{2k}(1 - x^{2k})^{1/(2k)-1}(-2kx^{2k-1}) = -x^{2k-1}(1 - x^{2k})^{1/(2k)-1}$



The total length is therefore

$$L_{2k} = 4\int_0^1 \sqrt{1 + [-x^{2k-1}(1 - x^{2k})^{1/(2k)-1}]^2}\,dx = 4\int_0^1 \sqrt{1 + x^{2(2k-1)}(1 - x^{2k})^{1/k-2}}\,dx$$

Now from the graph, we see that as k increases, the "corners" of these fat circles get closer to the points $(\pm 1, \pm 1)$ and $(\pm 1, \mp 1)$, and the "edges" of the fat circles approach the lines joining these four points. It seems plausible that as $k \to \infty$, the total length of the fat circle with $n = 2k$ will approach the length of the perimeter of the square with sides of length 2. This is supported by taking the limit as $k \to \infty$ of the equation of the fat circle in the first quadrant: $\lim_{k\to\infty}(1 - x^{2k})^{1/(2k)} = 1$ for $0 \le x < 1$. So we guess that $\lim_{k\to\infty} L_{2k} = 4 \cdot 2 = 8$.

DISCOVERY PROJECT Arc Length Contest

For advice on how to run the contest and a list of student entries, see the article "Arc Length Contest" by Larry Riddle in *The College Mathematics Journal*, Volume 29, No. 4, September 1998, pages 314–320.

8.2 Area of a Surface of Revolution

1. (a) (i) $y = \tan x \quad\Rightarrow\quad dy/dx = \sec^2 x \quad\Rightarrow\quad ds = \sqrt{1 + (dy/dx)^2}\,dx = \sqrt{1 + \sec^4 x}\,dx$. By (7), an integral for the area of the surface obtained by rotating the curve about the x-axis is $S = \int 2\pi y\,ds = \int_0^{\pi/3} 2\pi \tan x\sqrt{1 + \sec^4 x}\,dx$.

(ii) By (8), an integral for the area of the surface obtained by rotating the curve about the y-axis is $S = \int 2\pi x\,ds = \int_0^{\pi/3} 2\pi x\sqrt{1 + \sec^4 x}\,dx$.

(b) (i) 10.5017 (ii) 7.9353

2. (a) (i) $y = x^{-2} \quad\Rightarrow\quad dy/dx = -2x^{-3} \quad\Rightarrow\quad ds = \sqrt{1 + (dy/dx)^2}\,dx = \sqrt{1 + 4x^{-6}}\,dx$.

By (7), $S = \int 2\pi y\,ds = \int_1^2 2\pi x^{-2}\sqrt{1 + 4x^{-6}}\,dx$.

(ii) By (8), $S = \int 2\pi x\,ds = \int_1^2 2\pi x\sqrt{1 + 4x^{-6}}\,dx$.

(b) (i) 4.4566 (ii) 11.7299

3. (a) (i) $y = e^{-x^2} \quad\Rightarrow\quad dy/dx = e^{-x^2}\cdot(-2x) \quad\Rightarrow\quad ds = \sqrt{1 + (dy/dx)^2}\,dx = \sqrt{1 + 4x^2 e^{-2x^2}}\,dx$.

By (7), $S = \int 2\pi y\,ds = \int_{-1}^1 2\pi e^{-x^2}\sqrt{1 + 4x^2 e^{-2x^2}}\,dx$.

(ii) By (8), $S = \int 2\pi x\,ds = \int_0^1 2\pi x\sqrt{1 + 4x^2 e^{-2x^2}}\,dx$ [symmetric about the y-axis]

(b) (i) 11.0753 (ii) 3.9603

4. (a) (i) $x = \ln(2y + 1) \quad\Rightarrow\quad dx/dy = \dfrac{2}{2y + 1} \quad\Rightarrow\quad ds = \sqrt{1 + (dx/dy)^2}\,dy = \sqrt{1 + 4/(2y + 1)^2}\,dy$.

By (7), $S = \int 2\pi y\,ds = \int_0^1 2\pi y\sqrt{1 + 4/(2y + 1)^2}\,dy$.

(ii) By (8), $S = \int 2\pi x\,ds = \int_0^1 2\pi \ln(2y + 1)\sqrt{1 + 4/(2y + 1)^2}\,dy$.

(b) (i) 4.2583 (ii) 5.6053

5. (a) (i) $x = y + y^3 \quad\Rightarrow\quad dx/dy = 1 + 3y^2 \quad\Rightarrow\quad ds = \sqrt{1 + (dx/dy)^2}\,dy = \sqrt{1 + (1 + 3y^2)^2}\,dy$.

By (7), $S = \int 2\pi y\,ds = \int_0^1 2\pi y\sqrt{1 + (1 + 3y^2)^2}\,dy$.

(ii) By (8), $S = \int 2\pi x\,ds = \int_0^1 2\pi(y + y^3)\sqrt{1 + (1 + 3y^2)^2}\,dy$.

(b) (i) 8.5302 (ii) 13.5134

6. (a) (i) $y = \tan^{-1} x \quad\Rightarrow\quad dy/dx = 1/(1 + x^2) \quad\Rightarrow\quad ds = \sqrt{1 + (dy/dx)^2}\,dx = \sqrt{1 + 1/(1 + x^2)^2}\,dx$.

By (7), $S = \int 2\pi y\,ds = \int_0^2 2\pi \tan^{-1} x\sqrt{1 + 1/(1 + x^2)^2}\,dx$.

(ii) By (8), $S = \int 2\pi x\,ds = \int_0^2 2\pi x\sqrt{1 + 1/(1 + x^2)^2}\,dx$.

(b) (i) 9.7956 (ii) 13.7209

7. $y = x^3 \quad\Rightarrow\quad y' = 3x^2$. So

$$S = \int_0^2 2\pi y\,\sqrt{1+(y')^2}\,dx = 2\pi \int_0^2 x^3\,\sqrt{1+9x^4}\,dx = \tfrac{2\pi}{36}\int_1^{145}\sqrt{u}\,du \qquad [u = 1+9x^4,\, du = 36x^3\,dx]$$

$$= \tfrac{\pi}{18}\left[\tfrac{2}{3}u^{3/2}\right]_1^{145} = \tfrac{\pi}{27}\left(145\sqrt{145}-1\right)$$

8. $y = \sqrt{5-x} \quad\Rightarrow\quad y' = \frac{1}{2}(5-x)^{-1/2}(-1) = -1/(2\sqrt{5-x}\,)$. So

$$S = \int_3^5 2\pi y\sqrt{1+(y')^2}\,dx = \int_3^5 2\pi\sqrt{5-x}\,\sqrt{1+\frac{1}{4(5-x)}}\,dx = 2\pi\int_3^5\sqrt{5-x+\tfrac{1}{4}}\,dx$$

$$= 2\pi\int_3^5\sqrt{\tfrac{21}{4}-x}\,dx = 2\pi\int_{9/4}^{1/4}\sqrt{u}\,(-du) \qquad \begin{bmatrix} u = \frac{21}{4}-x, \\ du = -dx \end{bmatrix}$$

$$= 2\pi\int_{1/4}^{9/4}u^{1/2}\,du = 2\pi\left[\tfrac{2}{3}u^{3/2}\right]_{1/4}^{9/4} = \tfrac{4\pi}{3}\left(\tfrac{27}{8}-\tfrac{1}{8}\right) = \tfrac{13\pi}{3}$$

9. $y^2 = x+1 \quad\Rightarrow\quad y = \sqrt{x+1}$ (for $0 \le x \le 3$ and $1 \le y \le 2$) $\quad\Rightarrow\quad y' = 1/(2\sqrt{x+1}\,)$. So

$$S = \int_0^3 2\pi y\sqrt{1+(y')^2}\,dx = 2\pi\int_0^3\sqrt{x+1}\,\sqrt{1+\frac{1}{4(x+1)}}\,dx = 2\pi\int_0^3\sqrt{x+1+\tfrac{1}{4}}\,dx$$

$$= 2\pi\int_0^3\sqrt{x+\tfrac{5}{4}}\,dx = 2\pi\int_{5/4}^{17/4}\sqrt{u}\,du \qquad \begin{bmatrix} u = x+\frac{5}{4}, \\ du = dx \end{bmatrix}$$

$$= 2\pi\left[\tfrac{2}{3}u^{3/2}\right]_{5/4}^{17/4} = 2\pi\cdot\frac{2}{3}\left(\frac{17^{3/2}}{8}-\frac{5^{3/2}}{8}\right) = \frac{\pi}{6}(17\sqrt{17}-5\sqrt{5}).$$

10. $y = \sqrt{1+e^x} \quad\Rightarrow\quad y' = \frac{1}{2}(1+e^x)^{-1/2}(e^x) = \dfrac{e^x}{2\sqrt{1+e^x}} \quad\Rightarrow$

$$\sqrt{1+(y')^2} = \sqrt{1+\frac{e^{2x}}{4(1+e^x)}} = \sqrt{\frac{4+4e^x+e^{2x}}{4(1+e^x)}} = \sqrt{\frac{(e^x+2)^2}{4(1+e^x)}} = \frac{e^x+2}{2\sqrt{1+e^x}}.\text{ So}$$

$$S = \int_0^1 2\pi y\,\sqrt{1+(y')^2}\,dx = 2\pi\int_0^1\sqrt{1+e^x}\,\frac{e^x+2}{2\sqrt{1+e^x}}\,dx = \pi\int_0^1(e^x+2)\,dx$$

$$= \pi\left[e^x+2x\right]_0^1 = \pi[(e+2)-(1+0)] = \pi(e+1)$$

11. $y = \cos\left(\frac{1}{2}x\right) \quad\Rightarrow\quad y' = -\frac{1}{2}\sin\left(\frac{1}{2}x\right)$. So

$$S = \int_0^\pi 2\pi y\sqrt{1+(y')^2}\,dx = 2\pi\int_0^\pi\cos\left(\tfrac{1}{2}x\right)\sqrt{1+\tfrac{1}{4}\sin^2\left(\tfrac{1}{2}x\right)}\,dx$$

$$= 2\pi\int_0^1\sqrt{1+\tfrac{1}{4}u^2}\,(2\,du) \qquad \begin{bmatrix} u = \sin\left(\frac{1}{2}x\right), \\ du = \frac{1}{2}\cos\left(\frac{1}{2}x\right)dx \end{bmatrix}$$

$$= 2\pi\int_0^1\sqrt{4+u^2}\,du \overset{21}{=} 2\pi\left[\frac{u}{2}\sqrt{4+u^2}+2\ln\left(u+\sqrt{4+u^2}\right)\right]_0^1$$

$$= 2\pi\left[\left(\tfrac{1}{2}\sqrt{5}+2\ln(1+\sqrt{5}\,)\right)-(0+2\ln 2)\right] = \pi\sqrt{5}+4\pi\ln\left(\frac{1+\sqrt{5}}{2}\right)$$

12. $y = \dfrac{x^3}{6} + \dfrac{1}{2x} \quad \Rightarrow \quad \dfrac{dy}{dx} = \dfrac{x^2}{2} - \dfrac{1}{2x^2} \quad \Rightarrow \quad \sqrt{1 + \left(\dfrac{dy}{dx}\right)^2} = \sqrt{\dfrac{x^4}{4} + \dfrac{1}{2} + \dfrac{1}{4x^4}} = \sqrt{\left(\dfrac{x^2}{2} + \dfrac{1}{2x^2}\right)^2} = \dfrac{x^2}{2} + \dfrac{1}{2x^2} \quad \Rightarrow$

$$\begin{aligned} S &= \int_{1/2}^{1} 2\pi \left(\frac{x^3}{6} + \frac{1}{2x}\right)\left(\frac{x^2}{2} + \frac{1}{2x^2}\right) dx = 2\pi \int_{1/2}^{1} \left(\frac{x^5}{12} + \frac{x}{12} + \frac{x}{4} + \frac{1}{4x^3}\right) dx \\ &= 2\pi \int_{1/2}^{1} \left(\frac{x^5}{12} + \frac{x}{3} + \frac{x^{-3}}{4}\right) dx = 2\pi \left[\frac{x^6}{72} + \frac{x^2}{6} - \frac{x^{-2}}{8}\right]_{1/2}^{1} \\ &= 2\pi\left[\left(\tfrac{1}{72} + \tfrac{1}{6} - \tfrac{1}{8}\right) - \left(\tfrac{1}{64 \cdot 72} + \tfrac{1}{24} - \tfrac{1}{2}\right)\right] = 2\pi\left(\tfrac{263}{512}\right) = \tfrac{263}{256}\pi \end{aligned}$$

13. $x = \frac{1}{3}(y^2+2)^{3/2} \quad \Rightarrow \quad dx/dy = \frac{1}{2}(y^2+2)^{1/2}(2y) = y\sqrt{y^2+2} \quad \Rightarrow \quad 1 + (dx/dy)^2 = 1 + y^2(y^2+2) = (y^2+1)^2.$

So $S = 2\pi\int_1^2 y(y^2+1)\,dy = 2\pi\left[\frac{1}{4}y^4 + \frac{1}{2}y^2\right]_1^2 = 2\pi\left(4 + 2 - \frac{1}{4} - \frac{1}{2}\right) = \frac{21\pi}{2}.$

14. $x = 1 + 2y^2 \quad \Rightarrow \quad 1 + (dx/dy)^2 = 1 + (4y)^2 = 1 + 16y^2.$

So $S = 2\pi\int_1^2 y\sqrt{1+16y^2}\,dy = \frac{\pi}{16}\int_1^2 (16y^2+1)^{1/2} 32y\,dy = \frac{\pi}{16}\left[\frac{2}{3}(16y^2+1)^{3/2}\right]_1^2 = \frac{\pi}{24}\left(65\sqrt{65} - 17\sqrt{17}\right).$

15. $y = \frac{1}{3}x^{3/2} \quad \Rightarrow \quad y' = \frac{1}{2}x^{1/2} \quad \Rightarrow \quad 1 + (y')^2 = 1 + \frac{1}{4}x$. So

$$\begin{aligned} S &= \int_0^{12} 2\pi x\sqrt{1+(y')^2}\,dx = 2\pi\int_0^{12} x\sqrt{1+\tfrac{1}{4}x}\,dx = 2\pi\int_0^{12} x\,\tfrac{1}{2}\sqrt{4+x}\,dx \\ &= \pi\int_4^{16} (u-4)\sqrt{u}\,du \qquad \left[\begin{matrix} u = x+4, \\ du = dx \end{matrix}\right] \\ &= \pi\int_4^{16} (u^{3/2} - 4u^{1/2})\,du = \pi\left[\tfrac{2}{5}u^{5/2} - \tfrac{8}{3}u^{3/2}\right]_4^{16} = \pi\left[\left(\tfrac{2}{5}\cdot 1024 - \tfrac{8}{3}\cdot 64\right) - \left(\tfrac{2}{5}\cdot 32 - \tfrac{8}{3}\cdot 8\right)\right] \\ &= \pi\left(\tfrac{2}{5}\cdot 992 - \tfrac{8}{3}\cdot 56\right) = \pi\left(\tfrac{5952 - 2240}{15}\right) = \tfrac{3712\pi}{15} \end{aligned}$$

16. $x^{2/3} + y^{2/3} = 1$, $0 \le y \le 1$. The curve is symmetric about the y-axis from $x = -1$ to $x = 1$, so we'll use the portion of the curve from $x = 0$ to $x = 1$. $\quad y^{2/3} = 1 - x^{2/3} \quad \Rightarrow \quad y = (1 - x^{2/3})^{3/2} \quad \Rightarrow$

$y' = \frac{3}{2}(1 - x^{2/3})^{1/2}\left(-\frac{2}{3}x^{-1/3}\right) = -\dfrac{\sqrt{1 - x^{2/3}}}{x^{1/3}} \quad \Rightarrow \quad 1 + (y')^2 = 1 + \dfrac{1 - x^{2/3}}{x^{2/3}} = \dfrac{x^{2/3} + 1 - x^{2/3}}{x^{2/3}} = x^{-2/3}$. So

$S = \int_0^1 2\pi x\sqrt{1+(y')^2}\,dx = 2\pi\int_0^1 x(x^{-1/3})\,dx = 2\pi\int_0^1 x^{2/3}\,dx = 2\pi\left[\frac{3}{5}x^{5/3}\right]_0^1 = 2\pi\left(\frac{3}{5}\right) = \frac{6\pi}{5}.$

17. $x = \sqrt{a^2 - y^2} \quad \Rightarrow \quad dx/dy = \frac{1}{2}(a^2 - y^2)^{-1/2}(-2y) = -y/\sqrt{a^2 - y^2} \quad \Rightarrow$

$1 + \left(\dfrac{dx}{dy}\right)^2 = 1 + \dfrac{y^2}{a^2 - y^2} = \dfrac{a^2 - y^2}{a^2 - y^2} + \dfrac{y^2}{a^2 - y^2} = \dfrac{a^2}{a^2 - y^2} \quad \Rightarrow$

$S = \displaystyle\int_0^{a/2} 2\pi\sqrt{a^2 - y^2}\,\frac{a}{\sqrt{a^2 - y^2}}\,dy = 2\pi\int_0^{a/2} a\,dy = 2\pi a\left[\,y\,\right]_0^{a/2} = 2\pi a\left(\frac{a}{2} - 0\right) = \pi a^2.$

Note that this is $\frac{1}{4}$ the surface area of a sphere of radius a, and the length of the interval $y = 0$ to $y = a/2$ is $\frac{1}{4}$ the length of the interval $y = -a$ to $y = a$.

18. $y = \frac{1}{4}x^2 - \frac{1}{2}\ln x \quad\Rightarrow\quad \dfrac{dy}{dx} = \dfrac{x}{2} - \dfrac{1}{2x} \quad\Rightarrow\quad 1 + \left(\dfrac{dy}{dx}\right)^2 = 1 + \dfrac{x^2}{4} - \dfrac{1}{2} + \dfrac{1}{4x^2} = \dfrac{x^2}{4} + \dfrac{1}{2} + \dfrac{1}{4x^2} = \left(\dfrac{x}{2} + \dfrac{1}{2x}\right)^2$. So

$$S = \int_1^2 2\pi x \sqrt{\left(\frac{x}{2} + \frac{1}{2x}\right)^2}\,dx = 2\pi \int_1^2 x\left(\frac{x}{2} + \frac{1}{2x}\right)dx = \pi \int_1^2 (x^2 + 1)\,dx = \pi\left[\tfrac{1}{3}x^3 + x\right]_1^2$$
$$= \pi\left[\left(\tfrac{8}{3} + 2\right) - \left(\tfrac{1}{3} + 1\right)\right] = \tfrac{10}{3}\pi$$

19. $y = \frac{1}{5}x^5 \quad\Rightarrow\quad dy/dx = x^4 \quad\Rightarrow\quad 1 + (dy/dx)^2 = 1 + x^8 \quad\Rightarrow\quad S = \int_0^5 2\pi\left(\frac{1}{5}x^5\right)\sqrt{1 + x^8}\,dx$.

Let $f(x) = \frac{2}{5}\pi x^5\sqrt{1 + x^8}$. Since $n = 10$, $\Delta x = \frac{5 - 0}{10} = \frac{1}{2}$. Then

$$\begin{aligned} S \approx S_{10} &= \tfrac{1/2}{3}[f(0) + 4f(0.5) + 2f(1) + 4f(1.5) + 2f(2) + 4f(2.5) + 2f(3) \\ &\qquad + 4f(3.5) + 2f(4) + 4f(4.5) + f(5)] \\ &\approx 1{,}230{,}507 \end{aligned}$$

The value of the integral produced by a calculator is approximately 1,227,192.

20. $y = x + x^2 \quad\Rightarrow\quad dy/dx = 1 + 2x \quad\Rightarrow\quad 1 + (dy/dx)^2 = 1 + (1 + 2x)^2 \quad\Rightarrow\quad S = \int_0^1 2\pi(x + x^2)\sqrt{1 + (1 + 2x)^2}\,dx$.

Let $f(x) = 2\pi(x + x^2)\sqrt{1 + (1 + 2x)^2}$. Since $n = 10$, $\Delta x = \frac{1 - 0}{10} = \frac{1}{10}$. Then

$$\begin{aligned} S \approx S_{10} &= \tfrac{1/10}{3}[f(0) + 4f(0.1) + 2f(0.2) + 4f(0.3) + 2f(0.4) + 4f(0.5) + 2f(0.6) \\ &\qquad + 4f(0.7) + 2f(0.8) + 4f(0.9) + f(1)] \\ &\approx 13.649368 \end{aligned}$$

The value of the integral produced by a calculator is 13.649370 (to six decimal places).

21. $y = xe^x \quad\Rightarrow\quad dy/dx = xe^x + e^x \quad\Rightarrow\quad 1 + (dy/dx)^2 = 1 + (xe^x + e^x)^2 \quad\Rightarrow\quad S = \int_0^1 2\pi xe^x\sqrt{1 + (xe^x + e^x)^2}\,dx$.

Let $f(x) = 2\pi xe^x\sqrt{1 + (xe^x + e^x)^2}$. Since $n = 10$, $\Delta x = \frac{1 - 0}{10} = \frac{1}{10}$. Then

$$\begin{aligned} S \approx S_{10} &= \tfrac{1/10}{3}[f(0) + 4f(0.1) + 2f(0.2) + 4f(0.3) + 2f(0.4) + 4f(0.5) + 2f(0.6) \\ &\qquad + 4f(0.7) + 2f(0.8) + 4f(0.9) + f(1)] \\ &\approx 24.145807 \end{aligned}$$

The value of the integral produced by a calculator is 24.144251 (to six decimal places).

22. $y = x\ln x \quad\Rightarrow\quad dy/dx = x \cdot \dfrac{1}{x} + \ln x = 1 + \ln x \quad\Rightarrow\quad 1 + (dy/dx)^2 = 1 + (1 + \ln x)^2 \quad\Rightarrow$

$S = \int_1^2 2\pi x\ln x\sqrt{1 + (1 + \ln x)^2}\,dx$. Let $f(x) = 2\pi x\ln x\sqrt{1 + (1 + \ln x)^2}$. Since $n = 10$, $\Delta x = \frac{2 - 1}{10} = \frac{1}{10}$. Then

$$\begin{aligned} S \approx S_{10} &= \tfrac{1/10}{3}[f(1) + 4f(1.1) + 2f(1.2) + 4f(1.3) + 2f(1.4) + 4f(1.5) + 2f(1.6) \\ &\qquad + 4f(1.7) + 2f(1.8) + 4f(1.9) + f(2)] \\ &\approx 7.248933 \end{aligned}$$

The value of the integral produced by a calculator is 7.248934 (to six decimal places).

23. $y = 1/x \quad \Rightarrow \quad ds = \sqrt{1 + (dy/dx)^2}\,dx = \sqrt{1 + (-1/x^2)^2}\,dx = \sqrt{1 + 1/x^4}\,dx \quad \Rightarrow$

$$S = \int_1^2 2\pi \cdot \frac{1}{x}\sqrt{1 + \frac{1}{x^4}}\,dx = 2\pi\int_1^2 \frac{\sqrt{x^4+1}}{x^3}\,dx = 2\pi\int_1^4 \frac{\sqrt{u^2+1}}{u^2}\left(\tfrac{1}{2}\,du\right) \qquad [u = x^2,\, du = 2x\,dx]$$

$$= \pi\int_1^4 \frac{\sqrt{1+u^2}}{u^2}\,du \overset{24}{=} \pi\left[-\frac{\sqrt{1+u^2}}{u} + \ln\left(u + \sqrt{1+u^2}\right)\right]_1^4$$

$$= \pi\left[-\tfrac{\sqrt{17}}{4} + \ln\left(4 + \sqrt{17}\right) + \tfrac{\sqrt{2}}{1} - \ln\left(1 + \sqrt{2}\right)\right] = \frac{\pi}{4}\left[4\ln\left(\sqrt{17}+4\right) - 4\ln\left(\sqrt{2}+1\right) - \sqrt{17} + 4\sqrt{2}\right]$$

24. $y = \sqrt{x^2+1} \quad \Rightarrow \quad \dfrac{dy}{dx} = \dfrac{x}{\sqrt{x^2+1}} \quad \Rightarrow \quad ds = \sqrt{1 + \left(\dfrac{dy}{dx}\right)^2}\,dx = \sqrt{1 + \dfrac{x^2}{x^2+1}}\,dx \quad \Rightarrow$

$$S = \int_0^3 2\pi\sqrt{x^2+1}\sqrt{1 + \frac{x^2}{x^2+1}}\,dx = 2\pi\int_0^3 \sqrt{2x^2+1}\,dx = 2\sqrt{2}\,\pi\int_0^3 \sqrt{x^2 + \left(\tfrac{1}{\sqrt{2}}\right)^2}\,dx$$

$$\overset{21}{=} 2\sqrt{2}\pi\left[\tfrac{1}{2}x\sqrt{x^2+\tfrac{1}{2}} + \tfrac{1}{4}\ln\left(x + \sqrt{x^2+\tfrac{1}{2}}\right)\right]_0^3 = 2\sqrt{2}\pi\left[\tfrac{3}{2}\sqrt{9+\tfrac{1}{2}} + \tfrac{1}{4}\ln\left(3 + \sqrt{9+\tfrac{1}{2}}\right) - \tfrac{1}{4}\ln\tfrac{1}{\sqrt{2}}\right]$$

$$= 2\sqrt{2}\pi\left[\tfrac{3}{2}\sqrt{\tfrac{19}{2}} + \tfrac{1}{4}\ln\left(3 + \sqrt{\tfrac{19}{2}}\right) + \tfrac{1}{4}\ln\sqrt{2}\right] = 2\sqrt{2}\pi\left[\tfrac{3}{2}\tfrac{\sqrt{19}}{\sqrt{2}} + \tfrac{1}{4}\ln\left(3\sqrt{2} + \sqrt{19}\right)\right]$$

$$= 3\sqrt{19}\pi + \tfrac{\pi}{\sqrt{2}}\ln\left(3\sqrt{2} + \sqrt{19}\right)$$

25. $y = x^3$ and $0 \le y \le 1 \quad \Rightarrow \quad y' = 3x^2$ and $0 \le x \le 1$.

$$S = \int_0^1 2\pi x\sqrt{1 + (3x^2)^2}\,dx = 2\pi\int_0^3 \sqrt{1+u^2}\,\tfrac{1}{6}\,du \quad \begin{bmatrix} u = 3x^2, \\ du = 6x\,dx \end{bmatrix} \quad = \tfrac{\pi}{3}\int_0^3 \sqrt{1+u^2}\,du$$

$\overset{21}{=}$ [or use CAS] $\tfrac{\pi}{3}\left[\tfrac{1}{2}u\sqrt{1+u^2} + \tfrac{1}{2}\ln\left(u + \sqrt{1+u^2}\right)\right]_0^3 = \tfrac{\pi}{3}\left[\tfrac{3}{2}\sqrt{10} + \tfrac{1}{2}\ln\left(3 + \sqrt{10}\right)\right] = \tfrac{\pi}{6}\left[3\sqrt{10} + \ln\left(3 + \sqrt{10}\right)\right]$

26. $y = \ln(x+1),\, 0 \le x \le 1.\ ds = \sqrt{1 + \left(\dfrac{dy}{dx}\right)^2}\,dx = \sqrt{1 + \left(\dfrac{1}{x+1}\right)^2}\,dx$, so

$$S = \int_0^1 2\pi x\sqrt{1 + \frac{1}{(x+1)^2}}\,dx = \int_1^2 2\pi(u-1)\sqrt{1 + \frac{1}{u^2}}\,du \qquad [u = x+1,\, du = dx]$$

$$= 2\pi\int_1^2 u\,\frac{\sqrt{1+u^2}}{u}\,du - 2\pi\int_1^2 \frac{\sqrt{1+u^2}}{u}\,du = 2\pi\int_1^2 \sqrt{1+u^2}\,du - 2\pi\int_1^2 \frac{\sqrt{1+u^2}}{u}\,du$$

$\overset{21,\,23}{=}$ [or use CAS] $2\pi\left[\tfrac{1}{2}u\sqrt{1+u^2} + \tfrac{1}{2}\ln\left(u + \sqrt{1+u^2}\right)\right]_1^2 - 2\pi\left[\sqrt{1+u^2} - \ln\left(\dfrac{1+\sqrt{1+u^2}}{u}\right)\right]_1^2$

$$= 2\pi\left[\sqrt{5} + \tfrac{1}{2}\ln\left(2+\sqrt{5}\right) - \tfrac{1}{2}\sqrt{2} - \tfrac{1}{2}\ln\left(1+\sqrt{2}\right)\right] - 2\pi\left[\sqrt{5} - \ln\left(\tfrac{1+\sqrt{5}}{2}\right) - \sqrt{2} + \ln\left(1+\sqrt{2}\right)\right]$$

$$= 2\pi\left[\tfrac{1}{2}\ln\left(2+\sqrt{5}\right) + \ln\left(\tfrac{1+\sqrt{5}}{2}\right) + \tfrac{\sqrt{2}}{2} - \tfrac{3}{2}\ln\left(1+\sqrt{2}\right)\right]$$

27. $S = 2\pi\displaystyle\int_1^\infty y\sqrt{1 + \left(\frac{dy}{dx}\right)^2}\,dx = 2\pi\int_1^\infty \frac{1}{x}\sqrt{1 + \frac{1}{x^4}}\,dx = 2\pi\int_1^\infty \frac{\sqrt{x^4+1}}{x^3}\,dx$. Rather than trying to evaluate this integral, note that $\sqrt{x^4+1} > \sqrt{x^4} = x^2$ for $x > 0$. Thus, if the area is finite,

$S = 2\pi \int_1^\infty \frac{\sqrt{x^4+1}}{x^3}\,dx > 2\pi \int_1^\infty \frac{x^2}{x^3}\,dx = 2\pi \int_1^\infty \frac{1}{x}\,dx$. But we know that this integral diverges, so the area S is infinite.

28. $S = \int_0^\infty 2\pi y\sqrt{1+(dy/dx)^2}\,dx = 2\pi\int_0^\infty e^{-x}\sqrt{1+(-e^{-x})^2}\,dx \qquad [y = e^{-x},\, y' = -e^{-x}]$.

Evaluate $I = \int e^{-x}\sqrt{1+(-e^{-x})^2}\,dx$ by using the substitution $u = -e^{-x}$, $du = e^{-x}\,dx$:

$I = \int \sqrt{1+u^2}\,du \overset{21}{=} \frac{1}{2}u\sqrt{1+u^2} + \frac{1}{2}\ln\left(u + \sqrt{1+u^2}\right) + C = \frac{1}{2}(-e^{-x})\sqrt{1+e^{-2x}} + \frac{1}{2}\ln\left(-e^{-x} + \sqrt{1+e^{-2x}}\right) + C.$

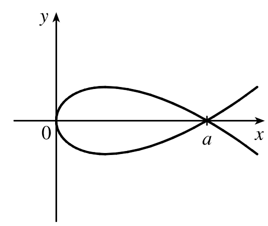
Returning to the surface area integral, we have

$$\begin{aligned}
S &= 2\pi \lim_{t\to\infty}\int_0^t e^{-x}\sqrt{1+(-e^{-x})^2}\,dx = 2\pi\lim_{t\to\infty}\left[\tfrac{1}{2}(-e^{-x})\sqrt{1+e^{-2x}} + \tfrac{1}{2}\ln\left(-e^{-x}+\sqrt{1+e^{-2x}}\right)\right]_0^t \\
&= 2\pi\lim_{t\to\infty}\left\{\left[\tfrac{1}{2}(-e^{-t})\sqrt{1+e^{-2t}} + \tfrac{1}{2}\ln\left(-e^{-t}+\sqrt{1+e^{-2t}}\right)\right] - \left[\tfrac{1}{2}(-1)\sqrt{1+1} + \tfrac{1}{2}\ln\left(-1+\sqrt{1+1}\right)\right]\right\} \\
&= 2\pi\left\{\left[\tfrac{1}{2}(0)\sqrt{1} + \tfrac{1}{2}\ln\left(0+\sqrt{1}\right)\right] - \left[-\tfrac{1}{2}\sqrt{2} + \tfrac{1}{2}\ln\left(-1+\sqrt{2}\right)\right]\right\} \\
&= 2\pi\left\{[0] + \tfrac{1}{2}\left[\sqrt{2} - \ln\left(\sqrt{2}-1\right)\right]\right\} = \pi\left[\sqrt{2} - \ln\left(\sqrt{2}-1\right)\right]
\end{aligned}$$

29. Since $a > 0$, the curve $3ay^2 = x(a-x)^2$ only has points with $x \geq 0$.

$[3ay^2 \geq 0 \;\Rightarrow\; x(a-x)^2 \geq 0 \;\Rightarrow\; x \geq 0.]$

The curve is symmetric about the *x*-axis (since the equation is unchanged when y is replaced by $-y$). $y = 0$ when $x = 0$ or a, so the curve's loop extends from $x = 0$ to $x = a$.



$$\frac{d}{dx}(3ay^2) = \frac{d}{dx}\left[x(a-x)^2\right] \;\Rightarrow\; 6ay\frac{dy}{dx} = x\cdot 2(a-x)(-1) + (a-x)^2 \;\Rightarrow\; \frac{dy}{dx} = \frac{(a-x)[-2x+a-x]}{6ay} \;\Rightarrow$$

$$\left(\frac{dy}{dx}\right)^2 = \frac{(a-x)^2(a-3x)^2}{36a^2y^2} = \frac{(a-x)^2(a-3x)^2}{36a^2}\cdot\frac{3a}{x(a-x)^2}\;\begin{bmatrix}\text{the last fraction}\\ \text{is } 1/y^2\end{bmatrix} = \frac{(a-3x)^2}{12ax} \;\Rightarrow$$

$$1 + \left(\frac{dy}{dx}\right)^2 = 1 + \frac{a^2-6ax+9x^2}{12ax} = \frac{12ax}{12ax} + \frac{a^2-6ax+9x^2}{12ax} = \frac{a^2+6ax+9x^2}{12ax} = \frac{(a+3x)^2}{12ax} \quad \text{for } x \neq 0.$$

(a) $S = \int_{x=0}^a 2\pi y\,ds = 2\pi\int_0^a \frac{\sqrt{x}\,(a-x)}{\sqrt{3a}}\cdot\frac{a+3x}{\sqrt{12ax}}\,dx = 2\pi\int_0^a \frac{(a-x)(a+3x)}{6a}\,dx$

$$= \frac{\pi}{3a}\int_0^a (a^2+2ax-3x^2)\,dx = \frac{\pi}{3a}\left[a^2x + ax^2 - x^3\right]_0^a = \frac{\pi}{3a}(a^3+a^3-a^3) = \frac{\pi}{3a}\cdot a^3 = \frac{\pi a^2}{3}.$$

Note that we have rotated the top half of the loop about the *x*-axis. This generates the full surface.

(b) We must rotate the full loop about the y-axis, so we get double the area obtained by rotating the top half of the loop:

$$\begin{aligned}
S &= 2\cdot 2\pi\int_{x=0}^a x\,ds = 4\pi\int_0^a x\frac{a+3x}{\sqrt{12ax}}\,dx = \frac{4\pi}{2\sqrt{3a}}\int_0^a x^{1/2}(a+3x)\,dx = \frac{2\pi}{\sqrt{3a}}\int_0^a (ax^{1/2}+3x^{3/2})\,dx \\
&= \frac{2\pi}{\sqrt{3a}}\left[\frac{2}{3}ax^{3/2} + \frac{6}{5}x^{5/2}\right]_0^a = \frac{2\pi\sqrt{3}}{3\sqrt{a}}\left(\frac{2}{3}a^{5/2} + \frac{6}{5}a^{5/2}\right) = \frac{2\pi\sqrt{3}}{3}\left(\frac{2}{3}+\frac{6}{5}\right)a^2 = \frac{2\pi\sqrt{3}}{3}\left(\frac{28}{15}\right)a^2 \\
&= \frac{56\pi\sqrt{3}\,a^2}{45}
\end{aligned}$$

30. In general, if the parabola $y = ax^2$, $-c \le x \le c$, is rotated about the y-axis, the surface area it generates is

$$2\pi \int_0^c x\sqrt{1+(2ax)^2}\,dx = 2\pi \int_0^{2ac} \frac{u}{2a}\sqrt{1+u^2}\,\frac{1}{2a}\,du \quad \begin{bmatrix} u = 2ax, \\ du = 2a\,dx \end{bmatrix} \quad = \frac{\pi}{4a^2}\int_0^{2ac} \left(1+u^2\right)^{1/2} 2u\,du$$

$$= \frac{\pi}{4a^2}\left[\tfrac{2}{3}\left(1+u^2\right)^{3/2}\right]_0^{2ac} = \frac{\pi}{6a^2}\left[\left(1+4a^2c^2\right)^{3/2} - 1\right]$$

Here $2c = 10$ ft and $ac^2 = 2$ ft, so $c = 5$ and $a = \frac{2}{25}$. Thus, the surface area is

$$S = \tfrac{\pi}{6}\tfrac{625}{4}\left[\left(1 + 4\cdot\tfrac{4}{625}\cdot 25\right)^{3/2} - 1\right] = \tfrac{625\pi}{24}\left[\left(1+\tfrac{16}{25}\right)^{3/2} - 1\right] = \tfrac{625\pi}{24}\left(\tfrac{41\sqrt{41}}{125} - 1\right) = \tfrac{5\pi}{24}\left(41\sqrt{41} - 125\right) \approx 90.01 \text{ ft}^2.$$

31. (a) $\dfrac{x^2}{a^2} + \dfrac{y^2}{b^2} = 1 \;\Rightarrow\; \dfrac{y\,(dy/dx)}{b^2} = -\dfrac{x}{a^2} \;\Rightarrow\; \dfrac{dy}{dx} = -\dfrac{b^2x}{a^2y} \;\Rightarrow$

$$1 + \left(\frac{dy}{dx}\right)^2 = 1 + \frac{b^4x^2}{a^4y^2} = \frac{b^4x^2 + a^4y^2}{a^4y^2} = \frac{b^4x^2 + a^4b^2\left(1 - x^2/a^2\right)}{a^4b^2\left(1 - x^2/a^2\right)} = \frac{a^4b^2 + b^4x^2 - a^2b^2x^2}{a^4b^2 - a^2b^2x^2}$$

$$= \frac{a^4 + b^2x^2 - a^2x^2}{a^4 - a^2x^2} = \frac{a^4 - \left(a^2 - b^2\right)x^2}{a^2(a^2 - x^2)}$$

The ellipsoid's surface area is twice the area generated by rotating the first-quadrant portion of the ellipse about the x-axis. Thus,

$$S = 2\int_0^a 2\pi y\sqrt{1 + \left(\frac{dy}{dx}\right)^2}\,dx = 4\pi\int_0^a \frac{b}{a}\sqrt{a^2-x^2}\,\frac{\sqrt{a^4 - (a^2-b^2)x^2}}{a\sqrt{a^2-x^2}}\,dx = \frac{4\pi b}{a^2}\int_0^a \sqrt{a^4 - (a^2-b^2)x^2}\,dx$$

$$= \frac{4\pi b}{a^2}\int_0^{a\sqrt{a^2-b^2}} \sqrt{a^4-u^2}\,\frac{du}{\sqrt{a^2-b^2}} \quad \left[u = \sqrt{a^2-b^2}\,x\right] \quad \overset{30}{=} \frac{4\pi b}{a^2\sqrt{a^2-b^2}}\left[\frac{u}{2}\sqrt{a^4-u^2} + \frac{a^4}{2}\sin^{-1}\!\left(\frac{u}{a^2}\right)\right]_0^{a\sqrt{a^2-b^2}}$$

$$= \frac{4\pi b}{a^2\sqrt{a^2-b^2}}\left[\frac{a\sqrt{a^2-b^2}}{2}\sqrt{a^4 - a^2(a^2-b^2)} + \frac{a^4}{2}\sin^{-1}\frac{\sqrt{a^2-b^2}}{a}\right] = 2\pi\left[b^2 + \frac{a^2b\sin^{-1}\dfrac{\sqrt{a^2-b^2}}{a}}{\sqrt{a^2-b^2}}\right]$$

(b) $\dfrac{x^2}{a^2} + \dfrac{y^2}{b^2} = 1 \;\Rightarrow\; \dfrac{x\,(dx/dy)}{a^2} = -\dfrac{y}{b^2} \;\Rightarrow\; \dfrac{dx}{dy} = -\dfrac{a^2y}{b^2x} \;\Rightarrow$

$$1 + \left(\frac{dx}{dy}\right)^2 = 1 + \frac{a^4y^2}{b^4x^2} = \frac{b^4x^2 + a^4y^2}{b^4x^2} = \frac{b^4a^2(1 - y^2/b^2) + a^4y^2}{b^4a^2(1 - y^2/b^2)} = \frac{a^2b^4 - a^2b^2y^2 + a^4y^2}{a^2b^4 - a^2b^2y^2}$$

$$= \frac{b^4 - b^2y^2 + a^2y^2}{b^4 - b^2y^2} = \frac{b^4 - (b^2 - a^2)y^2}{b^2(b^2 - y^2)}$$

The oblate spheroid's surface area is twice the area generated by rotating the first-quadrant portion of the ellipse about the y-axis. Thus,

$$S = 2\int_0^b 2\pi\,x\sqrt{1 + \left(\frac{dx}{dy}\right)^2}\,dy = 4\pi\int_0^b \frac{a}{b}\sqrt{b^2-y^2}\,\frac{\sqrt{b^4 - (b^2-a^2)y^2}}{b\sqrt{b^2-y^2}}\,dy$$

$$= \frac{4\pi a}{b^2}\int_0^b \sqrt{b^4 - (b^2-a^2)\,y^2}\,dy = \frac{4\pi a}{b^2}\int_0^b \sqrt{b^4 + (a^2-b^2)\,y^2}\,dy \qquad [\text{since } a > b]$$

$$= \frac{4\pi a}{b^2}\int_0^{b\sqrt{a^2-b^2}} \sqrt{b^4+u^2}\,\frac{du}{\sqrt{a^2-b^2}} \qquad \left[u = \sqrt{a^2-b^2}\,y\right]$$

$$\overset{21}{=} \frac{4\pi a}{b^2\sqrt{a^2-b^2}}\left[\frac{u}{2}\sqrt{b^4+u^2} + \frac{b^4}{2}\ln\!\left(u + \sqrt{b^4+u^2}\right)\right]_0^{b\sqrt{a^2-b^2}}$$

[continued]

$$= \frac{4\pi a}{b^2\sqrt{a^2-b^2}}\left\{\left[\frac{b\sqrt{a^2-b^2}}{2}(ab) + \frac{b^4}{2}\ln\left(b\sqrt{a^2-b^2}+ab\right)\right] - \left[0 + \frac{b^4}{2}\ln(b^2)\right]\right\}$$

$$= \frac{4\pi a}{b^2\sqrt{a^2-b^2}}\left[\frac{ab^2\sqrt{a^2-b^2}}{2} + \frac{b^4}{2}\ln\frac{b\sqrt{a^2-b^2}+ab}{b^2}\right] = 2\pi a^2 + \frac{2\pi ab^2}{\sqrt{a^2-b^2}}\ln\frac{\sqrt{a^2-b^2}+a}{b}$$

32. The upper half of the torus is generated by rotating the curve $(x-R)^2 + y^2 = r^2$, $y > 0$, about the y-axis.

$y\,\dfrac{dy}{dx} = -(x-R) \quad\Rightarrow\quad 1 + \left(\dfrac{dy}{dx}\right)^2 = 1 + \dfrac{(x-R)^2}{y^2} = \dfrac{y^2+(x-R)^2}{y^2} = \dfrac{r^2}{r^2-(x-R)^2}$. Thus,

$$S = 2\int_{R-r}^{R+r} 2\pi x\sqrt{1+\left(\frac{dy}{dx}\right)^2}\,dx = 4\pi\int_{R-r}^{R+r}\frac{rx}{\sqrt{r^2-(x-R)^2}}\,dx = 4\pi r\int_{-r}^{r}\frac{u+R}{\sqrt{r^2-u^2}}\,du \qquad [u = x-R]$$

$$= 4\pi r\int_{-r}^{r}\frac{u\,du}{\sqrt{r^2-u^2}} + 4\pi Rr\int_{-r}^{r}\frac{du}{\sqrt{r^2-u^2}} = 4\pi r\cdot 0 + 8\pi Rr\int_0^r\frac{du}{\sqrt{r^2-u^2}} \qquad \left[\begin{array}{c}\text{since the first integrand is odd}\\ \text{and the second is even}\end{array}\right]$$

$$= 8\pi Rr\left[\sin^{-1}(u/r)\right]_0^r = 8\pi Rr\left(\tfrac{\pi}{2}\right) = 4\pi^2 Rr$$

33. The analogue of $f(x_i^*)$ in the derivation of (4) is now $c - f(x_i^*)$, so

$$S = \lim_{n\to\infty}\sum_{i=1}^{n} 2\pi[c - f(x_i^*)]\sqrt{1+[f'(x_i^*)]^2}\,\Delta x = \int_a^b 2\pi[c-f(x)]\sqrt{1+[f'(x)]^2}\,dx.$$

34. $y = x^{1/2} \quad\Rightarrow\quad y' = \frac{1}{2}x^{-1/2} \quad\Rightarrow\quad 1 + (y')^2 = 1 + 1/4x$, so by Exercise 31, $S = \int_0^4 2\pi\left(4-\sqrt{x}\right)\sqrt{1+1/(4x)}\,dx$.

Using a CAS, we get $S = 2\pi\ln\left(\sqrt{17}+4\right) + \frac{\pi}{6}\left(31\sqrt{17}+1\right) \approx 80.6095$.

35. For the upper semicircle, $f(x) = \sqrt{r^2-x^2}$, $f'(x) = -x/\sqrt{r^2-x^2}$. The surface area generated is

$$S_1 = \int_{-r}^{r} 2\pi\left(r-\sqrt{r^2-x^2}\right)\sqrt{1+\frac{x^2}{r^2-x^2}}\,dx = 4\pi\int_0^r\left(r-\sqrt{r^2-x^2}\right)\frac{r}{\sqrt{r^2-x^2}}\,dx$$

$$= 4\pi\int_0^r\left(\frac{r^2}{\sqrt{r^2-x^2}} - r\right)dx$$

For the lower semicircle, $f(x) = -\sqrt{r^2-x^2}$ and $f'(x) = \dfrac{x}{\sqrt{r^2-x^2}}$, so $S_2 = 4\pi\displaystyle\int_0^r\left(\frac{r^2}{\sqrt{r^2-x^2}} + r\right)dx$.

Thus, the total area is $S = S_1 + S_2 = 8\pi\displaystyle\int_0^r\left(\frac{r^2}{\sqrt{r^2-x^2}}\right)dx = 8\pi\left[r^2\sin^{-1}\left(\frac{x}{r}\right)\right]_0^r = 8\pi r^2\left(\frac{\pi}{2}\right) = 4\pi^2 r^2$.

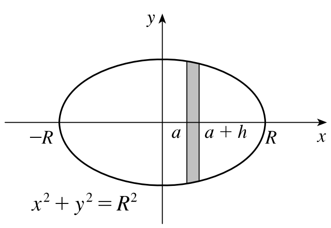
36. (a) Rotate $y = \sqrt{R^2-x^2}$ with $a \le x \le a+h$ about the x-axis to generate a zone of a sphere. $y = \sqrt{R^2-x^2} \quad\Rightarrow$

$y' = \frac{1}{2}(R^2-x^2)^{-1/2}(-2x) \quad\Rightarrow\quad ds = \sqrt{1+\left(\dfrac{-x}{\sqrt{R^2-x^2}}\right)^2}\,dx$. The surface area is

$$S = \int_a^{a+h} 2\pi y\,ds = 2\pi\int_a^{a+h}\sqrt{R^2-x^2}\sqrt{1+\frac{x^2}{R^2-x^2}}\,dx$$

$$= 2\pi\int_a^{a+h}\sqrt{R^2-x^2+x^2}\,dx = 2\pi R\left[\,x\,\right]_a^{a+h}$$

$$= 2\pi R(a+h-a) = 2\pi Rh$$



(b) Rotate $y = R$ with $0 \le x \le h$ about the x-axis to generate a zone of a cylinder. $y = R \quad \Rightarrow \quad y' = 0 \quad \Rightarrow$

$ds = \sqrt{1+0^2}\,dx = dx$. The surface area is $S = \int_0^h 2\pi y\,ds = 2\pi \int_0^h R\,dx = 2\pi R\left[\,x\,\right]_0^h = 2\pi Rh$.

37. $y = e^{x/2} + e^{-x/2} \quad \Rightarrow \quad y' = \frac{1}{2}e^{x/2} - \frac{1}{2}e^{-x/2} \quad \Rightarrow$

$1 + (y')^2 = 1 + \left(\frac{1}{2}e^{x/2} - \frac{1}{2}e^{-x/2}\right)^2 = 1 + \frac{1}{4}e^x - \frac{1}{2} + \frac{1}{4}e^{-x} = \frac{1}{4}e^x + \frac{1}{2} + \frac{1}{4}e^{-x} = \left(\frac{1}{2}e^{x/2} + \frac{1}{2}e^{-x/2}\right)^2$. If we rotate the curve about the x-axis on the interval $a \le x \le b$, the resulting surface area is

$S = \int_a^b 2\pi y\sqrt{1+(y')^2}\,dx = 2\pi \int_a^b (e^{x/2} + e^{-x/2})\left(\frac{1}{2}e^{x/2} + \frac{1}{2}e^{-x/2}\right)\,dx = \pi \int_a^b (e^{x/2} + e^{-x/2})^2\,dx$, which is the same as the volume obtained by rotating the curve y about the x-axis on the interval $a \le x \le b$, namely, $V = \pi \int_a^b y^2\,dx$.

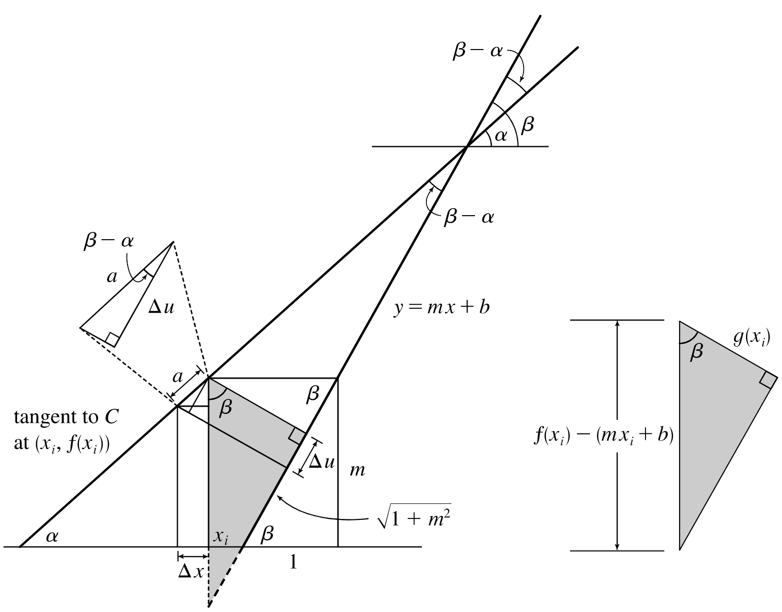
38. Since $g(x) = f(x) + c$, we have $g'(x) = f'(x)$. Thus,

$$\begin{aligned} S_g &= \int_a^b 2\pi g(x)\,\sqrt{1+[g'(x)]^2}\,dx = \int_a^b 2\pi[f(x)+c]\,\sqrt{1+[f'(x)]^2}\,dx \\ &= \int_a^b 2\pi f(x)\,\sqrt{1+[f'(x)]^2}\,dx + 2\pi c\int_a^b \sqrt{1+[f'(x)]^2}\,dx = S_f + 2\pi cL \end{aligned}$$

39. In the derivation of (4), we computed a typical contribution to the surface area to be $2\pi\,\dfrac{y_{i-1}+y_i}{2}\,|P_{i-1}P_i|$, the area of a frustum of a cone. When $f(x)$ is not necessarily positive, the approximations $y_i = f(x_i) \approx f(x_i^*)$ and $y_{i-1} = f(x_{i-1}) \approx f(x_i^*)$ must be replaced by $y_i = |f(x_i)| \approx |f(x_i^*)|$ and $y_{i-1} = |f(x_{i-1})| \approx |f(x_i^*)|$. Thus, $2\pi\,\dfrac{y_{i-1}+y_i}{2}\,|P_{i-1}P_i| \approx 2\pi\,|f(x_i^*)|\,\sqrt{1+[f'(x_i^*)]^2}\,\Delta x$. Continuing with the rest of the derivation as before, we obtain $S = \int_a^b 2\pi\,|f(x)|\,\sqrt{1+[f'(x)]^2}\,dx$.

DISCOVERY PROJECT Rotating on a Slant

1.



In the figure, the segment a lying above the interval $[x_i - \Delta x, x_i]$ along the tangent to C has length

$\Delta x \sec\alpha = \Delta x\sqrt{1+\tan^2\alpha} = \sqrt{1+[f'(x_i)]^2}\,\Delta x$. The segment from $(x_i, f(x_i))$ drawn perpendicular to the line $y = mx + b$ has length

$$g(x_i) = [f(x_i) - mx_i - b]\cos\beta = \frac{f(x_i) - mx_i - b}{\sec\beta} = \frac{f(x_i) - mx_i - b}{\sqrt{1+\tan^2\beta}} = \frac{f(x_i) - mx_i - b}{\sqrt{1+m^2}}$$

Also, $\cos(\beta - \alpha) = \dfrac{\Delta u}{\Delta x\ \sec\alpha} \quad \Rightarrow$

$$\Delta u = \Delta x\ \sec\alpha\ \cos(\beta-\alpha) = \Delta x\,\frac{\cos\beta\ \cos\alpha + \sin\beta\ \sin\alpha}{\cos\alpha} = \Delta x(\cos\beta + \sin\beta\ \tan\alpha)$$

$$= \Delta x\left[\frac{1}{\sqrt{1+m^2}} + \frac{m}{\sqrt{1+m^2}}f'(x_i)\right] = \frac{1+mf'(x_i)}{\sqrt{1+m^2}}\,\Delta x$$

Thus,
$$\text{Area}(\mathscr{R}) = \lim_{n\to\infty}\sum_{i=1}^{n} g(x_i)\,\Delta u = \lim_{n\to\infty}\sum_{i=1}^{n}\frac{f(x_i) - mx_i - b}{\sqrt{1+m^2}}\cdot\frac{1+mf'(x_i)}{\sqrt{1+m^2}}\,\Delta x$$

$$= \frac{1}{1+m^2}\int_p^q [f(x) - mx - b][1 + mf'(x)]\,dx$$

2. From Problem 1 with $m = 1$, $f(x) = x + \sin x$, $mx + b = x - 2$, $p = 0$, and $q = 2\pi$,

$$\text{Area} = \frac{1}{1\,+\,1^2}\int_0^{2\pi}[x + \sin x - (x-2)]\,[1 + 1(1+\cos x)]\,dx = \tfrac{1}{2}\int_0^{2\pi}(\sin x + 2)(2 + \cos x)\,dx$$

$$= \tfrac{1}{2}\int_0^{2\pi}(2\sin x + \sin x\ \cos x + 4 + 2\cos x)\,dx = \tfrac{1}{2}\left[-2\cos x + \tfrac{1}{2}\sin^2 x + 4x + 2\sin x\right]_0^{2\pi}$$

$$= \tfrac{1}{2}[(-2 + 0 + 8\pi + 0) - (-2 + 0 + 0 + 0)] = \tfrac{1}{2}(8\pi) = 4\pi$$

3. $V = \displaystyle\lim_{n\to\infty}\sum_{i=1}^{n}\pi[\,g(x_i)]^2\,\Delta u = \lim_{n\to\infty}\sum_{i=1}^{n}\pi\left[\frac{f(x_i) - mx_i - b}{\sqrt{1+m^2}}\right]^2\frac{1+mf'(x_i)}{\sqrt{1+m^2}}\,\Delta x$

$$= \frac{\pi}{(1+m^2)^{3/2}}\int_p^q [f(x) - mx - b]^2[1 + mf'(x)]\,dx$$

4. $V = \dfrac{\pi}{(1+1^2)^{3/2}}\displaystyle\int_0^{2\pi}(x + \sin x - x + 2)^2(1 + 1 + \cos x)\,dx$

$$= \frac{\pi}{2\sqrt{2}}\int_0^{2\pi}(\sin x + 2)^2(\cos x + 2)\,dx = \frac{\pi}{2\sqrt{2}}\int_0^{2\pi}\left(\sin^2 x + 4\sin x + 4\right)(\cos x + 2)\ dx$$

$$= \frac{\pi}{2\sqrt{2}}\int_0^{2\pi}\left(\sin^2 x\ \cos x + 4\sin x\ \cos x + 4\cos x + 2\sin^2 x + 8\sin x + 8\right)dx$$

$$= \frac{\pi}{2\sqrt{2}}\left[\tfrac{1}{3}\sin^3 x + 2\sin^2 x + 4\sin x + x - \tfrac{1}{2}\sin 2x - 8\cos x + 8x\right]_0^{2\pi} \qquad [\text{since } 2\sin^2 x = 1 - \cos 2x]$$

$$= \frac{\pi}{2\sqrt{2}}[(2\pi - 8 + 16\pi) - (-8)] = \frac{9\sqrt{2}}{2}\,\pi^2$$

5. $S = \displaystyle\int_p^q 2\pi g(x)\sqrt{1+[f'(x)]^2}\,dx = \frac{2\pi}{\sqrt{1+m^2}}\int_p^q [f(x) - mx - b]\sqrt{1+[f'(x)]^2}\,dx$

6. From Problem 5 with $f(x) = \sqrt{x}$, $p = 0$, $q = 4$, $m = \frac{1}{2}$, and $b = 0$,

$$S = \frac{2\pi}{\sqrt{1+\left(\frac{1}{2}\right)^2}}\int_0^4\left(\sqrt{x} - \tfrac{1}{2}x\right)\sqrt{1+\left(\frac{1}{2\sqrt{x}}\right)^2}\,dx \overset{\text{CAS}}{=} \frac{\pi}{\sqrt{5}}\left[\frac{\ln\left(\sqrt{17}+4\right)}{32} + \frac{37\sqrt{17}}{24} - \frac{1}{3}\right] \approx 8.554$$

8.3 Applications to Physics and Engineering

1. The weight density of water is $\delta = 62.5 \text{ lb/ft}^3$.

(a) $P = \delta d \approx (62.5 \text{ lb/ft}^3)(3 \text{ ft}) = 187.5 \text{ lb/ft}^2$

(b) $F = PA \approx (187.5 \text{ lb/ft}^2)(5 \text{ ft})(2 \text{ ft}) = 1875 \text{ lb}$. ($A$ is the area of the bottom of the tank.)

(c) As in Example 1, the area of the ith strip is $2\,(\Delta x)$ and the pressure is $\delta d = \delta x_i$. Thus,

$$F = \int_0^3 \delta x \cdot 2\,dx \approx (62.5)(2)\int_0^3 x\,dx = 125\left[\tfrac{1}{2}x^2\right]_0^3 = 125\left(\tfrac{9}{2}\right) = 562.5 \text{ lb}.$$

2. (a) $P = \rho g d = (820 \text{ kg/m}^3)(9.8 \text{ m/s}^2)(1.5 \text{ m}) = 12{,}054 \text{ Pa} \approx 12 \text{ kPa}$

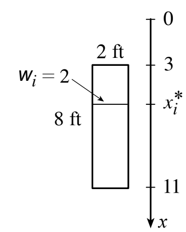
(b) $F = PA = (12{,}054 \text{ Pa})(8 \text{ m})(4 \text{ m}) \approx 3.86 \times 10^5 \text{ N}$ (A is the area at the bottom of the tank.)

(c) The area of the ith strip is $4(\Delta x)$ and the pressure is $\rho g d = \rho g\,x_i$. Thus,

$$F = \int_0^{1.5} \rho g x \cdot 4\,dx = (820)(9.8)\cdot 4\int_0^{1.5} x\,dx = 32{,}144\left[\tfrac{1}{2}x^2\right]_0^{3/2} = 16{,}072\left(\tfrac{9}{4}\right) \approx 3.62 \times 10^4 \text{ N}.$$

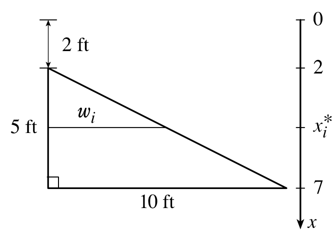
In Exercises 3–9, n is the number of subintervals of length Δx and x_i^* is a sample point in the ith subinterval $[x_{i-1}, x_i]$.

3. Set up a vertical x-axis as shown, with $x = 0$ at the water's surface and x increasing in the downward direction. Then the area of the ith rectangular strip is $2\,\Delta x$ and the pressure on the strip is δx_i^* (where $\delta \approx 62.5 \text{ lb/ft}^3$). Thus, the hydrostatic force on the strip is $\delta x_i^* \cdot 2\,\Delta x$ and the total hydrostatic force $\approx \sum_{i=1}^n \delta x_i^* \cdot 2\,\Delta x$. The total force



$$F = \lim_{n\to\infty}\sum_{i=1}^n \delta x_i^* \cdot 2\,\Delta x = \int_3^{11} \delta x \cdot 2\,dx = 2\delta\int_3^{11} x\,dx = 2\delta\left[\tfrac{1}{2}x^2\right]_3^{11} = \delta(121 - 9) = 112\delta \approx 7000 \text{ lb}$$

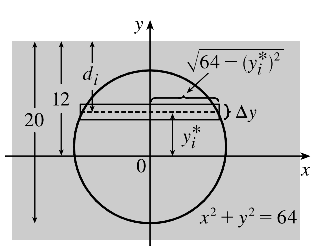
4. Set up a vertical axis as shown. Then the area of the ith rectangular strip is $2(x_i^* - 2)\,\Delta x$. $\left[\text{By similar triangles, } \dfrac{w_i}{x_i^* - 2} = \dfrac{10}{5}, \text{ so } w_i = 2(x_i^* - 2).\right]$ The pressure on the strip is δx_i^*, so the hydrostatic force on the strip is $\delta x_i^* \cdot 2(x_i^* - 2)\,\Delta x$ and the total hydrostatic force on the plate $\approx \sum_{i=1}^n \delta x_i^* \cdot 2(x_i^* - 2)\,\Delta x$. The total force



$$F = \lim_{n\to\infty}\sum_{i=1}^n \delta x_i^* \cdot 2(x_i^* - 2)\,\Delta x = \int_2^7 \delta x \cdot 2(x-2)\,dx = 2\delta\int_2^7 (x^2 - 2x)\,dx$$

$$= 2\delta\left[\tfrac{1}{3}x^3 - x^2\right]_2^7 = 2\delta\left[\left(\tfrac{343}{3} - 49\right) - \left(\tfrac{8}{3} - 4\right)\right] = 2\delta\left(\tfrac{200}{3}\right) = \tfrac{400}{3}\delta \approx \tfrac{400}{3}(62.5) = 8333.\overline{3} \text{ lb}.$$

5. Set up a coordinate system as shown. Then the area of the ith rectangular strip is $2\sqrt{8^2 - (y_i^*)^2}\,\Delta y$. The pressure on the strip is $\delta d_i = \rho g(12 - y_i^*)$, so the hydrostatic force on the strip is $\rho g(12 - y_i^*)\,2\sqrt{64 - (y_i^*)^2}\,\Delta y$ and the total hydrostatic force on the plate $\approx \sum_{i=1}^n \rho g(12 - y_i^*)\,2\sqrt{64 - (y_i^*)^2}\,\Delta y$.

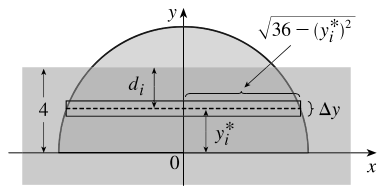


The total force $F = \lim_{n\to\infty} \sum_{i=1}^{n} \rho g(12 - y_i^*)\, 2\sqrt{64 - (y_i^*)^2}\,\Delta y = \int_{-8}^{8} \rho g(12 - y)\, 2\,\sqrt{64 - y^2}\,dy$

$= 2\rho g \cdot 12 \int_{-8}^{8} \sqrt{64 - y^2}\,dy - 2\rho g \int_{-8}^{8} y\sqrt{64 - y^2}\,dy.$

The second integral is 0 because the integrand is an odd function. The first integral is the area of a semicircular disk with radius 8. Thus, $F = 24\rho g\left(\frac{1}{2}\pi(8)^2\right) = 768\pi\rho g \approx 768\pi(1000)(9.8) \approx 2.36 \times 10^7$ N.

6. Set up a coordinate system as shown. Then the area of the ith rectangular strip is $2\sqrt{6^2 - (y_i^*)^2}\,\Delta y$. The pressure on the strip is $\delta d_i = \rho g(4 - y_i^*)$, so the hydrostatic force on the strip is $\rho g(4 - y_i^*)\,2\sqrt{36 - (y_i^*)^2}\,\Delta y$ and the hydrostatic force on the plate $\approx \sum_{i=1}^{n} \rho g(4 - y_i^*)\,2\sqrt{36 - (y_i^*)^2}\,\Delta y$. The total force $F = \lim_{n\to\infty} \sum_{i=1}^{n} \rho g(4 - y_i^*)\,2\sqrt{36 - (y_i^*)^2}\,\Delta y = \int_0^4 \rho g(4 - y)\,2\sqrt{36 - y^2}\,dy = 8\rho g I_1 - 2\rho g I_2.$



$I_1 = \int_0^4 \sqrt{36 - y^2}\,dy = \int_0^{\alpha} \sqrt{36 - 36\sin^2\theta}\,(6\cos\theta\,d\theta)$ $\quad\begin{bmatrix} y = 6\sin\theta, \\ dy = 6\cos\theta\,d\theta \\ \alpha = \sin^{-1}(2/3) \end{bmatrix}$

$= \int_0^{\alpha} 36\cos^2\theta\,d\theta = \int_0^{\alpha} 36 \cdot \frac{1}{2}(1 + \cos 2\theta)\,d\theta = 18\left[\theta + \frac{1}{2}\sin 2\theta\right]_0^{\alpha}$

$= 18\left(\alpha + \frac{1}{2}\sin 2\alpha\right) = 18(\alpha + \sin\alpha\,\cos\alpha).$

$I_2 = \int_0^4 y\sqrt{36 - y^2}\,dy = \int_{36}^{20} \sqrt{u}\,\left(-\frac{1}{2}du\right)$ $\quad\begin{bmatrix} u = 36 - y^2, \\ du = -2y\,dy \end{bmatrix}$

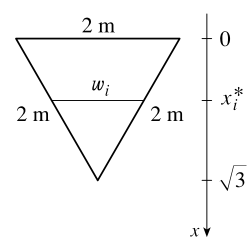
$= -\frac{1}{2}\left[\frac{2}{3}u^{3/2}\right]_{36}^{20} = -\frac{1}{3}(20^{3/2} - 216) = 72 - \frac{40}{3}\sqrt{5}.$

Thus,

$$F = 8\rho g \cdot 18(\alpha + \sin\alpha\,\cos\alpha) - 2\rho g\left(72 - \tfrac{40}{3}\sqrt{5}\right) = 144\rho g\left(\sin^{-1}\tfrac{2}{3} + \tfrac{2}{3}\tfrac{\sqrt{5}}{3}\right) - 2\rho g\left(72 - \tfrac{40}{3}\sqrt{5}\right)$$

$$= \rho g\left(144\sin^{-1}\tfrac{2}{3} + \tfrac{176}{3}\sqrt{5} - 144\right) \approx 9.04 \times 10^5 \text{ N} \quad [\rho = 1000,\ g \approx 9.8].$$

7. Set up a vertical x-axis as shown. Then the area of the ith rectangular strip is $\left(2 - \frac{2}{\sqrt{3}}\,x_i^*\right)\Delta x$. $\left[\text{By similar triangles, } \frac{w_i}{2} = \frac{\sqrt{3} - x_i^*}{\sqrt{3}}, \text{ so } w_i = 2 - \frac{2}{\sqrt{3}}\,x_i^*.\right]$ The pressure on the strip is $\rho g x_i^*$, so the hydrostatic force on the strip is $\rho g x_i^*\left(2 - \frac{2}{\sqrt{3}}\,x_i^*\right)\Delta x$ and the hydrostatic force on the plate $\approx \sum_{i=1}^{n} \rho g x_i^*\left(2 - \frac{2}{\sqrt{3}}\,x_i^*\right)\Delta x$.

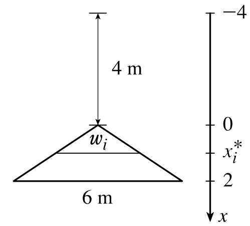


The total force

$$F = \lim_{n\to\infty} \sum_{i=1}^{n} \rho g x_i^*\left(2 - \frac{2}{\sqrt{3}}\,x_i^*\right)\Delta x = \int_0^{\sqrt{3}} \rho g x\left(2 - \frac{2}{\sqrt{3}}\,x\right)dx = \rho g \int_0^{\sqrt{3}} \left(2x - \frac{2}{\sqrt{3}}\,x^2\right)dx$$

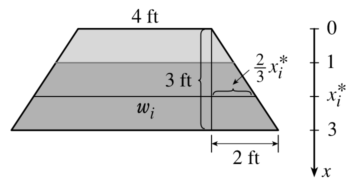
$$= \rho g\left[x^2 - \frac{2}{3\sqrt{3}}\,x^3\right]_0^{\sqrt{3}} = \rho g\,[(3 - 2) - 0] = \rho g \approx 1000 \cdot 9.8 = 9.8 \times 10^3 \text{ N}$$

8. Set up a vertical x-axis as shown. Then the area of the ith rectangular strip is $3x_i^*\,\Delta x$. $\left[\text{By similar triangles, } \dfrac{w_i}{x_i^*} = \dfrac{6}{2}, \text{ so } w_i = 3x_i^*.\right]$ The pressure on the strip is $\rho g(x_i^* + 4)$, so the hydrostatic force on the strip is $\rho g(x_i^* + 4)3x_i^*\,\Delta x$ and the hydrostatic force on the plate $\approx \sum_{i=1}^{n} \rho g(x_i^* + 4)3x_i^*\,\Delta x$. The total force



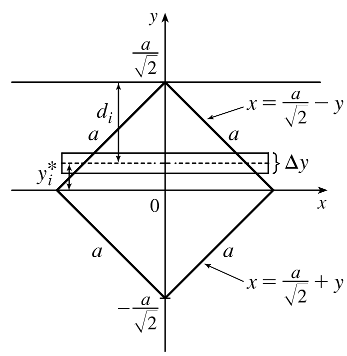
$$F = \lim_{n\to\infty} \sum_{i=1}^{n} \rho g(x_i^* + 4)\,3x_i^*\,\Delta x = \int_0^2 \rho g(x+4)\,3x\,dx = 3\rho g \int_0^2 (x^2 + 4x)\,dx$$
$$= 3\rho g\left[\tfrac{1}{3}x^3 + 2x^2\right]_0^2 = 3\rho g\left(\tfrac{8}{3} + 8\right) = 32\rho g = 313{,}600 \text{ N} \quad [\rho = 1000,\ g \approx 9.8]$$

9. Set up a vertical x-axis as shown. Then the area of the ith rectangular strip is $w_i\,\Delta x = \left(4 + 2\cdot\tfrac{2}{3}x_i^*\right)\Delta x$. The pressure on the strip is $\delta(x_i^* - 1)$, so the hydrostatic force on the strip is $\delta(x_i^* - 1)\left(4 + \tfrac{4}{3}x_i^*\right)\Delta x$ and the hydrostatic force on the plate $\approx \sum_{i=1}^{n} \delta(x_i^* - 1)\left(4 + \tfrac{4}{3}x_i^*\right)\Delta x$. The total force



$$F = \lim_{n\to\infty} \sum_{i=1}^{n} \delta(x_i^* - 1)\left(4 + \tfrac{4}{3}x_i^*\right)\Delta x = \int_1^3 \delta(x-1)\left(4 + \tfrac{4}{3}x\right)dx = \delta\int_1^3 \left(\tfrac{4}{3}x^2 + \tfrac{8}{3}x - 4\right)dx$$
$$= \delta\left[\tfrac{4}{9}x^3 + \tfrac{4}{3}x^2 - 4x\right]_1^3 = \delta\left[(12 + 12 - 12) - \left(\tfrac{4}{9} + \tfrac{4}{3} - 4\right)\right] = \delta\left(\tfrac{128}{9}\right) \approx 889 \text{ lb} \quad [\delta \approx 62.5]$$

10. Set up coordinate axes as shown in the figure. For the *top half,* the length of the ith strip is $2\left(a/\sqrt{2} - y_i^*\right)$ and its area is $2\left(a/\sqrt{2} - y_i^*\right)\Delta y$. The pressure on this strip is approximately $\delta d_i = \delta\left(a/\sqrt{2} - y_i^*\right)$ and so the force on the strip is approximately $2\delta\left(a/\sqrt{2} - y_i^*\right)^2\Delta y$. The total force



$$F_1 = \lim_{n\to\infty} \sum_{i=1}^{n} 2\delta\left(\frac{a}{\sqrt{2}} - y_i^*\right)^2 \Delta y = 2\delta \int_0^{a/\sqrt{2}} \left(\frac{a}{\sqrt{2}} - y\right)^2 dy$$
$$= 2\delta\left[-\frac{1}{3}\left(\frac{a}{\sqrt{2}} - y\right)^3\right]_0^{a/\sqrt{2}} = -\frac{2}{3}\delta\left[0 - \left(\frac{a}{\sqrt{2}}\right)^3\right] = \frac{2\delta}{3}\,\frac{a^3}{2\sqrt{2}} = \frac{\sqrt{2}\,a^3\delta}{6}$$

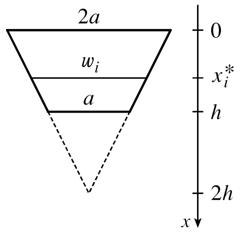
For the *bottom half,* the length is $2\left(a/\sqrt{2} + y_i^*\right)$ and the total force is

$$F_2 = \lim_{n\to\infty} \sum_{i=1}^{n} 2\delta\left(\frac{a}{\sqrt{2}} + y_i^*\right)\left(\frac{a}{\sqrt{2}} - y_i^*\right)\Delta y = 2\delta \int_{-a/\sqrt{2}}^{0} \left(\frac{a^2}{2} - y^2\right)dy = 2\delta\left[\tfrac{1}{2}a^2 y - \tfrac{1}{3}y^3\right]_{-a/\sqrt{2}}^{0}$$
$$= 2\delta\left[0 - \left(-\frac{\sqrt{2}\,a^3}{4} + \frac{\sqrt{2}\,a^3}{12}\right)\right] = 2\delta\left(\frac{\sqrt{2}\,a^3}{6}\right) = \frac{2\sqrt{2}\,a^3\delta}{6} \qquad [F_2 = 2F_1]$$

Thus, the total force $F = F_1 + F_2 = \dfrac{3\sqrt{2}\,a^3\delta}{6} = \dfrac{\sqrt{2}\,a^3\delta}{2}$.

11. Set up a vertical x-axis as shown. Then the area of the ith rectangular strip is

$\frac{a}{h}(2h - x_i^*)\,\Delta x$. $\left[\text{By similar triangles, } \frac{w_i}{2h - x_i^*} = \frac{2a}{2h}, \text{ so } w_i = \frac{a}{h}(2h - x_i^*).\right]$



The pressure on the strip is δx_i^*, so the hydrostatic force on the plate

$\approx \sum_{i=1}^{n} \delta x_i^* \, \frac{a}{h}(2h - x_i^*)\,\Delta x$. The total force

$$F = \lim_{n\to\infty} \sum_{i=1}^{n} \delta x_i^* \, \frac{a}{h}(2h - x_i^*)\,\Delta x = \delta\,\frac{a}{h}\int_0^h x(2h - x)\,dx = \frac{a\delta}{h}\int_0^h \left(2hx - x^2\right)dx$$

$$= \frac{a\delta}{h}\left[hx^2 - \tfrac{1}{3}x^3\right]_0^h = \frac{a\delta}{h}\left(h^3 - \tfrac{1}{3}h^3\right) = \frac{a\delta}{h}\left(\frac{2h^3}{3}\right) = \tfrac{2}{3}\delta a h^2$$

12. (a) The solution is similar to the solution for Example 2. The pressure on a strip is approximately $\delta d_i = 64.6(3 - y_i^*)$ and the total force is

$$F = \lim_{n\to\infty} \sum_{i=1}^{n} 64.6(3 - y_i^*)2\sqrt{9 - (y_i^*)^2}\,\Delta y = 129.2\int_{-3}^{3}(3 - y)\sqrt{9 - y^2}\,dy$$

$$= 129.2 \cdot 3\int_{-3}^{3}\sqrt{9 - y^2}\,dy - 129.2\int_{-3}^{3} y\sqrt{9 - y^2}\,dy$$

$$= 387.6 \cdot \tfrac{1}{2}\pi(3)^2 - 0$$ [the first integral is the area of a semicircular disk with radius 3 and the second integral is 0 because the integrand is an odd function]

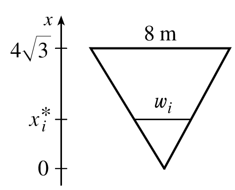
$$= (1744.2)\pi \approx 5480 \text{ lb}$$

(b) If the tank is half full, the surface of the milk is $y = 0$, so the pressure on a strip is approximately $\delta d_i = 64.6(0 - y_i^*)$. The upper limit of integration changes from 3 to 0 and the total force is

$$F = 129.2\int_{-3}^{0}(0 - y)\sqrt{9 - y^2}\,dy = 129.2\left[\tfrac{1}{3}(9 - y^2)^{3/2}\right]_{-3}^{0} = 129.2(9 - 0) = 1162.8 \text{ lb}$$

Note that this is about 21% of the force for a full tank.

13. By similar triangles, $\frac{8}{4\sqrt{3}} = \frac{w_i}{x_i^*} \;\Rightarrow\; w_i = \frac{2x_i^*}{\sqrt{3}}$. The area of the ith rectangular strip is $\frac{2x_i^*}{\sqrt{3}}\,\Delta x$ and the pressure on it is $\rho g\left(4\sqrt{3} - x_i^*\right)$.



$$F = \int_0^{4\sqrt{3}} \rho g\left(4\sqrt{3} - x\right)\frac{2x}{\sqrt{3}}\,dx = 8\rho g\int_0^{4\sqrt{3}} x\,dx - \frac{2\rho g}{\sqrt{3}}\int_0^{4\sqrt{3}} x^2\,dx$$

$$= 4\rho g\left[x^2\right]_0^{4\sqrt{3}} - \frac{2\rho g}{3\sqrt{3}}\left[x^3\right]_0^{4\sqrt{3}} = 192\rho g - \frac{2\rho g}{3\sqrt{3}}\,64 \cdot 3\sqrt{3} = 192\rho g - 128\rho g = 64\rho g$$

$$\approx 64(840)(9.8) \approx 5.27 \times 10^5 \text{ N}$$

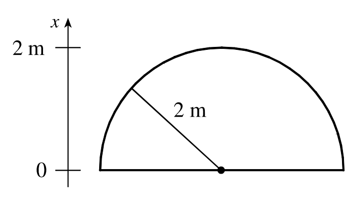
14. $F = \int_0^2 \rho g(10 - x)2\sqrt{4 - x^2}\,dx$

$$= 20\rho g\int_0^2 \sqrt{4 - x^2}\,dx - \rho g\int_0^2 \sqrt{4 - x^2}\,2x\,dx$$

$$= 20\rho g\tfrac{1}{4}\pi(2^2) - \rho g\int_0^4 u^{1/2}\,du \qquad [u = 4 - x^2,\ du = -2x\,dx]$$

$$= 20\pi\rho g - \tfrac{2}{3}\rho g\left[u^{3/2}\right]_0^4 = 20\pi\rho g - \tfrac{16}{3}\rho g = \rho g\left(20\pi - \tfrac{16}{3}\right)$$

$$= (1000)(9.8)\left(20\pi - \tfrac{16}{3}\right) \approx 5.63 \times 10^5 \text{ N}$$



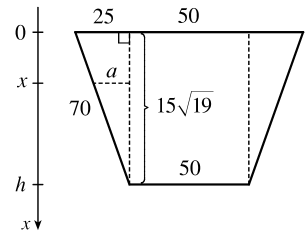
15. (a) The top of the cube has depth $d = 1\text{ m} - 20\text{ cm} = 80\text{ cm} = 0.8\text{ m}$.

$$F = \rho g d A \approx (1000)(9.8)(0.8)(0.2)^2 = 313.6 \approx 314\text{ N}$$

(b) The area of a strip is $0.2\,\Delta x$ and the pressure on it is $\rho g x_i^*$.

$$F = \int_{0.8}^{1} \rho g x(0.2)\,dx = 0.2\rho g\left[\tfrac{1}{2}x^2\right]_{0.8}^{1} = (0.2\rho g)(0.18) = 0.036\rho g = 0.036(1000)(9.8) = 352.8 \approx 353\text{ N}$$

16. The height of the dam is $h = \sqrt{70^2 - 25^2}\,\cos 30^\circ = 15\sqrt{19}\left(\frac{\sqrt{3}}{2}\right)$.



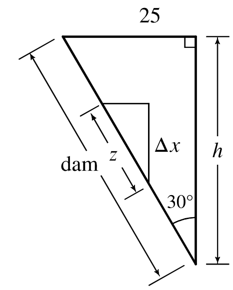
The width of the trapezoid is $w = 50 + 2a$.

By similar triangles, $\dfrac{25}{h} = \dfrac{a}{h-x} \quad\Rightarrow\quad a = \dfrac{25}{h}(h-x)$. Thus,

$$w = 50 + 2\cdot\frac{25}{h}(h-x) = 50 + \frac{50}{h}\cdot h - \frac{50}{h}\cdot x = 50 + 50 - \frac{50x}{h} = 100 - \frac{50x}{h}.$$

From the small triangle in the second figure, $\cos 30^\circ = \dfrac{\Delta x}{z} \quad\Rightarrow$

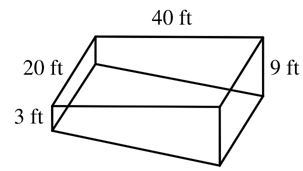
$z = \Delta x \sec 30^\circ = 2\,\Delta x/\sqrt{3}$.



$$F = \int_0^h \delta x\left(100 - \frac{50x}{h}\right)\frac{2}{\sqrt{3}}\,dx = \frac{200\delta}{\sqrt{3}}\int_0^h x\,dx - \frac{100\delta}{h\sqrt{3}}\int_0^h x^2\,dx$$

$$= \frac{200\delta}{\sqrt{3}}\,\frac{h^2}{2} - \frac{100\delta}{h\sqrt{3}}\,\frac{h^3}{3} = \frac{200\delta h^2}{3\sqrt{3}} = \frac{200(62.5)}{3\sqrt{3}}\cdot\frac{12{,}825}{4} \approx 7.71\times 10^6\text{ lb}$$

17. (a) The area of a strip is $20\,\Delta x$ and the pressure on it is δx_i.



$$F = \int_0^3 \delta x 20\,dx = 20\delta\left[\tfrac{1}{2}x^2\right]_0^3 = 20\delta\cdot\tfrac{9}{2} = 90\delta$$

$$= 90(62.5) = 5625\text{ lb} \approx 5.63\times 10^3\text{ lb}$$

(b) $F = \int_0^9 \delta x 20\,dx = 20\delta\left[\tfrac{1}{2}x^2\right]_0^9 = 20\delta\cdot\tfrac{81}{2} = 810\delta = 810(62.5) = 50{,}625\text{ lb} \approx 5.06\times 10^4\text{ lb}$.

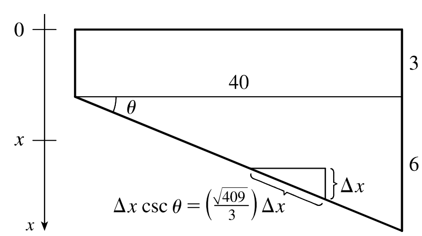
(c) For the first 3 ft, the length of the side is constant at 40 ft. For $3 < x \le 9$, we can use similar triangles to find the length a:

$$\frac{a}{40} = \frac{9-x}{6} \quad\Rightarrow\quad a = 40\cdot\frac{9-x}{6}.$$

$$F = \int_0^3 \delta x 40\,dx + \int_3^9 \delta x(40)\,\frac{9-x}{6}\,dx = 40\delta\left[\tfrac{1}{2}x^2\right]_0^3 + \tfrac{20}{3}\delta\int_3^9(9x - x^2)\,dx = 180\delta + \tfrac{20}{3}\delta\left[\tfrac{9}{2}x^2 - \tfrac{1}{3}x^3\right]_3^9$$

$$= 180\delta + \tfrac{20}{3}\delta\left[\left(\tfrac{729}{2} - 243\right) - \left(\tfrac{81}{2} - 9\right)\right] = 180\delta + 600\delta = 780\delta = 780(62.5) = 48{,}750\text{ lb} \approx 4.88\times 10^4\text{ lb}$$

(d) For any right triangle with hypotenuse on the bottom,



$$\sin\theta = \frac{\Delta x}{\text{hypotenuse}} \quad\Rightarrow$$

$$\text{hypotenuse} = \Delta x\csc\theta = \Delta x\,\frac{\sqrt{40^2 + 6^2}}{6} = \frac{\sqrt{409}}{3}\,\Delta x.$$

$$F = \int_3^9 \delta x 20\,\frac{\sqrt{409}}{3}\,dx = \tfrac{1}{3}\left(20\sqrt{409}\right)\delta\left[\tfrac{1}{2}x^2\right]_3^9$$

$$= \tfrac{1}{3}\cdot 10\sqrt{409}\,\delta(81 - 9) \approx 303{,}356\text{ lb} \approx 3.03\times 10^5\text{ lb}$$

18. Partition the interval $[a, b]$ by points x_i as usual and choose $x_i^* \in [x_{i-1}, x_i]$ for each i. The ith horizontal strip of the immersed plate is approximated by a rectangle of height Δx_i and width $w(x_i^*)$, so its area is $A_i \approx w(x_i^*)\,\Delta x_i$. For small Δx_i, the pressure P_i on the ith strip is almost constant and $P_i \approx \rho g x_i^*$ by Equation 1. The hydrostatic force F_i acting on the ith strip is $F_i = P_i A_i \approx \rho g x_i^* w(x_i^*)\,\Delta x_i$. Adding these forces and taking the limit as $n \to \infty$, we obtain the hydrostatic force on the immersed plate:

$$F = \lim_{n\to\infty} \sum_{i=1}^{n} F_i = \lim_{n\to\infty} \sum_{i=1}^{n} \rho g x_i^* w(x_i^*)\,\Delta x_i = \int_a^b \rho g x w(x)\,dx$$

19. From Exercise 18, we have $F = \int_a^b \rho g x w(x)\,dx = \int_{7.0}^{9.4} 64 x w(x)\,dx$. From the table, we see that $\Delta x = 0.4$, so using Simpson's Rule to estimate F, we get

$$\begin{aligned} F &\approx 64\,\tfrac{0.4}{3}[7.0w(7.0) + 4(7.4)w(7.4) + 2(7.8)w(7.8) + 4(8.2)w(8.2) + 2(8.6)w(8.6) + 4(9.0)w(9.0) + 9.4w(9.4)] \\ &= \tfrac{25.6}{3}[7(1.2) + 29.6(1.8) + 15.6(2.9) + 32.8(3.8) + 17.2(3.6) + 36(4.2) + 9.4(4.4)] \\ &= \tfrac{25.6}{3}(486.04) \approx 4148 \text{ lb} \end{aligned}$$

20. (a) From Equation 8, $\overline{x} = \frac{1}{A}\int_a^b xw(x)\,dx \;\Rightarrow\; A\overline{x} = \int_a^b xw(x)\,dx \;\Rightarrow\; \rho g A\overline{x} = \rho g \int_a^b xw(x)\,dx \;\Rightarrow$ $(\rho g\overline{x})A = \int_a^b \rho g\, xw(x)\,dx = F$ by Exercise 18.

(b) For the figure in Exercise 10, let the coordinates of the centroid $(\overline{x}, \overline{y}) = \left(a/\sqrt{2}, 0\right)$.

$$F = (\rho g\overline{x})A = \rho g\,\frac{a}{\sqrt{2}}\,a^2 = \delta\,\frac{\sqrt{2}\,a}{2}\,a^2 = \frac{\sqrt{2}\,a^3\delta}{2}.$$

21. The moment M of the system about the origin is $M = \sum_{i=1}^{2} m_i x_i = m_1x_1 + m_2x_2 = 6 \cdot 10 + 9 \cdot 30 = 330$.

The mass m of the system is $m = \sum_{i=1}^{2} m_i = m_1 + m_2 = 6 + 9 = 15$.

The center of mass of the system is $\overline{x} = M/m = \frac{330}{15} = 22$.

22. The moment M is $m_1x_1 + m_2x_2 + m_3x_3 = 12(-3) + 15(2) + 20(8) = 154$. The mass m is $m_1 + m_2 + m_3 = 12 + 15 + 20 = 47$. The center of mass is $\overline{x} = M/m = \frac{154}{47}$.

23. The mass is $m = \sum_{i=1}^{3} m_i = 4 + 2 + 4 = 10$. The moment about the x-axis is $M_x = \sum_{i=1}^{3} m_i y_i = 4(-3) + 2(1) + 4(5) = 10$.

The moment about the y-axis is $M_y = \sum_{i=1}^{3} m_i x_i = 4(2) + 2(-3) + 4(3) = 14$. The center of mass is

$$(\overline{x}, \overline{y}) = \left(\frac{M_y}{m}, \frac{M_x}{m}\right) = \left(\frac{14}{10}, \frac{10}{10}\right) = (1.4, 1).$$

24. The mass is $m = \sum_{i=1}^{4} m_i = 5 + 4 + 3 + 6 = 18$.

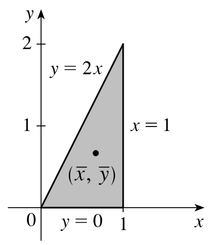
The moment about the x-axis is $M_x = \sum_{i=1}^{4} m_i y_i = 5(2) + 4(5) + 3(2) + 6(-2) = 24$.

[continued]

The moment about the y-axis is $M_y = \sum_{i=1}^{4} m_i x_i = 5(-4) + 4(0) + 3(3) + 6(1) = -5$.

The center of mass is $(\overline{x}, \overline{y}) = \left(\frac{M_y}{m}, \frac{M_x}{m}\right) = \left(\frac{-5}{18}, \frac{24}{18}\right) = \left(-\frac{5}{18}, \frac{4}{3}\right)$.

25. The region in the figure is "right-heavy" and "bottom-heavy," so we know that $\overline{x} > 0.5$ and $\overline{y} < 1$, and we might guess that $\overline{x} = 0.7$ and $\overline{y} = 0.7$.



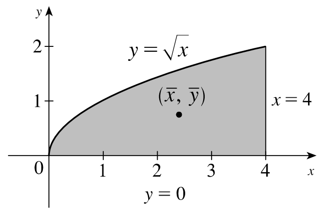
$A = \int_0^1 2x\,dx = \left[x^2\right]_0^1 = 1 - 0 = 1$.

$\overline{x} = \frac{1}{A}\int_0^1 x(2x)\,dx = \frac{1}{1}\left[\frac{2}{3}x^3\right]_0^1 = \frac{2}{3}$.

$\overline{y} = \frac{1}{A}\int_0^1 \frac{1}{2}(2x)^2\,dx = \frac{1}{1}\int_0^1 2x^2\,dx = \left[\frac{2}{3}x^3\right]_0^1 = \frac{2}{3}$.

Thus, the centroid is $(\overline{x}, \overline{y}) = \left(\frac{2}{3}, \frac{2}{3}\right)$.

26. The region in the figure is "right-heavy" and "bottom-heavy," so we know that $\overline{x} > 2$ and $\overline{y} < 1$, and we might guess that $\overline{x} = 2.3$ and $\overline{y} = 0.8$.



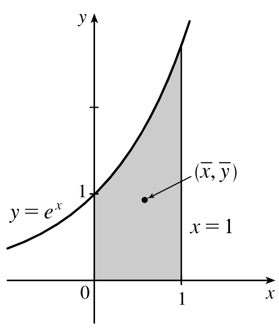
$A = \int_0^4 \sqrt{x}\,dx = \left[\frac{2}{3}x^{3/2}\right]_0^4 = \frac{16}{3}$.

$\overline{x} = \frac{1}{A}\int_0^4 x\left(\sqrt{x}\right)dx = \frac{3}{16}\int_0^4 x^{3/2}\,dx = \frac{3}{16}\left[\frac{2}{5}x^{5/2}\right]_0^4 = \frac{3}{40}(32 - 0) = \frac{12}{5}$.

$\overline{y} = \frac{1}{A}\int_0^4 \frac{1}{2}\left(\sqrt{x}\right)^2\,dx = \frac{3}{16}\int_0^4 \frac{1}{2}x\,dx = \frac{3}{32}\left[\frac{1}{2}x^2\right]_0^4 = \frac{3}{64}(16 - 0) = \frac{3}{4}$.

Thus, the centroid is $(\overline{x}, \overline{y}) = (2.4, 0.75)$.

27. The region in the figure is "right-heavy" and "bottom-heavy," so we know $\overline{x} > 0.5$ and $\overline{y} < 1$, and we might guess that $\overline{x} = 0.6$ and $\overline{y} = 0.9$.



$A = \int_0^1 e^x\,dx = \left[e^x\right]_0^1 = e - 1$.

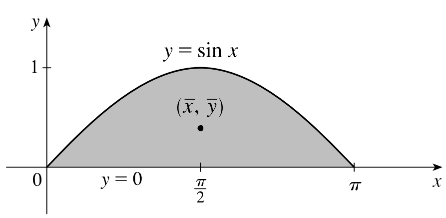
$\overline{x} = \frac{1}{A}\int_0^1 xe^x\,dx = \frac{1}{e-1}\left[xe^x - e^x\right]_0^1$ [by parts]

$= \frac{1}{e-1}[0 - (-1)] = \frac{1}{e-1}$.

$\overline{y} = \frac{1}{A}\int_0^1 \frac{1}{2}(e^x)^2\,dx = \frac{1}{e-1} \cdot \frac{1}{4}\left[e^{2x}\right]_0^1 = \frac{1}{4(e-1)}\left(e^2 - 1\right) = \frac{e+1}{4}$.

Thus, the centroid is $(\overline{x}, \overline{y}) = \left(\frac{1}{e-1}, \frac{e+1}{4}\right) \approx (0.58, 0.93)$.

28. Since the region in the figure is symmetric about the line $x = \frac{\pi}{2}$, we know that $\overline{x} = \frac{\pi}{2}$. The region is "bottom-heavy," so we know that $\overline{y} < 0.5$, and we might guess that $\overline{y} = 0.4$.



$A = \int_0^\pi \sin x\,dx = \left[-\cos x\right]_0^\pi = 1 - (-1) = 2$.

$\overline{x} = \frac{1}{A}\int_0^\pi x\sin x\,dx \overset{82}{=} \frac{1}{2}\left[\sin x - x\cos x\right]_0^\pi = \frac{1}{2}[(0 + \pi) - (0 - 0)] = \frac{\pi}{2}$.

$\overline{y} = \frac{1}{A}\int_0^\pi \frac{1}{2}(\sin x)^2\,dx = \frac{1}{2} \cdot \frac{1}{2}\int_0^\pi \frac{1}{2}(1 - \cos 2x)\,dx = \frac{1}{8}\left[x - \frac{1}{2}\sin 2x\right]_0^\pi = \frac{1}{8}[(\pi - 0) - (0 - 0)] = \frac{\pi}{8} \approx 0.39$.

Thus, the centroid is $(\overline{x}, \overline{y}) = \left(\frac{\pi}{2}, \frac{\pi}{8}\right)$.

29. $A = \int_0^1 (x^{1/2} - x^2)\,dx = \left[\frac{2}{3}x^{3/2} - \frac{1}{3}x^3\right]_0^1 = \left(\frac{2}{3} - \frac{1}{3}\right) - 0 = \frac{1}{3}$.

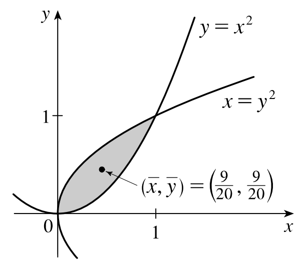
$\overline{x} = \frac{1}{A}\int_0^1 x(x^{1/2} - x^2)\,dx = 3\int_0^1 (x^{3/2} - x^3)\,dx$

$= 3\left[\frac{2}{5}x^{5/2} - \frac{1}{4}x^4\right]_0^1 = 3\left(\frac{2}{5} - \frac{1}{4}\right) = 3\left(\frac{3}{20}\right) = \frac{9}{20}$.

$\overline{y} = \frac{1}{A}\int_0^1 \frac{1}{2}\left[(x^{1/2})^2 - (x^2)^2\right]dx = 3\left(\frac{1}{2}\right)\int_0^1 (x - x^4)\,dx$

$= \frac{3}{2}\left[\frac{1}{2}x^2 - \frac{1}{5}x^5\right]_0^1 = \frac{3}{2}\left(\frac{1}{2} - \frac{1}{5}\right) = \frac{3}{2}\left(\frac{3}{10}\right) = \frac{9}{20}$.

Thus, the centroid is $(\overline{x}, \overline{y}) = \left(\frac{9}{20}, \frac{9}{20}\right)$.



30. The curves intersect when $2 - x^2 = x \;\Leftrightarrow\; 0 = x^2 + x - 2 \;\Leftrightarrow$
$0 = (x+2)(x-1) \;\Leftrightarrow\; x = -2$ or $x = 1$.

$A = \int_{-2}^1 (2 - x^2 - x)\,dx = \left[2x - \frac{1}{3}x^3 - \frac{1}{2}x^2\right]_{-2}^1 = \frac{7}{6} - \left(-\frac{10}{3}\right) = \frac{9}{2}$.

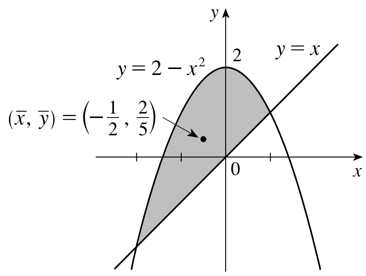
$\overline{x} = \frac{1}{A}\int_{-2}^1 x(2 - x^2 - x)\,dx = \frac{2}{9}\int_{-2}^1 (2x - x^3 - x^2)\,dx$

$= \frac{2}{9}\left[x^2 - \frac{1}{4}x^4 - \frac{1}{3}x^3\right]_{-2}^1 = \frac{2}{9}\left(\frac{5}{12} - \frac{8}{3}\right) = -\frac{1}{2}$.

$\overline{y} = \frac{1}{A}\int_{-2}^1 \frac{1}{2}\left[(2 - x^2)^2 - x^2\right]dx = \frac{2}{9}\cdot\frac{1}{2}\int_{-2}^1 (4 - 5x^2 + x^4)\,dx$

$= \frac{1}{9}\left[4x - \frac{5}{3}x^3 + \frac{1}{5}x^5\right]_{-2}^1 = \frac{1}{9}\left[\frac{38}{15} - \left(-\frac{16}{15}\right)\right] = \frac{2}{5}$.

Thus, the centroid is $(\overline{x}, \overline{y}) = \left(-\frac{1}{2}, \frac{2}{5}\right)$.

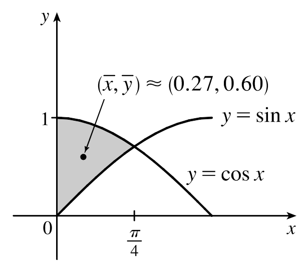


31. $A = \int_0^{\pi/4} (\cos x - \sin x)\,dx = \left[\sin x + \cos x\right]_0^{\pi/4} = \sqrt{2} - 1$.

$\overline{x} = A^{-1}\int_0^{\pi/4} x(\cos x - \sin x)\,dx$

$= A^{-1}\left[x(\sin x + \cos x) + \cos x - \sin x\right]_0^{\pi/4}$ [integration by parts]

$= A^{-1}\left(\frac{\pi}{4}\sqrt{2} - 1\right) = \dfrac{\frac{1}{4}\pi\sqrt{2} - 1}{\sqrt{2} - 1}$.



$\overline{y} = A^{-1}\int_0^{\pi/4} \frac{1}{2}(\cos^2 x - \sin^2 x)\,dx = \frac{1}{2A}\int_0^{\pi/4} \cos 2x\,dx = \frac{1}{4A}\left[\sin 2x\right]_0^{\pi/4} = \frac{1}{4A} = \frac{1}{4\left(\sqrt{2} - 1\right)}$.

Thus, the centroid is $(\overline{x}, \overline{y}) = \left(\dfrac{\pi\sqrt{2} - 4}{4\left(\sqrt{2} - 1\right)}, \dfrac{1}{4\left(\sqrt{2} - 1\right)}\right) \approx (0.27, 0.60)$.

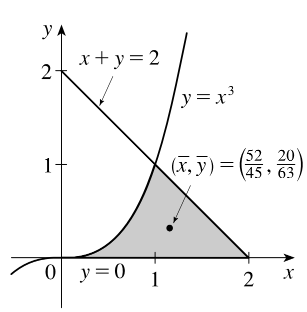
32. $A = \int_0^1 x^3 dx + \int_1^2 (2 - x)\,dx = \left[\frac{1}{4}x^4\right]_0^1 + \left[2x - \frac{1}{2}x^2\right]_1^2$

$= \frac{1}{4} + (4 - 2) - \left(2 - \frac{1}{2}\right) = \frac{3}{4}$.

$\overline{x} = \frac{1}{A}\left[\int_0^1 x(x^3)\,dx + \int_1^2 x(2 - x)\,dx\right] = \frac{4}{3}\left[\int_0^1 x^4\,dx + \int_1^2 (2x - x^2)\,dx\right]$

$= \frac{4}{3}\left\{\left[\frac{1}{5}x^5\right]_0^1 + \left[x^2 - \frac{1}{3}x^3\right]_1^2\right\} = \frac{4}{3}\left[\frac{1}{5} + \left(4 - \frac{8}{3}\right) - \left(1 - \frac{1}{3}\right)\right]$

$= \frac{4}{3}\left(\frac{13}{15}\right) = \frac{52}{45}$.



[continued]

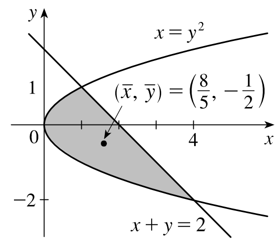
$\overline{y} = \frac{1}{A}\left[\int_0^1 \frac{1}{2}(x^3)^2\,dx + \int_1^2 \frac{1}{2}(2-x)^2\,dx\right] = \frac{2}{3}\left[\int_0^1 x^6 dx + \int_1^2 (x-2)^2\,dx\right] = \frac{2}{3}\left\{\left[\frac{1}{7}x^7\right]_0^1 + \left[\frac{1}{3}(x-2)^3\right]_1^2\right\}$

$= \frac{2}{3}\left(\frac{1}{7} - 0 + 0 + \frac{1}{3}\right) = \frac{2}{3}\left(\frac{10}{21}\right) = \frac{20}{63}.$

Thus, the centroid is $(\overline{x}, \overline{y}) = \left(\frac{52}{45}, \frac{20}{63}\right)$.

33. The curves intersect when $2 - y = y^2 \quad \Leftrightarrow \quad 0 = y^2 + y - 2 \quad \Leftrightarrow$

$0 = (y+2)(y-1) \quad \Leftrightarrow \quad y = -2$ or $y = 1$.



$A = \int_{-2}^{1} (2 - y - y^2)\,dy = \left[2y - \frac{1}{2}y^2 - \frac{1}{3}y^3\right]_{-2}^{1} = \frac{7}{6} - \left(-\frac{10}{3}\right) = \frac{9}{2}.$

$\overline{x} = \frac{1}{A}\int_{-2}^{1} \frac{1}{2}[(2-y)^2 - (y^2)^2]\,dy = \frac{2}{9}\cdot\frac{1}{2}\int_{-2}^{1}(4 - 4y + y^2 - y^4)\,dy$

$= \frac{1}{9}\left[4y - 2y^2 + \frac{1}{3}y^3 - \frac{1}{5}y^5\right]_{-2}^{1} = \frac{1}{9}\left[\frac{32}{15} - \left(-\frac{184}{15}\right)\right] = \frac{8}{5}.$

$\overline{y} = \frac{1}{A}\int_{-2}^{1} y(2 - y - y^2)\,dy = \frac{2}{9}\int_{-2}^{1}(2y - y^2 - y^3)\,dy$

$= \frac{2}{9}\left[y^2 - \frac{1}{3}y^3 - \frac{1}{4}y^4\right]_{-2}^{1} = \frac{2}{9}\left(\frac{5}{12} - \frac{8}{3}\right) = -\frac{1}{2}.$

Thus, the centroid is $(\overline{x}, \overline{y}) = \left(\frac{8}{5}, -\frac{1}{2}\right)$.

34. An equation of the line is $y = -\frac{3}{2}x + 3$. $A = \frac{1}{2}(2)(3) = 3$, so $m = \rho A = 4(3) = 12$.

$M_x = \rho\int_0^2 \frac{1}{2}\left(-\frac{3}{2}x + 3\right)^2\,dx = \frac{1}{2}\rho\int_0^2\left(\frac{9}{4}x^2 - 9x + 9\right)dx = \frac{1}{2}(4)\left[\frac{3}{4}x^3 - \frac{9}{2}x^2 + 9x\right]_0^2 = 2(6 - 18 + 18) = 12.$

$M_y = \rho\int_0^2 x\left(-\frac{3}{2}x + 3\right)dx = \rho\int_0^2\left(-\frac{3}{2}x^2 + 3x\right)dx = 4\left[-\frac{1}{2}x^3 + \frac{3}{2}x^2\right]_0^2 = 4(-4 + 6) = 8.$

$\overline{x} = \dfrac{M_y}{m} = \dfrac{8}{12} = \dfrac{2}{3}$ and $\overline{y} = \dfrac{M_x}{m} = \dfrac{12}{12} = 1$. Thus, the center of mass is $(\overline{x}, \overline{y}) = \left(\frac{2}{3}, 1\right)$. Since ρ is constant, the center of mass is also the centroid.

35. The quarter-circle has equation $y = \sqrt{4^2 - x^2}$ for $0 \le x \le 4$ and the line has equation $y = -2$.

$A = \frac{1}{4}\pi(4)^2 + 2(4) = 4\pi + 8 = 4(\pi + 2)$, so $m = \rho A = 6\cdot 4(\pi + 2) = 24(\pi + 2)$.

$M_x = \rho\int_0^4 \frac{1}{2}\left[\left(\sqrt{16 - x^2}\right)^2 - (-2)^2\right]dx = \frac{1}{2}\rho\int_0^4(16 - x^2 - 4)\,dx = \frac{1}{2}(6)\left[12x - \frac{1}{3}x^3\right]_0^4 = 3\left(48 - \frac{64}{3}\right) = 80.$

$M_y = \rho\int_0^4 x\left[\sqrt{16 - x^2} - (-2)\right]dx = \rho\int_0^4 x\sqrt{16 - x^2}\,dx + \rho\int_0^4 2x\,dx = 6\left[-\frac{1}{3}(16 - x^2)^{3/2}\right]_0^4 + 6\left[x^2\right]_0^4$

$= 6\left(0 + \frac{64}{3}\right) + 6(16) = 224.$

$\overline{x} = \dfrac{M_y}{m} = \dfrac{224}{24(\pi + 2)} = \dfrac{28}{3(\pi + 2)}$ and $\overline{y} = \dfrac{M_x}{m} = \dfrac{80}{24(\pi + 2)} = \dfrac{10}{3(\pi + 2)}$.

Thus, the center of mass is $\left(\dfrac{28}{3(\pi + 2)}, \dfrac{10}{3(\pi + 2)}\right) \approx (1.82, 0.65)$.

36. We'll use $n = 8$, so $\Delta x = \frac{b - a}{n} = \frac{8 - 0}{8} = 1$.

$$\begin{aligned} A = \int_0^8 f(x)\,dx \approx S_{10} &= \tfrac{1}{3}[f(0) + 4f(1) + 2f(2) + 4f(3) + 2f(4) + 4f(5) + 2f(6) + 4f(7) + f(8)] \\ &\approx \tfrac{1}{3}[0 + 4(2.0) + 2(2.6) + 4(2.3) + 2(2.2) + 4(3.3) + 2(4.0) + 4(3.2) + 0] \\ &= \tfrac{1}{3}(60.8) = 20.2\overline{6} \quad \left[\text{or } \tfrac{304}{15}\right] \end{aligned}$$

Now
$$\begin{aligned}\int_0^8 x\,f(x)\,dx &\approx \tfrac{1}{3}[0\cdot f(0)+4\cdot 1\cdot f(1)+2\cdot 2\cdot f(2)+4\cdot 3\cdot f(3)\\ &\qquad +2\cdot 4\cdot f(4)+4\cdot 5\cdot f(5)+2\cdot 6\cdot f(6)+4\cdot 7\cdot f(7)+8\cdot f(8)]\\ &\approx \tfrac{1}{3}[0+8+10.4+27.6+17.6+66+48+89.6+0]\\ &= \tfrac{1}{3}(267.2)=89.0\overline{6}\ \ \left[\text{or } \tfrac{1336}{15}\right],\text{ so } \overline{x}=\tfrac{1}{A}\int_0^8 xf(x)\,dx\approx 4.39.\end{aligned}$$

Also,
$$\begin{aligned}\int_0^8 [f(x)]^2\,dx &\approx \tfrac{1}{3}[0^2+4(2.0)^2+2(2.6)^2+4(2.3)^2+2(2.2)^2+4(3.3)^2+2(4.0)^2+4(3.2)^2+0^2]\\ &= \tfrac{1}{3}(176.88)=58.96,\ \text{ so }\ \overline{y}=\tfrac{1}{A}\int_0^8 \tfrac{1}{2}[f(x)]^2\,dx\approx 1.45.\end{aligned}$$

Thus, the centroid is $(\overline{x},\overline{y})\approx(4.4,1.5)$.

37. $A=\int_{-1}^1[(x^3-x)-(x^2-1)]\,dx=\int_{-1}^1(1-x^2)\,dx$ $\left[\begin{matrix}\text{odd-degree terms}\\ \text{drop out}\end{matrix}\right]$

$=2\int_0^1(1-x^2)\,dx=2\left[x-\frac{1}{3}x^3\right]_0^1=2\left(\frac{2}{3}\right)=\frac{4}{3}.$

$\overline{x}=\frac{1}{A}\int_{-1}^1 x(x^3-x-x^2+1)\,dx=\frac{3}{4}\int_{-1}^1(x^4-x^2-x^3+x)\,dx$

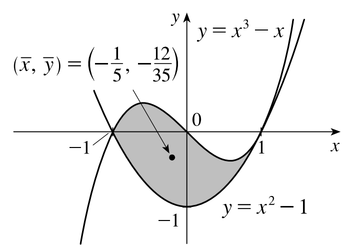
$=\frac{3}{4}\int_{-1}^1(x^4-x^2)\,dx=\frac{3}{4}\cdot 2\int_0^1(x^4-x^2)\,dx$

$=\frac{3}{2}\left[\frac{1}{5}x^5-\frac{1}{3}x^3\right]_0^1=\frac{3}{2}\left(-\frac{2}{15}\right)=-\frac{1}{5}.$

$\overline{y}=\frac{1}{A}\int_{-1}^1\frac{1}{2}[(x^3-x)^2-(x^2-1)^2]\,dx=\frac{3}{4}\cdot\frac{1}{2}\int_{-1}^1(x^6-2x^4+x^2-x^4+2x^2-1)\,dx$

$=\frac{3}{8}\cdot 2\int_0^1(x^6-3x^4+3x^2-1)\,dx=\frac{3}{4}\left[\frac{1}{7}x^7-\frac{3}{5}x^5+x^3-x\right]_0^1=\frac{3}{4}\left(-\frac{16}{35}\right)=-\frac{12}{35}.$

Thus, the centroid is $(\overline{x},\overline{y})=\left(-\frac{1}{5},-\frac{12}{35}\right)$.



38. The curves intersect at $x=a\approx-1.315974$ and $x=b\approx 0.53727445$.

$A=\int_a^b[(2-x^2)-e^x]\,dx=\left[2x-\frac{1}{3}x^3-e^x\right]_a^b\approx 1.452014.$

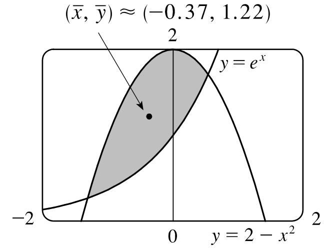
$\overline{x}=\frac{1}{A}\int_a^b x(2-x^2-e^x)\,dx=\frac{1}{A}\left[x^2-\frac{1}{4}x^4-xe^x+e^x\right]_a^b$

≈ -0.374293

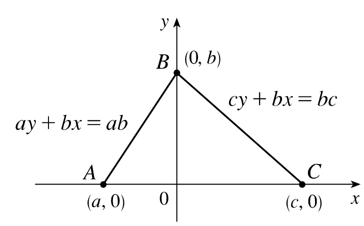
$\overline{y}=\frac{1}{A}\int_a^b\frac{1}{2}[(2-x^2)^2-(e^x)^2]\,dx=\frac{1}{2A}\int_a^b(4-4x^2+x^4-e^{2x})\,dx$

$=\frac{1}{2A}\left[4x-\frac{4}{3}x^3+\frac{1}{5}x^5-\frac{1}{2}e^{2x}\right]_a^b\approx 1.218131$

Thus, the centroid is $(\overline{x},\overline{y})\approx(-0.37,1.22)$.



39. Choose x- and y-axes so that the base (one side of the triangle) lies along the x-axis with the other vertex along the positive y-axis as shown. From geometry, we know the medians intersect at a point $\frac{2}{3}$ of the way from each vertex (along the median) to the opposite side. The median from B goes to the midpoint $\left(\frac{1}{2}(a+c),0\right)$ of side AC, so the point of intersection of the medians is $\left(\frac{2}{3}\cdot\frac{1}{2}(a+c),\frac{1}{3}b\right)=\left(\frac{1}{3}(a+c),\frac{1}{3}b\right)$.



This can also be verified by finding the equations of two medians, and solving them simultaneously to find their point of intersection. Now let us compute the location of the centroid of the triangle. The area is $A=\frac{1}{2}(c-a)b$.

[continued]

$$\overline{x} = \frac{1}{A}\left[\int_a^0 x \cdot \frac{b}{a}(a-x)\,dx + \int_0^c x \cdot \frac{b}{c}(c-x)\,dx\right] = \frac{1}{A}\left[\frac{b}{a}\int_a^0 (ax - x^2)\,dx + \frac{b}{c}\int_0^c (cx - x^2)\,dx\right]$$

$$= \frac{b}{Aa}\left[\frac{1}{2}ax^2 - \frac{1}{3}x^3\right]_a^0 + \frac{b}{Ac}\left[\frac{1}{2}cx^2 - \frac{1}{3}x^3\right]_0^c = \frac{b}{Aa}\left[-\frac{1}{2}a^3 + \frac{1}{3}a^3\right] + \frac{b}{Ac}\left[\frac{1}{2}c^3 - \frac{1}{3}c^3\right]$$

$$= \frac{2}{a\,(c\,-\,a)} \cdot \frac{-a^3}{6} + \frac{2}{c\,(c\,-\,a)} \cdot \frac{c^3}{6} = \frac{1}{3\,(c\,-\,a)}(c^2 - a^2) = \frac{a\,+\,c}{3}$$

and $$\overline{y} = \frac{1}{A}\left[\int_a^0 \frac{1}{2}\left(\frac{b}{a}(a-x)\right)^2 dx + \int_0^c \frac{1}{2}\left(\frac{b}{c}(c-x)\right)^2 dx\right]$$

$$= \frac{1}{A}\left[\frac{b^2}{2a^2}\int_a^0 (a^2 - 2ax + x^2)\,dx + \frac{b^2}{2c^2}\int_0^c (c^2 - 2cx + x^2)\,dx\right]$$

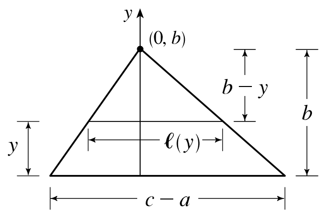
$$= \frac{1}{A}\left[\frac{b^2}{2a^2}\left[a^2x - ax^2 + \tfrac{1}{3}x^3\right]_a^0 + \frac{b^2}{2c^2}\left[c^2x - cx^2 + \tfrac{1}{3}x^3\right]_0^c\right]$$

$$= \frac{1}{A}\left[\frac{b^2}{2a^2}\left(-a^3 + a^3 - \tfrac{1}{3}a^3\right) + \frac{b^2}{2c^2}\left(c^3 - c^3 + \tfrac{1}{3}c^3\right)\right] = \frac{1}{A}\left[\frac{b^2}{6}\,(-a+c)\right] = \frac{2}{(c\,-\,a)\,b} \cdot \frac{(c-a)b^2}{6} = \frac{b}{3}$$

Thus, the centroid is $(\overline{x}, \overline{y}) = \left(\dfrac{a+c}{3}, \dfrac{b}{3}\right)$, as claimed.

Remarks: Actually the computation of $\overline{y}$ is all that is needed. By considering each side of the triangle in turn to be the base, we see that the centroid is $\frac{1}{3}$ of the way from each side to the opposite vertex and must therefore be the intersection of the medians.

The computation of $\overline{y}$ in this problem (and many others) can be simplified by using horizontal rather than vertical approximating rectangles. If the length of a thin rectangle at coordinate y is $\ell(y)$, then its area is $\ell(y)\,\Delta y$, its mass is $\rho\ell(y)\,\Delta y$, and its moment about the x-axis is $\Delta M_x = \rho y\ell(y)\,\Delta y$. Thus,



$$M_x = \int \rho y\ell(y)\,dy \qquad \text{and} \qquad \overline{y} = \frac{\int \rho y\ell(y)\,dy}{\rho A} = \frac{1}{A}\int y\ell(y)\,dy$$

In this problem, $\ell(y) = \dfrac{c-a}{b}\,(b-y)$ by similar triangles, so

$$\overline{y} = \frac{1}{A}\int_0^b \frac{c-a}{b}\,y(b-y)\,dy = \frac{2}{b^2}\int_0^b (by - y^2)\,dy = \frac{2}{b^2}\left[\tfrac{1}{2}by^2 - \tfrac{1}{3}y^3\right]_0^b = \frac{2}{b^2} \cdot \frac{b^3}{6} = \frac{b}{3}$$

Notice that only one integral is needed when this method is used.

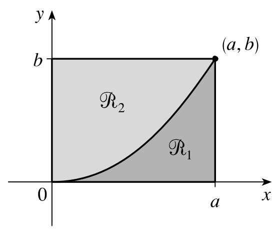
40. The rectangle to the left of the y-axis has centroid $\left(-\frac{1}{2}, 1\right)$ and area 2. The triangle to the right of the y-axis has area 2 and centroid $\left(\frac{2}{3}, \frac{2}{3}\right)$ [by Exercise 39, the centroid is two-thirds of the way from the vertex $(0,0)$ to the point $(1,1)$].

$\overline{x} = \dfrac{M_y}{m} = \dfrac{1}{m}\displaystyle\sum_{i=1}^{2} m_i x_i = \dfrac{1}{2+2}\left[2\left(-\tfrac{1}{2}\right) + 2\left(\tfrac{2}{3}\right)\right] = \tfrac{1}{4}\left(\tfrac{1}{3}\right) = \tfrac{1}{12}$.

$\overline{y} = \dfrac{M_x}{m} = \dfrac{1}{m}\displaystyle\sum_{i=1}^{2} m_i y_i = \dfrac{1}{2+2}\left[2(1) + 2\left(\tfrac{2}{3}\right)\right] = \tfrac{1}{4}\left(\tfrac{10}{3}\right) = \tfrac{5}{6}$. Thus, the centroid is $(\overline{x}, \overline{y}) = \left(\frac{1}{12}, \frac{5}{6}\right)$.

41. Divide the lamina into two triangles and one rectangle with respective masses of 2, 2 and 4, so that the total mass is 8. Using the result of Exercise 39, the triangles have centroids $\left(-1, \frac{2}{3}\right)$ and $\left(1, \frac{2}{3}\right)$. The centroid of the rectangle (its center) is $\left(0, -\frac{1}{2}\right)$. So, using Formulas 5 and 7, we have $\overline{y} = \dfrac{M_x}{m} = \dfrac{1}{m}\sum_{i=1}^{3} m_i\,y_i = \frac{1}{8}\left[2\left(\frac{2}{3}\right) + 2\left(\frac{2}{3}\right) + 4\left(-\frac{1}{2}\right)\right] = \frac{1}{8}\left(\frac{2}{3}\right) = \frac{1}{12}$, and $\overline{x} = 0$, since the lamina is symmetric about the line $x = 0$. Thus, the centroid is $(\overline{x}, \overline{y}) = \left(0, \frac{1}{12}\right)$.

42. The parabola has equation $y = kx^2$ and passes through (a, b), so $b = ka^2 \quad\Rightarrow\quad k = \dfrac{b}{a^2}$ and hence, $y = \dfrac{b}{a^2}x^2$.



$\mathcal{R}_1$ has area $A_1 = \displaystyle\int_0^a \frac{b}{a^2}x^2\,dx = \frac{b}{a^2}\left[\frac{1}{3}x^3\right]_0^a = \frac{b}{a^2}\left(\frac{a^3}{3}\right) = \frac{1}{3}ab.$

Since $\mathcal{R}$ has area ab, $\mathcal{R}_2$ has area $A_2 = ab - \frac{1}{3}ab = \frac{2}{3}ab$.

For $\mathcal{R}_1$:

$$\overline{x}_1 = \frac{1}{A_1}\int_0^a x\left(\frac{b}{a^2}\,x^2\right)dx = \frac{3}{ab}\,\frac{b}{a^2}\int_0^a x^3\,dx = \frac{3}{a^3}\left[\frac{1}{4}x^4\right]_0^a = \frac{3}{a^3}\left(\frac{1}{4}a^4\right) = \frac{3}{4}a$$

$$\overline{y}_1 = \frac{1}{A_1}\int_0^a \frac{1}{2}\left(\frac{b}{a^2}\,x^2\right)^2 dx = \frac{3}{ab}\,\frac{b^2}{2a^4}\int_0^a x^4\,dx = \frac{3b}{2a^5}\left[\frac{1}{5}x^5\right]_0^a = \frac{3b}{2a^5}\left(\frac{1}{5}a^5\right) = \frac{3}{10}b$$

Thus, the centroid for $\mathcal{R}_1$ is $(\overline{x}_1, \overline{y}_1) = \left(\frac{3}{4}a, \frac{3}{10}b\right)$.

For $\mathcal{R}_2$:

$$\overline{x}_2 = \frac{1}{A_2}\int_0^a x\left(b - \frac{b}{a^2}\,x^2\right)dx = \frac{3}{2ab}\int_0^a b\left(x - \frac{1}{a^2}\,x^3\right)dx = \frac{3}{2a}\left[\frac{1}{2}x^2 - \frac{1}{4a^2}x^4\right]_0^a$$
$$= \frac{3}{2a}\left(\frac{a^2}{2} - \frac{a^2}{4}\right) = \frac{3}{2a}\left(\frac{a^2}{4}\right) = \frac{3}{8}a$$

$$\overline{y}_2 = \frac{1}{A_2}\int_0^a \frac{1}{2}\left[(b)^2 - \left(\frac{b}{a^2}\,x^2\right)^2\right]dx = \frac{3}{2ab}\,\frac{1}{2}\int_0^a b^2\left(1 - \frac{1}{a^4}\,x^4\right)dx = \frac{3b}{4a}\left[x - \frac{1}{5a^4}\,x^5\right]_0^a$$
$$= \frac{3b}{4a}\left(a - \frac{1}{5}a\right) = \frac{3b}{4a}\left(\frac{4a}{5}\right) = \frac{3}{5}b$$

Thus, the centroid for $\mathcal{R}_2$ is $(\overline{x}_2, \overline{y}_2) = \left(\frac{3}{8}a, \frac{3}{5}b\right)$. Note the relationships: $A_2 = 2A_1$, $\overline{x}_1 = 2\,\overline{x}_2$, $\overline{y}_2 = 2\,\overline{y}_1$.

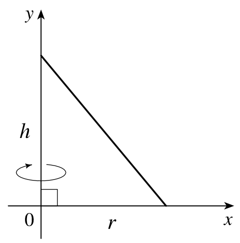
43. $\int_a^b (cx + d)\,f(x)\,dx = \int_a^b cx\,f(x)\,dx + \int_a^b d\,f(x)\,dx = c\int_a^b x\,f(x)\,dx + d\int_a^b f(x)\,dx = c\overline{x}A + d\int_a^b f(x)\,dx$ [by (8)]
$= c\overline{x}\int_a^b f(x)\,dx + d\int_a^b f(x)\,dx = (c\overline{x} + d)\int_a^b f(x)\,dx$

44. A sphere can be generated by rotating a semicircle about its diameter. The center of mass travels a distance $2\pi\overline{y} = 2\pi\left(\dfrac{4r}{3\pi}\right)$ [from Example 4] $= \dfrac{8r}{3}$, so by the Theorem of Pappus, the volume of the sphere is

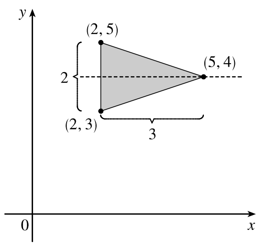
$V = Ad = \dfrac{\pi r^2}{2}\cdot\dfrac{8r}{3} = \dfrac{4}{3}\pi r^3.$

45. A cone of height h and radius r can be generated by rotating a right triangle about one of its legs as shown. By Exercise 39, $\overline{x} = \frac{1}{3}r$, so by the Theorem of Pappus, the volume of the cone is

$$V = Ad = \left(\tfrac{1}{2} \cdot \text{base} \cdot \text{height}\right) \cdot (2\pi\overline{x}) = \tfrac{1}{2}rh \cdot 2\pi\left(\tfrac{1}{3}r\right) = \tfrac{1}{3}\pi r^2 h.$$



46. From the symmetry in the figure, $\overline{y} = 4$. So the distance traveled by the centroid when rotating the triangle about the x-axis is $d = 2\pi \cdot 4 = 8\pi$. The area of the triangle is $A = \frac{1}{2}bh = \frac{1}{2}(2)(3) = 3$. By the Theorem of Pappus, the volume of the resulting solid is $Ad = 3(8\pi) = 24\pi$.



47. The curve C is the quarter-circle $y = \sqrt{16 - x^2}$, $0 \le x \le 4$. Its length L is $\frac{1}{4}(2\pi \cdot 4) = 2\pi$.

Now $y' = \frac{1}{2}(16 - x^2)^{-1/2}(-2x) = \dfrac{-x}{\sqrt{16 - x^2}} \quad \Rightarrow \quad 1 + (y')^2 = 1 + \dfrac{x^2}{16 - x^2} = \dfrac{16}{16 - x^2} \quad \Rightarrow$

$ds = \sqrt{1 + (y')^2}\,dx = \dfrac{4}{\sqrt{16 - x^2}}\,dx$, so

$\overline{x} = \dfrac{1}{L}\displaystyle\int x\,ds = \dfrac{1}{2\pi}\int_0^4 4x(16 - x^2)^{-1/2}\,dx = \dfrac{4}{2\pi}\Big[-(16 - x^2)^{1/2}\Big]_0^4 = \dfrac{2}{\pi}(0 + 4) = \dfrac{8}{\pi}$ and

$\overline{y} = \dfrac{1}{L}\displaystyle\int y\,ds = \dfrac{1}{2\pi}\int_0^4 \sqrt{16 - x^2} \cdot \dfrac{4}{\sqrt{16 - x^2}}\,dx = \dfrac{4}{2\pi}\int_0^4 dx = \dfrac{2}{\pi}\Big[x\Big]_0^4 = \dfrac{2}{\pi}(4 - 0) = \dfrac{8}{\pi}$. Thus, the centroid is $\left(\dfrac{8}{\pi}, \dfrac{8}{\pi}\right)$. Note that the centroid does not lie on the curve, but does lie on the line $y = x$, as expected, due to the symmetry of the curve.

48. (a) From Exercise 47, we have $\overline{y} = (1/L)\int y\,ds \quad \Leftrightarrow \quad \overline{y}L = \int y\,ds$. The surface area is

$S = \int 2\pi y\,ds = 2\pi \int y\,ds = 2\pi(\overline{y}L) = L(2\pi\overline{y})$, which is the product of the arc length of C and the distance traveled by the centroid of C.

(b) From Exercise 47, $L = 2\pi$ and $\overline{y} = \frac{8}{\pi}$. By the Second Theorem of Pappus, the surface area is

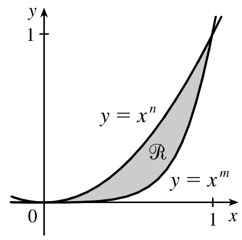
$S = L(2\pi\overline{y}) = 2\pi(2\pi \cdot \frac{8}{\pi}) = 32\pi$.

A geometric formula for the surface area of a half-sphere is $S = 2\pi r^2$. With $r = 4$, we get $S = 32\pi$, which agrees with our first answer.

49. The circle has arc length (circumference) $L = 2\pi r$. As in Example 7, the distance traveled by the centroid during a rotation is $d = 2\pi R$. Therefore, by the Second Theorem of Pappus, the surface area is

$$S = Ld = (2\pi r)(2\pi R) = 4\pi^2 rR$$

50. (a) Let $0 \le x \le 1$. If $n < m$, then $x^n > x^m$; that is, raising x to a larger power produces a smaller number.



(b) Using Formulas 9 and the fact that the area of $\mathcal{R}$ is

$A = \int_0^1 (x^n - x^m)\,dx = \dfrac{1}{n+1} - \dfrac{1}{m+1} = \dfrac{m-n}{(n+1)(m+1)}$, we get

$$\overline{x} = \frac{(n+1)(m+1)}{m-n} \int_0^1 x[x^n - x^m]\,dx = \frac{(n+1)(m+1)}{m-n} \int_0^1 \left(x^{n+1} - x^{m+1}\right) dx$$
$$= \frac{(n+1)(m+1)}{m-n} \left[\frac{1}{n+2} - \frac{1}{m+2}\right] = \frac{(n+1)(m+1)}{(n+2)(m+2)}$$

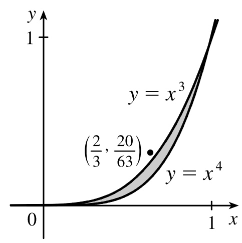
and

$$\overline{y} = \frac{(n+1)(m+1)}{m-n} \int_0^1 \tfrac{1}{2}\left[(x^n)^2 - (x^m)^2\right] dx = \frac{(n+1)(m+1)}{2(m-n)} \int_0^1 \left(x^{2n} - x^{2m}\right) dx$$
$$= \frac{(n+1)(m+1)}{2(m-n)} \left[\frac{1}{2n+1} - \frac{1}{2m+1}\right] = \frac{(n+1)(m+1)}{(2n+1)(2m+1)}$$

(c) If we take $n = 3$ and $m = 4$, then

$$(\overline{x}, \overline{y}) = \left(\frac{4 \cdot 5}{5 \cdot 6}, \frac{4 \cdot 5}{7 \cdot 9}\right) = \left(\frac{2}{3}, \frac{20}{63}\right)$$

which lies outside $\mathcal{R}$ since $\left(\frac{2}{3}\right)^3 = \frac{8}{27} < \frac{20}{63}$. This is the simplest of many possibilities.



51. Suppose the region lies between two curves $y = f(x)$ and $y = g(x)$ where $f(x) \ge g(x)$, as illustrated in Figure 13. Choose points x_i with $a = x_0 < x_1 < \cdots < x_n = b$ and choose x_i^* to be the midpoint of the ith subinterval; that is, $x_i^* = \overline{x}_i = \frac{1}{2}(x_{i-1} + x_i)$. Then the centroid of the ith approximating rectangle R_i is its center $C_i = \left(\overline{x}_i, \frac{1}{2}[f(\overline{x}_i) + g(\overline{x}_i)]\right)$. Its area is $[f(\overline{x}_i) - g(\overline{x}_i)]\,\Delta x$, so its mass is

$\rho[f(\overline{x}_i) - g(\overline{x}_i)]\,\Delta x$. Thus, $M_y(R_i) = \rho[f(\overline{x}_i) - g(\overline{x}_i)]\,\Delta x \cdot \overline{x}_i = \rho\overline{x}_i\,[f(\overline{x}_i) - g(\overline{x}_i)]\,\Delta x$ and

$M_x(R_i) = \rho[f(\overline{x}_i) - g(\overline{x}_i)]\,\Delta x \cdot \frac{1}{2}[f(\overline{x}_i) + g(\overline{x}_i)] = \rho \cdot \frac{1}{2}\left[f(\overline{x}_i)^2 - g(\overline{x}_i)^2\right]\Delta x$. Summing over i and taking the limit as $n \to \infty$, we get $M_y = \lim\limits_{n\to\infty} \sum_i \rho\overline{x}_i\,[f(\overline{x}_i) - g(\overline{x}_i)]\,\Delta x = \rho \int_a^b x[f(x) - g(x)]\,dx$ and

$M_x = \lim\limits_{n\to\infty} \sum_i \rho \cdot \frac{1}{2}\left[f(\overline{x}_i)^2 - g(\overline{x}_i)^2\right]\Delta x = \rho \int_a^b \frac{1}{2}\left[f(x)^2 - g(x)^2\right] dx$.

Thus, $\overline{x} = \dfrac{M_y}{m} = \dfrac{M_y}{\rho A} = \dfrac{1}{A}\displaystyle\int_a^b x[f(x) - g(x)]\,dx$ and $\overline{y} = \dfrac{M_x}{m} = \dfrac{M_x}{\rho A} = \dfrac{1}{A}\displaystyle\int_a^b \tfrac{1}{2}\left[f(x)^2 - g(x)^2\right] dx$.

DISCOVERY PROJECT Complementary Coffee Cups

1. Cup A has volume $V_A = \int_0^h \pi[f(y)]^2\,dy$ and cup B has volume

$$V_B = \int_0^h \pi[k - f(y)]^2\,dy = \int_0^h \pi\{k^2 - 2kf(y) + [f(y)]^2\}\,dy$$
$$= \left[\pi k^2 y\right]_0^h - 2\pi k \int_0^h f(y)\,dy + \int_0^h \pi[f(y)]^2\,dy = \pi k^2 h - 2\pi k A_1 + V_A$$

Thus, $V_A = V_B \;\Leftrightarrow\; \pi k(kh - 2A_1) = 0 \;\Leftrightarrow\; k = 2(A_1/h)$; that is, k is twice the average value of f on the interval $[0, h]$.

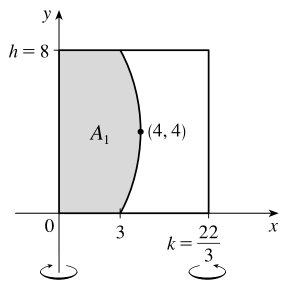
2. From Problem 1, $V_A = V_B \;\Leftrightarrow\; kh = 2A_1 \;\Leftrightarrow\; A_1 + A_2 = 2A_1 \;\Leftrightarrow\; A_2 = A_1$.

3. Let $\overline{x}_1$ and $\overline{x}_2$ denote the x-coordinates of the centroids of A_1 and A_2, respectively. By Pappus's Theorem,

$V_A = 2\pi\overline{x}_1 A_1$ and $V_B = 2\pi(k - \overline{x}_2)A_2$, so $V_A = V_B \;\Leftrightarrow\; \overline{x}_1 A_1 = kA_2 - \overline{x}_2 A_2 \;\Leftrightarrow\; kA_2 = \overline{x}_1 A_1 + \overline{x}_2 A_2 \;\overset{(\star)}{\Leftrightarrow}$ $kA_2 = \frac{1}{2}k\,(A_1 + A_2) \;\Leftrightarrow\; \frac{1}{2}kA_2 = \frac{1}{2}kA_1 \;\Leftrightarrow\; A_2 = A_1$, as shown in Problem 2. [$(\star)$ The sum of the moments of the regions of areas A_1 and A_2 about the y-axis equals the moment of the entire k-by-h rectangle about the y-axis.]

So, since $A_1 + A_2 = kh$, we have $V_A = V_B \;\Leftrightarrow\; A_1 = A_2 \;\Leftrightarrow\; A_1 = \frac{1}{2}(A_1 + A_2) \;\Leftrightarrow\; A_1 = \frac{1}{2}(kh) \;\Leftrightarrow$ $k = 2\,(A_1/h)$, as shown in Problem 1.

4. We'll use a cup that is $h = 8$ cm high with a diameter of 6 cm on the top and the bottom and symmetrically bulging to a diameter of 8 cm in the middle (all inside dimensions).



For an equation, we'll use a parabola with a vertex at $(4, 4)$; that is, $x = a(y-4)^2 + 4$. To find a, use the point $(3, 0)$: $3 = a(0-4)^2 + 4 \;\Rightarrow\; -1 = 16a \;\Rightarrow\; a = -\frac{1}{16}$. To find k, we'll use the relationship in Problem 1, so we need A_1.

$$A_1 = \int_0^8 \left[-\tfrac{1}{16}(y-4)^2 + 4\right] dy = \int_{-4}^4 \left(-\tfrac{1}{16}u^2 + 4\right) du \quad [u = y - 4]$$
$$= 2\int_0^4 \left(-\tfrac{1}{16}u^2 + 4\right) du = 2\left[-\tfrac{1}{48}u^3 + 4u\right]_0^4 = 2\left(-\tfrac{4}{3} + 16\right) = \tfrac{88}{3}.$$

Thus, $k = 2(A_1/h) = 2\left(\frac{88/3}{8}\right) = \frac{22}{3}$.

So with $h = 8$ and curve $x = -\frac{1}{16}(y-4)^2 + 4$, we have

$$V_A = \int_0^8 \pi\left[-\tfrac{1}{16}(y-4)^2 + 4\right]^2 dy = \pi\int_{-4}^4 \left(-\tfrac{1}{16}u^2 + 4\right)^2 du \quad [u = y - 4] \quad = 2\pi\int_0^4 \left(\tfrac{1}{256}u^4 - \tfrac{1}{2}u^2 + 16\right) du$$
$$= 2\pi\left[\tfrac{1}{1280}u^5 - \tfrac{1}{6}u^3 + 16u\right]_0^4 = 2\pi\left(\tfrac{4}{5} - \tfrac{32}{3} + 64\right) = 2\pi\left(\tfrac{812}{15}\right) = \tfrac{1624}{15}\pi$$

This is approximately 340 cm^3 or 11.5 fl. oz. And with $k = \frac{22}{3}$, we know from Problem 1 that cup B holds the same amount.

8.4 Applications to Economics and Biology

1. By the Net Change Theorem, $C(4000) - C(0) = \int_0^{4000} C'(x)\,dx \quad \Rightarrow$

$$C(4000) = 18{,}000 + \int_0^{4000} (0.82 - 0.000\,03x + 0.000\,000\,003x^2)\,dx$$
$$= 18{,}000 + \left[0.82x - 0.000\,015x^2 + 0.000\,000\,001x^3\right]_0^{4000} = 18{,}000 + 3104 = \$21{,}104$$

2. By the Net Change Theorem,

$$R(10{,}000) - R(5000) = \int_{5000}^{10{,}000} R'(x)\,dx = \int_{5000}^{10{,}000} (48 - 0.0012x)\,dx = \left[48x - 0.0006x^2\right]_{5000}^{10{,}000}$$
$$= 420{,}000 - 225{,}000 = \$195{,}000$$

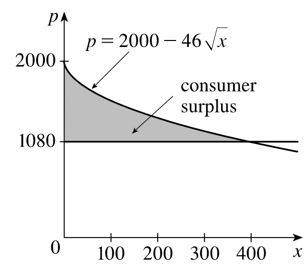
3. By the Net Change Theorem, $C(50) - C(0) = \int_0^{50} (0.6 + 0.008x)\,dx \quad \Rightarrow$

$C(50) = 100 + \left[0.6x + 0.004x^2\right]_0^{50} = 100 + (40 - 0) = 140$, or \$140,000. Similarly,

$C(100) - C(50) = \left[0.6x + 0.004x^2\right]_{50}^{100} = 100 - 40 = 60$, or \$60,000.

4. Consumer surplus $= \int_0^{400} [p(x) - p(400)]\,dx = \int_0^{400} [(2000 - 46\sqrt{x}) - 1080]\,dx$

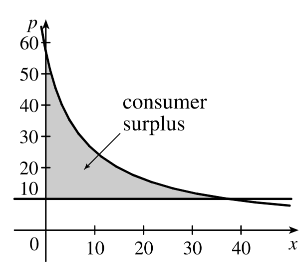
$$= \int_0^{400} (920 - 46\sqrt{x})\,dx = 46\int_0^{400} (20 - x^{1/2})\,dx$$
$$= 46\left[20x - \tfrac{2}{3}x^{3/2}\right]_0^{400} = 46\left(8000 - \tfrac{2}{3}\cdot 8000\right)$$
$$= 46\cdot\tfrac{1}{3}\cdot 8000 \approx \$122{,}666.67$$



5. $p(x) = 10 \quad \Rightarrow \quad \dfrac{450}{x+8} = 10 \quad \Rightarrow \quad x + 8 = 45 \quad \Rightarrow \quad x = 37.$

Consumer surplus $= \displaystyle\int_0^{37} [p(x) - 10]\,dx = \int_0^{37}\left(\frac{450}{x+8} - 10\right)dx$

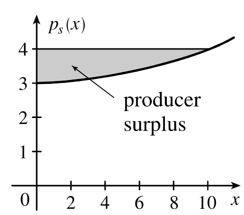
$$= \left[450\ln(x+8) - 10x\right]_0^{37} = (450\ln 45 - 370) - 450\ln 8$$
$$= 450\ln\left(\tfrac{45}{8}\right) - 370 \approx \$407.25$$



6. $p_S(x) = 3 + 0.01x^2. \quad P = p_S(10) = 3 + 1 = 4.$

Producer surplus $= \int_0^{10} [P - p_S(x)]\,dx = \int_0^{10} \left[4 - 3 - 0.01x^2\right]dx$

$$= \left[x - \tfrac{0.01}{3}x^3\right]_0^{10} \approx 10 - 3.33 = \$6.67$$



7. $P = p_S(x) \quad \Rightarrow \quad 625 = 125 + 0.002x^2 \quad \Rightarrow \quad 500 = \frac{1}{500}x^2 \quad \Rightarrow \quad x^2 = 500^2 \quad \Rightarrow \quad x = 500.$

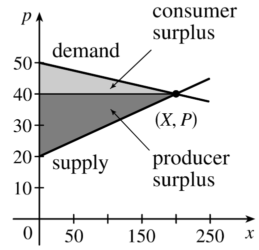
Producer surplus $= \int_0^{500} [P - p_S(x)]\,dx = \int_0^{500} [625 - (125 + 0.002x^2)]\,dx = \int_0^{500} \left(500 - \frac{1}{500}x^2\right)dx$

$$= \left[500x - \tfrac{1}{1500}x^3\right]_0^{500} = 500^2 - \tfrac{1}{1500}(500^3) \approx \$166{,}666.67$$

8. (a) Demand curve $p_D(x) =$ supply curve $p_S(x) \iff 50 - \frac{1}{20}x = 20 + \frac{1}{10}x \iff 30 = \frac{3}{20}x \iff x = 200$.

$p_D(200) = 50 - \frac{1}{20}(200) = 40$, so the market for this good is in equilibrium when the quantity is 200 and the price is \$40.

(b) At equilibrium, the



$$\text{Consumer surplus} = \int_0^{200}[p_D(x) - 40]\,dx = \int_0^{200}\left(50 - \tfrac{1}{20}x - 40\right)dx = \left[10x - \tfrac{1}{40}x^2\right]_0^{200} = \$1000$$

and the

$$\text{Producer surplus} = \int_0^{200}[40 - p_S(x)]\,dx = \int_0^{200}\left(40 - 20 - \tfrac{1}{10}x\right)dx = \left[20x - \tfrac{1}{20}x^2\right]_0^{200} = \$2000$$

9. (a) Demand function $p(x) =$ supply function $p_S(x) \iff 228.4 - 18x = 27x + 57.4 \iff 171 = 45x \iff$ $x = \frac{19}{5}$ [3.8 thousand]. $p(3.8) = 228.4 - 18(3.8) = 160$. The market for the stereos is in equilibrium when the quantity is 3800 and the price is \$160.

(b) $$\text{Consumer surplus} = \int_0^{3.8}[p(x) - 160]\,dx = \int_0^{3.8}(228.4 - 18x - 160)\,dx = \int_0^{3.8}(68.4 - 18x)\,dx = \left[68.4x - 9x^2\right]_0^{3.8} = 68.4(3.8) - 9(3.8)^2 = 129.96$$

$$\text{Producer surplus} = \int_0^{3.8}[160 - p_S(x)]\,dx = \int_0^{3.8}[160 - (27x + 57.4)]\,dx = \int_0^{3.8}(102.6 - 27x)\,dx = \left[102.6x - 13.5x^2\right]_0^{3.8} = 102.6(3.8) - 13.5(3.8)^2 = 194.94$$

Thus, the maximum total surplus for the stereos is $129.96 + 194.94 = 324.9$, or \$324,900.

10. $p(x) = p_S(x) \iff 312e^{-0.14x} = 26e^{0.2x} \iff \dfrac{312}{26} = \dfrac{e^{0.2x}}{e^{-0.14x}} \iff 12 = e^{0.34x} \iff \ln 12 = 0.34x \iff$

$x = X = \dfrac{\ln 12}{0.34}$. $X \approx 7.3085$ (in thousands) and $p(X) \approx 112.1465$.

Consumer surplus $= \int_0^X [p(x) - p(X)]\,dx \approx \int_0^{7.3085}(312e^{-0.14x} - 112.1465)\,dx \approx 607.896$

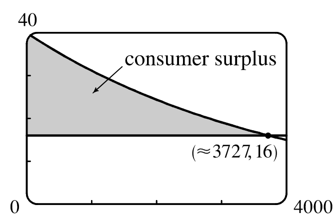
Producer surplus $= \int_0^X [p_S(X) - p_S(x)]\,dx \approx \int_0^{7.3085}(112.1465 - 26e^{0.2x})\,dx \approx 388.896$

Maximum total surplus $\approx 607.896 + 388.896 = 996.792$, or \$996,792.

Note: Since $p(X) = p_S(X)$, the maximum total surplus could be found by calculating $\int_0^X [p(x) - p_S(x)]\,dx$.

11. $p(x) = \dfrac{800{,}000e^{-x/5000}}{x + 20{,}000} = 16 \Rightarrow x = x_1 \approx 3727.04$.

Consumer surplus $= \int_0^{x_1}[p(x) - 16]\,dx \approx \$37{,}753$



12. The demand function is linear with slope $\frac{-0.5}{50} = -\frac{1}{100}$ and $p(500) = 10$, so an equation is $p - 10 = -\frac{1}{100}(x - 500)$ or $p = -\frac{1}{100}x + 15$. A selling price of \$8 implies that $8 = -\frac{1}{100}x + 15 \Rightarrow \frac{1}{100}x = 7 \Rightarrow x = 700$.

Consumer surplus $= \int_0^{700} \left(-\frac{1}{100}x + 15 - 8\right) dx = \left[-\frac{1}{200}x^2 + 7x\right]_0^{700} = \$2450$.

13. $f(8) - f(4) = \int_4^8 f'(t)\,dt = \int_4^8 \sqrt{t}\,dt = \left[\frac{2}{3}t^{3/2}\right]_4^8 = \frac{2}{3}\left(16\sqrt{2} - 8\right) \approx \$9.75$ million

14. The total revenue R obtained in the first four years is

$$R = \int_0^4 f(t)\,dt = \int_0^4 9000\sqrt{1+2t}\,dt = \int_1^9 9000u^{1/2}\left(\tfrac{1}{2}\,du\right) \qquad [u = 1 + 2t,\ du = 2\,dt]$$
$$= 4500\left[\tfrac{2}{3}u^{3/2}\right]_1^9 = 3000(27 - 1) = \$78{,}000$$

15. Future value $= \int_0^T f(t)\,e^{r(T-t)}\,dt = \int_0^6 8000e^{0.04t}\,e^{0.062(6-t)}\,dt = 8000\int_0^6 e^{0.04t}\,e^{0.372 - 0.062t}\,dt$

$$= 8000\int_0^6 e^{0.372-0.022t}\,dt = 8000e^{0.372}\int_0^6 e^{-0.022t}\,dt = 8000e^{0.372}\left[\frac{e^{-0.022t}}{-0.022}\right]_0^6$$
$$= \frac{8000e^{0.372}}{-0.022}(e^{-0.132} - 1) \approx \$65{,}230.48$$

16. Present value $= \int_0^T f(t)\,e^{-rt}\,dt = \int_0^6 8000e^{0.04t}\,e^{-0.062t}\,dt = 8000\int_0^6 e^{-0.022t}\,dt = 8000\left[\frac{e^{-0.022t}}{-0.022}\right]_0^6$

$$= \frac{8000}{-0.022}\,(e^{-0.132} - 1) \approx \$44{,}966.91$$

17. $N = \displaystyle\int_a^b Ax^{-k}\,dx = A\left[\frac{x^{-k+1}}{-k+1}\right]_a^b = \frac{A}{1-k}\,(b^{1-k} - a^{1-k})$.

Similarly, $\displaystyle\int_a^b Ax^{1-k}\,dx = A\left[\frac{x^{2-k}}{2-k}\right]_a^b = \frac{A}{2-k}\,(b^{2-k} - a^{2-k})$.

Thus, $\overline{x} = \dfrac{1}{N}\displaystyle\int_a^b Ax^{1-k}\,dx = \frac{[A/(2-k)](b^{2-k} - a^{2-k})}{[A/(1-k)](b^{1-k} - a^{1-k})} = \frac{(1-k)(b^{2-k} - a^{2-k})}{(2-k)(b^{1-k} - a^{1-k})}$.

18. $n(9) - n(5) = \displaystyle\int_5^9 (2200 + 10e^{0.8t})\,dt = \left[2200t + \frac{10e^{0.8t}}{0.8}\right]_5^9 = \left[2200t\right]_5^9 + \frac{25}{2}\left[e^{0.8t}\right]_5^9$

$$= 2200(9 - 5) + 12.5(e^{7.2} - e^4) \approx 24{,}860$$

19. $F = \dfrac{\pi PR^4}{8\eta l} = \dfrac{\pi(4000)(0.008)^4}{8(0.027)(2)} \approx 1.19 \times 10^{-4}\ \text{cm}^3/\text{s}$

20. If the flux remains constant, then $\dfrac{\pi P_0 R_0^4}{8\eta l} = \dfrac{\pi PR^4}{8\eta l} \Rightarrow P_0R_0^4 = PR^4 \Rightarrow \dfrac{P}{P_0} = \left(\dfrac{R_0}{R}\right)^4$.

$R = \frac{3}{4}R_0 \Rightarrow \dfrac{P}{P_0} = \left(\dfrac{R_0}{\frac{3}{4}R_0}\right)^4 \Rightarrow P = P_0\left(\frac{4}{3}\right)^4 \approx 3.1605P_0 > 3P_0$; that is, the blood pressure is more than tripled.

21. From (3), $F = \dfrac{A}{\int_0^T c(t)\,dt} = \dfrac{6}{20I}$, where

$$I = \int_0^{10} te^{-0.6t}\,dt = \left[\frac{1}{(-0.6)^2}(-0.6t-1)\,e^{-0.6t}\right]_0^{10} \quad \begin{bmatrix}\text{integrating}\\ \text{by parts}\end{bmatrix} = \tfrac{1}{0.36}(-7e^{-6}+1)$$

Thus, $F = \dfrac{6(0.36)}{20(1-7e^{-6})} = \dfrac{0.108}{1-7e^{-6}} \approx 0.1099$ L/s or 6.594 L/min.

22. As in Example 2, we will estimate the cardiac output using Simpson's Rule with $\Delta t = (16-0)/8 = 2$.

$$\begin{aligned}\textstyle\int_0^{16} c(t)\,dt &\approx \tfrac{2}{3}[c(0)+4c(2)+2c(4)+4c(6)+2c(8)+4c(10)+2c(12)+4c(14)+c(16)]\\ &= \tfrac{2}{3}[0+4(4.1)+2(8.9)+4(8.5)+2(6.7)+4(4.3)+2(2.5)+4(1.2)+0.2]\\ &= \tfrac{2}{3}(108.8) = 72.5\overline{3}\text{ mg}\cdot\text{s/L}\end{aligned}$$

Therefore, $F \approx \dfrac{A}{72.5\overline{3}} = \dfrac{5.5}{72.5\overline{3}} \approx 0.0758$ L/s or 4.55 L/min.

23. As in Example 2, we will estimate the cardiac output using Simpson's Rule with $\Delta t = (16-0)/8 = 2$.

$$\begin{aligned}\textstyle\int_0^{16} c(t)\,dt &\approx \tfrac{2}{3}[c(0)+4c(2)+2c(4)+4c(6)+2c(8)+4c(10)+2c(12)+4c(14)+c(16)]\\ &\approx \tfrac{2}{3}[0+4(6.1)+2(7.4)+4(6.7)+2(5.4)+4(4.1)+2(3.0)+4(2.1)+1.5]\\ &= \tfrac{2}{3}(109.1) = 72.7\overline{3}\text{ mg}\cdot\text{s/L}\end{aligned}$$

Therefore, $F \approx \dfrac{A}{72.7\overline{3}} = \dfrac{7}{72.7\overline{3}} \approx 0.0962$ L/s or 5.77 L/min.

8.5 Probability

1. (a) $\int_{30{,}000}^{40{,}000} f(x)\,dx$ is the probability that a randomly chosen tire will have a lifetime between 30,000 and 40,000 miles.

(b) $\int_{25{,}000}^{\infty} f(x)\,dx$ is the probability that a randomly chosen tire will have a lifetime of at least 25,000 miles.

2. (a) The probability that you drive to school in less than 15 minutes is $\int_0^{15} f(t)\,dt$.

(b) The probability that it takes you more than half an hour to get to school is $\int_{30}^{\infty} f(t)\,dt$.

3. (a) In general, we must satisfy the two conditions that are mentioned before Example 1 — namely, **(1)** $f(x) \geq 0$ for all x, and **(2)** $\int_{-\infty}^{\infty} f(x)\,dx = 1$. For $0 \leq x \leq 1$, $f(x) = 30x^2(1-x)^2 \geq 0$ and $f(x) = 0$ for all other values of x, so $f(x) \geq 0$ for all x. Also,

$$\begin{aligned}\textstyle\int_{-\infty}^{\infty} f(x)\,dx &= \textstyle\int_0^1 30x^2(1-x)^2\,dx = \int_0^1 30x^2(1-2x+x^2)\,dx = \int_0^1 (30x^2-60x^3+30x^4)\,dx\\ &= \left[10x^3-15x^4+6x^5\right]_0^1 = 10-15+6 = 1\end{aligned}$$

Therefore, f is a probability density function.

(b) $P\left(X \leq \frac{1}{3}\right) = \int_{-\infty}^{1/3} f(x)\,dx = \int_0^{1/3} 30x^2(1-x)^2\,dx = \left[10x^3-15x^4+6x^5\right]_0^{1/3} = \frac{10}{27} - \frac{15}{81} + \frac{6}{243} = \frac{17}{81}$

4. (a) In general, we must satisfy the two conditions that are mentioned before Example 1 — namely, **(1)** $f(x) \geq 0$ for all x, and **(2)** $\int_{-\infty}^{\infty} f(x)\,dx = 1$. For $f(x) = \dfrac{e^{3-x}}{(1+e^{3-x})^2}$, the numerator and denominator are both positive, so $f(x) \geq 0$ for all x. Also,

$$\int_{-\infty}^{\infty} f(x)\,dx = \int_{-\infty}^{0} f(x)\,dx + \int_{0}^{\infty} f(x)\,dx = \lim_{t\to-\infty}\int_t^0 \frac{e^{3-x}}{(1+e^{3-x})^2}\,dx + \lim_{s\to\infty}\int_0^s \frac{e^{3-x}}{(1+e^{3-x})^2}\,dx$$

$$= \lim_{t\to-\infty}\int_{x=t}^{0}\frac{-du}{u^2} + \lim_{s\to\infty}\int_{x=0}^{s}\frac{-du}{u^2} \qquad \begin{bmatrix} u = 1+e^{3-x}, \\ du = -e^{3-x}\,dx \end{bmatrix}$$

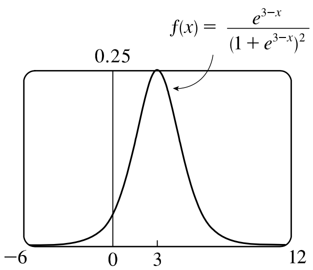
$$= \lim_{t\to-\infty}\left[\frac{1}{u}\right]_{x=t}^{0} + \lim_{s\to\infty}\left[\frac{1}{u}\right]_{x=0}^{s} = \lim_{t\to-\infty}\left[\frac{1}{1+e^{3-x}}\right]_t^0 + \lim_{s\to\infty}\left[\frac{1}{1+e^{3-x}}\right]_0^s$$

$$= \lim_{t\to-\infty}\left(\frac{1}{1+e^3} - \frac{1}{1+e^{3-t}}\right) + \lim_{s\to\infty}\left(\frac{1}{1+e^{3-s}} - \frac{1}{1+e^3}\right) = \frac{1}{1+e^3} - 0 + 1 - \frac{1}{1+e^3} = 1.$$

Therefore, f is a probability density function.

(b) $P(3 \leq X \leq 4) = \displaystyle\int_3^4 f(x)\,dx = \left[\frac{1}{1+e^{3-x}}\right]_3^4$ [from part (a)] $= \dfrac{1}{1+e^{-1}} - \dfrac{1}{1+1} \approx 0.231$

(c)



The graph of f appears to be symmetric about the line $x = 3$, so the mean appears to be 3. Similarly, half the area under the graph of f appears to lie to the right of $x = 3$, so the median also appears to be 3.

5. (a) In general, we must satisfy the two conditions that are mentioned before Example 1—namely, (1) $f(x) \geq 0$ for all x, and (2) $\int_{-\infty}^{\infty} f(x)\,dx = 1$. If $c \geq 0$, then $f(x) \geq 0$, so condition (1) is satisfied. For condition (2), we see that

$\displaystyle\int_{-\infty}^{\infty} f(x)\,dx = \int_{-\infty}^{\infty}\frac{c}{1+x^2}\,dx$ and

$$\int_0^{\infty}\frac{c}{1+x^2}\,dx = \lim_{t\to\infty}\int_0^t \frac{c}{1+x^2}\,dx = c\lim_{t\to\infty}\left[\tan^{-1}x\right]_0^t = c\lim_{t\to\infty}\tan^{-1}t = c\left(\frac{\pi}{2}\right)$$

Similarly, $\displaystyle\int_{-\infty}^{0}\frac{c}{1+x^2}\,dx = c\left(\frac{\pi}{2}\right)$, so $\displaystyle\int_{-\infty}^{\infty}\frac{c}{1+x^2}\,dx = 2c\left(\frac{\pi}{2}\right) = c\pi$.

Since $c\pi$ must equal 1, we must have $c = 1/\pi$ so that f is a probability density function.

(b) $P(-1 < X < 1) = \displaystyle\int_{-1}^{1}\frac{1/\pi}{1+x^2}\,dx = \frac{2}{\pi}\int_0^1\frac{1}{1+x^2}\,dx = \frac{2}{\pi}\left[\tan^{-1}x\right]_0^1 = \frac{2}{\pi}\left(\frac{\pi}{4} - 0\right) = \frac{1}{2}$

6. (a) For $0 \leq x \leq 3$, we have $f(x) = k(3x - x^2)$, which is nonnegative if and only if $k \geq 0$. Also, $\int_{-\infty}^{\infty} f(x)\,dx = \int_0^3 k(3x-x^2)\,dx = k\left[\frac{3}{2}x^2 - \frac{1}{3}x^3\right]_0^3 = k\left(\frac{27}{2} - 9\right) = \frac{9}{2}k$. Now $\frac{9}{2}k = 1 \quad\Rightarrow\quad k = \frac{2}{9}$. Therefore, f is a probability density function if and only if $k = \frac{2}{9}$.

(b) Let $k = \frac{2}{9}$.

$P(X > 1) = \int_1^\infty f(x)\,dx = \int_1^3 \frac{2}{9}(3x - x^2)\,dx = \frac{2}{9}\left[\frac{3}{2}x^2 - \frac{1}{3}x^3\right]_1^3 = \frac{2}{9}\left[\left(\frac{27}{2} - 9\right) - \left(\frac{3}{2} - \frac{1}{3}\right)\right] = \frac{2}{9}\left(\frac{10}{3}\right) = \frac{20}{27}$.

(c) The mean $\mu = \int_{-\infty}^\infty xf(x)\,dx = \int_0^3 x\left[\frac{2}{9}(3x - x^2)\right]dx = \frac{2}{9}\int_0^3 (3x^2 - x^3)\,dx$

$= \frac{2}{9}\left[x^3 - \frac{1}{4}x^4\right]_0^3 = \frac{2}{9}\left(27 - \frac{81}{4}\right) = \frac{2}{9}\left(\frac{27}{4}\right) = \frac{3}{2}$.

7. (a) In general, we must satisfy the two conditions that are mentioned before Example 1—namely, (1) $f(x) \geq 0$ for all x, and (2) $\int_{-\infty}^\infty f(x)\,dx = 1$. Since $f(x) = 0$ or $f(x) = 0.1$, condition (1) is satisfied. For condition (2), we see that $\int_{-\infty}^\infty f(x)\,dx = \int_0^{10} 0.1\,dx = \left[\frac{1}{10}x\right]_0^{10} = 1$. Thus, $f(x)$ is a probability density function for the spinner's values.

(b) Since all the numbers between 0 and 10 are equally likely to be selected, we expect the mean to be halfway between the endpoints of the interval; that is, $x = 5$.

$$\mu = \int_{-\infty}^\infty xf(x)\,dx = \int_0^{10} x(0.1)\,dx = \left[\tfrac{1}{20}x^2\right]_0^{10} = \tfrac{100}{20} = 5, \quad \text{as expected.}$$

8. (a) As in the preceding exercise, (1) $f(x) \geq 0$ and (2) $\int_{-\infty}^\infty f(x)\,dx = \int_0^{10} f(x)\,dx = \frac{1}{2}(10)(0.2)$ [area of a triangle] $= 1$. So $f(x)$ is a probability density function.

(b) (i) $P(X < 3) = \int_0^3 f(x)\,dx = \frac{1}{2}(3)(0.1) = \frac{3}{20} = 0.15$

(ii) We first compute $P(X > 8)$ and then subtract that value and our answer in (i) from 1 (the total probability).

$P(X > 8) = \int_8^{10} f(x)\,dx = \frac{1}{2}(2)(0.1) = \frac{2}{20} = 0.10$. So $P(3 \leq X \leq 8) = 1 - 0.15 - 0.10 = 0.75$.

(c) We find equations of the lines from $(0, 0)$ to $(6, 0.2)$ and from $(6, 0.2)$ to $(10, 0)$, and find that

$$f(x) = \begin{cases} \frac{1}{30}x & \text{if } 0 \leq x < 6 \\ -\frac{1}{20}x + \frac{1}{2} & \text{if } 6 \leq x < 10 \\ 0 & \text{otherwise} \end{cases}$$

$$\mu = \int_{-\infty}^\infty xf(x)\,dx = \int_0^6 x\left(\tfrac{1}{30}x\right)dx + \int_6^{10} x\left(-\tfrac{1}{20}x + \tfrac{1}{2}\right)dx = \left[\tfrac{1}{90}x^3\right]_0^6 + \left[-\tfrac{1}{60}x^3 + \tfrac{1}{4}x^2\right]_6^{10}$$
$$= \tfrac{216}{90} + \left(-\tfrac{1000}{60} + \tfrac{100}{4}\right) - \left(-\tfrac{216}{60} + \tfrac{36}{4}\right) = \tfrac{16}{3} = 5.\overline{3}$$

9. We need to find m so that $\int_m^\infty f(t)\,dt = \frac{1}{2} \quad\Rightarrow\quad \lim\limits_{x\to\infty}\int_m^x \frac{1}{5}e^{-t/5}\,dt = \frac{1}{2} \quad\Rightarrow\quad \lim\limits_{x\to\infty}\left[\frac{1}{5}(-5)e^{-t/5}\right]_m^x = \frac{1}{2} \quad\Rightarrow$ $(-1)(0 - e^{-m/5}) = \frac{1}{2} \quad\Rightarrow\quad e^{-m/5} = \frac{1}{2} \quad\Rightarrow\quad -m/5 = \ln\frac{1}{2} \quad\Rightarrow\quad m = -5\ln\frac{1}{2} = 5\ln 2 \approx 3.47$ min.

10. (a) $\mu = 1000 \quad\Rightarrow\quad f(t) = \begin{cases} 0 & \text{if } t < 0 \\ \frac{1}{1000}e^{-t/1000} & \text{if } t \geq 0 \end{cases}$

(i) $P(0 \leq X \leq 200) = \int_0^{200} \frac{1}{1000}e^{-t/1000}\,dt = \left[-e^{-t/1000}\right]_0^{200} = -e^{-1/5} + 1 \approx 0.181$

(ii) $P(X > 800) = \int_{800}^\infty \frac{1}{1000}e^{-t/1000}\,dt = \lim\limits_{x\to\infty}\left[-e^{-t/1000}\right]_{800}^x = 0 + e^{-4/5} \approx 0.449$

(b) We need to find m so that $\int_m^\infty f(t)\,dt = \frac{1}{2} \quad\Rightarrow\quad \lim\limits_{x\to\infty}\int_m^x \frac{1}{1000}e^{-t/1000}\,dt = \frac{1}{2} \quad\Rightarrow\quad \lim\limits_{x\to\infty}\left[-e^{-t/1000}\right]_m^x = \frac{1}{2} \quad\Rightarrow$ $0 + e^{-m/1000} = \frac{1}{2} \quad\Rightarrow\quad -m/1000 = \ln\frac{1}{2} \quad\Rightarrow\quad m = -1000\ln\frac{1}{2} = 1000\ln 2 \approx 693.1$ h.

11. (a) An exponential density function with $\mu = 1.6$ is $f(t) = \begin{cases} 0 & \text{if } t < 0 \\ \frac{1}{1.6}e^{-t/1.6} & \text{if } t \geq 0 \end{cases}$.

The probability that a customer waits less than a second is

$$P(X < 1) = \int_0^1 f(t)\,dt = \int_0^1 \tfrac{1}{1.6}e^{-t/1.6}\,dt = \left[-e^{-t/1.6}\right]_0^1 = -e^{-1/1.6} + 1 \approx 0.465.$$

(b) The probability that a customer waits more than 3 seconds is

$$P(X > 3) = \int_3^\infty f(t)\,dt = \lim_{s\to\infty}\int_3^s f(t)\,dt = \lim_{s\to\infty}\left[-e^{-t/1.6}\right]_3^s = \lim_{s\to\infty}(-e^{-s/1.6} + e^{-3/1.6}) = e^{-3/1.6} \approx 0.153.$$

Or: Calculate $1 - \int_0^3 f(t)\,dt$.

(c) We want to find b such that $P(X > b) = 0.05$. From part (b), $P(X > b) = e^{-b/1.6}$. Solving $e^{-b/1.6} = 0.05$ gives us $-\frac{b}{1.6} = \ln 0.05 \quad\Rightarrow\quad b = -1.6\ln 0.05 \approx 4.79$ seconds.

Or: Solve $\int_0^b f(t)\,dt = 0.95$ for b.

12. (a) We first find an antiderivative of $g(t) = t^2\,e^{at}$.

$$\begin{aligned}
\int t^2\,e^{at}\,dt &= \frac{1}{a}t^2\,e^{at} - \int \frac{2}{a}t\,e^{at}\,dt \qquad \begin{bmatrix} u = t^2, & dv = e^{at}\,dt \\ du = 2t\,dt, & v = \frac{1}{a}e^{at} \end{bmatrix} \\
&= \frac{1}{a}t^2\,e^{at} - \frac{2}{a}\left[\frac{1}{a}t\,e^{at} - \int \frac{1}{a}\,e^{at}\,dt\right] \qquad \begin{bmatrix} u = t, & dv = e^{at}\,dt \\ du = dt, & v = \frac{1}{a}e^{at} \end{bmatrix} \\
&= \frac{1}{a}t^2\,e^{at} - \frac{2}{a^2}\,t\,e^{at} + \frac{2}{a^3}\,e^{at} + C = \frac{1}{a}\,e^{at}\left(t^2 - \frac{2}{a}t + \frac{2}{a^2}\right) + C \\
&= -20e^{-0.05t}(t^2 + 40t + 800) + C \qquad [\text{with } a = -0.05]
\end{aligned}$$

$$\begin{aligned}
P(0 \leq X \leq 48) &= \int_0^{48} f(t)\,dt = \frac{1}{15{,}676}\int_0^{48} g(t)\,dt = \frac{1}{15{,}676}\left[-20e^{-0.05t}(t^2 + 40t + 800)\right]_0^{48} \\
&= \frac{-20}{15{,}676}(5024e^{-2.4} - 800) \approx 0.439.
\end{aligned}$$

(b)
$$\begin{aligned}
P(X > 36) = P(36 < X \leq 150) &= \frac{1}{15{,}676}\int_{36}^{150} g(t)\,dt = \frac{1}{15{,}676}\left[-20e^{-0.05t}(t^2 + 40t + 800)\right]_{36}^{150} \\
&= \frac{-20}{15{,}676}(29{,}300e^{-7.5} - 3536e^{-1.8}) \approx 0.725
\end{aligned}$$

13. (a) $f(t) = \begin{cases} \frac{1}{1600}t & \text{if } 0 \leq t \leq 40 \\ \frac{1}{20} - \frac{1}{1600}t & \text{if } 40 < t \leq 80 \\ 0 & \text{otherwise} \end{cases}$

$$\begin{aligned}
P(30 \leq T \leq 60) &= \int_{30}^{60} f(t)\,dt = \int_{30}^{40} \frac{t}{1600}\,dt + \int_{40}^{60}\left(\frac{1}{20} - \frac{t}{1600}\right)dt = \left[\frac{t^2}{3200}\right]_{30}^{40} + \left[\frac{t}{20} - \frac{t^2}{3200}\right]_{40}^{60} \\
&= \left(\frac{1600}{3200} - \frac{900}{3200}\right) + \left(\frac{60}{20} - \frac{3600}{3200}\right) - \left(\frac{40}{20} - \frac{1600}{3200}\right) = -\frac{1300}{3200} + 1 = \frac{19}{32}
\end{aligned}$$

The probability that the amount of REM sleep is between 30 and 60 minutes is $\frac{19}{32} \approx 59.4\%$.

(b) $\mu = \int_{-\infty}^{\infty} t\,f(t)\,dt = \int_0^{40} t\left(\frac{t}{1600}\right)dt + \int_{40}^{80} t\left(\frac{1}{20} - \frac{t}{1600}\right)dt = \left[\frac{t^3}{4800}\right]_0^{40} + \left[\frac{t^2}{40} - \frac{t^3}{4800}\right]_{40}^{80}$

$$= \frac{64{,}000}{4800} + \left(\frac{6400}{40} - \frac{512{,}000}{4800}\right) - \left(\frac{1600}{40} - \frac{64{,}000}{4800}\right) = -\frac{384{,}000}{4800} + 120 = 40$$

The mean amount of REM sleep is 40 minutes.

14. (a) With $\mu = 69$ and $\sigma = 2.8$, we have $P(65 \le X \le 73) = \int_{65}^{73} \frac{1}{2.8\sqrt{2\pi}} \exp\left(-\frac{(x-69)^2}{2\cdot 2.8^2}\right)dx \approx 0.847$

(using a calculator or computer to estimate the integral).

(b) $P(X > 6 \text{ feet}) = P(X > 72 \text{ inches}) = 1 - P(0 \le X \le 72) \approx 1 - 0.858 = 0.142$, so 14.2% of the adult male population is more than 6 feet tall.

15. $P(X \ge 10) = \int_{10}^{\infty} \frac{1}{4.2\sqrt{2\pi}} \exp\left(-\frac{(x-9.4)^2}{2\cdot 4.2^2}\right)dx$. To avoid the improper integral we approximate it by the integral from 10 to 100. Thus, $P(X \ge 10) \approx \int_{10}^{100} \frac{1}{4.2\sqrt{2\pi}} \exp\left(-\frac{(x-9.4)^2}{2\cdot 4.2^2}\right)dx \approx 0.443$ (using a calculator or computer to estimate the integral), so about 44 percent of the households throw out at least 10 lb of paper a week.

Note: We can't evaluate $1 - P(0 \le X \le 10)$ for this problem since a significant amount of area lies to the left of $X = 0$.

16. (a) $P(0 \le X \le 480) = \int_0^{480} \frac{1}{12\sqrt{2\pi}} \exp\left(-\frac{(x-500)^2}{2\cdot 12^2}\right)dx \approx 0.0478$ (using a calculator or computer to estimate the integral), so there is about a 4.78% chance that a particular box contains less than 480 g of cereal.

(b) We need to find μ so that $P(0 \le X < 500) = 0.05$. Using our calculator or computer to find $P(0 \le X \le 500)$ for various values of μ, we find that if $\mu = 519.73$, $P = 0.05007$; and if $\mu = 519.74$, $P = 0.04998$. So a good target weight is at least 519.74 g.

17. (a) $P(0 \le X \le 100) = \int_0^{100} \frac{1}{8\sqrt{2\pi}} \exp\left(-\frac{(x-112)^2}{2\cdot 8^2}\right)dx \approx 0.0668$ (using a calculator or computer to estimate the integral), so there is about a 6.68% chance that a randomly chosen vehicle is traveling at a legal speed.

(b) $P(X \ge 125) = \int_{125}^{\infty} \frac{1}{8\sqrt{2\pi}} \exp\left(-\frac{(x-112)^2}{2\cdot 8^2}\right)dx = \int_{125}^{\infty} f(x)\,dx$. In this case, we could use a calculator or computer to estimate either $\int_{125}^{300} f(x)\,dx$ or $1 - \int_0^{125} f(x)\,dx$. Both are approximately 0.0521, so about 5.21% of the motorists are targeted.

18. $f(x) = \frac{1}{\sigma\sqrt{2\pi}} e^{-(x-\mu)^2/(2\sigma^2)} \quad\Rightarrow\quad f'(x) = \frac{1}{\sigma\sqrt{2\pi}} e^{-(x-\mu)^2/(2\sigma^2)} \frac{-2(x-\mu)}{2\sigma^2} = \frac{-1}{\sigma^3\sqrt{2\pi}} e^{-(x-\mu)^2/(2\sigma^2)}(x-\mu) \quad\Rightarrow$

$$f''(x) = \frac{-1}{\sigma^3\sqrt{2\pi}}\left[e^{-(x-\mu)^2/(2\sigma^2)}\cdot 1 + (x-\mu)e^{-(x-\mu)^2/(2\sigma^2)}\frac{-2(x-\mu)}{2\sigma^2}\right]$$

$$= \frac{-1}{\sigma^3\sqrt{2\pi}} e^{-(x-\mu)^2/(2\sigma^2)}\left[1 - \frac{(x-\mu)^2}{\sigma^2}\right] = \frac{1}{\sigma^5\sqrt{2\pi}} e^{-(x-\mu)^2/(2\sigma^2)}\left[(x-\mu)^2 - \sigma^2\right]$$

$f''(x) < 0 \quad\Rightarrow\quad (x-\mu)^2 - \sigma^2 < 0 \quad\Rightarrow\quad |x-\mu| < \sigma \quad\Rightarrow\quad -\sigma < x - \mu < \sigma \quad\Rightarrow\quad \mu - \sigma < x < \mu + \sigma$ and similarly, $f''(x) > 0 \quad\Rightarrow\quad x < \mu - \sigma$ or $x > \mu + \sigma$. Thus, f changes concavity and has inflection points at $x = \mu \pm \sigma$.

19. $P(\mu - 2\sigma \le X \le \mu + 2\sigma) = \int_{\mu-2\sigma}^{\mu+2\sigma} \dfrac{1}{\sigma\sqrt{2\pi}} \exp\left(-\dfrac{(x-\mu)^2}{2\sigma^2}\right) dx$. Substituting $t = \dfrac{x-\mu}{\sigma}$ and $dt = \dfrac{1}{\sigma}\,dx$ gives us

$\int_{-2}^{2} \dfrac{1}{\sigma\sqrt{2\pi}} e^{-t^2/2}(\sigma\,dt) = \dfrac{1}{\sqrt{2\pi}} \int_{-2}^{2} e^{-t^2/2}\,dt \approx 0.9545.$

20. Let $f(x) = \begin{cases} 0 & \text{if } x < 0 \\ ce^{-cx} & \text{if } x \ge 0 \end{cases}$ where $c = 1/\mu$. By using parts, tables, or a CAS, we find that

(1): $\int xe^{bx}\,dx = (e^{bx}/b^2)(bx - 1)$

(2): $\int x^2e^{bx}\,dx = (e^{bx}/b^3)(b^2x^2 - 2bx + 2)$

Now

$$\begin{aligned} \sigma^2 &= \textstyle\int_{-\infty}^{\infty}(x-\mu)^2 f(x)\,dx = \int_{-\infty}^{0}(x-\mu)^2 f(x)\,dx + \int_{0}^{\infty}(x-\mu)^2 f(x)\,dx \\ &= 0 + \lim_{t\to\infty} c\textstyle\int_0^t (x-\mu)^2 e^{-cx}\,dx = c \cdot \lim_{t\to\infty} \int_0^t \left(x^2e^{-cx} - 2x\mu e^{-cx} + \mu^2 e^{-cx}\right) dx \end{aligned}$$

Next we use (2) and (1) with $b = -c$ to get

$$\sigma^2 = c\lim_{t\to\infty}\left[-\frac{e^{-cx}}{c^3}\left(c^2x^2 + 2cx + 2\right) - 2\mu\frac{e^{-cx}}{c^2}(-cx - 1) + \mu^2\frac{e^{-cx}}{-c}\right]_0^t$$

Using l'Hospital's Rule several times, along with the fact that $\mu = 1/c$, we get

$$\sigma^2 = c\left[0 - \left(-\frac{2}{c^3} + \frac{2}{c}\cdot\frac{1}{c^2} + \frac{1}{c^2}\cdot\frac{1}{-c}\right)\right] = c\left(\frac{1}{c^3}\right) = \frac{1}{c^2} \quad\Rightarrow\quad \sigma = \frac{1}{c} = \mu$$

21. (a) First $p(r) = \dfrac{4}{a_0^3} r^2 e^{-2r/a_0} \ge 0$ for $r \ge 0$. Next,

$$\int_{-\infty}^{\infty} p(r)\,dr = \int_0^{\infty} \frac{4}{a_0^3} r^2 e^{-2r/a_0}\,dr = \frac{4}{a_0^3}\lim_{t\to\infty}\int_0^t r^2 e^{-2r/a_0}\,dr$$

By using parts, tables, or a CAS [or as in Exercise 20] , we find that $\int x^2e^{bx}\,dx = (e^{bx}/b^3)(b^2x^2 - 2bx + 2)$. $(\star)$

Next, we use $(\star)$ (with $b = -2/a_0$) and l'Hospital's Rule to get $\dfrac{4}{a_0^3}\left[\dfrac{a_0^3}{-8}(-2)\right] = 1$. This satisfies the second condition for a function to be a probability density function.

(b) Using l'Hospital's Rule, $\dfrac{4}{a_0^3}\lim\limits_{r\to\infty}\dfrac{r^2}{e^{2r/a_0}} = \dfrac{4}{a_0^3}\lim\limits_{r\to\infty}\dfrac{2r}{(2/a_0)e^{2r/a_0}} = \dfrac{2}{a_0^2}\lim\limits_{r\to\infty}\dfrac{2}{(2/a_0)e^{2r/a_0}} = 0.$

To find the maximum of p, we differentiate:

$$p'(r) = \frac{4}{a_0^3}\left[r^2e^{-2r/a_0}\left(-\frac{2}{a_0}\right) + e^{-2r/a_0}(2r)\right] = \frac{4}{a_0^3}e^{-2r/a_0}(2r)\left(-\frac{r}{a_0} + 1\right)$$

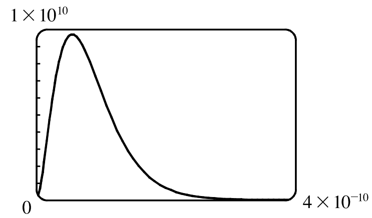
$p'(r) = 0 \quad\Leftrightarrow\quad r = 0$ or $1 = \dfrac{r}{a_0} \quad\Leftrightarrow\quad r = a_0 \quad [a_0 \approx 5.59 \times 10^{-11}\text{ m}]$.

$p'(r)$ changes from positive to negative at $r = a_0$, so $p(r)$ has its maximum value at $r = a_0$.

(c) It is fairly difficult to find a viewing rectangle, but knowing the maximum value from part (b) helps.

$$p(a_0) = \frac{4}{a_0^3}\, a_0^2 e^{-2a_0/a_0} = \frac{4}{a_0}\, e^{-2} \approx 9{,}684{,}098{,}979$$

With a maximum of nearly 10 billion and a total area under the curve of 1, we know that the "hump" in the graph must be extremely narrow.



(d) $P(r) = \int_0^r \frac{4}{a_0^3} s^2 e^{-2s/a_0}\, ds \;\Rightarrow\; P(4a_0) = \int_0^{4a_0} \frac{4}{a_0^3} s^2 e^{-2s/a_0}\, ds$. Using ($\star$) from part (a) [with $b = -2/a_0$],

$$P(4a_0) = \frac{4}{a_0^3}\left[\frac{e^{-2s/a_0}}{-8/a_0^3}\left(\frac{4}{a_0^2}s^2 + \frac{4}{a_0}s + 2\right)\right]_0^{4a_0} = \frac{4}{a_0^3}\left(\frac{a_0^3}{-8}\right)[e^{-8}(64+16+2) - 1(2)] = -\tfrac{1}{2}(82e^{-8} - 2)$$

$$= 1 - 41e^{-8} \approx 0.986$$

(e) $\mu = \int_{-\infty}^{\infty} rp(r)\, dr = \frac{4}{a_0^3} \lim_{t\to\infty} \int_0^t r^3 e^{-2r/a_0}\, dr$. Integrating by parts three times or using a CAS, we find that

$\int x^3 e^{bx}\, dx = \frac{e^{bx}}{b^4}\left(b^3x^3 - 3b^2x^2 + 6bx - 6\right)$. So with $b = -\frac{2}{a_0}$, we use l'Hospital's Rule, and get

$\mu = \frac{4}{a_0^3}\left[-\frac{a_0^4}{16}(-6)\right] = \frac{3}{2}a_0$.

8 Review

EXERCISES

1. $y = 4(x-1)^{3/2} \;\Rightarrow\; \frac{dy}{dx} = 6(x-1)^{1/2} \;\Rightarrow\; 1 + \left(\frac{dy}{dx}\right)^2 = 1 + 36(x-1) = 36x - 35$. Thus,

$$L = \int_1^4 \sqrt{36x-35}\, dx = \int_1^{109} \sqrt{u}\left(\tfrac{1}{36}\, du\right) \qquad \begin{bmatrix} u = 36x - 35, \\ du = 36\, dx \end{bmatrix}$$

$$= \tfrac{1}{36}\left[\tfrac{2}{3}u^{3/2}\right]_1^{109} = \tfrac{1}{54}\left(109\sqrt{109} - 1\right)$$

2. $y = 2\ln\left(\sin\frac{1}{2}x\right) \;\Rightarrow\; \frac{dy}{dx} = 2 \cdot \frac{1}{\sin\left(\frac{1}{2}x\right)} \cdot \cos\left(\frac{1}{2}x\right) \cdot \frac{1}{2} = \cot\left(\frac{1}{2}x\right) \;\Rightarrow\; 1 + \left(\frac{dy}{dx}\right)^2 = 1 + \cot^2\left(\frac{1}{2}x\right) = \csc^2\left(\frac{1}{2}x\right)$.

Thus,

$$L = \int_{\pi/3}^{\pi} \sqrt{\csc^2\left(\tfrac{1}{2}x\right)}\, dx = \int_{\pi/3}^{\pi} \left|\csc\left(\tfrac{1}{2}x\right)\right| dx = \int_{\pi/3}^{\pi} \csc\left(\tfrac{1}{2}x\right) dx = \int_{\pi/6}^{\pi/2} \csc u\,(2\, du) \qquad \begin{bmatrix} u = \frac{1}{2}x, \\ du = \frac{1}{2}\, dx \end{bmatrix}$$

$$= 2\Big[\ln|\csc u - \cot u|\Big]_{\pi/6}^{\pi/2} = 2\left[\ln\left|\csc\tfrac{\pi}{2} - \cot\tfrac{\pi}{2}\right| - \ln\left|\csc\tfrac{\pi}{6} - \cot\tfrac{\pi}{6}\right|\right]$$

$$= 2\left[\ln|1 - 0| - \ln\left|2 - \sqrt{3}\right|\right] = -2\ln\left(2 - \sqrt{3}\right) \approx 2.63$$

3. $12x = 4y^3 + 3y^{-1} \quad \Rightarrow \quad x = \frac{1}{3}y^3 + \frac{1}{4}y^{-1} \quad \Rightarrow \quad \dfrac{dx}{dy} = y^2 - \frac{1}{4}y^{-2} \quad \Rightarrow$

$1 + \left(\dfrac{dx}{dy}\right)^2 = 1 + y^4 - \frac{1}{2} + \frac{1}{16}y^{-4} = y^4 + \frac{1}{2} + \frac{1}{16}y^{-4} = (y^2 + \frac{1}{4}y^{-2})^2$. Thus,

$$L = \int_1^3 \sqrt{\left(y^2 + \tfrac{1}{4}y^{-2}\right)^2}\,dy = \int_1^3 \left|y^2 + \tfrac{1}{4}y^{-2}\right|\,dy = \int_1^3 \left(y^2 + \tfrac{1}{4}y^{-2}\right)\,dy = \left[\tfrac{1}{3}y^3 - \tfrac{1}{4}y^{-1}\right]_1^3$$
$$= (9 - \tfrac{1}{12}) - (\tfrac{1}{3} - \tfrac{1}{4}) = \tfrac{106}{12} = \tfrac{53}{6}$$

4. (a) $y = \dfrac{x^4}{16} + \dfrac{1}{2x^2} = \dfrac{1}{16}x^4 + \dfrac{1}{2}x^{-2} \quad \Rightarrow \quad \dfrac{dy}{dx} = \dfrac{1}{4}x^3 - x^{-3} \quad \Rightarrow$

$1 + (dy/dx)^2 = 1 + \left(\frac{1}{4}x^3 - x^{-3}\right)^2 = 1 + \frac{1}{16}x^6 - \frac{1}{2} + x^{-6} = \frac{1}{16}x^6 + \frac{1}{2} + x^{-6} = \left(\frac{1}{4}x^3 + x^{-3}\right)^2$.

Thus, $L = \int_1^2 \left(\frac{1}{4}x^3 + x^{-3}\right)dx = \left[\frac{1}{16}x^4 - \frac{1}{2}x^{-2}\right]_1^2 = \left(1 - \frac{1}{8}\right) - \left(\frac{1}{16} - \frac{1}{2}\right) = \frac{21}{16}$.

(b) $S = \int_1^2 2\pi x\left(\frac{1}{4}x^3 + x^{-3}\right)dx = 2\pi\int_1^2 \left(\frac{1}{4}x^4 + x^{-2}\right)dx = 2\pi\left[\frac{1}{20}x^5 - \frac{1}{x}\right]_1^2$

$= 2\pi\left[\left(\frac{32}{20} - \frac{1}{2}\right) - \left(\frac{1}{20} - 1\right)\right] = 2\pi\left(\frac{8}{5} - \frac{1}{2} - \frac{1}{20} + 1\right) = 2\pi\left(\frac{41}{20}\right) = \frac{41}{10}\pi$

5. (a) $y = \dfrac{2}{x+1} \quad \Rightarrow \quad y' = \dfrac{-2}{(x+1)^2} \quad \Rightarrow \quad 1 + (y')^2 = 1 + \dfrac{4}{(x+1)^4}$.

For $0 \le x \le 3$, $L = \int_0^3 \sqrt{1 + (y')^2}\,dx = \int_0^3 \sqrt{1 + 4/(x+1)^4}\,dx \approx 3.5121$.

(b) The area of the surface obtained by rotating C about the x-axis is

$$S = \int_0^3 2\pi y\,ds = 2\pi\int_0^3 \frac{2}{x+1}\sqrt{1 + 4/(x+1)^4}\,dx \approx 22.1391.$$

(c) The area of the surface obtained by rotating C about the y-axis is

$S = \int_0^3 2\pi x\,ds = 2\pi\int_0^3 x\sqrt{1 + 4/(x+1)^4}\,dx \approx 29.8522.$

6. (a) $y = x^2 \quad \Rightarrow \quad 1 + (y')^2 = 1 + 4x^2$. Rotate about the y-axis for $0 \le x \le 1$:

$$S = \int_0^1 2\pi x\sqrt{1 + 4x^2}\,dx = \int_1^5 \tfrac{\pi}{4}\sqrt{u}\,du \quad [u = 1 + 4x^2] = \tfrac{\pi}{6}\left[u^{3/2}\right]_1^5 = \tfrac{\pi}{6}(5^{3/2} - 1)$$

(b) $y = x^2 \quad \Rightarrow \quad 1 + (y')^2 = 1 + 4x^2$. Rotate about the x-axis for $0 \le x \le 1$:

$$S = 2\pi\int_0^1 x^2\sqrt{1 + 4x^2}\,dx = 2\pi\int_0^2 \tfrac{1}{4}u^2\sqrt{1 + u^2}\,\tfrac{1}{2}\,du \quad [u = 2x] \quad = \tfrac{\pi}{4}\int_0^2 u^2\sqrt{1 + u^2}\,du$$
$$= \tfrac{\pi}{4}\left[\tfrac{1}{8}u(1 + 2u^2)\sqrt{1 + u^2} - \tfrac{1}{8}\ln\left|u + \sqrt{1 + u^2}\right|\right]_0^2 \qquad [u = \tan\theta \text{ or use Formula 22}]$$
$$= \tfrac{\pi}{4}\left[\tfrac{1}{4}(9)\sqrt{5} - \tfrac{1}{8}\ln(2 + \sqrt{5}) - 0\right] = \tfrac{\pi}{32}\left[18\sqrt{5} - \ln(2 + \sqrt{5})\right]$$

7. $y = \sin x \quad \Rightarrow \quad y' = \cos x \quad \Rightarrow \quad 1 + (y')^2 = 1 + \cos^2 x$. Let $f(x) = \sqrt{1 + \cos^2 x}$. Then

$L = \int_0^\pi f(x)\,dx \approx S_{10}$

$$= \tfrac{(\pi - 0)/10}{3}\left[f(0) + 4f\left(\tfrac{\pi}{10}\right) + 2f\left(\tfrac{2\pi}{10}\right) + 4f\left(\tfrac{3\pi}{10}\right) + 2f\left(\tfrac{4\pi}{10}\right)\right.$$
$$\left. + 4f\left(\tfrac{5\pi}{10}\right) + 2f\left(\tfrac{6\pi}{10}\right) + 4f\left(\tfrac{7\pi}{10}\right) + 2f\left(\tfrac{8\pi}{10}\right) + 4f\left(\tfrac{9\pi}{10}\right) + f(\pi)\right]$$

≈ 3.820188

8. $S=\int_0^\pi 2\pi y\,ds=\int_0^\pi 2\pi\sin x\sqrt{1+\cos^2 x}\,dx$. Let $g(x)=2\pi\sin x\sqrt{1+\cos^2 x}$. Then

$$S=\int_0^\pi g(x)\,dx\approx S_{10}$$
$$=\tfrac{(\pi-0)/10}{3}\left[g(0)+4g\left(\tfrac{\pi}{10}\right)+2g\left(\tfrac{2\pi}{10}\right)+4g\left(\tfrac{3\pi}{10}\right)+2g\left(\tfrac{4\pi}{10}\right)+4g\left(\tfrac{5\pi}{10}\right)+2g\left(\tfrac{6\pi}{10}\right)+4g\left(\tfrac{7\pi}{10}\right)+2g\left(\tfrac{8\pi}{10}\right)+4g\left(\tfrac{9\pi}{10}\right)+g(\pi)\right]$$
$$\approx 14.426045$$

9. $y=\int_1^x\sqrt{\sqrt{t}-1}\,dt \quad\Rightarrow\quad dy/dx=\sqrt{\sqrt{x}-1} \quad\Rightarrow\quad 1+(dy/dx)^2=1+\left(\sqrt{x}-1\right)=\sqrt{x}$.

Thus, $L=\int_1^{16}\sqrt{\sqrt{x}}\,dx=\int_1^{16}x^{1/4}\,dx=\frac{4}{5}\left[x^{5/4}\right]_1^{16}=\frac{4}{5}(32-1)=\frac{124}{5}$.

10. $S=\int_1^{16}2\pi x\,ds=2\pi\int_1^{16}x\cdot x^{1/4}\,dx=2\pi\int_1^{16}x^{5/4}\,dx=2\pi\cdot\frac{4}{9}\left[x^{9/4}\right]_1^{16}=\frac{8\pi}{9}(512-1)=\frac{4088}{9}\pi$

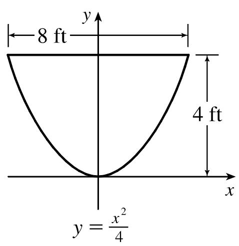
11. As in Example 8.3.1, $\dfrac{a}{2-x}=\dfrac{1}{2} \quad\Rightarrow\quad 2a=2-x$ and $w=2(1.5+a)=3+2a=3+2-x=5-x$.

Thus, $F=\int_0^2\delta x(5-x)\,dx=\delta\left[\frac{5}{2}x^2-\frac{1}{3}x^3\right]_0^2=\delta\left(10-\frac{8}{3}\right)=\frac{22}{3}\delta\approx 458$ lb $[\delta\approx 62.5\text{ lb/ft}^3]$.

12. $F=\int_0^4\delta(4-y)2\left(2\sqrt{y}\right)dy=4\delta\int_0^4\left(4y^{1/2}-y^{3/2}\right)dy$

$=4\delta\left[\frac{8}{3}y^{3/2}-\frac{2}{5}y^{5/2}\right]_0^4=4\delta\left(\frac{64}{3}-\frac{64}{5}\right)=256\delta\left(\frac{1}{3}-\frac{1}{5}\right)$

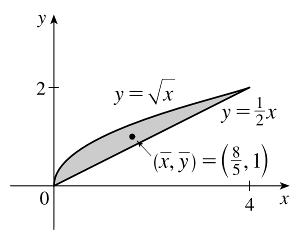
$=\frac{512}{15}\delta\approx 2133.3$ lb $\quad[\delta\approx 62.5\text{ lb/ft}^3]$



13. $A=\int_0^4\left(\sqrt{x}-\frac{1}{2}x\right)dx=\left[\frac{2}{3}x^{3/2}-\frac{1}{4}x^2\right]_0^4=\frac{16}{3}-4=\frac{4}{3}$

$\overline{x}=\frac{1}{A}\int_0^4 x\left(\sqrt{x}-\frac{1}{2}x\right)dx=\frac{3}{4}\int_0^4\left(x^{3/2}-\frac{1}{2}x^2\right)dx$

$=\frac{3}{4}\left[\frac{2}{5}x^{5/2}-\frac{1}{6}x^3\right]_0^4=\frac{3}{4}\left(\frac{64}{5}-\frac{64}{6}\right)=\frac{3}{4}\left(\frac{64}{30}\right)=\frac{8}{5}$



$\overline{y}=\frac{1}{A}\int_0^4\frac{1}{2}\left[\left(\sqrt{x}\right)^2-\left(\frac{1}{2}x\right)^2\right]dx=\frac{3}{4}\int_0^4\frac{1}{2}\left(x-\frac{1}{4}x^2\right)dx=\frac{3}{8}\left[\frac{1}{2}x^2-\frac{1}{12}x^3\right]_0^4=\frac{3}{8}\left(8-\frac{16}{3}\right)=\frac{3}{8}\left(\frac{8}{3}\right)=1$

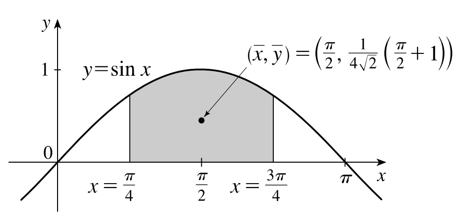
Thus, the centroid is $(\overline{x},\overline{y})=\left(\frac{8}{5},1\right)$.

14. From the symmetry of the region, $\overline{x}=\frac{\pi}{2}$. $\quad A=\int_{\pi/4}^{3\pi/4}\sin x\,dx=\left[-\cos x\right]_{\pi/4}^{3\pi/4}=\frac{1}{\sqrt{2}}-\left(-\frac{1}{\sqrt{2}}\right)=\sqrt{2}$

$\overline{y}=\dfrac{1}{A}\displaystyle\int_{\pi/4}^{3\pi/4}\frac{1}{2}\sin^2 x\,dx=\dfrac{1}{A}\int_{\pi/4}^{3\pi/4}\frac{1}{4}\left(1-\cos 2x\right)dx$

$=\dfrac{1}{4\sqrt{2}}\left[x-\frac{1}{2}\sin 2x\right]_{\pi/4}^{3\pi/4}$

$=\dfrac{1}{4\sqrt{2}}\left[\frac{3\pi}{4}-\frac{1}{2}(-1)-\frac{\pi}{4}+\frac{1}{2}\cdot 1\right]=\frac{1}{4\sqrt{2}}\left(\frac{\pi}{2}+1\right)$



Thus, the centroid is $(\overline{x},\overline{y})=\left(\frac{\pi}{2},\frac{1}{4\sqrt{2}}\left(\frac{\pi}{2}+1\right)\right)\approx(1.57,0.45)$.

15. The area of the triangular region is $A = \frac{1}{2}(2)(4) = 4$. An equation of the line is $y = \frac{1}{2}x$ or $x = 2y$.

$$\overline{x} = \frac{1}{A}\int_0^2 \frac{1}{2}[f(y)]^2\,dy = \frac{1}{4}\int_0^2 \frac{1}{2}(2y)^2\,dy = \frac{1}{8}\int_0^2 4y^2\,dy = \frac{1}{8}\left[\frac{4}{3}y^3\right]_0^2 = \frac{1}{6}(8) = \frac{4}{3}$$

$$\overline{y} = \frac{1}{A}\int_0^2 y\,f(y)\,dy = \frac{1}{4}\int_0^2 y(2y)\,dy = \frac{1}{2}\int_0^2 y^2\,dy = \frac{1}{2}\left[\frac{1}{3}y^3\right]_0^2 = \frac{1}{6}(8) = \frac{4}{3}$$

The centroid of the region is $\left(\frac{4}{3}, \frac{4}{3}\right)$.

16. An equation of the line is $y = 8 - x$. An equation of the quarter-circle is $y = -\sqrt{8^2 - x^2}$ with $0 \le x \le 8$. The area of the region is $A = \frac{1}{2}(8)(8) + \frac{1}{4}\pi(8)^2 = 32 + 16\pi = 16(2 + \pi)$.

$$\begin{aligned}\overline{x} &= \frac{1}{A}\int_0^8 x[f(x) - g(x)]\,dx = \frac{1}{A}\int_0^8 x\left[(8 - x) + \sqrt{64 - x^2}\,\right]dx \\ &= \frac{1}{A}\int_0^8 \left[8x - x^2 + x(64 - x^2)^{1/2}\right]dx = \frac{1}{A}\left[4x^2 - \frac{1}{3}x^3 - \frac{1}{3}(64 - x^2)^{3/2}\right]_0^8 \\ &= \frac{1}{A}\left[\left(256 - \frac{512}{3} - 0\right) - \left(0 - 0 - \frac{512}{3}\right)\right] = \frac{256}{16(2 + \pi)} = \frac{16}{2 + \pi}\end{aligned}$$

$$\begin{aligned}\overline{y} &= \frac{1}{A}\int_0^8 \frac{1}{2}\{[f(x)]^2 - [g(x)]^2\}\,dx = \frac{1}{2A}\int_0^8 \left[(8 - x)^2 - (-\sqrt{64 - x^2}\,)^2\right]dx \\ &= \frac{1}{2A}\int_0^8 \left[64 - 16x + x^2 - (64 - x^2)\right]dx = \frac{1}{2A}\int_0^8 (2x^2 - 16x)\,dx \\ &= \frac{1}{A}\int_0^8 (x^2 - 8x)\,dx = \frac{1}{A}\left[\frac{1}{3}x^3 - 4x^2\right]_0^8 = \frac{1}{A}\left(\frac{512}{3} - 256\right) \\ &= \frac{1}{16(2 + \pi)}\left(-\frac{256}{3}\right) = -\frac{16}{3(2 + \pi)}\end{aligned}$$

The centroid of the region is $\left(\frac{16}{2 + \pi}, -\frac{16}{3(2 + \pi)}\right) \approx (3.11, -1.04)$.

17. The centroid of this circle, $(1, 0)$, travels a distance $2\pi(1)$ when the lamina is rotated about the y-axis. The area of the circle is $\pi(1)^2$. So by the Theorem of Pappus, $V = A(2\pi\overline{x}) = \pi(1)^2 2\pi(1) = 2\pi^2$.

18. The semicircular region has an area of $\frac{1}{2}\pi r^2$, and sweeps out a sphere of radius r when rotated about the x-axis. $\overline{x} = 0$ because of symmetry about the line $x = 0$. And by the Theorem of Pappus, $V = A(2\pi\overline{y}) \;\Rightarrow$ $\frac{4}{3}\pi r^3 = \frac{1}{2}\pi r^2(2\pi\overline{y}) \;\Rightarrow\; \overline{y} = \frac{4}{3\pi}r$. Thus, the centroid is $(\overline{x}, \overline{y}) = \left(0, \frac{4}{3\pi}r\right)$.

19. $x = 100 \;\Rightarrow\; P = 2000 - 0.1(100) - 0.01(100)^2 = 1890$

$$\begin{aligned}\text{Consumer surplus} &= \textstyle\int_0^{100}[p(x) - P]\,dx = \int_0^{100}\left(2000 - 0.1x - 0.01x^2 - 1890\right)dx \\ &= \left[110x - 0.05x^2 - \tfrac{0.01}{3}x^3\right]_0^{100} = 11{,}000 - 500 - \tfrac{10{,}000}{3} \approx \$7166.67\end{aligned}$$

20. $\int_0^{24} c(t)\,dt \approx S_{12} = \frac{24-0}{12\cdot 3}[1(0)+4(1.9)+2(3.3)+4(5.1)+2(7.6)+4(7.1)+2(5.8)$
$+4(4.7)+2(3.3)+4(2.1)+2(1.1)+4(0.5)+1(0)]$
$= \frac{2}{3}(127.8) = 85.2 \text{ mg}\cdot\text{s/L}$

Therefore, $F \approx A/85.2 = 6/85.2 \approx 0.0704$ L/s or 4.225 L/min.

21. $f(x) = \begin{cases} \frac{\pi}{20}\sin\left(\frac{\pi}{10}x\right) & \text{if } 0 \le x \le 10 \\ 0 & \text{if } x < 0 \text{ or } x > 10 \end{cases}$

(a) $f(x) \ge 0$ for all real numbers x and

$$\int_{-\infty}^{\infty} f(x)\,dx = \int_0^{10} \frac{\pi}{20}\sin\left(\frac{\pi}{10}x\right)dx = \frac{\pi}{20}\cdot\frac{10}{\pi}\left[-\cos\left(\frac{\pi}{10}x\right)\right]_0^{10} = \frac{1}{2}(-\cos\pi + \cos 0) = \frac{1}{2}(1+1) = 1$$

Therefore, f is a probability density function.

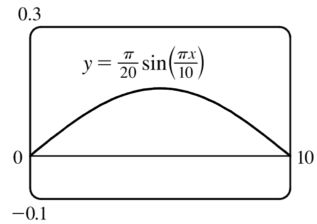
(b) $P(X < 4) = \int_{-\infty}^{4} f(x)\,dx = \int_0^4 \frac{\pi}{20}\sin\left(\frac{\pi}{10}x\right)dx = \frac{1}{2}\left[-\cos\left(\frac{\pi}{10}x\right)\right]_0^4 = \frac{1}{2}\left(-\cos\frac{2\pi}{5} + \cos 0\right)$

$\approx \frac{1}{2}(-0.309017 + 1) \approx 0.3455$

(c) $\mu = \int_{-\infty}^{\infty} xf(x)\,dx = \int_0^{10} \frac{\pi}{20}x\sin\left(\frac{\pi}{10}x\right)dx$

$= \int_0^{\pi} \frac{\pi}{20}\cdot\frac{10}{\pi}u(\sin u)\left(\frac{10}{\pi}\right)du \qquad \left[u = \frac{\pi}{10}x,\ du = \frac{\pi}{10}\,dx\right]$

$= \frac{5}{\pi}\int_0^{\pi} u\sin u\,du \overset{82}{=} \frac{5}{\pi}\left[\sin u - u\cos u\right]_0^{\pi} = \frac{5}{\pi}[0 - \pi(-1)] = 5$



This answer is expected because the graph of f is symmetric about the line $x = 5$.

22. $P(250 \le X \le 280) = \displaystyle\int_{250}^{280} \frac{1}{\sigma\sqrt{2\pi}}\,e^{-(x-\mu)^2/(2\sigma^2)}\,dx = \int_{250}^{280} \frac{1}{15\sqrt{2\pi}}\exp\left(\frac{-(x-268)^2}{2\cdot 15^2}\right)dx \approx 0.673.$

Thus, the percentage of pregnancies that last between 250 and 280 days is about 67.3%.

23. (a) The probability density function is $f(t) = \begin{cases} 0 & \text{if } t < 0 \\ \frac{1}{8}e^{-t/8} & \text{if } t \ge 0 \end{cases}$

$P(0 \le X \le 3) = \int_0^3 \frac{1}{8}e^{-t/8}\,dt = \left[-e^{-t/8}\right]_0^3 = -e^{-3/8} + 1 \approx 0.3127$

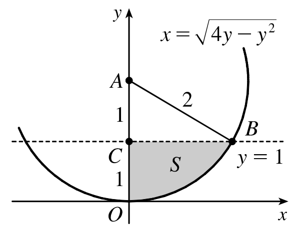
(b) $P(X > 10) = \int_{10}^{\infty} \frac{1}{8}e^{-t/8}\,dt = \lim\limits_{x\to\infty}\left[-e^{-t/8}\right]_{10}^{x} = \lim\limits_{x\to\infty}\left(-e^{-x/8} + e^{-10/8}\right) = 0 + e^{-5/4} \approx 0.2865$

(c) We need to find m such that $P(X \ge m) = \frac{1}{2} \Rightarrow \int_m^{\infty} \frac{1}{8}e^{-t/8}\,dt = \frac{1}{2} \Rightarrow \lim\limits_{x\to\infty}\left[-e^{-t/8}\right]_m^x = \frac{1}{2} \Rightarrow$

$\lim\limits_{x\to\infty}\left(-e^{-x/8} + e^{-m/8}\right) = \frac{1}{2} \Rightarrow e^{-m/8} = \frac{1}{2} \Rightarrow -m/8 = \ln\frac{1}{2} \Rightarrow m = -8\ln\frac{1}{2} = 8\ln 2 \approx 5.55$ minutes.

☐ PROBLEMS PLUS

1. $x^2 + y^2 \le 4y \quad \Leftrightarrow \quad x^2 + (y-2)^2 \le 4$, so S is part of a circle, as shown in the diagram. The area of S is



$$\int_0^1 \sqrt{4y - y^2}\,dy \overset{113}{=} \left[\tfrac{y-2}{2}\sqrt{4y-y^2} + 2\cos^{-1}\left(\tfrac{2-y}{2}\right)\right]_0^1 \quad [a = 2]$$
$$= -\tfrac{1}{2}\sqrt{3} + 2\cos^{-1}\left(\tfrac{1}{2}\right) - 2\cos^{-1} 1$$
$$= -\tfrac{\sqrt{3}}{2} + 2\left(\tfrac{\pi}{3}\right) - 2(0) = \tfrac{2\pi}{3} - \tfrac{\sqrt{3}}{2}$$

Another method (without calculus): Note that $\theta = \angle CAB = \frac{\pi}{3}$, so the area is

$$(\text{area of sector } OAB) - (\text{area of } \triangle ABC) = \tfrac{1}{2}\left(2^2\right)\tfrac{\pi}{3} - \tfrac{1}{2}(1)\sqrt{3} = \tfrac{2\pi}{3} - \tfrac{\sqrt{3}}{2}$$

2. $y = \pm\sqrt{x^3 - x^4} \quad \Rightarrow$ The loop of the curve is symmetric about $y = 0$, and therefore $\overline{y} = 0$. At each point x where $0 \le x \le 1$, the lamina has a vertical length of $\sqrt{x^3 - x^4} - \left(-\sqrt{x^3 - x^4}\right) = 2\sqrt{x^3 - x^4}$. Therefore,

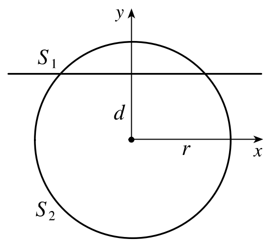
$$\overline{x} = \frac{\int_0^1 x \cdot 2\sqrt{x^3 - x^4}\,dx}{\int_0^1 2\sqrt{x^3 - x^4}\,dx} = \frac{\int_0^1 x\sqrt{x^3 - x^4}\,dx}{\int_0^1 \sqrt{x^3 - x^4}\,dx}.$$ We evaluate the integrals separately:

$$\int_0^1 x\sqrt{x^3 - x^4}\,dx = \int_0^1 x^{5/2}\sqrt{1-x}\,dx$$
$$= \int_0^{\pi/2} 2\sin^6\theta\cos\theta\sqrt{1-\sin^2\theta}\,d\theta \qquad \left[\begin{array}{c}\sin\theta = \sqrt{x}, \cos\theta\,d\theta = dx/(2\sqrt{x}\,), \\ 2\sin\theta\,\cos\theta\,d\theta = dx\end{array}\right]$$
$$= \int_0^{\pi/2} 2\sin^6\theta\cos^2\theta\,d\theta = \int_0^{\pi/2} 2\left[\tfrac{1}{2}\left(1-\cos 2\theta\right)\right]^3 \tfrac{1}{2}(1+\cos 2\theta)d\theta$$
$$= \int_0^{\pi/2} \tfrac{1}{8}(1 - 2\cos 2\theta + 2\cos^3 2\theta - \cos^4 2\theta)\,d\theta$$
$$= \int_0^{\pi/2} \tfrac{1}{8}\left[1 - 2\cos 2\theta + 2\cos 2\theta(1-\sin^2 2\theta) - \tfrac{1}{4}(1+\cos 4\theta)^2\right]d\theta$$
$$= \tfrac{1}{8}\left[\theta - \tfrac{1}{3}\sin^3 2\theta\right]_0^{\pi/2} - \tfrac{1}{32}\int_0^{\pi/2}\left(1 + 2\cos 4\theta + \cos^2 4\theta\right)d\theta$$
$$= \tfrac{\pi}{16} - \tfrac{1}{32}\left[\theta + \tfrac{1}{2}\sin 4\theta\right]_0^{\pi/2} - \tfrac{1}{64}\int_0^{\pi/2}(1+\cos 8\theta)\,d\theta$$
$$= \tfrac{\pi}{16} - \tfrac{1}{32}\left[\theta + \tfrac{1}{2}\sin 4\theta\right]_0^{\pi/2} - \tfrac{1}{64}\int_0^{\pi/2}(1+\cos 8\theta)\,d\theta$$
$$= \tfrac{3\pi}{64} - \tfrac{1}{64}\left[\theta + \tfrac{1}{8}\sin 8\theta\right]_0^{\pi/2} = \tfrac{5\pi}{128}$$

$$\int_0^1 \sqrt{x^3 - x^4}\,dx = \int_0^1 x^{3/2}\sqrt{1-x}\,dx = \int_0^{\pi/2} 2\sin^4\theta\cos\theta\sqrt{1-\sin^2\theta}\,d\theta \qquad [\sin\theta = \sqrt{x}\,]$$
$$= \int_0^{\pi/2} 2\sin^4\theta\cos^2\theta\,d\theta = \int_0^{\pi/2} 2\cdot\tfrac{1}{4}(1-\cos 2\theta)^2\cdot\tfrac{1}{2}(1+\cos 2\theta)\,d\theta$$
$$= \int_0^{\pi/2} \tfrac{1}{4}(1 - \cos 2\theta - \cos^2 2\theta + \cos^3 2\theta)\,d\theta$$
$$= \int_0^{\pi/2} \tfrac{1}{4}\left[1 - \cos 2\theta - \tfrac{1}{2}(1+\cos 4\theta) + \cos 2\theta(1-\sin^2 2\theta)\right]d\theta$$
$$= \tfrac{1}{4}\left[\tfrac{\theta}{2} - \tfrac{1}{8}\sin 4\theta - \tfrac{1}{6}\sin^3 2\theta\right]_0^{\pi/2} = \tfrac{\pi}{16}$$

Therefore, $\overline{x} = \dfrac{5\pi/128}{\pi/16} = \dfrac{5}{8}$, and $(\overline{x}, \overline{y}) = \left(\frac{5}{8}, 0\right)$.

3. (a) The two spherical zones, whose surface areas we will call S_1 and S_2, are generated by rotation about the y-axis of circular arcs, as indicated in the figure. The arcs are the upper and lower portions of the circle $x^2 + y^2 = r^2$ that are obtained when the circle is cut with the line $y = d$. The portion of the upper arc in the first quadrant is sufficient to generate the upper spherical zone. That portion of the arc can be described by the relation $x = \sqrt{r^2 - y^2}$ for $d \le y \le r$. Thus, $dx/dy = -y/\sqrt{r^2 - y^2}$ and



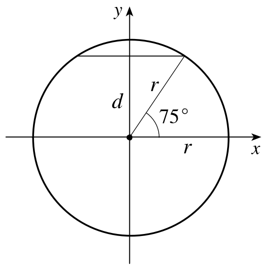
$$ds = \sqrt{1 + \left(\frac{dx}{dy}\right)^2}\,dy = \sqrt{1 + \frac{y^2}{r^2 - y^2}}\,dy = \sqrt{\frac{r^2}{r^2 - y^2}}\,dy = \frac{r\,dy}{\sqrt{r^2 - y^2}}$$

From Formula 8.2.8 we have

$$S_1 = \int_d^r 2\pi x\sqrt{1 + \left(\frac{dx}{dy}\right)^2}\,dy = \int_d^r 2\pi\,\sqrt{r^2 - y^2}\,\frac{r\,dy}{\sqrt{r^2 - y^2}} = \int_d^r 2\pi r\,dy = 2\pi r(r - d)$$

Similarly, we can compute $S_2 = \int_{-r}^{d} 2\pi x\,\sqrt{1 + (dx/dy)^2}\,dy = \int_{-r}^{d} 2\pi r\,dy = 2\pi r(r + d)$. Note that $S_1 + S_2 = 4\pi r^2$, the surface area of the entire sphere.

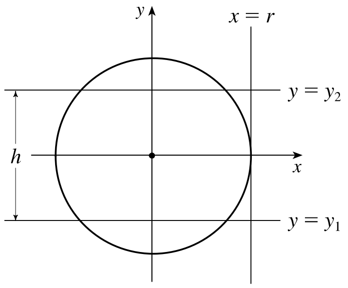
(b) $r = 3960$ mi and $d = r\,(\sin 75^\circ) \approx 3825$ mi, so the surface area of the Arctic Ocean is about $2\pi r(r - d) \approx 2\pi(3960)(135) \approx 3.36\times 10^6$ mi^2.



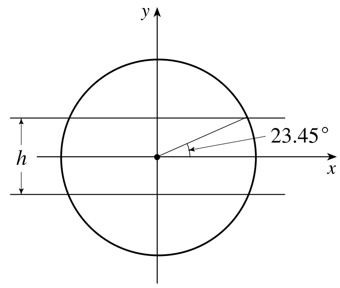
(c) The area on the sphere lies between planes $y = y_1$ and $y = y_2$, where $y_2 - y_1 = h$. Thus, we compute the surface area on the sphere to be $S = \int_{y_1}^{y_2} 2\pi x\sqrt{1 + \left(\frac{dx}{dy}\right)^2}\,dy = \int_{y_1}^{y_2} 2\pi r\,dy = 2\pi r(y_2 - y_1) = 2\pi rh$.

This equals the lateral area of a cylinder of radius r and height h, since such a cylinder is obtained by rotating the line $x = r$ about the y-axis, so the surface area of the cylinder between the planes $y = y_1$ and $y = y_2$ is

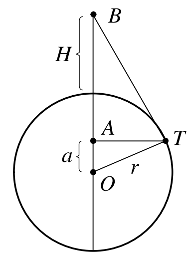
$$A = \int_{y_1}^{y_2} 2\pi x\sqrt{1 + \left(\frac{dx}{dy}\right)^2}\,dy = \int_{y_1}^{y_2} 2\pi r\,\sqrt{1 + 0^2}\,dy$$
$$= 2\pi r y\Big|_{y=y_1}^{y_2} = 2\pi r(y_2 - y_1) = 2\pi rh$$



(d) $h = 2r \sin 23.45^\circ \approx 3152$ mi, so the surface area of the Torrid Zone is $2\pi rh \approx 2\pi(3960)(3152) \approx 7.84 \times 10^7$ mi^2.



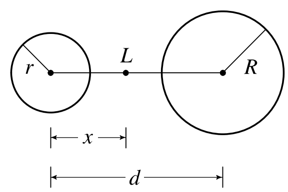
4. (a) Since the right triangles OAT and OTB are similar, we have $\dfrac{r+H}{r} = \dfrac{r}{a} \Rightarrow$ $a = \dfrac{r^2}{r+H}$. The surface area visible from B is $S = \int_a^r 2\pi x \sqrt{1 + (dx/dy)^2}\, dy$.



From $x^2 + y^2 = r^2$, we get $\dfrac{d}{dy}(x^2 + y^2) = \dfrac{d}{dy}(r^2) \Rightarrow 2x\dfrac{dx}{dy} + 2y = 0 \Rightarrow$ $\dfrac{dx}{dy} = -\dfrac{y}{x}$ and $1 + \left(\dfrac{dx}{dy}\right)^2 = \dfrac{x^2 + y^2}{x^2} = \dfrac{r^2}{x^2}$. Thus,

$$S = \int_a^r 2\pi x \cdot \frac{r}{x}\, dy = 2\pi r(r-a) = 2\pi r\left(r - \frac{r^2}{r+H}\right) = 2\pi r^2\left(1 - \frac{r}{r+H}\right) = 2\pi r^2 \cdot \frac{H}{r+H} = \frac{2\pi r^2 H}{r+H}.$$

(b) Assume $R \geq r$. If a light is placed at point L, at a distance x from the center of the sphere of radius r, then from part (a) we find that the total illuminated area A on the two spheres is [with $r + H = x$ and $r + H = d - x$].



$$A(x) = \frac{2\pi r^2(x-r)}{x} + \frac{2\pi R^2(d-x-R)}{d-x} \quad [r \leq x \leq d - R]. \quad \frac{A(x)}{2\pi} = r^2\left(1 - \frac{r}{x}\right) + R^2\left(1 - \frac{R}{d-x}\right),$$

so $A'(x) = 0 \Leftrightarrow 0 = r^2 \cdot \dfrac{r}{x^2} + R^2 \cdot \dfrac{-R}{(d-x)^2} \Leftrightarrow \dfrac{r^3}{x^2} = \dfrac{R^3}{(d-x)^2} \Leftrightarrow \dfrac{(d-x)^2}{x^2} = \dfrac{R^3}{r^3} \Leftrightarrow$

$$\left(\frac{d}{x} - 1\right)^2 = \left(\frac{R}{r}\right)^3 \Rightarrow \frac{d}{x} - 1 = \left(\frac{R}{r}\right)^{3/2} \Leftrightarrow \frac{d}{x} = 1 + \left(\frac{R}{r}\right)^{3/2} \Leftrightarrow x = x^* = \frac{d}{1 + (R/r)^{3/2}}.$$

Now $A'(x) = 2\pi\left(\dfrac{r^3}{x^2} - \dfrac{R^3}{(d-x)^2}\right) \Rightarrow A''(x) = 2\pi\left(-\dfrac{2r^3}{x^3} - \dfrac{2R^3}{(d-x)^3}\right)$ and $A''(x^*) < 0$, so we have a local maximum at $x = x^*$.

However, x^* may not be an allowable value of x — we must show that x^* is between r and $d - R$.

(1) $x^* \geq r \Leftrightarrow \dfrac{d}{1 + (R/r)^{3/2}} \geq r \Leftrightarrow d \geq r + R\sqrt{R/r}$

(2) $x^* \leq d - R \Leftrightarrow \dfrac{d}{1 + (R/r)^{3/2}} \leq d - R \Leftrightarrow d \leq d - R + d\left(\dfrac{R}{r}\right)^{3/2} - R\left(\dfrac{R}{r}\right)^{3/2} \Leftrightarrow$

$R + R\left(\dfrac{R}{r}\right)^{3/2} \leq d\left(\dfrac{R}{r}\right)^{3/2} \Leftrightarrow d \geq \dfrac{R}{(R/r)^{3/2}} + R = R + r\sqrt{r/R}$, but

$R + r\sqrt{r/R} \leq R + r$, and since $d > r + R$ [given], we conclude that $x^* \leq d - R$.

[continued]

Thus, from (1) and (2), x^* is not an allowable value of x if $d < r + R\sqrt{R/r}$.

So A may have a maximum at $x = r$, x^*, or $d - R$.

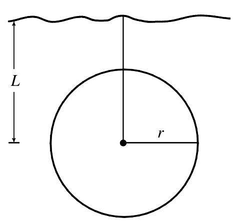
$$A(r) = \frac{2\pi R^2(d-r-R)}{d-r} \qquad \text{and} \qquad A(d-R) = \frac{2\pi r^2(d-r-R)}{d-R}$$

$A(r) > A(d-R) \Leftrightarrow \dfrac{R^2}{d-r} > \dfrac{r^2}{d-R} \Leftrightarrow R^2(d-R) > r^2(d-r) \Leftrightarrow R^2 d - R^3 > r^2 d - r^3 \Leftrightarrow$ $R^2 d - r^2 d > R^3 - r^3 \Leftrightarrow d(R-r)(R+r) > (R-r)(R^2 + Rr + r^2) \Leftrightarrow d > (R^2 + Rr + r^2)/(R+r) \Leftrightarrow$ $d > [(R+r)^2 - Rr]/(R+r) \Leftrightarrow d > R + r - Rr/(R+r)$. Now $R + r - Rr/(R+r) < R + r$, and we know that $d > R + r$, so we conclude that $A(r) > A(d-R)$.

In conclusion, A has an absolute maximum at $x = x^*$ provided $d \geq r + R\sqrt{R/r}$; otherwise, A has its maximum at $x = r$.

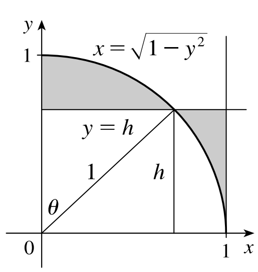
5. (a) Choose a vertical x-axis pointing downward with its origin at the surface. In order to calculate the pressure at depth z, consider n subintervals of the interval $[0, z]$ by points x_i and choose a point $x_i^* \in [x_{i-1}, x_i]$ for each i. The thin layer of water lying between depth x_{i-1} and depth x_i has a density of approximately $\rho(x_i^*)$, so the weight of a piece of that layer with unit cross-sectional area is $\rho(x_i^*)g\,\Delta x$. The total weight of a column of water extending from the surface to depth z (with unit cross-sectional area) would be approximately $\sum_{i=1}^{n} \rho(x_i^*)g\,\Delta x$. The estimate becomes exact if we take the limit as $n \to \infty$; weight (or force) per unit area at depth z is $W = \lim_{n\to\infty} \sum_{i=1}^{n} \rho(x_i^*)g\,\Delta x$. In other words, $P(z) = \int_0^z \rho(x)g\,dx$. More generally, if we make no assumptions about the location of the origin, then $P(z) = P_0 + \int_0^z \rho(x)g\,dx$, where P_0 is the pressure at $x = 0$. Differentiating, we get $dP/dz = \rho(z)g$.

(b)



$$\begin{aligned} F &= \int_{-r}^{r} P(L+x)\cdot 2\sqrt{r^2-x^2}\,dx \\ &= \int_{-r}^{r} \left(P_0 + \int_0^{L+x} \rho_0 e^{z/H} g\,dz\right)\cdot 2\sqrt{r^2-x^2}\,dx \\ &= P_0 \int_{-r}^{r} 2\sqrt{r^2-x^2}\,dx + \rho_0 gH \int_{-r}^{r}\left(e^{(L+x)/H} - 1\right)\cdot 2\sqrt{r^2-x^2}\,dx \\ &= (P_0 - \rho_0 gH)\int_{-r}^{r} 2\sqrt{r^2-x^2}\,dx + \rho_0 gH \int_{-r}^{r} e^{(L+x)/H}\cdot 2\sqrt{r^2-x^2}\,dx \\ &= (P_0 - \rho_0 gH)(\pi r^2) + \rho_0 gHe^{L/H}\int_{-r}^{r} e^{x/H}\cdot 2\sqrt{r^2-x^2}\,dx \end{aligned}$$

6. The problem can be reduced to finding the line which minimizes the shaded area in the diagram. An equation of the circle in the first quadrant is $x = \sqrt{1-y^2}$. So the shaded area is



$$\begin{aligned} A(h) &= \int_0^h \left(1 - \sqrt{1-y^2}\right)dy + \int_h^1 \sqrt{1-y^2}\,dy \\ &= \int_0^h \left(1 - \sqrt{1-y^2}\right)dy - \int_1^h \sqrt{1-y^2}\,dy \end{aligned}$$

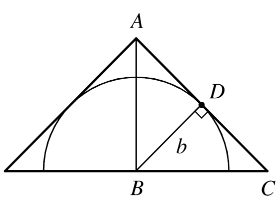
$A'(h) = 1 - \sqrt{1-h^2} - \sqrt{1-h^2}$ [by FTC] $= 1 - 2\sqrt{1-h^2}$

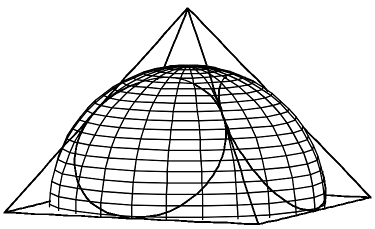
$A' = 0 \Leftrightarrow \sqrt{1-h^2} = \frac{1}{2} \Rightarrow 1 - h^2 = \frac{1}{4} \Rightarrow h^2 = \frac{3}{4} \Rightarrow h = \frac{\sqrt{3}}{2}$.

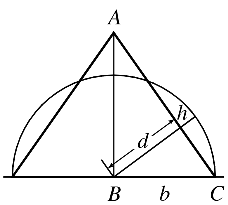
$A''(h) = -2 \cdot \frac{1}{2}(1 - h^2)^{-1/2}(-2h) = \dfrac{2h}{\sqrt{1 - h^2}} > 0$, so $h = \dfrac{\sqrt{3}}{2}$ gives a minimum value of A.

Note: Another strategy is to use the angle θ as the variable (see the diagram above) and show that $A = \theta + \cos\theta - \frac{\pi}{4} - \frac{1}{2}\sin 2\theta$, which is minimized when $\theta = \frac{\pi}{6}$.

7. To find the height of the pyramid, we use similar triangles. The first figure shows a cross-section of the pyramid passing through the top and through two opposite corners of the square base. Now $|BD| = b$, since it is a radius of the sphere, which has diameter $2b$ since it is tangent to the opposite sides of the square base. Also, $|AD| = b$ since $\triangle ADB$ is isosceles. So the height is $|AB| = \sqrt{b^2 + b^2} = \sqrt{2}\,b$.





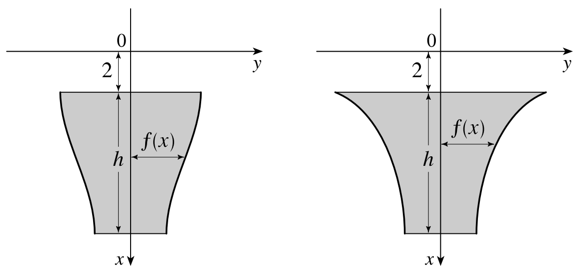


We first observe that the shared volume is equal to half the volume of the sphere, minus the sum of the four equal volumes (caps of the sphere) cut off by the triangular faces of the pyramid. See Exercise 6.2.49 for a derivation of the formula for the volume of a cap of a sphere. To use the formula, we need to find the perpendicular distance h of each triangular face from the surface of the sphere. We first find the distance d from the center of the sphere to one of the triangular faces. The third figure shows a cross-section of the pyramid through the top and through the midpoints of opposite sides of the square base. From similar triangles we find that

$$\frac{d}{b} = \frac{|AB|}{|AC|} = \frac{\sqrt{2}\,b}{\sqrt{b^2 + \left(\sqrt{2}\,b\right)^2}} \quad \Rightarrow \quad d = \frac{\sqrt{2}\,b^2}{\sqrt{3b^2}} = \frac{\sqrt{6}}{3}\,b$$

So $h = b - d = b - \frac{\sqrt{6}}{3}b = \frac{3 - \sqrt{6}}{3}b$. So, using the formula $V = \pi h^2(r - h/3)$ from Exercise 6.2.49 with $r = b$, we find that the volume of each of the caps is $\pi\left(\frac{3 - \sqrt{6}}{3}b\right)^2\left(b - \frac{3 - \sqrt{6}}{3 \cdot 3}b\right) = \frac{15 - 6\sqrt{6}}{9} \cdot \frac{6 + \sqrt{6}}{9}\pi b^3 = \left(\frac{2}{3} - \frac{7}{27}\sqrt{6}\right)\pi b^3$. So, using our first observation, the shared volume is $V = \frac{1}{2}\left(\frac{4}{3}\pi b^3\right) - 4\left(\frac{2}{3} - \frac{7}{27}\sqrt{6}\right)\pi b^3 = \left(\frac{28}{27}\sqrt{6} - 2\right)\pi b^3$.

8. Orient the positive x-axis as in the figure. Suppose that the plate has height h and is symmetric about the x-axis. At depth x below the water $(2 \le x \le 2 + h)$, let the width of the plate be $2f(x)$. Now each of the n horizontal strips has height h/n and the ith strip $(1 \le i \le n)$ goes from



$x = 2 + \left(\dfrac{i-1}{n}\right)h$ to $x = 2 + \left(\dfrac{i}{n}\right)h$. The hydrostatic force on the ith strip is $F(i) = \displaystyle\int_{2+[(i-1)/n]h}^{2+(i/n)h} 62.5x[2f(x)]\,dx$.

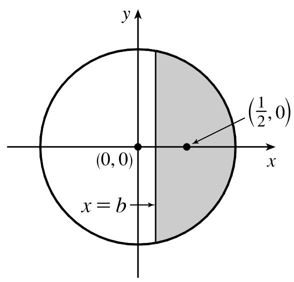
[continued]

If we now let $x[2f(x)] = k$ (a constant) so that $f(x) = k/(2x)$, then

$$F(i) = \int_{2+[(i-1)/n]h}^{2+(i/n)h} 62.5k\,dx = 62.5k\left[\,x\,\right]_{2+[(i-1)/n]h}^{2+(i/n)h} = 62.5k\left[\left(2+\frac{i}{n}h\right)-\left(2+\frac{i-1}{n}\,h\right)\right] = 62.5k\left(\frac{h}{n}\right)$$

So the hydrostatic force on the ith strip is independent of i, that is, the force on each strip is the same. So the plate can be shaped as shown in the figure. (In fact, the required condition is satisfied whenever the plate has width C/x at depth x, for some constant C. Many shapes are possible.)

9. We can assume that the cut is made along a vertical line $x = b > 0$, that the disk's boundary is the circle $x^2 + y^2 = 1$, and that the center of mass of the smaller piece (to the right of $x = b$) is $\left(\frac{1}{2}, 0\right)$. We wish to find b to two decimal places. We have $\dfrac{1}{2} = \overline{x} = \dfrac{\int_b^1 x \cdot 2\sqrt{1-x^2}\,dx}{\int_b^1 2\sqrt{1-x^2}\,dx}$. Evaluating the



numerator gives us $-\int_b^1 (1-x^2)^{1/2}(-2x)\,dx = -\frac{2}{3}\left[\left(1-x^2\right)^{3/2}\right]_b^1 = -\frac{2}{3}\left[0-\left(1-b^2\right)^{3/2}\right] = \frac{2}{3}(1-b^2)^{3/2}$.

Using Formula 30 in the table of integrals, we find that the denominator is

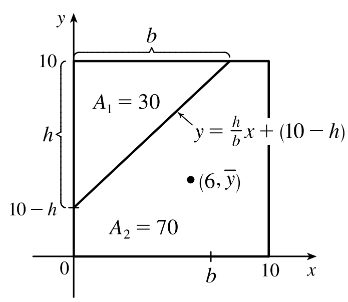
$\left[x\sqrt{1-x^2}+\sin^{-1}x\right]_b^1 = \left(0+\frac{\pi}{2}\right)-\left(b\sqrt{1-b^2}+\sin^{-1}b\right)$. Thus, we have $\dfrac{1}{2} = \overline{x} = \dfrac{\frac{2}{3}(1-b^2)^{3/2}}{\frac{\pi}{2}-b\sqrt{1-b^2}-\sin^{-1}b}$, or, equivalently, $\frac{2}{3}(1-b^2)^{3/2} = \frac{\pi}{4}-\frac{1}{2}b\sqrt{1-b^2}-\frac{1}{2}\sin^{-1}b$. Solving this equation numerically with a calculator or CAS, we obtain $b \approx 0.138173$, or $b = 0.14$ m to two decimal places.

10. $A_1 = 30 \quad\Rightarrow\quad \frac{1}{2}bh = 30 \quad\Rightarrow\quad bh = 60.$

$\overline{x} = 6 \quad\Rightarrow\quad \dfrac{1}{A_2}\displaystyle\int_0^{10} xf(x)\,dx = 6 \quad\Rightarrow$

$\displaystyle\int_0^b x\left(\frac{h}{b}x+10-h\right)dx + \int_b^{10} x(10)\,dx = 6(70) \quad\Rightarrow$

$\displaystyle\int_0^b \left(\frac{h}{b}x^2+10x-hx\right)dx + 10\cdot\tfrac{1}{2}\left[x^2\right]_b^{10} = 420 \quad\Rightarrow$



$\left[\dfrac{h}{3b}x^3+5x^2-\dfrac{h}{2}x^2\right]_0^b + 5(100-b^2) = 420 \quad\Rightarrow\quad \frac{1}{3}hb^2+5b^2-\frac{1}{2}hb^2+500-5b^2 = 420 \quad\Rightarrow\quad 80 = \frac{1}{6}hb^2 \quad\Rightarrow$

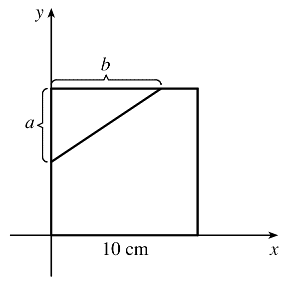
$480 = (hb)b \quad\Rightarrow\quad 480 = 60b \quad\Rightarrow\quad b = 8$. So $h = \frac{60}{8} = \frac{15}{2}$ and an equation of the line is

$y = \dfrac{15/2}{8}x + \left(10-\dfrac{15}{2}\right) = \dfrac{15}{16}x+\dfrac{5}{2}$. Now

$$\begin{aligned}\overline{y} &= \frac{1}{A_2}\int_0^{10}\tfrac{1}{2}[f(x)]^2\,dx = \frac{1}{70\cdot 2}\left[\int_0^8\left(\frac{15}{16}x+\frac{5}{2}\right)^2dx+\int_8^{10}(10)^2\,dx\right]\\ &= \tfrac{1}{140}\left[\int_0^8\left(\tfrac{225}{256}x^2+\tfrac{75}{16}x+\tfrac{25}{4}\right)dx+100(10-8)\right] = \tfrac{1}{140}\left(\left[\tfrac{225}{768}x^3+\tfrac{75}{32}x^2+\tfrac{25}{4}x\right]_0^8+200\right)\\ &= \tfrac{1}{140}(150+150+50+200) = \tfrac{550}{140} = \tfrac{55}{14}\end{aligned}$$

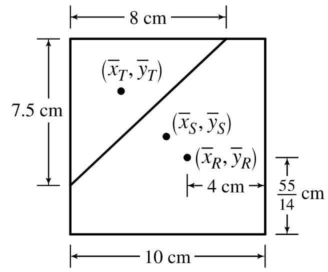
[continued]

Another solution: Assume that the right triangle cut from the square has legs a cm and b cm long as shown. The triangle has area 30 cm^2, so $\frac{1}{2}ab = 30$ and $ab = 60$. We place the square in the first quadrant of the xy-plane as shown, and we let T, R, and S denote the triangle, the remaining portion of the square, and the full square, respectively. By symmetry, the centroid of S is $(5, 5)$. By Exercise 8.3.39, the centroid of T is $\left(\dfrac{b}{3}, 10 - \dfrac{a}{3}\right)$.



We are given that the centroid of R is $(6, c)$, where c is to be determined. We take the density of the square to be 1, so that areas can be used as masses. Then T has mass $m_T = 30$, S has mass $m_S = 100$, and R has mass $m_R = m_S - m_T = 70$. As in Exercises 40 and 41 of Section 8.3, we view S as consisting of a mass m_T at the centroid $(\overline{x}_T, \overline{y}_T)$ of T and a mass R at the centroid $(\overline{x}_R, \overline{y}_R)$ of R. Then $\overline{x}_S = \dfrac{m_T\overline{x}_T + m_R\overline{x}_R}{m_T + m_R}$ and $\overline{y}_S = \dfrac{m_T\overline{y}_T + m_R\overline{y}_R}{m_T + m_R}$; that is, $5 = \dfrac{30(b/3) + 70(6)}{100}$ and $5 = \dfrac{30(10 - a/3) + 70c}{100}$.

Solving the first equation for b, we get $b = 8$ cm. Since $ab = 60$ cm^2, it follows that $a = \frac{60}{8} = 7.5$ cm. Now the second equation says that $70c = 200 + 10a$, so $7c = 20 + a = \frac{55}{2}$ and $c = \frac{55}{14} = 3.9\overline{285714}$ cm. The solution is depicted in the figure.

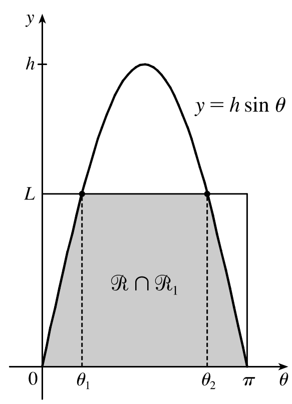


11. If $h = L$, then $P = \dfrac{\text{area under } y = L\sin\theta}{\text{area of rectangle}} = \dfrac{\int_0^\pi L\sin\theta\,d\theta}{\pi L} = \dfrac{[-\cos\theta]_0^\pi}{\pi} = \dfrac{-(-1)+1}{\pi} = \dfrac{2}{\pi}$.

If $h = L/2$, then $P = \dfrac{\text{area under } y = \frac{1}{2}L\sin\theta}{\text{area of rectangle}} = \dfrac{\int_0^\pi \frac{1}{2}L\sin\theta\,d\theta}{\pi L} = \dfrac{[-\cos\theta]_0^\pi}{2\pi} = \dfrac{2}{2\pi} = \dfrac{1}{\pi}$.

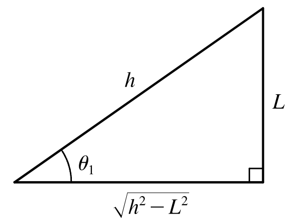
12. (a) The total set of possibilities can be identified with the rectangular region $\mathcal{R} = \{(\theta, y) \mid 0 \le y < L, 0 \le \theta < \pi\}$. Even when $h > L$, the needle intersects at least one line if and only if $y \le h\sin\theta$. Let $\mathcal{R}_1 = \{(\theta, y) \mid 0 \le y \le h\sin\theta, 0 \le \theta < \pi\}$. When $h \le L$, $\mathcal{R}_1$ is contained in $\mathcal{R}$, but that is no longer true when $h > L$. Thus, the probability that the needle intersects a line becomes

$$P = \frac{\text{area}(\mathcal{R} \cap \mathcal{R}_1)}{\text{area}(\mathcal{R})} = \frac{\text{area}(\mathcal{R} \cap \mathcal{R}_1)}{\pi L}$$



When $h > L$, the curve $y = h\sin\theta$ intersects the line $y = L$ twice—at $\left(\sin^{-1}(L/h), L\right)$ and at $\left(\pi - \sin^{-1}(L/h), L\right)$. Set $\theta_1 = \sin^{-1}(L/h)$ and $\theta_2 = \pi - \theta_1$. Then

$$\text{area}(\mathcal{R} \cap \mathcal{R}_1) = \int_0^{\theta_1} h \sin\theta \, d\theta + \int_{\theta_1}^{\theta_2} L \, d\theta + \int_{\theta_2}^{\pi} h \sin\theta \, d\theta$$
$$= 2\int_0^{\theta_1} h \sin\theta \, d\theta + L(\theta_2 - \theta_1) = 2h\left[-\cos\theta\right]_0^{\theta_1} + L(\pi - 2\theta_1)$$
$$= 2h(1 - \cos\theta_1) + L(\pi - 2\theta_1)$$
$$= 2h\left(1 - \frac{\sqrt{h^2 - L^2}}{h}\right) + L\left[\pi - 2\sin^{-1}\left(\frac{L}{h}\right)\right]$$
$$= 2h - 2\sqrt{h^2 - L^2} + \pi L - 2L\sin^{-1}\left(\frac{L}{h}\right)$$

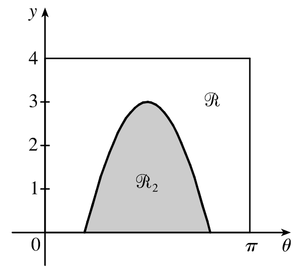


We are told that $L = 4$ and $h = 7$, so $\text{area}(\mathcal{R} \cap \mathcal{R}_1) = 14 - 2\sqrt{33} + 4\pi - 8\sin^{-1}\left(\frac{4}{7}\right) \approx 10.21128$ and $P = \frac{1}{4\pi}\,\text{area}(\mathcal{R} \cap \mathcal{R}_1) \approx 0.812588$. (By comparison, $P = \frac{2}{\pi} \approx 0.636620$ when $h = L$, as shown in the solution to Problem 11.)

(b) The needle intersects at least two lines when $y + L \le h \sin\theta$; that is, when $y \le h\sin\theta - L$. Set $\mathcal{R}_2 = \{(\theta, y) \mid 0 \le y \le h\sin\theta - L, 0 \le \theta < \pi\}$. Then the probability that the needle intersects at least two lines is

$$P_2 = \frac{\text{area}(\mathcal{R} \cap \mathcal{R}_2)}{\text{area}(\mathcal{R})} = \frac{\text{area}(\mathcal{R} \cap \mathcal{R}_2)}{\pi L}$$

When $L = 4$ and $h = 7$, $\mathcal{R}_2$ is contained in $\mathcal{R}$ (see the figure). Thus,



$$P_2 = \frac{1}{4\pi}\,\text{area}(\mathcal{R}_2) = \frac{1}{4\pi}\int_{\sin^{-1}(4/7)}^{\pi - \sin^{-1}(4/7)} (7\sin\theta - 4)\, d\theta = \tfrac{1}{4\pi} \cdot 2\int_{\sin^{-1}(4/7)}^{\pi/2} (7\sin\theta - 4)\, d\theta$$
$$= \frac{1}{2\pi}\left[-7\cos\theta - 4\theta\right]_{\sin^{-1}(4/7)}^{\pi/2} = \frac{1}{2\pi}\left[0 - 2\pi + 7\frac{\sqrt{33}}{7} + 4\sin^{-1}\left(\tfrac{4}{7}\right)\right] = \frac{\sqrt{33} + 4\sin^{-1}\left(\frac{4}{7}\right) - 2\pi}{2\pi}$$
$$\approx 0.301497$$

(c) The needle intersects at least three lines when $y + 2L \le h\sin\theta$: that is, when $y \le h\sin\theta - 2L$. Set $\mathcal{R}_3 = \{(\theta, y) \mid 0 \le y \le h\sin\theta - 2L, 0 \le \theta < \pi\}$. Then the probability that the needle intersects at least three lines is $P_3 = \dfrac{\text{area}(\mathcal{R} \cap \mathcal{R}_3)}{\text{area}(\mathcal{R})} = \dfrac{\text{area}(\mathcal{R} \cap \mathcal{R}_3)}{\pi L}$. (At this point, the generalization to P_n, n any positive integer, should be clear.)

Under the given assumption,

$$P_3 = \frac{1}{\pi L}\,\text{area}(\mathcal{R}_3) = \frac{1}{\pi L}\int_{\sin^{-1}(2L/h)}^{\pi - \sin^{-1}(2L/h)} (h\sin\theta - 2L)\, d\theta = \frac{2}{\pi L}\int_{\sin^{-1}(2L/h)}^{\pi/2} (h\sin\theta - 2L)\, d\theta$$
$$= \frac{2}{\pi L}\left[-h\cos\theta - 2L\theta\right]_{\sin^{-1}(2L/h)}^{\pi/2} = \frac{2}{\pi L}\left[-\pi L + \sqrt{h^2 - 4L^2} + 2L\sin^{-1}(2L/h)\right]$$

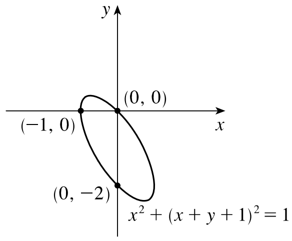
Note that the probability that a needle touches exactly one line is $P_1 - P_2$, the probability that it touches exactly two lines is $P_2 - P_3$, and so on.

13. Solve for y: $x^2 + (x+y+1)^2 = 1 \;\Rightarrow\; (x+y+1)^2 = 1 - x^2 \;\Rightarrow\; x+y+1 = \pm\sqrt{1-x^2} \;\Rightarrow$

$y = -x - 1 \pm \sqrt{1-x^2}$.

$$A = \int_{-1}^{1} \left[\left(-x-1+\sqrt{1-x^2}\right) - \left(-x-1-\sqrt{1-x^2}\right)\right] dx$$

$$= \int_{-1}^{1} 2\sqrt{1-x^2}\,dx = 2\left(\tfrac{\pi}{2}\right) \quad \left[\begin{matrix}\text{area of}\\\text{semicircle}\end{matrix}\right] \quad = \pi$$



$$\overline{x} = \frac{1}{A}\int_{-1}^{1} x \cdot 2\sqrt{1-x^2}\,dx = 0 \quad [\text{odd integrand}]$$

$$\overline{y} = \frac{1}{A}\int_{-1}^{1} \frac{1}{2}\left[\left(-x-1+\sqrt{1-x^2}\right)^2 - \left(-x-1-\sqrt{1-x^2}\right)^2\right] dx = \frac{1}{\pi}\int_{-1}^{1} \frac{1}{2}\left(-4x\sqrt{1-x^2} - 4\sqrt{1-x^2}\right) dx$$

$$= -\frac{2}{\pi}\int_{-1}^{1}\left(x\sqrt{1-x^2} + \sqrt{1-x^2}\right) dx = -\frac{2}{\pi}\int_{-1}^{1} x\sqrt{1-x^2}\,dx - \frac{2}{\pi}\int_{-1}^{1}\sqrt{1-x^2}\,dx$$

$$= -\frac{2}{\pi}(0) \quad [\text{odd integrand}] \quad -\frac{2}{\pi}\left(\frac{\pi}{2}\right) \quad \left[\begin{matrix}\text{area of}\\\text{semicircle}\end{matrix}\right] \quad = -1$$

Thus, as expected, the centroid is $(\overline{x}, \overline{y}) = (0, -1)$. We might expect this result since the centroid of an ellipse is located at its center.

9 □ DIFFERENTIAL EQUATIONS

9.1 Modeling with Differential Equations

1. $y = \frac{2}{3}e^x + e^{-2x} \quad \Rightarrow \quad y' = \frac{2}{3}e^x - 2e^{-2x}$. To show that y is a solution of the differential equation, we will substitute the expressions for y and y' in the left-hand side of the equation and show that the left-hand side is equal to the right-hand side.

$$\begin{aligned}\text{LHS} = y' + 2y &= \tfrac{2}{3}e^x - 2e^{-2x} + 2\left(\tfrac{2}{3}e^x + e^{-2x}\right) = \tfrac{2}{3}e^x - 2e^{-2x} + \tfrac{4}{3}e^x + 2e^{-2x} \\ &= \tfrac{6}{3}e^x = 2e^x = \text{RHS}\end{aligned}$$

2. $y = -t\cos t - t \quad \Rightarrow \quad dy/dt = -t(-\sin t) + \cos t(-1) - 1 = t\sin t - \cos t - 1$.

$$\begin{aligned}\text{LHS} = t\,\frac{dy}{dt} &= t(t\sin t - \cos t - 1) = t^2\sin t - t\cos t - t \\ &= t^2 \sin t + y = \text{RHS},\end{aligned}$$

so y is a solution of the differential equation. Also $y(\pi) = -\pi\cos\pi - \pi = -\pi(-1) - \pi = \pi - \pi = 0$, so the initial condition is satisfied.

3. (a) $y = e^{rx} \quad \Rightarrow \quad y' = re^{rx} \quad \Rightarrow \quad y'' = r^2e^{rx}$. Substituting these expressions into the differential equation $2y'' + y' - y = 0$, we get $2r^2e^{rx} + re^{rx} - e^{rx} = 0 \quad \Rightarrow \quad (2r^2 + r - 1)e^{rx} = 0 \quad \Rightarrow$ $(2r - 1)(r + 1) = 0 \quad$ [since e^{rx} is never zero] $\quad \Rightarrow \quad r = \frac{1}{2}$ or -1.

(b) Let $r_1 = \frac{1}{2}$ and $r_2 = -1$, so we need to show that every member of the family of functions $y = ae^{x/2} + be^{-x}$ is a solution of the differential equation $2y'' + y' - y = 0$.

$y = ae^{x/2} + be^{-x} \quad \Rightarrow \quad y' = \frac{1}{2}ae^{x/2} - be^{-x} \quad \Rightarrow \quad y'' = \frac{1}{4}ae^{x/2} + be^{-x}$.

$$\begin{aligned}\text{LHS} = 2y'' + y' - y &= 2\left(\tfrac{1}{4}ae^{x/2} + be^{-x}\right) + \left(\tfrac{1}{2}ae^{x/2} - be^{-x}\right) - \left(ae^{x/2} + be^{-x}\right) \\ &= \tfrac{1}{2}ae^{x/2} + 2be^{-x} + \tfrac{1}{2}ae^{x/2} - be^{-x} - ae^{x/2} - be^{-x} \\ &= \left(\tfrac{1}{2}a + \tfrac{1}{2}a - a\right)e^{x/2} + (2b - b - b)e^{-x} \\ &= 0 = \text{RHS}\end{aligned}$$

4. (a) $y = \cos kt \quad \Rightarrow \quad y' = -k\sin kt \quad \Rightarrow \quad y'' = -k^2\cos kt$. Substituting these expressions into the differential equation $4y'' = -25y$, we get $4(-k^2\cos kt) = -25(\cos kt) \quad \Rightarrow \quad (25 - 4k^2)\cos kt = 0 \quad$ [for all t] $\quad \Rightarrow \quad 25 - 4k^2 = 0 \quad \Rightarrow$ $k^2 = \frac{25}{4} \quad \Rightarrow \quad k = \pm\frac{5}{2}$.

(b) $y = A\sin kt + B\cos kt \quad \Rightarrow \quad y' = Ak\cos kt - Bk\sin kt \quad \Rightarrow \quad y'' = -Ak^2\sin kt - Bk^2\cos kt$.

The given differential equation $4y'' = -25y$ is equivalent to $4y'' + 25y = 0$. Thus,

$$\begin{aligned}\text{LHS} = 4y'' + 25y &= 4(-Ak^2\sin kt - Bk^2\cos kt) + 25(A\sin kt + B\cos kt) \\ &= -4Ak^2\sin kt - 4Bk^2\cos kt + 25A\sin kt + 25B\cos kt \\ &= (25 - 4k^2)A\sin kt + (25 - 4k^2)B\cos kt \\ &= 0 \quad \text{since } k^2 = \tfrac{25}{4}.\end{aligned}$$

5. (a) $y = \sin x \quad\Rightarrow\quad y' = \cos x \quad\Rightarrow\quad y'' = -\sin x$.

LHS $= y'' + y = -\sin x + \sin x = 0 \neq \sin x$, so $y = \sin x$ **is not** a solution of the differential equation.

(b) $y = \cos x \quad\Rightarrow\quad y' = -\sin x \quad\Rightarrow\quad y'' = -\cos x$.

LHS $= y'' + y = -\cos x + \cos x = 0 \neq \sin x$, so $y = \cos x$ **is not** a solution of the differential equation.

(c) $y = \frac{1}{2}x\sin x \quad\Rightarrow\quad y' = \frac{1}{2}(x\cos x + \sin x) \quad\Rightarrow\quad y'' = \frac{1}{2}(-x\sin x + \cos x + \cos x)$.

LHS $= y'' + y = \frac{1}{2}(-x\sin x + 2\cos x) + \frac{1}{2}x\sin x = \cos x \neq \sin x$, so $y = \frac{1}{2}x\sin x$ **is not** a solution of the differential equation.

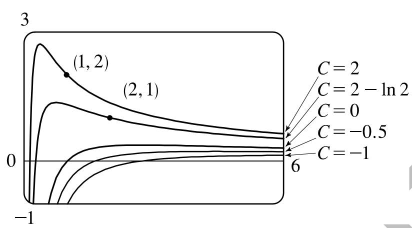
(d) $y = -\frac{1}{2}x\cos x \quad\Rightarrow\quad y' = -\frac{1}{2}(-x\sin x + \cos x) \quad\Rightarrow\quad y'' = -\frac{1}{2}(-x\cos x - \sin x - \sin x)$.

LHS $= y'' + y = -\frac{1}{2}(-x\cos x - 2\sin x) + \left(-\frac{1}{2}x\cos x\right) = \sin x =$ RHS, so $y = -\frac{1}{2}x\cos x$ **is** a solution of the differential equation.

6. (a) $y = \dfrac{\ln x + C}{x} \quad\Rightarrow\quad y' = \dfrac{x \cdot (1/x) - (\ln x + C)}{x^2} = \dfrac{1 - \ln x - C}{x^2}$.

$$\text{LHS} = x^2y' + xy = x^2 \cdot \frac{1 - \ln x - C}{x^2} + x \cdot \frac{\ln x + C}{x}$$
$$= 1 - \ln x - C + \ln x + C = 1 = \text{RHS}, \text{ so } y \text{ is a solution of the differential equation.}$$

(b)



A few notes about the graph of $y = (\ln x + C)/x$:

(1) There is a vertical asymptote of $x = 0$.

(2) There is a horizontal asymptote of $y = 0$.

(3) $y = 0 \quad\Rightarrow\quad \ln x + C = 0 \quad\Rightarrow\quad x = e^{-C}$, so there is an x-intercept at e^{-C}.

(4) $y' = 0 \quad\Rightarrow\quad \ln x = 1 - C \quad\Rightarrow\quad x = e^{1-C}$, so there is a local maximum at $x = e^{1-C}$.

(c) $y(1) = 2 \quad\Rightarrow\quad 2 = \dfrac{\ln 1 + C}{1} \quad\Rightarrow\quad 2 = C$, so the solution is $y = \dfrac{\ln x + 2}{x}$ [shown in part (b)].

(d) $y(2) = 1 \quad\Rightarrow\quad 1 = \dfrac{\ln 2 + C}{2} \quad\Rightarrow\quad 2 + \ln 2 + C \quad\Rightarrow\quad C = 2 - \ln 2$, so the solution is $y = \dfrac{\ln x + 2 - \ln 2}{x}$ [shown in part (b)].

7. (a) Since the derivative $y' = -y^2$ is always negative (or 0 if $y = 0$), the function y must be decreasing (or equal to 0) on any interval on which it is defined.

(b) $y = \dfrac{1}{x + C} \quad\Rightarrow\quad y' = -\dfrac{1}{(x + C)^2}$. LHS $= y' = -\dfrac{1}{(x + C)^2} = -\left(\dfrac{1}{x + C}\right)^2 = -y^2 =$ RHS

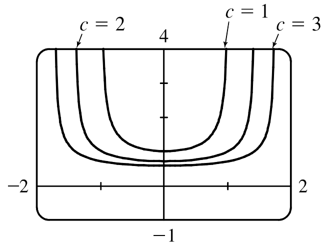
(c) $y = 0$ is a solution of $y' = -y^2$ that is not a member of the family in part (b).

(d) If $y(x) = \dfrac{1}{x + C}$, then $y(0) = \dfrac{1}{0 + C} = \dfrac{1}{C}$. Since $y(0) = 0.5$, $\dfrac{1}{C} = \dfrac{1}{2} \quad\Rightarrow\quad C = 2$, so $y = \dfrac{1}{x + 2}$.

8. (a) If x is close to 0, then xy^3 is close to 0, and hence, y' is close to 0. Thus, the graph of y must have a tangent line that is nearly horizontal. If x is large, then xy^3 is large, and the graph of y must have a tangent line that is nearly vertical. (In both cases, we assume reasonable values for y.)

(b) $y = (c - x^2)^{-1/2} \quad \Rightarrow \quad y' = x(c - x^2)^{-3/2}$. RHS $= xy^3 = x[(c - x^2)^{-1/2}]^3 = x(c - x^2)^{-3/2} = y' =$ LHS

(c)



When x is close to 0, y' is also close to 0.

As x gets larger, so does $|y'|$.

(d) $y(0) = (c - 0)^{-1/2} = 1/\sqrt{c}$ and $y(0) = 2 \quad \Rightarrow \quad \sqrt{c} = \frac{1}{2} \quad \Rightarrow \quad c = \frac{1}{4}$, so $y = \left(\frac{1}{4} - x^2\right)^{-1/2}$.

9. (a) $\dfrac{dP}{dt} = 1.2P\left(1 - \dfrac{P}{4200}\right)$. Now $\dfrac{dP}{dt} > 0 \quad \Rightarrow \quad 1 - \dfrac{P}{4200} > 0$ [assuming that $P > 0$] $\Rightarrow \quad \dfrac{P}{4200} < 1 \quad \Rightarrow$

$P < 4200 \quad \Rightarrow$ the population is increasing for $0 < P < 4200$.

(b) $\dfrac{dP}{dt} < 0 \quad \Rightarrow \quad P > 4200$

(c) $\dfrac{dP}{dt} = 0 \quad \Rightarrow \quad P = 4200$ or $P = 0$

10. (a) $\dfrac{dv}{dt} = -v[v^2 - (1 + a)v + a] = -v(v - a)(v - 1)$, so $\dfrac{dv}{dt} = 0 \quad \Leftrightarrow \quad v = 0, a$, or 1.

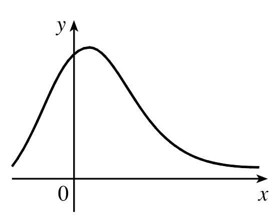
(b) With $0 < a < 1$, $dv/dt = -v(v - a)(v - 1) > 0 \quad \Leftrightarrow \quad v < 0$ or $a < v < 1$, so v is increasing on $(-\infty, 0)$ and $(a, 1)$.

(c) With $0 < a < 1$, $dv/dt = -v(v - a)(v - 1) < 0 \quad \Leftrightarrow \quad 0 < v < a$ or $v > 1$, so v is decreasing on $(0, a)$ and $(1, \infty)$.

11. (a) This function is increasing *and* also decreasing. But $dy/dt = e^t(y - 1)^2 \geq 0$ for all t, implying that the graph of the solution of the differential equation cannot be decreasing on any interval.

(b) When $y = 1$, $dy/dt = 0$, but the graph does not have a horizontal tangent line.

12. The graph for this exercise is shown in the figure at the right.



A. $y' = 1 + xy > 1$ for points in the first quadrant, but we can see that $y' < 0$ for some points in the first quadrant.

B. $y' = -2xy = 0$ when $x = 0$, but we can see that $y' > 0$ for $x = 0$. Thus, equations A and B are incorrect, so the correct equation is C.

C. $y' = 1 - 2xy$ seems reasonable since:

(1) When $x = 0$, y' could be 1.

(2) When $x < 0$, y' could be greater than 1.

(3) Solving $y' = 1 - 2xy$ for y gives us $y = \dfrac{1 - y'}{2x}$. If y' takes on small negative values, then as $x \to \infty$, $y \to 0^+$, as shown in the figure.

13. (a) $y' = 1 + x^2 + y^2 \geq 1$ and $y' \to \infty$ as $x \to \infty$. The only curve satisfying these conditions is labeled III.

(b) $y' = xe^{-x^2-y^2} > 0$ if $x > 0$ and $y' < 0$ if $x < 0$. The only curve with negative tangent slopes when $x < 0$ and positive tangent slopes when $x > 0$ is labeled I.

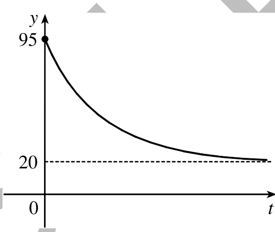
(c) $y' = \dfrac{1}{1 + e^{x^2+y^2}} > 0$ and $y' \to 0$ as $x \to \infty$. The only curve satisfying these conditions is labeled IV.

(d) $y' = \sin(xy)\,\cos(xy) = 0$ if $y = 0$, which is the solution graph labeled II.

14. (a) The coffee cools most quickly as soon as it is removed from the heat source. The rate of cooling decreases toward 0 since the coffee approaches room temperature.

(b) $\dfrac{dy}{dt} = k(y - R)$, where k is a proportionality constant, y is the temperature of the coffee, and R is the room temperature. The initial condition is $y(0) = 95^\circ\text{C}$. The answer and the model support each other because as y approaches R, dy/dt approaches 0, so the model seems appropriate.

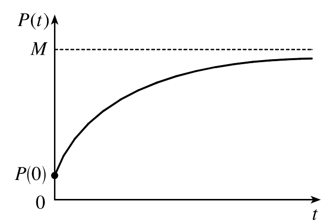
(c)



15. (a) P increases most rapidly at the beginning, since there are usually many simple, easily-learned sub-skills associated with learning a skill. As t increases, we would expect dP/dt to remain positive, but decrease. This is because as time progresses, the only points left to learn are the more difficult ones.

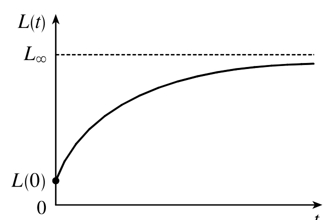
(b) $\dfrac{dP}{dt} = k(M - P)$ is always positive, so the level of performance P is increasing. As P gets close to M, dP/dt gets close to 0; that is, the performance levels off, as explained in part (a).

(c)



16. (a) $\dfrac{dL}{dt} = k(L_\infty - L)$. Assuming $L_\infty > L$, we have $k > 0$ and $dL/dt > 0$ for all t.

(b)



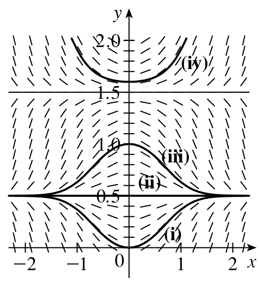
17. If $c(t) = c_s\left(1 - e^{-\alpha t^{1-b}}\right) = c_s - c_s e^{-\alpha t^{1-b}}$ for $t > 0$, where $k > 0$, $c_s > 0$, $0 < b < 1$, and $\alpha = k/(1 - b)$, then

$$\frac{dc}{dt} = c_s\left[0 - e^{-\alpha t^{1-b}} \cdot \frac{d}{dt}\left(-\alpha t^{1-b}\right)\right] = -c_s e^{-\alpha t^{1-b}} \cdot (-\alpha)(1-b)t^{-b} = \frac{\alpha(1-b)}{t^b}\, c_s\, e^{-\alpha t^{1-b}} = \frac{k}{t^b}(c_s - c).$$ The

equation for c indicates that as t increases, c approaches c_s. The differential equation indicates that as t increases, the rate of increase of c decreases steadily and approaches 0 as c approaches c_s.

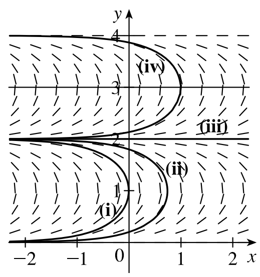
9.2 Direction Fields and Euler's Method

1. (a)



(b) It appears that the constant functions $y = 0.5$ and $y = 1.5$ are equilibrium solutions. Note that these two values of y satisfy the given differential equation $y' = x\cos\pi y$.

2. (a)



(b) It appears that the constant functions $y = 0$, $y = 2$, and $y = 4$ are equilibrium solutions. Note that these three values of y satisfy the given differential equation $y' = \tan\left(\frac{1}{2}\pi y\right)$.

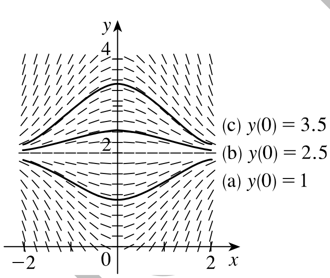
3. $y' = 2 - y$. The slopes at each point are independent of x, so the slopes are the same along each line parallel to the x-axis. Thus, III is the direction field for this equation. Note that for $y = 2$, $y' = 0$.

4. $y' = x(2 - y) = 0$ on the lines $x = 0$ and $y = 2$. Direction field I satisfies these conditions.

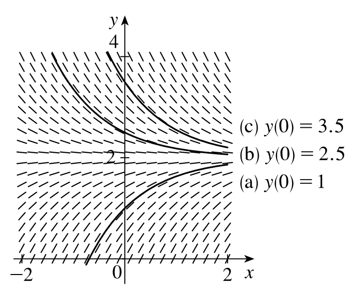
5. $y' = x + y - 1 = 0$ on the line $y = -x + 1$. Direction field IV satisfies this condition. Notice also that on the line $y = -x$ we have $y' = -1$, which is true in IV.

6. $y' = \sin x \sin y = 0$ on the lines $x = 0$ and $y = 0$, and $y' > 0$ for $0 < x < \pi$, $0 < y < \pi$. Direction field II satisfies these conditions.

7.



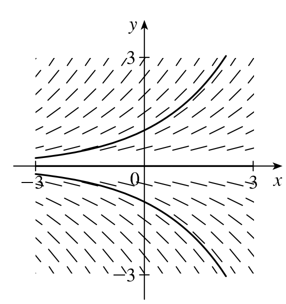
8.



9.

x	y	$y' = \frac{1}{2}y$
0	0	0
0	1	0.5
0	2	1
0	-3	-1.5
0	-2	-1

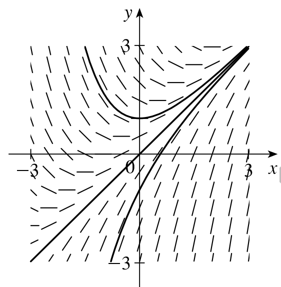
Note that for $y = 0$, $y' = 0$. The three solution curves sketched go through $(0, 0)$, $(0, 1)$, and $(0, -1)$.



10.

x	y	$y' = x - y + 1$
-1	0	0
-1	-1	1
0	0	1
0	1	0
0	2	-1
0	-1	2
0	-2	3
1	0	2
1	1	1

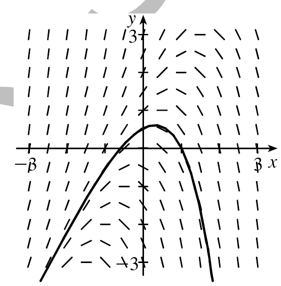
Note that $y' = 0$ for $y = x + 1$ and that $y' = 1$ for $y = x$. For any constant value of x, y' decreases as y increases and y' increases as y decreases. The three solution curves sketched go through $(0, 0)$, $(0, 1)$, and $(0, -1)$.



11.

x	y	$y' = y - 2x$
-2	-2	2
-2	2	6
2	2	-2
2	-2	-6

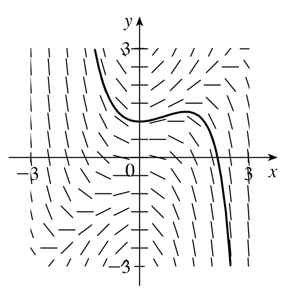
Note that $y' = 0$ for any point on the line $y = 2x$. The slopes are positive to the left of the line and negative to the right of the line. The solution curve in the graph passes through $(1, 0)$.



12.

x	y	$y' = xy - x^2$
2	3	2
-2	-3	2
± 2	0	-4
0	0	0
2	2	0

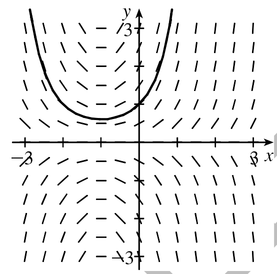
$y' = xy - x^2 = x(y - x)$, so $y' = 0$ for $x = 0$ and $y = x$. The slopes are positive only in the regions in quadrants I and III that are bounded by $x = 0$ and $y = x$. The solution curve in the graph passes through $(0, 1)$.



13.

x	y	$y' = y + xy$
0	± 2	± 2
1	± 2	± 4
-3	± 2	∓ 4

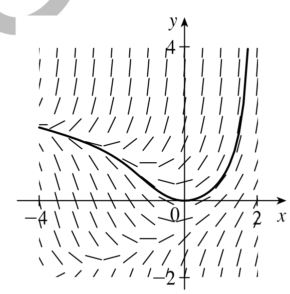
Note that $y' = y(x+1) = 0$ for any point on $y = 0$ or on $x = -1$. The slopes are positive when the factors y and $x + 1$ have the same sign and negative when they have opposite signs. The solution curve in the graph passes through $(0, 1)$.



14.

x	y	$y' = x + y^2$
-2	± 1	-1
-2	± 2	2
2	± 1	3
0	± 2	4
0	0	0

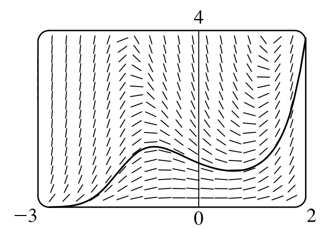
Note that $y' = x + y^2 = 0$ only on the parabola $x = -y^2$. The slopes are positive "outside" $x = -y^2$ and negative "inside" $x = -y^2$. The solution curve in the graph passes through $(0, 0)$.



15. $y' = x^2 y - \frac{1}{2}y^2$ and $y(0) = 1$.

In Maple, use the following commands to obtain a similar figure.

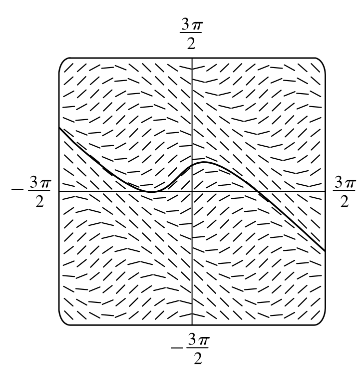
```
with(DETools):
ODE:=diff(y(x),x)=x^2*y(x)-(1/2)*y(x)^2;
ivs:=[y(0)=1];
DEplot({ODE},y(x),x=-3..2,y=0..4,ivs,linecolor=black);
```



16. $y' = \cos(x + y)$ and $y(0) = 1$.

In Maple, use the following commands to obtain a similar figure.

```
with(DETools):
ODE:=diff(y(x),x)=cos(x+y(x));
ivs:=[y(0)=1];
DEplot({ODE},y(x),x=-1.5*Pi..1.5*Pi,y=-1.5*Pi..1.5*Pi,
ivs,linecolor=black);
```



17. 
The direction field is for the differential equation $y' = y^3 - 4y$.

$L = \lim_{t\to\infty} y(t)$ exists for $-2 \le c \le 2$;

$L = \pm 2$ for $c = \pm 2$ and $L = 0$ for $-2 < c < 2$.

For other values of c, L does not exist.

18. 
Note that when $f(y) = 0$ on the graph in the text, we have $y' = f(y) = 0$; so we get horizontal segments at $y = \pm 1, \pm 2$. We get segments with negative slopes only for $1 < |y| < 2$. All other segments have positive slope. For the limiting behavior of solutions:

- If $y(0) > 2$, then $\lim_{t\to\infty} y = \infty$ and $\lim_{t\to-\infty} y = 2$.
- If $1 < y(0) < 2$, then $\lim_{t\to\infty} y = 1$ and $\lim_{t\to-\infty} y = 2$.
- If $-1 < y(0) < 1$, then $\lim_{t\to\infty} y = 1$ and $\lim_{t\to-\infty} y = -1$.
- If $-2 < y(0) < -1$, then $\lim_{t\to\infty} y = -2$ and $\lim_{t\to-\infty} y = -1$.
- If $y < -2$, then $\lim_{t\to\infty} y = -2$ and $\lim_{t\to-\infty} y = -\infty$.

19. (a) $y' = F(x, y) = y$ and $y(0) = 1 \;\Rightarrow\; x_0 = 0, y_0 = 1$.

(i) $h = 0.4$ and $y_1 = y_0 + hF(x_0, y_0) \;\Rightarrow\; y_1 = 1 + 0.4 \cdot 1 = 1.4$. $x_1 = x_0 + h = 0 + 0.4 = 0.4$, so $y_1 = y\,(0.4) = 1.4$.

(ii) $h = 0.2 \;\Rightarrow\; x_1 = 0.2$ and $x_2 = 0.4$, so we need to find y_2.

$y_1 = y_0 + hF(x_0, y_0) = 1 + 0.2y_0 = 1 + 0.2 \cdot 1 = 1.2$,

$y_2 = y_1 + hF(x_1, y_1) = 1.2 + 0.2y_1 = 1.2 + 0.2 \cdot 1.2 = 1.44$.

(iii) $h = 0.1 \;\Rightarrow\; x_4 = 0.4$, so we need to find y_4. $y_1 = y_0 + hF(x_0, y_0) = 1 + 0.1y_0 = 1 + 0.1 \cdot 1 = 1.1$,

$y_2 = y_1 + hF(x_1, y_1) = 1.1 + 0.1y_1 = 1.1 + 0.1 \cdot 1.1 = 1.21$,

$y_3 = y_2 + hF(x_2, y_2) = 1.21 + 0.1y_2 = 1.21 + 0.1 \cdot 1.21 = 1.331$,

$y_4 = y_3 + hF(x_3, y_3) = 1.331 + 0.1y_3 = 1.331 + 0.1 \cdot 1.331 = 1.4641$.

(b) 
We see that the estimates are underestimates since they are all below the graph of $y = e^x$.

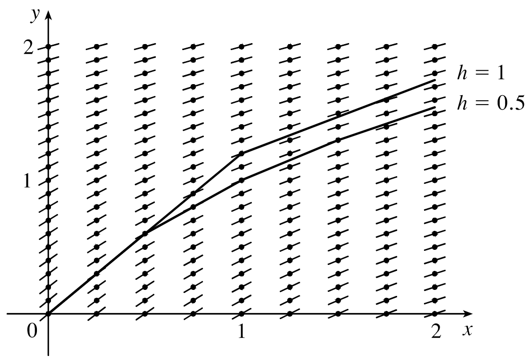
(c) (i) For $h = 0.4$: (exact value) − (approximate value) $= e^{0.4} - 1.4 \approx 0.0918$

(ii) For $h = 0.2$: (exact value) − (approximate value) $= e^{0.4} - 1.44 \approx 0.0518$

(iii) For $h = 0.1$: (exact value) − (approximate value) $= e^{0.4} - 1.4641 \approx 0.0277$

Each time the step size is halved, the error estimate also appears to be halved (approximately).

20.



As x increases, the slopes decrease and all of the estimates are above the true values. Thus, all of the estimates are overestimates.

21. $h = 0.5$, $x_0 = 1$, $y_0 = 0$, and $F(x, y) = y - 2x$.

Note that $x_1 = x_0 + h = 1 + 0.5 = 1.5$, $x_2 = 2$, and $x_3 = 2.5$.

$y_1 = y_0 + hF(x_0, y_0) = 0 + 0.5F(1, 0) = 0.5[0 - 2(1)] = -1.$

$y_2 = y_1 + hF(x_1, y_1) = -1 + 0.5F(1.5, -1) = -1 + 0.5[-1 - 2(1.5)] = -3.$

$y_3 = y_2 + hF(x_2, y_2) = -3 + 0.5F(2, -3) = -3 + 0.5[-3 - 2(2)] = -6.5.$

$y_4 = y_3 + hF(x_3, y_3) = -6.5 + 0.5F(2.5, -6.5) = -6.5 + 0.5[-6.5 - 2(2.5)] = -12.25.$

22. $h = 0.2$, $x_0 = 0$, $y_0 = 1$, and $F(x, y) = x^2y - \frac{1}{2}y^2$. Note that $x_1 = x_0 + h = 0 + 0.2 = 0.2$, $x_2 = 0.4$, $x_3 = 0.6$, $x_4 = 0.8$, and $x_5 = 1$.

$y_1 = y_0 + hF(x_0, y_0) = 1 + 0.2F(0, 1) = 1 + 0.2\left[0^2(1) - \frac{1}{2}(1)^2\right] = 1 + 0.2\left(-\frac{1}{2}\right) = 0.9.$

$y_2 = y_1 + hF(x_1, y_1) = 0.9 + 0.2F(0.2, 0.9) = 0.9 + 0.2\left[(0.2)^2(0.9) - \frac{1}{2}(0.9)^2\right] = 0.8262.$

$y_3 = y_2 + hF(x_2, y_2) = 0.8262 + 0.2F(0.4, 0.8262) = 0.8262 + 0.2\left[(0.4)^2(0.8262) - \frac{1}{2}(0.8262)^2\right] = 0.784377756.$

$y_4 = y_3 + hF(x_3, y_3) = 0.784377756 + 0.2F(0.6, 0.784377756) \approx 0.779328108.$

$y_5 = y_4 + hF(x_4, y_4) \approx 0.779328108 + 0.2F(0.8, 0.779328108) \approx 0.818346876.$

Thus, $y(1) \approx 0.8183$.

23. $h = 0.1$, $x_0 = 0$, $y_0 = 1$, and $F(x, y) = y + xy$.

Note that $x_1 = x_0 + h = 0 + 0.1 = 0.1$, $x_2 = 0.2$, $x_3 = 0.3$, and $x_4 = 0.4$.

$y_1 = y_0 + hF(x_0, y_0) = 1 + 0.1F(0, 1) = 1 + 0.1[1 + (0)(1)] = 1.1.$

$y_2 = y_1 + hF(x_1, y_1) = 1.1 + 0.1F(0.1, 1.1) = 1.1 + 0.1[1.1 + (0.1)(1.1)] = 1.221.$

$y_3 = y_2 + hF(x_2, y_2) = 1.221 + 0.1F(0.2, 1.221) = 1.221 + 0.1[1.221 + (0.2)(1.221)] = 1.36752.$

$$y_4 = y_3 + hF(x_3, y_3) = 1.36752 + 0.1F(0.3, 1.36752) = 1.36752 + 0.1[1.36752 + (0.3)(1.36752)] = 1.5452976.$$

$$y_5 = y_4 + hF(x_4, y_4) = 1.5452976 + 0.1F(0.4, 1.5452976) = 1.5452976 + 0.1[1.5452976 + (0.4)(1.5452976)] = 1.761639264.$$

Thus, $y(0.5) \approx 1.7616$.

24. (a) $h = 0.2$, $x_0 = 0$, $y_0 = 0$, and $F(x, y) = \cos(x + y)$. Note that $x_1 = x_0 + h = 0 + 0.2 = 0.2$, $x_2 = 0.4$, and $x_3 = 0.6$.

$y_1 = y_0 + hF(x_0, y_0) = 0 + 0.2F(0, 0) = 0.2\cos(0 + 0) = 0.2(1) = 0.2$.

$y_2 = y_1 + hF(x_1, y_1) = 0.2 + 0.2F(0.2, 0.2) = 0.2 + 0.2\cos(0.4) \approx 0.3842121988$.

$y_3 = y_2 + hF(x_2, y_2) \approx 0.3842 + 0.2F(0.4, 0.3842) \approx 0.5258011763$.

Thus, $y(0.6) \approx 0.5258$.

(b) Now use $h = 0.1$. For $1 \leq n \leq 6$, $x_n = 0.n$.

$y_1 = y_0 + hF(x_0, y_0) = 0 + 0.1\cos(0 + 0) = 0.1(1) = 0.1$.

$y_2 = y_1 + hF(x_1, y_1) = 0.1 + 0.1\cos(0.2) \approx 0.1980$.

$y_3 = y_2 + hF(x_2, y_2) \approx 0.1980 + 0.1\cos(0.3980) \approx 0.2902$.

$y_4 = y_3 + hF(x_3, y_3) \approx 0.2902 + 0.1\cos(0.5902) \approx 0.3733$.

$y_5 = y_4 + hF(x_4, y_4) \approx 0.3733 + 0.1\cos(0.7733) \approx 0.4448$.

$y_6 = y_5 + hF(x_5, y_5) \approx 0.4448 + 0.1\cos(0.9448) \approx 0.5034$.

Thus, $y(0.6) \approx 0.5034$.

25. (a) $dy/dx + 3x^2y = 6x^2 \quad \Rightarrow \quad y' = 6x^2 - 3x^2y$. Store this expression in Y_1 and use the following simple program to evaluate $y(1)$ for each part, using $\text{H} = h = 1$ and $\text{N} = 1$ for part (i), $\text{H} = 0.1$ and $\text{N} = 10$ for part (ii), and so forth.

$h \to$ H: 0 → X: 3 → Y:
For(I, 1, N): Y + H × Y_1 → Y: X + H → X:
End(loop):
Display Y. [To see all iterations, include this statement in the loop.]

(i) $\text{H} = 1, \text{N} = 1 \quad \Rightarrow \quad y(1) = 3$

(ii) $\text{H} = 0.1, \text{N} = 10 \quad \Rightarrow \quad y(1) \approx 2.3928$

(iii) $\text{H} = 0.01, \text{N} = 100 \quad \Rightarrow \quad y(1) \approx 2.3701$

(iv) $\text{H} = 0.001, \text{N} = 1000 \quad \Rightarrow \quad y(1) \approx 2.3681$

(b) $y = 2 + e^{-x^3} \quad \Rightarrow \quad y' = -3x^2e^{-x^3}$

$$\text{LHS} = y' + 3x^2y = -3x^2e^{-x^3} + 3x^2\left(2 + e^{-x^3}\right) = -3x^2e^{-x^3} + 6x^2 + 3x^2e^{-x^3} = 6x^2 = \text{RHS}$$

$y(0) = 2 + e^{-0} = 2 + 1 = 3$

(c) The exact value of $y(1)$ is $2 + e^{-1^3} = 2 + e^{-1}$.

(i) For $h = 1$: (exact value) − (approximate value) $= 2 + e^{-1} - 3 \approx -0.6321$

(ii) For $h = 0.1$: (exact value) − (approximate value) $= 2 + e^{-1} - 2.3928 \approx -0.0249$

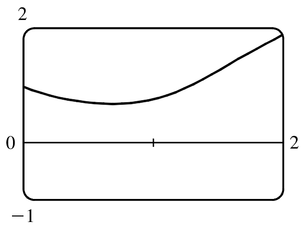
(iii) For $h = 0.01$: (exact value) − (approximate value) $= 2 + e^{-1} - 2.3701 \approx -0.0022$

(iv) For $h = 0.001$: (exact value) − (approximate value) $= 2 + e^{-1} - 2.3681 \approx -0.0002$

In (ii)–(iv), it seems that when the step size is divided by 10, the error estimate is also divided by 10 (approximately).

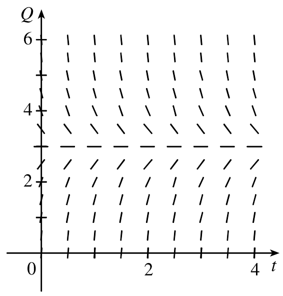
26. (a) We use the program from the solution to Exercise 25 with $Y_1 = x^3 - y^3$, $H = 0.01$, and $N = \frac{2-0}{0.01} = 200$. With $(x_0, y_0) = (0, 1)$, we get $y(2) \approx 1.9000$.

(b)



Notice from the graph that $y(2) \approx 1.9$, which serves as a check on our calculation in part (a).

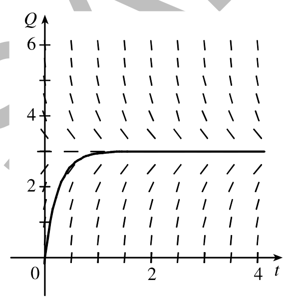
27. (a) $R\,\dfrac{dQ}{dt} + \dfrac{1}{C}Q = E(t)$ becomes $5Q' + \dfrac{1}{0.05}Q = 60$ or $Q' + 4Q = 12$.



(b) From the graph, it appears that the limiting value of the charge Q is about 3.

(c) If $Q' = 0$, then $4Q = 12 \;\Rightarrow\; Q = 3$ is an equilibrium solution.

(d)



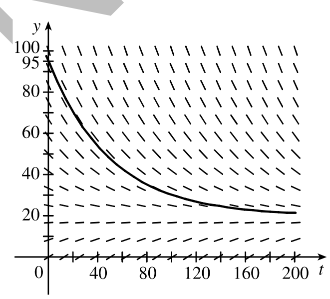
(e) $Q' + 4Q = 12 \;\Rightarrow\; Q' = 12 - 4Q$. Now $Q(0) = 0$, so $t_0 = 0$ and $Q_0 = 0$.

$$Q_1 = Q_0 + hF(t_0, Q_0) = 0 + 0.1(12 - 4 \cdot 0) = 1.2$$
$$Q_2 = Q_1 + hF(t_1, Q_1) = 1.2 + 0.1(12 - 4 \cdot 1.2) = 1.92$$
$$Q_3 = Q_2 + hF(t_2, Q_2) = 1.92 + 0.1(12 - 4 \cdot 1.92) = 2.352$$
$$Q_4 = Q_3 + hF(t_3, Q_3) = 2.352 + 0.1(12 - 4 \cdot 2.352) = 2.6112$$
$$Q_5 = Q_4 + hF(t_4, Q_4) = 2.6112 + 0.1(12 - 4 \cdot 2.6112) = 2.76672$$

Thus, $Q_5 = Q(0.5) \approx 2.77$ C.

28. (a) From Exercise 9.1.14, we have $dy/dt = k(y - R)$. We are given that $R = 20°\text{C}$ and $dy/dt = -1°\text{C/min}$ when $y = 70°\text{C}$. Thus, $-1 = k(70 - 20) \;\Rightarrow\; k = -\frac{1}{50}$ and the differential equation becomes $dy/dt = -\frac{1}{50}(y - 20)$.

(b)



The limiting value of the temperature is 20°C; that is, the temperature of the room.

(c) From part (a), $dy/dt = -\frac{1}{50}(y - 20)$. With $t_0 = 0$, $y_0 = 95$, and $h = 2$ min, we get

$$\begin{aligned}
y_1 &= y_0 + hF(t_0, y_0) = 95 + 2\left[-\tfrac{1}{50}(95 - 20)\right] = 92 \\
y_2 &= y_1 + hF(t_1, y_1) = 92 + 2\left[-\tfrac{1}{50}(92 - 20)\right] = 89.12 \\
y_3 &= y_2 + hF(t_2, y_2) = 89.12 + 2\left[-\tfrac{1}{50}(89.12 - 20)\right] = 86.3552 \\
y_4 &= y_3 + hF(t_3, y_3) = 86.3552 + 2\left[-\tfrac{1}{50}(86.3552 - 20)\right] = 83.700992 \\
y_5 &= y_4 + hF(t_4, y_4) = 83.700992 + 2\left[-\tfrac{1}{50}(83.700992 - 20)\right] = 81.15295232
\end{aligned}$$

Thus, $y(10) \approx 81.15°\text{C}$.

9.3 Separable Equations

1. $\dfrac{dy}{dx} = 3x^2y^2 \;\Rightarrow\; \dfrac{dy}{y^2} = 3x^2\,dx \;\; [y \neq 0] \;\Rightarrow\; \int y^{-2}\,dy = \int 3x^2\,dx \;\Rightarrow\; -y^{-1} = x^3 + C \;\Rightarrow$

$\dfrac{-1}{y} = x^3 + C \;\Rightarrow\; y = \dfrac{-1}{x^3 + C}$. $y = 0$ is also a solution.

2. $\dfrac{dy}{dx} = x\sqrt{y} \;\Rightarrow\; \dfrac{dy}{\sqrt{y}} = x\,dx \;\; [y \neq 0] \;\Rightarrow\; \int y^{-1/2}\,dy = \int x\,dx \;\Rightarrow\; 2y^{1/2} = \frac{1}{2}x^2 + K \;\Rightarrow$

$\sqrt{y} = \frac{1}{4}x^2 + \frac{1}{2}K \;\Rightarrow\; y = \left(\frac{1}{4}x^2 + C\right)^2$, where $C = \frac{1}{2}K$. $y = 0$ is also a solution.

3. $xyy' = x^2 + 1 \;\Rightarrow\; xy\,\dfrac{dy}{dx} = x^2 + 1 \;\Rightarrow\; y\,dy = \dfrac{x^2 + 1}{x}\,dx \;\; [x \neq 0] \;\Rightarrow\; \displaystyle\int y\,dy = \int \left(x + \frac{1}{x}\right)dx \;\Rightarrow$

$\frac{1}{2}y^2 = \frac{1}{2}x^2 + \ln|x| + K \;\Rightarrow\; y^2 = x^2 + 2\ln|x| + 2K \;\Rightarrow\; y = \pm\sqrt{x^2 + 2\ln|x| + C}$, where $C = 2K$.

4. $y' + xe^y = 0 \;\Rightarrow\; \dfrac{dy}{dx} = -xe^y \;\Rightarrow\; e^{-y}\,dy = -x\,dx \;\Rightarrow\; \int e^{-y}\,dy = \int -x\,dx \;\Rightarrow\; -e^{-y} = -\frac{1}{2}x^2 + C \;\Rightarrow$

$e^{-y} = \frac{1}{2}x^2 - C \;\Rightarrow\; -y = \ln\left(\frac{1}{2}x^2 - C\right) \;\Rightarrow\; y = -\ln\left(\frac{1}{2}x^2 - C\right)$

5. $(e^y - 1)y' = 2 + \cos x \;\Rightarrow\; (e^y - 1)\dfrac{dy}{dx} = 2 + \cos x \;\Rightarrow\; (e^y - 1)\,dy = (2 + \cos x)\,dx \;\Rightarrow$

$\int (e^y - 1)\,dy = \int (2 + \cos x)\,dx \;\Rightarrow\; e^y - y = 2x + \sin x + C$. We cannot solve explicitly for y.

6. $\dfrac{du}{dt} = \dfrac{1 + t^4}{ut^2 + u^4t^2} \;\Rightarrow\; \dfrac{du}{dt} = \dfrac{1 + t^4}{t^2(u + u^4)} \;\Rightarrow\; (u + u^4)\,du = \dfrac{1 + t^4}{t^2}\,dt \;\Rightarrow\; \int (u + u^4)\,du = \int (t^{-2} + t^2)\,dt \;\Rightarrow$

$\dfrac{1}{2}u^2 + \dfrac{1}{5}u^5 = -\dfrac{1}{t} + \dfrac{1}{3}t^3 + C$. We cannot solve explicitly for u.

7. $\dfrac{d\theta}{dt} = \dfrac{t\sec\theta}{\theta e^{t^2}} \;\Rightarrow\; \theta\cos\theta\,d\theta = te^{-t^2}\,dt \;\Rightarrow\; \int \theta\cos\theta\,d\theta = \int te^{-t^2}\,dt \;\Rightarrow$

$\theta\sin\theta + \cos\theta = -\frac{1}{2}e^{-t^2} + C$ [by parts]. We cannot solve explicitly for θ.

8. $\dfrac{dH}{dR} = \dfrac{RH^2\sqrt{1 + R^2}}{\ln H} \;\Rightarrow\; \dfrac{\ln H}{H^2}\,dH = R\sqrt{1 + R^2}\,dR \;\Rightarrow\; \displaystyle\int \frac{\ln H}{H^2}\,dH = \int R(1 + R^2)^{1/2}\,dR \;\Rightarrow$

$-\dfrac{\ln H}{H} - \dfrac{1}{H} = \dfrac{1}{3}(1 + R^2)^{3/2} + C$ [by parts]. We cannot solve explicitly for H.

9. $\dfrac{dp}{dt} = t^2p - p + t^2 - 1 = p(t^2-1) + 1(t^2-1) = (p+1)(t^2-1) \quad\Rightarrow\quad \dfrac{1}{p+1}\,dp = (t^2-1)\,dt \quad\Rightarrow$

$\displaystyle\int \frac{1}{p+1}\,dp = \int (t^2-1)\,dt \quad\Rightarrow\quad \ln|p+1| = \tfrac{1}{3}t^3 - t + C \quad\Rightarrow\quad |p+1| = e^{t^3/3-t+C} \quad\Rightarrow\quad p+1 = \pm e^C e^{t^3/3-t} \quad\Rightarrow$

$p = Ke^{t^3/3-t} - 1$, where $K = \pm e^C$. Since $p = -1$ is also a solution, K can equal 0, and hence, K can be any real number.

10. $\dfrac{dz}{dt} + e^{t+z} = 0 \quad\Rightarrow\quad \dfrac{dz}{dt} = -e^t e^z \quad\Rightarrow\quad \int e^{-z}\,dz = -\int e^t\,dt \quad\Rightarrow\quad -e^{-z} = -e^t + C \quad\Rightarrow\quad e^{-z} = e^t - C \quad\Rightarrow$

$\dfrac{1}{e^z} = e^t - C \quad\Rightarrow\quad e^z = \dfrac{1}{e^t - C} \quad\Rightarrow\quad z = \ln\!\left(\dfrac{1}{e^t - C}\right) \quad\Rightarrow\quad z = -\ln\!\left(e^t - C\right)$

11. $\dfrac{dy}{dx} = xe^y \quad\Rightarrow\quad e^{-y}\,dy = x\,dx \quad\Rightarrow\quad \int e^{-y}\,dy = \int x\,dx \quad\Rightarrow\quad -e^{-y} = \tfrac{1}{2}x^2 + C.$

$y(0) = 0 \quad\Rightarrow\quad -e^{-0} = \tfrac{1}{2}(0)^2 + C \quad\Rightarrow\quad C = -1$, so $-e^{-y} = \tfrac{1}{2}x^2 - 1 \quad\Rightarrow\quad e^{-y} = -\tfrac{1}{2}x^2 + 1 \quad\Rightarrow$

$-y = \ln\!\left(1 - \tfrac{1}{2}x^2\right) \quad\Rightarrow\quad y = -\ln\!\left(1 - \tfrac{1}{2}x^2\right).$

12. $\dfrac{dy}{dx} = \dfrac{x\sin x}{y} \quad\Rightarrow\quad y\,dy = x\sin x\,dx \quad\Rightarrow\quad \int y\,dy = \int x\sin x\,dx \quad\Rightarrow\quad \tfrac{1}{2}y^2 = -x\cos x + \sin x + C$ [by parts].

$y(0) = -1 \quad\Rightarrow\quad \tfrac{1}{2}(-1)^2 = -0\cos 0 + \sin 0 + C \quad\Rightarrow\quad C = \tfrac{1}{2}$, so $\tfrac{1}{2}y^2 = -x\cos x + \sin x + \tfrac{1}{2} \quad\Rightarrow$

$y^2 = -2x\cos x + 2\sin x + 1 \quad\Rightarrow\quad y = -\sqrt{-2x\cos x + 2\sin x + 1}$ since $y(0) = -1 < 0$.

13. $\dfrac{du}{dt} = \dfrac{2t + \sec^2 t}{2u}$, $u(0) = -5$. $\int 2u\,du = \int \left(2t + \sec^2 t\right)dt \quad\Rightarrow\quad u^2 = t^2 + \tan t + C,$

where $[u(0)]^2 = 0^2 + \tan 0 + C \quad\Rightarrow\quad C = (-5)^2 = 25$. Therefore, $u^2 = t^2 + \tan t + 25$, so $u = \pm\sqrt{t^2 + \tan t + 25}$.

Since $u(0) = -5 < 0$, we must have $u = -\sqrt{t^2 + \tan t + 25}$.

14. $x + 3y^2\sqrt{x^2+1}\,\dfrac{dy}{dx} = 0 \quad\Rightarrow\quad 3y^2\sqrt{x^2+1}\,\dfrac{dy}{dx} = -x \quad\Rightarrow\quad 3y^2\,dy = \dfrac{-x}{\sqrt{x^2+1}}\,dx \quad\Rightarrow$

$\int 3y^2\,dy = \int -x(x^2+1)^{-1/2}\,dx \quad\Rightarrow\quad y^3 = -(x^2+1)^{1/2} + C.\quad y(0) = 1 \quad\Rightarrow\quad 1^3 = -(0^2+1)^{1/2} + C \quad\Rightarrow$

$C = 2$, so $y^3 = -(x^2+1)^{1/2} + 2 \quad\Rightarrow\quad y = \left(2 - \sqrt{x^2+1}\right)^{1/3}.$

15. $x\ln x = y\left(1 + \sqrt{3+y^2}\right)y'$, $y(1) = 1$. $\int x\ln x\,dx = \int \left(y + y\sqrt{3+y^2}\right)dy \quad\Rightarrow\quad \tfrac{1}{2}x^2\ln x - \int \tfrac{1}{2}x\,dx$

[use parts with $u = \ln x$, $dv = x\,dx$] $= \tfrac{1}{2}y^2 + \tfrac{1}{3}(3+y^2)^{3/2} \quad\Rightarrow\quad \tfrac{1}{2}x^2\ln x - \tfrac{1}{4}x^2 + C = \tfrac{1}{2}y^2 + \tfrac{1}{3}(3+y^2)^{3/2}.$

Now $y(1) = 1 \quad\Rightarrow\quad 0 - \tfrac{1}{4} + C = \tfrac{1}{2} + \tfrac{1}{3}(4)^{3/2} \quad\Rightarrow\quad C = \tfrac{1}{2} + \tfrac{8}{3} + \tfrac{1}{4} = \tfrac{41}{12}$, so

$\tfrac{1}{2}x^2\ln x - \tfrac{1}{4}x^2 + \tfrac{41}{12} = \tfrac{1}{2}y^2 + \tfrac{1}{3}(3+y^2)^{3/2}$. We do not solve explicitly for y.

16. $\dfrac{dP}{dt} = \sqrt{Pt} \quad\Rightarrow\quad dP/\sqrt{P} = \sqrt{t}\,dt \quad\Rightarrow\quad \int P^{-1/2}\,dP = \int t^{1/2}\,dt \quad\Rightarrow\quad 2P^{1/2} = \tfrac{2}{3}t^{3/2} + C.$

$P(1) = 2 \quad\Rightarrow\quad 2\sqrt{2} = \tfrac{2}{3} + C \quad\Rightarrow\quad C = 2\sqrt{2} - \tfrac{2}{3}$, so $2P^{1/2} = \tfrac{2}{3}t^{3/2} + 2\sqrt{2} - \tfrac{2}{3} \quad\Rightarrow\quad \sqrt{P} = \tfrac{1}{3}t^{3/2} + \sqrt{2} - \tfrac{1}{3} \quad\Rightarrow$

$P = \left(\tfrac{1}{3}t^{3/2} + \sqrt{2} - \tfrac{1}{3}\right)^2.$

17. $y' \tan x = a + y,\ 0 < x < \pi/2 \quad\Rightarrow\quad \dfrac{dy}{dx} = \dfrac{a+y}{\tan x} \quad\Rightarrow\quad \dfrac{dy}{a+y} = \cot x\,dx \quad [a + y \neq 0] \quad\Rightarrow$

$\displaystyle\int \frac{dy}{a+y} = \int \frac{\cos x}{\sin x}\,dx \quad\Rightarrow\quad \ln|a+y| = \ln|\sin x| + C \quad\Rightarrow\quad |a+y| = e^{\ln|\sin x|+C} = e^{\ln|\sin x|}\cdot e^C = e^C\,|\sin x| \quad\Rightarrow$

$a + y = K\sin x$, where $K = \pm e^C$. (In our derivation, K was nonzero, but we can restore the excluded case

$y = -a$ by allowing K to be zero.) $\quad y(\pi/3) = a \quad\Rightarrow\quad a + a = K\sin\left(\dfrac{\pi}{3}\right) \quad\Rightarrow\quad 2a = K\,\dfrac{\sqrt{3}}{2} \quad\Rightarrow\quad K = \dfrac{4a}{\sqrt{3}}.$

Thus, $a + y = \dfrac{4a}{\sqrt{3}}\sin x$ and so $y = \dfrac{4a}{\sqrt{3}}\sin x - a$.

18. $\dfrac{dL}{dt} = kL^2\ln t \quad\Rightarrow\quad \dfrac{dL}{L^2} = k\ln t\,dt \quad\Rightarrow\quad \displaystyle\int \frac{dL}{L^2} = \int k\ln t\,dt \quad\Rightarrow\quad -\frac{1}{L} = kt\ln t - \int k\,dt$

[by parts with $u = \ln t$, $dv = k\,dt$] $\Rightarrow\quad -\dfrac{1}{L} = kt\ln t - kt + C \quad\Rightarrow\quad L = \dfrac{1}{kt - kt\ln t - C}.$

$L(1) = -1 \quad\Rightarrow\quad -1 = \dfrac{1}{k - k\ln 1 - C} \quad\Rightarrow\quad C - k = 1 \quad\Rightarrow\quad C = k + 1.$ Thus, $L = \dfrac{1}{kt - kt\ln t - k - 1}.$

19. $\dfrac{dy}{dx} = \dfrac{x}{y} \quad\Rightarrow\quad y\,dy = x\,dx \quad\Rightarrow\quad \int y\,dy = \int x\,dx \quad\Rightarrow\quad \tfrac{1}{2}y^2 = \tfrac{1}{2}x^2 + C. \quad y(0) = 2 \quad\Rightarrow\quad \tfrac{1}{2}(2)^2 = \tfrac{1}{2}(0)^2 + C \quad\Rightarrow$

$C = 2$, so $\tfrac{1}{2}y^2 = \tfrac{1}{2}x^2 + 2 \quad\Rightarrow\quad y^2 = x^2 + 4 \quad\Rightarrow\quad y = \sqrt{x^2+4}$ since $y(0) = 2 > 0$.

20. $f'(x) = x\,f(x) - x \quad\Rightarrow\quad \dfrac{dy}{dx} = xy - x \quad\Rightarrow\quad \dfrac{dy}{dx} = x(y-1) \quad\Rightarrow\quad \dfrac{dy}{y-1} = x\,dx \quad [y \neq 1] \quad\Rightarrow$

$\displaystyle\int \frac{dy}{y-1} = \int x\,dx \quad\Rightarrow\quad \ln|y-1| = \tfrac{1}{2}x^2 + C. \quad f(0) = 2 \quad\Rightarrow\quad \ln|2-1| = \tfrac{1}{2}(0)^2 + C \quad\Rightarrow\quad C = 0$, so

$\ln|y-1| = \tfrac{1}{2}x^2 \quad\Rightarrow\quad |y-1| = e^{x^2/2} \quad\Rightarrow\quad y - 1 = e^{x^2/2}$ [since $f(0) = 2$] $\Rightarrow\quad y = e^{x^2/2} + 1.$

21. $u = x + y \quad\Rightarrow\quad \dfrac{d}{dx}(u) = \dfrac{d}{dx}(x+y) \quad\Rightarrow\quad \dfrac{du}{dx} = 1 + \dfrac{dy}{dx}$, but $\dfrac{dy}{dx} = x + y = u$, so $\dfrac{du}{dx} = 1 + u \quad\Rightarrow$

$\dfrac{du}{1+u} = dx \quad [u \neq -1] \quad\Rightarrow\quad \displaystyle\int \frac{du}{1+u} = \int dx \quad\Rightarrow\quad \ln|1+u| = x + C \quad\Rightarrow\quad |1+u| = e^{x+C} \quad\Rightarrow$

$1 + u = \pm e^C e^x \quad\Rightarrow\quad u = \pm e^C e^x - 1 \quad\Rightarrow\quad x + y = \pm e^C e^x - 1 \quad\Rightarrow\quad y = Ke^x - x - 1,$ where $K = \pm e^C \neq 0$.

If $u = -1$, then $-1 = x + y \quad\Rightarrow\quad y = -x - 1$, which is just $y = Ke^x - x - 1$ with $K = 0$. Thus, the general solution is $y = Ke^x - x - 1$, where $K \in \mathbb{R}$.

22. $xy' = y + xe^{y/x} \quad\Rightarrow\quad y' = y/x + e^{y/x} \quad\Rightarrow\quad \dfrac{dy}{dx} = v + e^v$. Also, $v = y/x \quad\Rightarrow\quad xv = y \quad\Rightarrow\quad \dfrac{dy}{dx} = x\dfrac{dv}{dx} + v,$

so $v + e^v = x\dfrac{dv}{dx} + v \quad\Rightarrow\quad \dfrac{dv}{e^v} = \dfrac{dx}{x} \quad [x \neq 0] \quad\Rightarrow\quad \displaystyle\int \frac{dv}{e^v} = \int \frac{dx}{x} \quad\Rightarrow\quad -e^{-v} = \ln|x| + C \quad\Rightarrow$

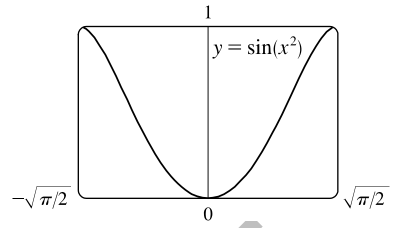
$e^{-v} = -\ln|x| - C \quad\Rightarrow\quad -v = \ln(-\ln|x| - C) \quad\Rightarrow\quad y/x = -\ln(-\ln|x| - C) \quad\Rightarrow\quad y = -x\ln(-\ln|x| - C).$

23. (a) $y' = 2x\sqrt{1-y^2} \;\Rightarrow\; \dfrac{dy}{dx} = 2x\sqrt{1-y^2} \;\Rightarrow\; \dfrac{dy}{\sqrt{1-y^2}} = 2x\,dx \;\Rightarrow\; \displaystyle\int \frac{dy}{\sqrt{1-y^2}} = \int 2x\,dx \;\Rightarrow$

$\sin^{-1} y = x^2 + C$ for $-\frac{\pi}{2} \le x^2 + C \le \frac{\pi}{2}$.

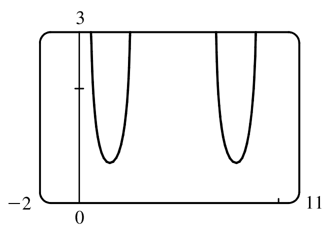
(b) $y(0) = 0 \;\Rightarrow\; \sin^{-1} 0 = 0^2 + C \;\Rightarrow\; C = 0$,

so $\sin^{-1} y = x^2$ and $y = \sin(x^2)$ for $-\sqrt{\pi/2} \le x \le \sqrt{\pi/2}$.

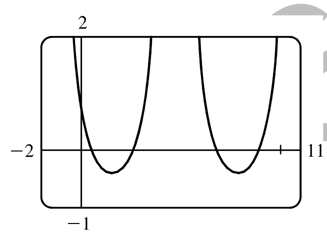


(c) For $\sqrt{1-y^2}$ to be a real number, we must have $-1 \le y \le 1$; that is, $-1 \le y(0) \le 1$. Thus, the initial-value problem $y' = 2x\sqrt{1-y^2}$, $y(0) = 2$ does *not* have a solution.

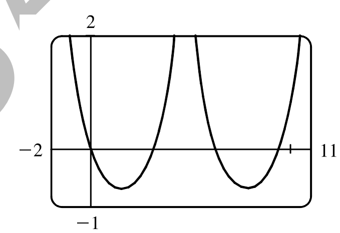
24. $e^{-y}y' + \cos x = 0 \;\Leftrightarrow\; \int e^{-y}\,dy = -\int \cos x\,dx \;\Leftrightarrow\; -e^{-y} = -\sin x + C_1 \;\Leftrightarrow\; y = -\ln(\sin x + C)$. The solution is periodic, with period 2π. Note that for $C > 1$, the domain of the solution is $\mathbb{R}$, but for $-1 < C \le 1$ it is only defined on the intervals where $\sin x + C > 0$, and it is meaningless for $C \le -1$, since then $\sin x + C \le 0$, and the logarithm is undefined.



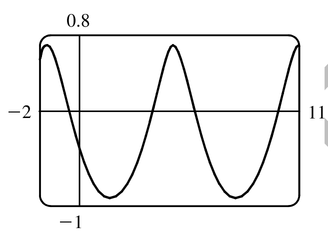
$C = -0.5$



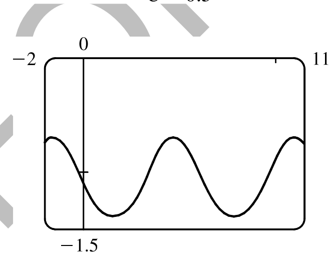
$C = 0.5$



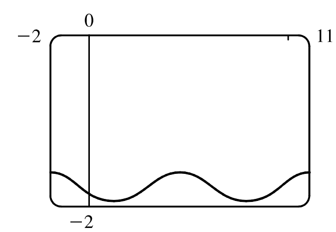
$C = 1$



$C = 1.5$



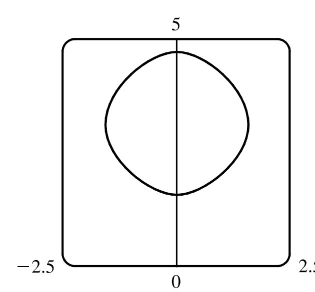
$C = 3$



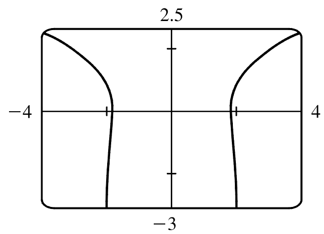
$C = 6$

For $-1 < C < 1$, the solution curve consists of concave-up pieces separated by intervals on which the solution is not defined (where $\sin x + C \le 0$). For $C = 1$, the solution curve consists of concave-up pieces separated by vertical asymptotes at the points where $\sin x + C = 0 \;\Leftrightarrow\; \sin x = -1$. For $C > 1$, the curve is continuous, and as C increases, the graph moves downward, and the amplitude of the oscillations decreases.

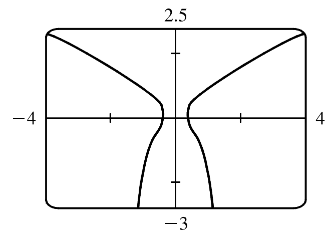
25. $\dfrac{dy}{dx} = \dfrac{\sin x}{\sin y}$, $y(0) = \dfrac{\pi}{2}$. So $\int \sin y\,dy = \int \sin x\,dx \;\Leftrightarrow\; -\cos y = -\cos x + C \;\Leftrightarrow\; \cos y = \cos x - C$. From the initial condition, we need $\cos\frac{\pi}{2} = \cos 0 - C \;\Rightarrow\; 0 = 1 - C \;\Rightarrow\; C = 1$, so the solution is $\cos y = \cos x - 1$. Note that we cannot take $\cos^{-1}$ of both sides, since that would unnecessarily restrict the solution to the case where $-1 \le \cos x - 1 \;\Leftrightarrow\; 0 \le \cos x$, as $\cos^{-1}$ is defined only on $[-1, 1]$. Instead we plot the graph using Maple's `plots[implicitplot]` or Mathematica's `Plot[Evaluate[···]]`.



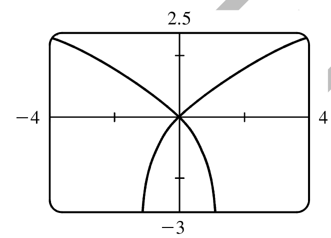
26. $\dfrac{dy}{dx} = \dfrac{x\sqrt{x^2+1}}{ye^y} \quad \Leftrightarrow \quad \int ye^y\,dy = \int x\sqrt{x^2+1}\,dx$. We use parts on the LHS with $u = y$, $dv = e^y\,dy$, and on the RHS we use the substitution $z = x^2 + 1$, so $dz = 2x\,dx$. The equation becomes $ye^y - \int e^y\,dy = \frac{1}{2}\int \sqrt{z}\,dz \quad \Leftrightarrow$ $e^y(y-1) = \frac{1}{3}(x^2+1)^{3/2} + C$, so we see that the curves are symmetric about the y-axis. Every point (x, y) in the plane lies on one of the curves, namely the one for which $C = (y-1)e^y - \frac{1}{3}(x^2+1)^{3/2}$. For example, along the y-axis, $C = (y-1)e^y - \frac{1}{3}$, so the origin lies on the curve with $C = -\frac{4}{3}$. We use Maple's `plots[implicitplot]` command or `Plot[Evaluate[···]]` in Mathematica to plot the solution curves for various values of C.



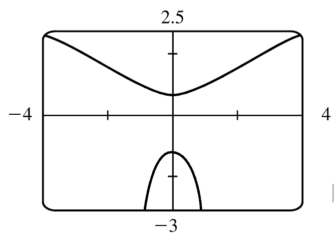
$C = -4$



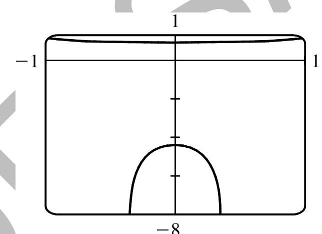
$C = -1.4$



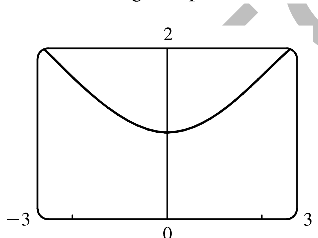
$C = -4/3$



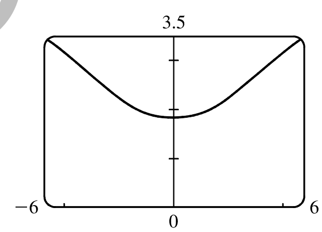
$C = -1$



$C = -0.4$



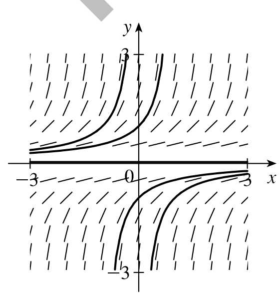
$C = -1/3$



$C = 5$

It seems that the transitional values of C are $-\frac{4}{3}$ and $-\frac{1}{3}$. For $C < -\frac{4}{3}$, the graph consists of left and right branches. At $C = -\frac{4}{3}$, the two branches become connected at the origin, and as C increases, the graph splits into top and bottom branches. At $C = -\frac{1}{3}$, the bottom half disappears. As C increases further, the graph moves upward, but doesn't change shape much.

27. (a), (c)

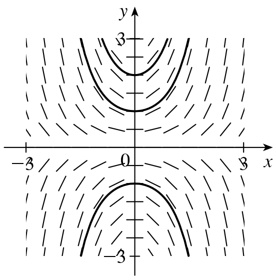


(b) $y' = y^2 \quad \Rightarrow \quad \dfrac{dy}{dx} = y^2 \quad \Rightarrow \quad \displaystyle\int y^{-2}\,dy = \int dx \quad \Rightarrow$

$-y^{-1} = x + C \quad \Rightarrow \quad \dfrac{1}{y} = -x - C \quad \Rightarrow$

$y = \dfrac{1}{K - x}$, where $K = -C$. $y = 0$ is also a solution.

28. (a), (c)



(b) $y' = xy \Rightarrow \dfrac{dy}{dx} = xy \Rightarrow \displaystyle\int \frac{dy}{y} = \int x\,dx \Rightarrow$

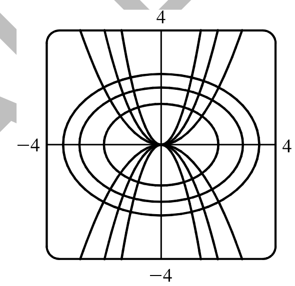
$\ln|y| = \frac{1}{2}x^2 + C \Rightarrow |y| = e^{x^2/2 + C} = e^{x^2/2}e^C \Rightarrow$

$y = Ke^{x^2/2}$, where $K = \pm e^C$. Taking $K = 0$ gives us the solution $y = 0$.

29. The curves $x^2 + 2y^2 = k^2$ form a family of ellipses with major axis on the x-axis. Differentiating gives $\dfrac{d}{dx}(x^2 + 2y^2) = \dfrac{d}{dx}(k^2) \Rightarrow 2x + 4yy' = 0 \Rightarrow 4yy' = -2x \Rightarrow y' = \dfrac{-x}{2y}$. Thus, the slope of the tangent line at any point (x, y) on one of the ellipses is $y' = \dfrac{-x}{2y}$, so the orthogonal trajectories must satisfy $y' = \dfrac{2y}{x} \Leftrightarrow \dfrac{dy}{dx} = \dfrac{2y}{x} \Leftrightarrow \dfrac{dy}{y} = 2 = \dfrac{dx}{x} \Leftrightarrow$

$\displaystyle\int \frac{dy}{y} = 2\int \frac{dx}{x} \Leftrightarrow \ln|y| = 2\ln|x| + C_1 \Leftrightarrow \ln|y| = \ln|x|^2 + C_1 \Leftrightarrow$

$|y| = e^{\ln x^2 + C_1} \Leftrightarrow y = \pm x^2 \cdot e^{C_1} = Cx^2$. This is a family of parabolas.

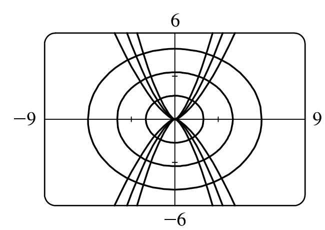


30. The curves $y^2 = kx^3$ form a family of power functions. Differentiating gives $\dfrac{d}{dx}(y^2) = \dfrac{d}{dx}(kx^3) \Rightarrow 2yy' = 3kx^2 \Rightarrow$

$y' = \dfrac{3kx^2}{2y} = \dfrac{3(y^2/x^3)x^2}{2y} = \dfrac{3y}{2x}$, the slope of the tangent line at (x, y) on one of the curves. Thus, the orthogonal trajectories must satisfy $y' = -\dfrac{2x}{3y} \Leftrightarrow \dfrac{dy}{dx} = -\dfrac{2x}{3y} \Leftrightarrow$

$3y\,dy = -2x\,dx \Leftrightarrow \int 3y\,dy = \int -2x\,dx \Leftrightarrow \frac{3}{2}y^2 = -x^2 + C_1 \Leftrightarrow$

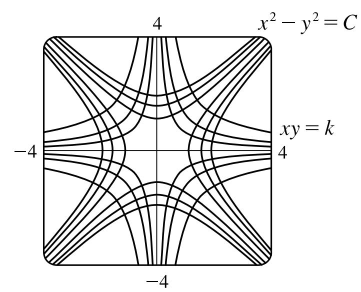
$3y^2 = -2x^2 + C_2 \Leftrightarrow 2x^2 + 3y^2 = C$. This is a family of ellipses.



31. The curves $y = k/x$ form a family of hyperbolas with asymptotes $x = 0$ and $y = 0$. Differentiating gives $\dfrac{d}{dx}(y) = \dfrac{d}{dx}\left(\dfrac{k}{x}\right) \Rightarrow y' = -\dfrac{k}{x^2} \Rightarrow y' = -\dfrac{xy}{x^2}$ [since $y = k/x \Rightarrow xy = k$] $\Rightarrow y' = -\dfrac{y}{x}$. Thus, the slope of the tangent line at any point (x, y) on one of the hyperbolas is $y' = -y/x$, so the orthogonal trajectories must satisfy $y' = x/y \Leftrightarrow \dfrac{dy}{dx} = \dfrac{x}{y} \Leftrightarrow$

$y\,dy = x\,dx \Leftrightarrow \int y\,dy = \int x\,dx \Leftrightarrow \frac{1}{2}y^2 = \frac{1}{2}x^2 + C_1 \Leftrightarrow$

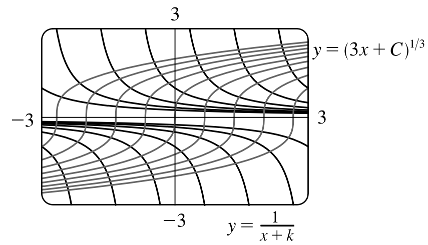
$y^2 = x^2 + C_2 \Leftrightarrow x^2 - y^2 = C$. This is a family of hyperbolas with asymptotes $y = \pm x$.



32. The curves $y = 1/(x + k)$ form a family of hyperbolas with asymptotes $x = -k$ and $y = 0$. Differentiating gives $\dfrac{d}{dx}(y) = \dfrac{d}{dx}\left(\dfrac{1}{x + k}\right) \Rightarrow y' = -\dfrac{1}{(x + k)^2} \Rightarrow y' = -y^2$ [since $y = 1/(x + k)$]. Thus, the slope of the tangent line at any point (x, y) on one of the hyperbolas is $y' = -y^2$, so the orthogonal trajectories must satisfy $y' = 1/y^2 \quad \Leftrightarrow \quad \dfrac{dy}{dx} = \dfrac{1}{y^2} \quad \Leftrightarrow$

$y^2\,dy = dx \quad \Leftrightarrow \quad \int y^2\,dy = \int dx \quad \Leftrightarrow \quad \frac{1}{3}y^3 = x + C_1 \quad \Leftrightarrow$

$y^3 = 3x + C \quad \Leftrightarrow \quad y = (3x + C)^{1/3}$. This is a family of cube root functions with vertical tangents on the x-axis $\quad [y = 0]$.



33. $y(x) = 2 + \displaystyle\int_2^x [t - ty(t)]\,dt \quad \Rightarrow \quad y'(x) = x - xy(x)$ [by FTC 1] $\quad \Rightarrow \quad \dfrac{dy}{dx} = x(1 - y) \quad \Rightarrow$

$\displaystyle\int \frac{dy}{1 - y} = \int x\,dx \quad \Rightarrow \quad -\ln|1 - y| = \frac{1}{2}x^2 + C$. Letting $x = 2$ in the original integral equation gives us $y(2) = 2 + 0 = 2$. Thus, $-\ln|1 - 2| = \frac{1}{2}(2)^2 + C \quad \Rightarrow \quad 0 = 2 + C \quad \Rightarrow \quad C = -2$.

Thus, $-\ln|1 - y| = \frac{1}{2}x^2 - 2 \quad \Rightarrow \quad \ln|1 - y| = 2 - \frac{1}{2}x^2 \quad \Rightarrow \quad |1 - y| = e^{2 - x^2/2} \quad \Rightarrow$

$1 - y = \pm e^{2 - x^2/2} \quad \Rightarrow \quad y = 1 + e^{2 - x^2/2}$ $[y(2) = 2]$.

34. $y(x) = 2 + \displaystyle\int_1^x \frac{dt}{ty(t)}, x > 0 \quad \Rightarrow \quad y'(x) = \frac{1}{xy(x)} \quad \Rightarrow \quad \frac{dy}{dx} = \frac{1}{xy} \quad \Rightarrow \quad \int y\,dy = \int \frac{1}{x}\,dx \quad \Rightarrow$

$\frac{1}{2}y^2 = \ln x + C$ $[x > 0]$. Letting $x = 1$ in the original integral equation gives us $y(1) = 2 + 0 = 2$.

Thus, $\frac{1}{2}(2)^2 = \ln 1 + C \quad \Rightarrow \quad C = 2$. $\frac{1}{2}y^2 = \ln x + 2 \quad \Rightarrow \quad y^2 = 2\ln x + 4$ $[> 0]$ $\quad \Rightarrow \quad y = \sqrt{2\ln x + 4}$.

35. $y(x) = 4 + \displaystyle\int_0^x 2t\sqrt{y(t)}\,dt \quad \Rightarrow \quad y'(x) = 2x\sqrt{y(x)} \quad \Rightarrow \quad \frac{dy}{dx} = 2x\sqrt{y} \quad \Rightarrow \quad \int \frac{dy}{\sqrt{y}} = \int 2x\,dx \quad \Rightarrow$

$2\sqrt{y} = x^2 + C$. Letting $x = 0$ in the original integral equation gives us $y(0) = 4 + 0 = 4$.

Thus, $2\sqrt{4} = 0^2 + C \quad \Rightarrow \quad C = 4$. $2\sqrt{y} = x^2 + 4 \quad \Rightarrow \quad \sqrt{y} = \frac{1}{2}x^2 + 2 \quad \Rightarrow \quad y = \left(\frac{1}{2}x^2 + 2\right)^2$.

36. $(t^2 + 1)f'(t) + [f(t)]^2 + 1 = 0 \quad \Rightarrow \quad (t^2 + 1)\dfrac{dy}{dt} + y^2 + 1 = 0 \quad \Rightarrow \quad \dfrac{dy}{dt} = \dfrac{-y^2 - 1}{t^2 + 1} \quad \Rightarrow$

$\displaystyle\int \frac{dy}{y^2 + 1} = -\int \frac{dt}{t^2 + 1} \quad \Rightarrow \quad \arctan y = -\arctan t + C \quad \Rightarrow \quad \arctan t + \arctan y = C \quad \Rightarrow$

$\tan(\arctan t + \arctan y) = \tan C \quad \Rightarrow \quad \dfrac{\tan(\arctan t) + \tan(\arctan y)}{1 - \tan(\arctan t)\,\tan(\arctan y)} = \tan C \quad \Rightarrow \quad \dfrac{t + y}{1 - ty} = \tan C = k \quad \Rightarrow$

$t + y = k - kty \quad \Rightarrow \quad y + kty = k - t \quad \Rightarrow \quad y(1 + kt) = k - t \quad \Rightarrow \quad f(t) = y = \dfrac{k - t}{1 + kt}$.

Since $f(3) = 2 = \dfrac{k - 3}{1 + 3k} \quad \Rightarrow \quad 2 + 6k = k - 3 \quad \Rightarrow \quad 5k = -5 \quad \Rightarrow \quad k = -1$, we have $y = \dfrac{-1 - t}{1 + (-1)t} = \dfrac{t + 1}{t - 1}$.

37. From Exercise 9.2.27, $\dfrac{dQ}{dt} = 12 - 4Q \quad \Leftrightarrow \quad \displaystyle\int \frac{dQ}{12 - 4Q} = \int dt \quad \Leftrightarrow \quad -\frac{1}{4}\ln|12 - 4Q| = t + C \quad \Leftrightarrow$

$\ln|12 - 4Q| = -4t - 4C \quad \Leftrightarrow \quad |12 - 4Q| = e^{-4t - 4C} \quad \Leftrightarrow \quad 12 - 4Q = Ke^{-4t}$ $[K = \pm e^{-4C}]$ $\quad \Leftrightarrow$

$4Q = 12 - Ke^{-4t} \quad \Leftrightarrow \quad Q = 3 - Ae^{-4t}$ $[A = K/4]$. $Q(0) = 0 \quad \Leftrightarrow \quad 0 = 3 - A \quad \Leftrightarrow \quad A = 3 \quad \Leftrightarrow$

$Q(t) = 3 - 3e^{-4t}$. As $t \to \infty$, $Q(t) \to 3 - 0 = 3$ (the limiting value).

38. From Exercise 9.2.28, $\frac{dy}{dt} = -\frac{1}{50}(y-20) \quad \Leftrightarrow \quad \int \frac{dy}{y-20} = \int \left(-\frac{1}{50}\right) dt \quad \Leftrightarrow \quad \ln|y-20| = -\frac{1}{50}t + C \quad \Leftrightarrow$

$y - 20 = Ke^{-t/50} \quad \Leftrightarrow \quad y(t) = Ke^{-t/50} + 20.$ $y(0) = 95 \quad \Leftrightarrow \quad 95 = K + 20 \quad \Leftrightarrow \quad K = 75 \quad \Leftrightarrow$

$y(t) = 75e^{-t/50} + 20.$

39. $\frac{dP}{dt} = k(M-P) \quad \Leftrightarrow \quad \int \frac{dP}{P-M} = \int (-k)\,dt \quad \Leftrightarrow \quad \ln|P-M| = -kt + C \quad \Leftrightarrow \quad |P-M| = e^{-kt+C} \quad \Leftrightarrow$

$P - M = Ae^{-kt} \quad [A = \pm e^C] \quad \Leftrightarrow \quad P = M + Ae^{-kt}$. If we assume that performance is at level 0 when $t = 0$, then

$P(0) = 0 \quad \Leftrightarrow \quad 0 = M + A \quad \Leftrightarrow \quad A = -M \quad \Leftrightarrow \quad P(t) = M - Me^{-kt}.$ $\lim_{t\to\infty} P(t) = M - M \cdot 0 = M.$

40. (a) $\frac{dx}{dt} = k(a-x)(b-x),\ a \neq b$. Using partial fractions, $\frac{1}{(a-x)(b-x)} = \frac{1/(b-a)}{a-x} - \frac{1/(b-a)}{b-x}$, so

$$\int \frac{dx}{(a-x)(b-x)} = \int k\,dt \quad \Rightarrow \quad \frac{1}{b-a}\left(-\ln|a-x| + \ln|b-x|\right) = kt + C \quad \Rightarrow \quad \ln\left|\frac{b-x}{a-x}\right| = (b-a)(kt+C).$$

The concentrations [A] $= a - x$ and [B] $= b - x$ cannot be negative, so $\frac{b-x}{a-x} \geq 0$ and $\left|\frac{b-x}{a-x}\right| = \frac{b-x}{a-x}$.

We now have $\ln\left(\frac{b-x}{a-x}\right) = (b-a)(kt+C)$. Since $x(0) = 0$, we get $\ln\left(\frac{b}{a}\right) = (b-a)C$. Hence,

$$\ln\left(\frac{b-x}{a-x}\right) = (b-a)kt + \ln\left(\frac{b}{a}\right) \quad \Rightarrow \quad \frac{b-x}{a-x} = \frac{b}{a}e^{(b-a)kt} \quad \Rightarrow \quad x = \frac{b[e^{(b-a)kt} - 1]}{be^{(b-a)kt}/a - 1} = \frac{ab[e^{(b-a)kt} - 1]}{be^{(b-a)kt} - a}\ \frac{\text{moles}}{\text{L}}.$$

(b) If $b = a$, then $\frac{dx}{dt} = k(a-x)^2$, so $\int \frac{dx}{(a-x)^2} = \int k\,dt$ and $\frac{1}{a-x} = kt + C$. Since $x(0) = 0$, we get $C = \frac{1}{a}$.

Thus, $a - x = \frac{1}{kt + 1/a}$ and $x = a - \frac{a}{akt+1} = \frac{a^2kt}{akt+1}\ \frac{\text{moles}}{\text{L}}$. Suppose $x = $ [C] $= a/2$ when $t = 20$. Then

$$x(20) = a/2 \quad \Rightarrow \quad \frac{a}{2} = \frac{20a^2k}{20ak+1} \quad \Rightarrow \quad 40a^2k = 20a^2k + a \quad \Rightarrow \quad 20a^2k = a \quad \Rightarrow \quad k = \frac{1}{20a}, \text{ so}$$

$$x = \frac{a^2t/(20a)}{1 + at/(20a)} = \frac{at/20}{1+t/20} = \frac{at}{t+20}\ \frac{\text{moles}}{\text{L}}.$$

41. (a) If $a = b$, then $\frac{dx}{dt} = k(a-x)(b-x)^{1/2}$ becomes $\frac{dx}{dt} = k(a-x)^{3/2} \quad \Rightarrow \quad (a-x)^{-3/2}\,dx = k\,dt \quad \Rightarrow$

$\int (a-x)^{-3/2}\,dx = \int k\,dt \quad \Rightarrow \quad 2(a-x)^{-1/2} = kt + C$ [by substitution] $\Rightarrow \quad \frac{2}{kt+C} = \sqrt{a-x} \quad \Rightarrow$

$\left(\frac{2}{kt+C}\right)^2 = a - x \quad \Rightarrow \quad x(t) = a - \frac{4}{(kt+C)^2}$. The initial concentration of HBr is 0, so $x(0) = 0 \quad \Rightarrow$

$0 = a - \frac{4}{C^2} \quad \Rightarrow \quad \frac{4}{C^2} = a \quad \Rightarrow \quad C^2 = \frac{4}{a} \quad \Rightarrow \quad C = 2/\sqrt{a}$ [C is positive since $kt + C = 2(a-x)^{-1/2} > 0$].

Thus, $x(t) = a - \frac{4}{(kt + 2/\sqrt{a})^2}$.

(b) $\dfrac{dx}{dt} = k(a-x)(b-x)^{1/2} \quad\Rightarrow\quad \dfrac{dx}{(a-x)\sqrt{b-x}} = k\,dt \quad\Rightarrow\quad \displaystyle\int \frac{dx}{(a-x)\sqrt{b-x}} = \int k\,dt \quad (\star).$

From the hint, $u = \sqrt{b-x} \quad\Rightarrow\quad u^2 = b - x \quad\Rightarrow\quad 2u\,du = -dx$, so

$$\int \frac{dx}{(a-x)\sqrt{b-x}} = \int \frac{-2u\,du}{[a-(b-u^2)]u} = -2\int \frac{du}{a-b+u^2} = -2\int \frac{du}{\left(\sqrt{a-b}\right)^2 + u^2}$$

$$\overset{17}{=} -2\left(\frac{1}{\sqrt{a-b}}\tan^{-1}\frac{u}{\sqrt{a-b}}\right)$$

So $(\star)$ becomes $\dfrac{-2}{\sqrt{a-b}}\tan^{-1}\dfrac{\sqrt{b-x}}{\sqrt{a-b}} = kt + C$. Now $x(0) = 0 \quad\Rightarrow\quad C = \dfrac{-2}{\sqrt{a-b}}\tan^{-1}\dfrac{\sqrt{b}}{\sqrt{a-b}}$ and we have

$\dfrac{-2}{\sqrt{a-b}}\tan^{-1}\dfrac{\sqrt{b-x}}{\sqrt{a-b}} = kt - \dfrac{2}{\sqrt{a-b}}\tan^{-1}\dfrac{\sqrt{b}}{\sqrt{a-b}} \quad\Rightarrow\quad \dfrac{2}{\sqrt{a-b}}\left(\tan^{-1}\sqrt{\dfrac{b}{a-b}} - \tan^{-1}\sqrt{\dfrac{b-x}{a-b}}\right) = kt \quad\Rightarrow$

$t(x) = \dfrac{2}{k\sqrt{a-b}}\left(\tan^{-1}\sqrt{\dfrac{b}{a-b}} - \tan^{-1}\sqrt{\dfrac{b-x}{a-b}}\right).$

42. If $S = \dfrac{dT}{dr}$, then $\dfrac{dS}{dr} = \dfrac{d^2T}{dr^2}$. The differential equation $\dfrac{d^2T}{dr^2} + \dfrac{2}{r}\dfrac{dT}{dr} = 0$ can be written as $\dfrac{dS}{dr} + \dfrac{2}{r}S = 0$. Thus,

$\dfrac{dS}{dr} = \dfrac{-2S}{r} \quad\Rightarrow\quad \dfrac{dS}{S} = -\dfrac{2}{r}\,dr \quad\Rightarrow\quad \displaystyle\int \frac{1}{S}\,dS = \int -\frac{2}{r}\,dr \quad\Rightarrow\quad \ln|S| = -2\ln|r| + C$. Assuming $S = dT/dr > 0$

and $r > 0$, we have $S = e^{-2\ln r + C} = e^{\ln r^{-2}}e^C = r^{-2}k \quad [k = e^C] \quad\Rightarrow\quad S = \dfrac{1}{r^2}k \quad\Rightarrow\quad \dfrac{dT}{dr} = \dfrac{1}{r^2}k \quad\Rightarrow$

$dT = \dfrac{1}{r^2}k\,dr \quad\Rightarrow\quad \displaystyle\int dT = \int \frac{1}{r^2}k\,dr \quad\Rightarrow\quad T(r) = -\frac{k}{r} + A.$

$T(1) = 15 \quad\Rightarrow\quad 15 = -k + A$ **(1)** and $T(2) = 25 \quad\Rightarrow\quad 25 = -\frac{1}{2}k + A$ **(2)**.

Now solve for k and A: -2**(2)** $+$ **(1)** $\quad\Rightarrow\quad -35 = -A$, so $A = 35$ and $k = 20$, and $T(r) = -20/r + 35$.

43. (a) $\dfrac{dC}{dt} = r - kC \quad\Rightarrow\quad \dfrac{dC}{dt} = -(kC - r) \quad\Rightarrow\quad \displaystyle\int \frac{dC}{kC - r} = \int -dt \quad\Rightarrow\quad (1/k)\ln|kC - r| = -t + M_1 \quad\Rightarrow$

$\ln|kC - r| = -kt + M_2 \quad\Rightarrow\quad |kC - r| = e^{-kt + M_2} \quad\Rightarrow\quad kC - r = M_3e^{-kt} \quad\Rightarrow\quad kC = M_3e^{-kt} + r \quad\Rightarrow$

$C(t) = M_4e^{-kt} + r/k.\ C(0) = C_0 \quad\Rightarrow\quad C_0 = M_4 + r/k \quad\Rightarrow\quad M_4 = C_0 - r/k \quad\Rightarrow$

$C(t) = (C_0 - r/k)e^{-kt} + r/k.$

(b) If $C_0 < r/k$, then $C_0 - r/k < 0$ and the formula for $C(t)$ shows that $C(t)$ increases and $\lim\limits_{t\to\infty} C(t) = r/k$.

As t increases, the formula for $C(t)$ shows how the role of C_0 steadily diminishes as that of r/k increases.

44. (a) Use 1 billion dollars as the x-unit and 1 day as the t-unit. Initially, there is \$10 billion of old currency in circulation, so all of the \$50 million returned to the banks is old. At time t, the amount of new currency is $x(t)$ billion dollars, so $10 - x(t)$ billion dollars of currency is old. The fraction of circulating money that is old is $[10 - x(t)]/10$, and the amount of old currency being returned to the banks each day is $\dfrac{10 - x(t)}{10}\,0.05$ billion dollars. This amount of new currency per day is introduced into circulation, so $\dfrac{dx}{dt} = \dfrac{10 - x}{10} \cdot 0.05 = 0.005(10 - x)$ billion dollars per day.

(b) $\dfrac{dx}{10-x} = 0.005\,dt \quad\Rightarrow\quad \dfrac{-dx}{10-x} = -0.005\,dt \quad\Rightarrow\quad \ln(10-x) = -0.005t + c \quad\Rightarrow\quad 10 - x = Ce^{-0.005t}$,

where $C = e^c \quad\Rightarrow\quad x(t) = 10 - Ce^{-0.005t}$. From $x(0) = 0$, we get $C = 10$, so $x(t) = 10(1 - e^{-0.005t})$.

(c) The new bills make up 90% of the circulating currency when $x(t) = 0.9 \cdot 10 = 9$ billion dollars.

$9 = 10(1 - e^{-0.005t}) \quad\Rightarrow\quad 0.9 = 1 - e^{-0.005t} \quad\Rightarrow\quad e^{-0.005t} = 0.1 \quad\Rightarrow\quad -0.005t = -\ln 10 \quad\Rightarrow$

$t = 200 \ln 10 \approx 460.517$ days ≈ 1.26 years.

45. (a) Let $y(t)$ be the amount of salt (in kg) after t minutes. Then $y(0) = 15$. The amount of liquid in the tank is 1000 L at all times, so the concentration at time t (in minutes) is $y(t)/1000$ kg/L and $\dfrac{dy}{dt} = -\left[\dfrac{y(t)}{1000}\,\dfrac{\text{kg}}{\text{L}}\right]\left(10\,\dfrac{\text{L}}{\text{min}}\right) = -\dfrac{y(t)}{100}\,\dfrac{\text{kg}}{\text{min}}$.

$\displaystyle\int \frac{dy}{y} = -\frac{1}{100}\int dt \quad\Rightarrow\quad \ln y = -\frac{t}{100} + C$, and $y(0) = 15 \quad\Rightarrow\quad \ln 15 = C$, so $\ln y = \ln 15 - \dfrac{t}{100}$.

It follows that $\ln\left(\dfrac{y}{15}\right) = -\dfrac{t}{100}$ and $\dfrac{y}{15} = e^{-t/100}$, so $y = 15e^{-t/100}$ kg.

(b) After 20 minutes, $y = 15e^{-20/100} = 15e^{-0.2} \approx 12.3$ kg.

46. Let $y(t)$ be the amount of carbon dioxide in the room after t minutes. Then $y(0) = 0.0015(180) = 0.27\ \text{m}^3$. The amount of air in the room is $180\ \text{m}^3$ at all times, so the percentage at time t (in mimutes) is $y(t)/180 \times 100$, and the change in the amount of carbon dioxide with respect to time is

$$\frac{dy}{dt} = (0.0005)\left(2\,\frac{\text{m}^3}{\text{min}}\right) - \frac{y(t)}{180}\left(2\,\frac{\text{m}^3}{\text{min}}\right) = 0.001 - \frac{y}{90} = \frac{9 - 100y}{9000}\,\frac{\text{m}^3}{\text{min}}$$

Hence, $\displaystyle\int \frac{dy}{9 - 100y} = \int \frac{dt}{9000}$ and $-\dfrac{1}{100}\ln|9 - 100y| = \dfrac{1}{9000}t + C$. Because $y(0) = 0.27$, we have $-\frac{1}{100}\ln 18 = C$, so $-\frac{1}{100}\ln|9 - 100y| = \frac{1}{9000}t - \frac{1}{100}\ln 18 \quad\Rightarrow\quad \ln|9 - 100y| = -\frac{1}{90}t + \ln 18 \quad\Rightarrow$ $\ln|9 - 100y| = \ln e^{-t/90} + \ln 18 \quad\Rightarrow\quad \ln|9 - 100y| = \ln(18e^{-t/90})$, and $|9 - 100y| = 18e^{-t/90}$. Since y is continuous, $y(0) = 0.27$, and the right-hand side is never zero, we deduce that $9 - 100y$ is always negative. Thus, $|9 - 100y| = 100y - 9$ and we have $100y - 9 = 18e^{-t/90} \quad\Rightarrow\quad 100y = 9 + 18e^{-t/90} \quad\Rightarrow\quad y = 0.09 + 0.18e^{-t/90}$. The percentage of carbon dioxide in the room is

$$p(t) = \frac{y}{180} \times 100 = \frac{0.09 + 0.18e^{-t/90}}{180} \times 100 = (0.0005 + 0.001e^{-t/90}) \times 100 = 0.05 + 0.1e^{-t/90}$$

In the long run, we have $\lim\limits_{t\to\infty} p(t) = 0.05 + 0.1(0) = 0.05$; that is, the amount of carbon dioxide approaches 0.05% as time goes on.

47. Let $y(t)$ be the amount of alcohol in the vat after t minutes. Then $y(0) = 0.04(500) = 20$ gal. The amount of beer in the vat is 500 gallons at all times, so the percentage at time t (in minutes) is $y(t)/500 \times 100$, and the change in the amount of alcohol with respect to time t is $\dfrac{dy}{dt} = \text{rate in} - \text{rate out} = 0.06\left(5\,\dfrac{\text{gal}}{\text{min}}\right) - \dfrac{y(t)}{500}\left(5\,\dfrac{\text{gal}}{\text{min}}\right) = 0.3 - \dfrac{y}{100} = \dfrac{30 - y}{100}\,\dfrac{\text{gal}}{\text{min}}$.

Hence, $\displaystyle\int \frac{dy}{30 - y} = \int \frac{dt}{100}$ and $-\ln|30 - y| = \frac{1}{100}t + C$. Because $y(0) = 20$, we have $-\ln 10 = C$, so

$-\ln|30-y| = \frac{1}{100}t - \ln 10 \Rightarrow \ln|30-y| = -t/100 + \ln 10 \Rightarrow \ln|30-y| = \ln e^{-t/100} + \ln 10 \Rightarrow$ $\ln|30-y| = \ln(10e^{-t/100}) \Rightarrow |30-y| = 10e^{-t/100}$. Since y is continuous, $y(0)=20$, and the right-hand side is never zero, we deduce that $30-y$ is always positive. Thus, $30-y = 10e^{-t/100} \Rightarrow y = 30 - 10e^{-t/100}$. The percentage of alcohol is $p(t) = y(t)/500 \times 100 = y(t)/5 = 6 - 2e^{-t/100}$. The percentage of alcohol after one hour is $p(60) = 6 - 2e^{-60/100} \approx 4.9$.

48. (a) If $y(t)$ is the amount of salt (in kg) after t minutes, then $y(0)=0$ and the total amount of liquid in the tank remains constant at 1000 L.

$$\frac{dy}{dt} = \left(0.05\,\frac{\text{kg}}{\text{L}}\right)\left(5\,\frac{\text{L}}{\text{min}}\right) + \left(0.04\,\frac{\text{kg}}{\text{L}}\right)\left(10\,\frac{\text{L}}{\text{min}}\right) - \left(\frac{y(t)}{1000}\,\frac{\text{kg}}{\text{L}}\right)\left(15\,\frac{\text{L}}{\text{min}}\right)$$
$$= 0.25 + 0.40 - 0.015y = 0.65 - 0.015y = \frac{130-3y}{200}\,\frac{\text{kg}}{\text{min}}$$

Hence, $\int \frac{dy}{130-3y} = \int \frac{dt}{200}$ and $-\frac{1}{3}\ln|130-3y| = \frac{1}{200}t + C$. Because $y(0)=0$, we have $-\frac{1}{3}\ln 130 = C$, so $-\frac{1}{3}\ln|130-3y| = \frac{1}{200}t - \frac{1}{3}\ln 130 \Rightarrow \ln|130-3y| = -\frac{3}{200}t + \ln 130 = \ln(130e^{-3t/200})$, and $|130-3y| = 130e^{-3t/200}$. Since y is continuous, $y(0)=0$, and the right-hand side is never zero, we deduce that $130-3y$ is always positive. Thus, $130-3y = 130e^{-3t/200}$ and $y = \frac{130}{3}(1-e^{-3t/200})$ kg.

(b) After one hour, $y = \frac{130}{3}(1-e^{-3\cdot 60/200}) = \frac{130}{3}(1-e^{-0.9}) \approx 25.7$ kg.

Note: As $t \to \infty$, $y(t) \to \frac{130}{3} = 43\frac{1}{3}$ kg.

49. Assume that the raindrop begins at rest, so that $v(0)=0$. $dm/dt = km$ and $(mv)' = gm \Rightarrow mv' + vm' = gm \Rightarrow$ $mv' + v(km) = gm \Rightarrow v' + vk = g \Rightarrow \frac{dv}{dt} = g - kv \Rightarrow \int \frac{dv}{g-kv} = \int dt \Rightarrow$ $-(1/k)\ln|g-kv| = t + C \Rightarrow \ln|g-kv| = -kt - kC \Rightarrow g - kv = Ae^{-kt}$. $v(0)=0 \Rightarrow A = g$. So $kv = g - ge^{-kt} \Rightarrow v = (g/k)(1-e^{-kt})$. Since $k>0$, as $t\to\infty$, $e^{-kt}\to 0$ and therefore, $\lim_{t\to\infty} v(t) = g/k$.

50. (a) $m\frac{dv}{dt} = -kv \Rightarrow \frac{dv}{v} = -\frac{k}{m}\,dt \Rightarrow \ln|v| = -\frac{k}{m}t + C$. Since $v(0)=v_0$, $\ln|v_0| = C$. Therefore, $\ln\left|\frac{v}{v_0}\right| = -\frac{k}{m}t \Rightarrow \left|\frac{v}{v_0}\right| = e^{-kt/m} \Rightarrow v(t) = \pm v_0 e^{-kt/m}$. The sign is $+$ when $t=0$, and we assume v is continuous, so that the sign is $+$ for all t. Thus, $v(t) = v_0e^{-kt/m}$. $ds/dt = v_0e^{-kt/m} \Rightarrow$ $s(t) = -\frac{mv_0}{k}e^{-kt/m} + C'$.

From $s(0)=s_0$, we get $s_0 = -\frac{mv_0}{k} + C'$, so $C' = s_0 + \frac{mv_0}{k}$ and $s(t) = s_0 + \frac{mv_0}{k}(1-e^{-kt/m})$.

The distance traveled from time 0 to time t is $s(t) - s_0$, so the total distance traveled is $\lim_{t\to\infty}[s(t)-s_0] = \frac{mv_0}{k}$.

Note: In finding the limit, we use the fact that $k>0$ to conclude that $\lim_{t\to\infty} e^{-kt/m} = 0$.

(b) $m\,\dfrac{dv}{dt} = -kv^2 \;\Rightarrow\; \dfrac{dv}{v^2} = -\dfrac{k}{m}\,dt \;\Rightarrow\; \dfrac{-1}{v} = -\dfrac{kt}{m} + C \;\Rightarrow\; \dfrac{1}{v} = \dfrac{kt}{m} - C$. Since $v(0) = v_0$,

$C = -\dfrac{1}{v_0}$ and $\dfrac{1}{v} = \dfrac{kt}{m} + \dfrac{1}{v_0}$. Therefore, $v(t) = \dfrac{1}{kt/m + 1/v_0} = \dfrac{mv_0}{kv_0t + m}$. $\dfrac{ds}{dt} = \dfrac{mv_0}{kv_0t + m} \;\Rightarrow$

$s(t) = \dfrac{m}{k}\displaystyle\int \dfrac{kv_0\,dt}{kv_0t + m} = \dfrac{m}{k}\ln|kv_0t + m| + C'$. Since $s(0) = s_0$, we get $s_0 = \dfrac{m}{k}\ln m + C' \;\Rightarrow$

$C' = s_0 - \dfrac{m}{k}\ln m \;\Rightarrow\; s(t) = s_0 + \dfrac{m}{k}(\ln|kv_0t + m| - \ln m) = s_0 + \dfrac{m}{k}\ln\left|\dfrac{kv_0t + m}{m}\right|$.

We can rewrite the formulas for $v(t)$ and $s(t)$ as $v(t) = \dfrac{v_0}{1 + (kv_0/m)t}$ and $s(t) = s_0 + \dfrac{m}{k}\ln\left|1 + \dfrac{kv_0}{m}t\right|$.

Remarks: This model of horizontal motion through a resistive medium was designed to handle the case in which $v_0 > 0$. Then the term $-kv^2$ representing the resisting force causes the object to decelerate. The absolute value in the expression for $s(t)$ is unnecessary (since k, v_0, and m are all positive), and $\lim\limits_{t\to\infty} s(t) = \infty$. In other words, the object travels infinitely far. However, $\lim\limits_{t\to\infty} v(t) = 0$. When $v_0 < 0$, the term $-kv^2$ increases the magnitude of the object's negative velocity. According to the formula for $s(t)$, the position of the object approaches $-\infty$ as t approaches $m/k(-v_0)$: $\lim\limits_{t\to -m/(kv_0)} s(t) = -\infty$. Again the object travels infinitely far, but this time the feat is accomplished in a finite amount of time. Notice also that $\lim\limits_{t\to -m/(kv_0)} v(t) = -\infty$ when $v_0 < 0$, showing that the speed of the object increases without limit.

51. (a) $\dfrac{1}{L_1}\dfrac{dL_1}{dt} = k\dfrac{1}{L_2}\dfrac{dL_2}{dt} \;\Rightarrow\; \dfrac{d}{dt}(\ln L_1) = \dfrac{d}{dt}(k\ln L_2) \;\Rightarrow\; \displaystyle\int \dfrac{d}{dt}(\ln L_1)\,dt = \int \dfrac{d}{dt}(\ln L_2^k)\,dt \;\Rightarrow$

$\ln L_1 = \ln L_2^k + C \;\Rightarrow\; L_1 = e^{\ln L_2^k + C} = e^{\ln L_2^k}e^C \;\Rightarrow\; L_1 = KL_2^k$, where $K = e^C$.

(b) From part (a) with $L_1 = B$, $L_2 = V$, and $k = 0.0794$, we have $B = KV^{0.0794}$.

52. (a) $\dfrac{dV}{dt} = a(\ln b - \ln V)V \;\Rightarrow\; \dfrac{dV}{dt} = -aV(\ln V - \ln b) \;\Rightarrow\; \dfrac{dV}{V\ln(V/b)} = -a\,dt \;\Rightarrow$

$\displaystyle\int \dfrac{dV}{V\ln(V/b)} = \int -a\,dt \;\Rightarrow\; \int \dfrac{1}{u}\,du = \int -a\,dt \quad \begin{bmatrix} u = \ln(V/b), \\ du = (1/V)\,dV \end{bmatrix} \;\Rightarrow\; \ln|u| = -at + k \;\Rightarrow$

$|u| = e^{-at}e^k \;\Rightarrow\; u = Ce^{-at}$ [where $C = \pm e^k$] $\;\Rightarrow\; \ln(V/b) = Ce^{-at} \;\Rightarrow\; \dfrac{V}{b} = e^{Ce^{-at}} \;\Rightarrow$

$V = be^{Ce^{-at}}$ with $C \neq 0$.

(b) $V(0) = 1 \;\Rightarrow\; 1 = be^{Ce^{-a(0)}} \;\Rightarrow\; 1 = be^C \;\Rightarrow\; b = e^{-C}$, so $V = e^{-C}e^{Ce^{-at}} = e^{Ce^{-at} - C} = e^{C(e^{-at} - 1)}$.

53. (a) The rate of growth of the area is jointly proportional to $\sqrt{A(t)}$ and $M - A(t)$; that is, the rate is proportional to the product of those two quantities. So for some constant k, $dA/dt = k\sqrt{A}\,(M - A)$. We are interested in the maximum of the function dA/dt (when the tissue grows the fastest), so we differentiate, using the Chain Rule and then substituting for

dA/dt from the differential equation:

$$\frac{d}{dt}\left(\frac{dA}{dt}\right) = k\left[\sqrt{A}\,(-1)\frac{dA}{dt} + (M-A)\cdot\tfrac{1}{2}A^{-1/2}\frac{dA}{dt}\right] = \tfrac{1}{2}kA^{-1/2}\frac{dA}{dt}\,[-2A + (M-A)]$$

$$= \tfrac{1}{2}kA^{-1/2}\left[k\sqrt{A}(M-A)\right][M-3A] = \tfrac{1}{2}k^2(M-A)(M-3A)$$

This is 0 when $M - A = 0$ [this situation never actually occurs, since the graph of $A(t)$ is asymptotic to the line $y = M$, as in the logistic model] and when $M - 3A = 0 \quad\Leftrightarrow\quad A(t) = M/3$. This represents a maximum by the First Derivative Test, since $\dfrac{d}{dt}\left(\dfrac{dA}{dt}\right)$ goes from positive to negative when $A(t) = M/3$.

(b) From the CAS, we get $A(t) = M\left(\dfrac{Ce^{\sqrt{M}kt} - 1}{Ce^{\sqrt{M}kt} + 1}\right)^2$. To get C in terms of the initial area A_0 and the maximum area M, we substitute $t = 0$ and $A = A_0 = A(0)$: $A_0 = M\left(\dfrac{C-1}{C+1}\right)^2 \quad\Leftrightarrow\quad (C+1)\sqrt{A_0} = (C-1)\sqrt{M} \quad\Leftrightarrow$

$C\sqrt{A_0} + \sqrt{A_0} = C\sqrt{M} - \sqrt{M} \quad\Leftrightarrow\quad \sqrt{M} + \sqrt{A_0} = C\sqrt{M} - C\sqrt{A_0} \quad\Leftrightarrow$

$\sqrt{M} + \sqrt{A_0} = C\left(\sqrt{M} - \sqrt{A_0}\right) \quad\Leftrightarrow\quad C = \dfrac{\sqrt{M} + \sqrt{A_0}}{\sqrt{M} - \sqrt{A_0}}$. [Notice that if $A_0 = 0$, then $C = 1$.]

54. (a) According to the hint we use the Chain Rule: $m\dfrac{dv}{dt} = m\dfrac{dv}{dx}\cdot\dfrac{dx}{dt} = mv\dfrac{dv}{dx} = -\dfrac{mgR^2}{(x+R)^2} \quad\Rightarrow$

$\displaystyle\int v\,dv = \int \frac{-gR^2\,dx}{(x+R)^2} \quad\Rightarrow\quad \frac{v^2}{2} = \frac{gR^2}{x+R} + C$. When $x = 0$, $v = v_0$, so $\dfrac{v_0^2}{2} = \dfrac{gR^2}{0+R} + C \quad\Rightarrow$

$C = \frac{1}{2}v_0^2 - gR \quad\Rightarrow\quad \frac{1}{2}v^2 - \frac{1}{2}v_0^2 = \dfrac{gR^2}{x+R} - gR$. Now at the top of its flight, the rocket's velocity will be 0, and its height will be $x = h$. Solving for v_0: $-\frac{1}{2}v_0^2 = \dfrac{gR^2}{h+R} - gR \quad\Rightarrow\quad \dfrac{v_0^2}{2} = g\left[-\dfrac{R^2}{R+h} + \dfrac{R(R+h)}{R+h}\right] = \dfrac{gRh}{R+h} \quad\Rightarrow$

$v_0 = \sqrt{\dfrac{2gRh}{R+h}}$.

(b) $v_e = \displaystyle\lim_{h\to\infty} v_0 = \lim_{h\to\infty}\sqrt{\frac{2gRh}{R+h}} = \lim_{h\to\infty}\sqrt{\frac{2gR}{(R/h)+1}} = \sqrt{2gR}$

(c) $v_e = \sqrt{2\cdot 32\text{ ft/s}^2\cdot 3960\text{ mi}\cdot 5280\text{ ft/mi}} \approx 36{,}581\text{ ft/s} \approx 6.93\text{ mi/s}$

APPLIED PROJECT How Fast Does a Tank Drain?

1. (a) $V = \pi r^2 h \quad\Rightarrow\quad \dfrac{dV}{dt} = \pi r^2\dfrac{dh}{dt}$ [implicit differentiation] $\Rightarrow$

$$\frac{dh}{dt} = \frac{1}{\pi r^2}\frac{dV}{dt} = \frac{1}{\pi r^2}\left(-a\sqrt{2gh}\right) = \frac{1}{\pi 2^2}\left[-\pi\left(\tfrac{1}{12}\right)^2\sqrt{2\cdot 32}\,\sqrt{h}\right] = -\tfrac{1}{72}\sqrt{h}$$

(b) $\dfrac{dh}{dt} = -\frac{1}{72}\sqrt{h} \quad\Rightarrow\quad h^{-1/2}\,dh = -\frac{1}{72}\,dt \quad\Rightarrow\quad 2\sqrt{h} = -\frac{1}{72}t + C$.

$h(0) = 6 \quad\Rightarrow\quad 2\sqrt{6} = 0 + C \quad\Rightarrow\quad C = 2\sqrt{6} \quad\Rightarrow\quad h(t) = \left(-\frac{1}{144}t + \sqrt{6}\right)^2$.

(c) We want to find t when $h = 0$, so we set $h = 0 = \left(-\frac{1}{144}t + \sqrt{6}\right)^2 \Rightarrow t = 144\sqrt{6} \approx 5$ min 53 s.

2. (a) $\dfrac{dh}{dt} = k\sqrt{h} \Rightarrow h^{-1/2}\,dh = k\,dt \quad [h \neq 0] \Rightarrow 2\sqrt{h} = kt + C \Rightarrow$

$h(t) = \frac{1}{4}(kt + C)^2$. Since $h(0) = 10$ cm, the relation $2\sqrt{h(t)} = kt + C$ gives us $2\sqrt{10} = C$. Also, $h(68) = 3$ cm, so $2\sqrt{3} = 68k + 2\sqrt{10}$ and

$k = -\dfrac{\sqrt{10} - \sqrt{3}}{34}$. Thus,

$$h(t) = \frac{1}{4}\left(2\sqrt{10} - \frac{\sqrt{10} - \sqrt{3}}{34}\,t\right)^2 \approx 10 - 0.133t + 0.00044t^2.$$

Here is a table of values of $h(t)$ correct to one decimal place.

t (in s)	$h(t)$ (in cm)
10	8.7
20	7.5
30	6.4
40	5.4
50	4.5
60	3.6

(b) The answers to this part are to be obtained experimentally. See the article by Tom Farmer and Fred Gass, *Physical Demonstrations in the Calculus Classroom,* College Mathematics Journal 1992, pp. 146–148.

3. $V(t) = \pi r^2 h(t) = 100\pi h(t) \Rightarrow \dfrac{dV}{dh} = 100\pi$ and $\dfrac{dV}{dt} = \dfrac{dV}{dh}\dfrac{dh}{dt} = 100\pi\dfrac{dh}{dt}$.

Diameter $= 2.5$ inches $\Rightarrow$ radius $= 1.25$ inches $= \frac{5}{4}\cdot\frac{1}{12}$ foot $= \frac{5}{48}$ foot. Thus, $\dfrac{dV}{dt} = -a\sqrt{2gh} \Rightarrow$

$100\pi\dfrac{dh}{dt} = -\pi\left(\frac{5}{48}\right)^2\sqrt{2\cdot 32h} = -\dfrac{25\pi}{288}\sqrt{h} \Rightarrow \dfrac{dh}{dt} = -\dfrac{\sqrt{h}}{1152} \Rightarrow \int h^{-1/2}\,dh = \int -\frac{1}{1152}\,dt \Rightarrow$

$2\sqrt{h} = -\frac{1}{1152}t + C \Rightarrow \sqrt{h} = -\frac{1}{2304}t + k \Rightarrow h(t) = \left(-\frac{1}{2304}t + k\right)^2$. The water pressure after t seconds is $62.5h(t)$ lb/ft^2, so the condition that the pressure be at least 2160 lb/ft^2 for 10 minutes (600 seconds) is the condition $62.5\cdot h(600) \geq 2160$; that is, $\left(k - \frac{600}{2304}\right)^2 \geq \frac{2160}{62.5} \Rightarrow \left|k - \frac{25}{96}\right| \geq \sqrt{34.56} \Rightarrow k \geq \frac{25}{96} + \sqrt{34.56}$. Now $h(0) = k^2$, so the height of the tank should be at least $\left(\frac{25}{96} + \sqrt{34.56}\right)^2 \approx 37.69$ ft.

4. (a) If the radius of the circular cross-section at height h is r, then the Pythagorean Theorem gives $r^2 = 2^2 - (2-h)^2$ since the radius of the tank is 2 m. So $A(h) = \pi r^2 = \pi[4 - (2-h)^2] = \pi(4h - h^2)$. Thus, $A(h)\dfrac{dh}{dt} = -a\sqrt{2gh} \Rightarrow$

$\pi(4h - h^2)\dfrac{dh}{dt} = -\pi(0.01)^2\sqrt{2\cdot 10h} \Rightarrow (4h - h^2)\dfrac{dh}{dt} = -0.0001\sqrt{20h}$.

(b) From part (a) we have $(4h^{1/2} - h^{3/2})\,dh = \left(-0.0001\sqrt{20}\right)dt \Rightarrow \frac{8}{3}h^{3/2} - \frac{2}{5}h^{5/2} = \left(-0.0001\sqrt{20}\right)t + C$.

$h(0) = 2 \Rightarrow \frac{8}{3}(2)^{3/2} - \frac{2}{5}(2)^{5/2} = C \Rightarrow C = \left(\frac{16}{3} - \frac{8}{5}\right)\sqrt{2} = \frac{56}{15}\sqrt{2}$. To find out how long it will take to drain all the water we evaluate t when $h = 0$: $0 = \left(-0.0001\sqrt{20}\right)t + C \Rightarrow$

$$t = \frac{C}{0.0001\sqrt{20}} = \frac{56\sqrt{2}/15}{0.0001\sqrt{20}} = \frac{11{,}200\sqrt{10}}{3} \approx 11{,}806 \text{ s} \approx 3 \text{ h } 17 \text{ min}$$

APPLIED PROJECT Which Is Faster, Going Up or Coming Down?

1. $mv' = -pv - mg \;\Rightarrow\; m\dfrac{dv}{dt} = -(pv + mg) \;\Rightarrow\; \displaystyle\int \frac{dv}{pv + mg} = \int -\frac{1}{m}\,dt \;\Rightarrow$

$\dfrac{1}{p}\ln(pv + mg) = -\dfrac{1}{m}t + C$ $[pv + mg > 0]$. At $t = 0$, $v = v_0$, so $C = \dfrac{1}{p}\ln(pv_0 + mg)$.

Thus, $\dfrac{1}{p}\ln(pv + mg) = -\dfrac{1}{m}t + \dfrac{1}{p}\ln(pv_0 + mg) \;\Rightarrow\; \ln(pv + mg) = -\dfrac{p}{m}t + \ln(pv_0 + mg) \;\Rightarrow$

$pv + mg = e^{-pt/m}(pv_0 + mg) \;\Rightarrow\; pv = (pv_0 + mg)e^{-pt/m} - mg \;\Rightarrow\; v(t) = \left(v_0 + \dfrac{mg}{p}\right)e^{-pt/m} - \dfrac{mg}{p}$.

2. $y(t) = \int v(t)\,dt = \displaystyle\int\left[\left(v_0 + \frac{mg}{p}\right)e^{-pt/m} - \frac{mg}{p}\right]dt = \left(v_0 + \frac{mg}{p}\right)e^{-pt/m}\left(-\frac{m}{p}\right) - \frac{mg}{p}t + C.$

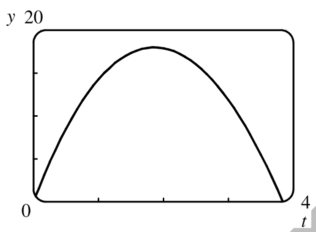
At $t = 0$, $y = 0$, so $C = \left(v_0 + \dfrac{mg}{p}\right)\dfrac{m}{p}$. Thus,

$$y(t) = \left(v_0 + \frac{mg}{p}\right)\frac{m}{p} - \left(v_0 + \frac{mg}{p}\right)\frac{m}{p}e^{-pt/m} - \frac{mgt}{p} = \left(v_0 + \frac{mg}{p}\right)\frac{m}{p}\left(1 - e^{-pt/m}\right) - \frac{mgt}{p}$$

3. $v(t) = 0 \;\Rightarrow\; \dfrac{mg}{p} = \left(v_0 + \dfrac{mg}{p}\right)e^{-pt/m} \;\Rightarrow\; e^{pt/m} = \dfrac{pv_0}{mg} + 1 \;\Rightarrow\; \dfrac{pt}{m} = \ln\left(\dfrac{pv_0}{mg} + 1\right) \;\Rightarrow$

$t_1 = \dfrac{m}{p}\ln\left(\dfrac{mg + pv_0}{mg}\right)$. With $m = 1$, $v_0 = 20$, $p = \frac{1}{10}$, and $g = 9.8$, we have $t_1 = 10\ln\left(\frac{11.8}{9.8}\right) \approx 1.86$ s.

4.



The figure shows the graph of $y = 1180(1 - e^{-0.1t}) - 98t$. The zeros are at $t = 0$ and $t_2 \approx 3.84$. Thus, $t_1 - 0 \approx 1.86$ and $t_2 - t_1 \approx 1.98$. So the time it takes to come down is about 0.12 s longer than the time it takes to go up; hence, going up is faster.

5. $y(2t_1) = \left(v_0 + \dfrac{mg}{p}\right)\dfrac{m}{p}(1 - e^{-2pt_1/m}) - \dfrac{mg}{p}\cdot 2t_1$

$= \left(\dfrac{pv_0 + mg}{p}\right)\dfrac{m}{p}\left[1 - (e^{pt_1/m})^{-2}\right] - \dfrac{mg}{p}\cdot 2\dfrac{m}{p}\ln\left(\dfrac{pv_0 + mg}{mg}\right)$

Substituting $x = e^{pt_1/m} = \dfrac{pv_0}{mg} + 1 = \dfrac{pv_0 + mg}{mg}$ (from Problem 3), we get

$y(2t_1) = \left(x\cdot\dfrac{mg}{p}\right)\dfrac{m}{p}(1 - x^{-2}) - \dfrac{m^2g}{p^2}\cdot 2\ln x = \dfrac{m^2g}{p^2}\left(x - \dfrac{1}{x} - 2\ln x\right)$. Now $p > 0$, $m > 0$, $t_1 > 0 \;\Rightarrow$

$x = e^{pt_1/m} > e^0 = 1$. $f(x) = x - \dfrac{1}{x} - 2\ln x \;\Rightarrow\; f'(x) = 1 + \dfrac{1}{x^2} - \dfrac{2}{x} = \dfrac{x^2 - 2x + 1}{x^2} = \dfrac{(x-1)^2}{x^2} > 0$

for $x > 1 \;\Rightarrow\; f(x)$ is increasing for $x > 1$. Since $f(1) = 0$, it follows that $f(x) > 0$ for every $x > 1$. Therefore,

$y(2t_1) = \dfrac{m^2g}{p^2}f(x)$ is positive, which means that the ball has not yet reached the ground at time $2t_1$. This tells us that the time spent going up is always less than the time spent coming down, so *ascent is faster*.

9.4 Models for Population Growth

1. (a) Comparing the given equation, $\dfrac{dP}{dt} = 0.04P\left(1 - \dfrac{P}{M}\right)$, to Equation 4, $\dfrac{dP}{dt} = kP\left(1 - \dfrac{P}{M}\right)$, we see that the carrying capacity is $M = 1200$ and the value of k is 0.04.

(b) By Equation 7, the solution of the equation is $P(t) = \dfrac{M}{1 + Ae^{-kt}}$, where $A = \dfrac{M - P_0}{P_0}$. Since $P(0) = P_0 = 60$, we have $A = \dfrac{1200 - 60}{60} = 19$, and hence, $P(t) = \dfrac{1200}{1 + 19e^{-0.04t}}$.

(c) The population after 10 weeks is $P(10) = \dfrac{1200}{1 + 19e^{-0.04(10)}} \approx 87$.

2. (a) $dP/dt = 0.02P - 0.00004P^2 = 0.02P(1 - 0.002P) = 0.02P(1 - P/500)$. Comparing to Equation 4, $dP/dt = kP(1 - P/M)$, we see that the carrying capacity is $M = 500$ and the value of k is 0.02.

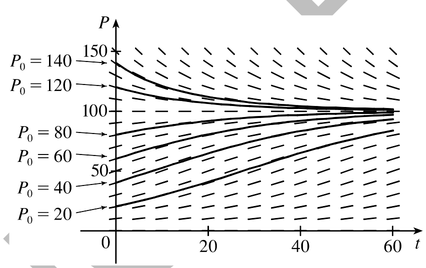
(b) By Equation 7, the solution of the equation is $P(t) = \dfrac{M}{1 + Ae^{-kt}}$, where $A = \dfrac{M - P_0}{P_0}$. Since $P(0) = P_0 = 40$, we have $A = \dfrac{500 - 40}{40} = 11.5$, and hence, $P(t) = \dfrac{500}{1 + 11.5e^{-0.02t}}$.

(c) The population after 10 weeks is $P(10) = \dfrac{500}{1 + 11.5e^{-0.02(10)}} \approx 48$.

3. (a) $dP/dt = 0.05P - 0.0005P^2 = 0.05P(1 - 0.01P) = 0.05P(1 - P/100)$. Comparing to Equation 4, $dP/dt = kP(1 - P/M)$, we see that the carrying capacity is $M = 100$ and the value of k is 0.05.

(b) The slopes close to 0 occur where P is near 0 or 100. The largest slopes appear to be on the line $P = 50$. The solutions are increasing for $0 < P_0 < 100$ and decreasing for $P_0 > 100$.

(c)

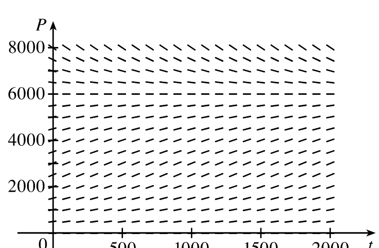


All of the solutions approach $P = 100$ as t increases. As in part (b), the solutions differ since for $0 < P_0 < 100$ they are increasing, and for $P_0 > 100$ they are decreasing. Also, some have an IP and some don't. It appears that the solutions which have $P_0 = 20$ and $P_0 = 40$ have inflection points at $P = 50$.

(d) The equilibrium solutions are $P = 0$ (trivial solution) and $P = 100$. The increasing solutions move away from $P = 0$ and all nonzero solutions approach $P = 100$ as $t \to \infty$.

4. (a) $M = 6000$ and $k = 0.0015 \quad \Rightarrow \quad dP/dt = 0.0015P(1 - P/6000)$.

(b)



All of the solution curves approach 6000 as $t \to \infty$.

(c) 
The curves with $P_0 = 1000$ and $P_0 = 2000$ appear to be concave upward at first and then concave downward. The curve with $P_0 = 4000$ appears to be concave downward everywhere. The curve with $P_0 = 8000$ appears to be concave upward everywhere. The inflection points are where the population grows the fastest.

(d) See the solution to Exercise 9.2.25 for a possible program to calculate $P(50)$. [In this case, we use $\mathrm{X} = 0$, $\mathrm{H} = 1$, $\mathrm{N} = 50$, $\mathrm{Y}_1 = 0.0015y(1 - y/6000)$, and $\mathrm{Y} = 1000$.] We find that $P(50) \approx 1064$.

(e) Using Equation 7 with $M = 6000$, $k = 0.0015$, and $P_0 = 1000$, we have $P(t) = \dfrac{M}{1 + Ae^{-kt}} = \dfrac{6000}{1 + Ae^{-0.0015t}}$, where $A = \dfrac{M - P_0}{P_0} = \dfrac{6000 - 1000}{1000} = 5$. Thus, $P\,(50) = \dfrac{6000}{1 + 5e^{-0.0015(50)}} \approx 1064.1$, which is extremely close to the estimate obtained in part (d).

(f) 
The curves are very similar.

5. (a) $\dfrac{dy}{dt} = ky\left(1 - \dfrac{y}{M}\right) \;\Rightarrow\; y(t) = \dfrac{M}{1 + Ae^{-kt}}$ with $A = \dfrac{M - y(0)}{y(0)}$. With $M = 8 \times 10^7$, $k = 0.71$, and $y(0) = 2 \times 10^7$, we get the model $y(t) = \dfrac{8 \times 10^7}{1 + 3e^{-0.71t}}$, so $y(1) = \dfrac{8 \times 10^7}{1 + 3e^{-0.71}} \approx 3.23 \times 10^7$ kg.

(b) $y(t) = 4 \times 10^7 \;\Rightarrow\; \dfrac{8 \times 10^7}{1 + 3e^{-0.71t}} = 4 \times 10^7 \;\Rightarrow\; 2 = 1 + 3e^{-0.71t} \;\Rightarrow\; e^{-0.71t} = \frac{1}{3} \;\Rightarrow$

$-0.71t = \ln\frac{1}{3} \;\Rightarrow\; t = \dfrac{\ln 3}{0.71} \approx 1.55$ years

6. (a) $\dfrac{dP}{dt} = 0.4P - 0.001P^2 = 0.4P(1 - 0.0025P)\ \left[\frac{0.001}{0.4} = 0.0025\right] = 0.4P\left(1 - \dfrac{P}{400}\right)\ \left[0.0025^{-1} = 400\right]$

Thus, by Equation 4, $k = 0.4$ and the carrying capacity is 400.

(b) Using the fact that $P(0) = 50$ and the formula for dP/dt, we get

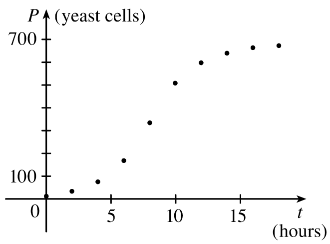
$$P'(0) = \left.\frac{dP}{dt}\right|_{t=0} = 0.4(50) - 0.001(50)^2 = 20 - 2.5 = 17.5.$$

(c) From Equation 7, $A = \dfrac{M - P_0}{P_0} = \dfrac{400 - 50}{50} = 7$, so $P = \dfrac{400}{1 + 7e^{-0.4t}}$. The population reaches 50% of the carrying capacity, 200, when $200 = \dfrac{400}{1 + 7e^{-0.4t}} \;\Rightarrow\; 1 + 7e^{-0.4t} = 2 \;\Rightarrow\; e^{-0.4t} = \frac{1}{7} \;\Rightarrow\; -0.4t = \ln\frac{1}{7} \;\Rightarrow$

$t = \left(\ln\frac{1}{7}\right)/(-0.4) \approx 4.86$ years.

7. Using (7), $A = \dfrac{M - P_0}{P_0} = \dfrac{10{,}000 - 1000}{1000} = 9$, so $P(t) = \dfrac{10{,}000}{1 + 9e^{-kt}}$. $P(1) = 2500 \Rightarrow 2500 = \dfrac{10{,}000}{1 + 9e^{-k(1)}} \Rightarrow$ $1 + 9e^{-k} = 4 \Rightarrow 9e^{-k} = 3 \Rightarrow e^{-k} = \frac{1}{3} \Rightarrow -k = \ln\frac{1}{3} \Rightarrow k = \ln 3$. After another three years, $t = 4$, and $P(4) = \dfrac{10{,}000}{1 + 9e^{-(\ln 3)4}} = \dfrac{10{,}000}{1 + 9\left(e^{\ln 3}\right)^{-4}} = \dfrac{10{,}000}{1 + 9(3)^{-4}} = \dfrac{10{,}000}{1 + \frac{1}{9}} = \dfrac{10{,}000}{\frac{10}{9}} = 9000$.

8. (a)



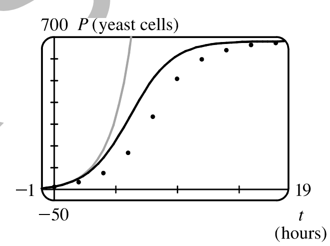
From the graph, we estimate the carrying capacity M for the yeast population to be 680.

(b) An estimate of the initial relative growth rate is $\dfrac{1}{P_0}\dfrac{dP}{dt} = \dfrac{1}{18} \cdot \dfrac{39 - 18}{2 - 0} = \dfrac{7}{12} = 0.58\overline{3}$.

(c) An exponential model is $P(t) = 18e^{7t/12}$. A logistic model is $P(t) = \dfrac{680}{1 + Ae^{-7t/12}}$, where $A = \frac{680 - 18}{18} = \frac{331}{9}$.

(d)

Time in Hours	Observed Values	Exponential Model	Logistic Model
0	18	18	18
2	39	58	55
4	80	186	149
6	171	596	322
8	336	1914	505
10	509	6147	614
12	597	19,739	658
14	640	63,389	673
16	664	203,558	678
18	672	653,679	679



The exponential model is a poor fit for anything beyond the first two observed values. The logistic model varies more for the middle values than it does for the values at either end, but provides a good general fit, as shown in the figure.

(e) $P(7) = \dfrac{680}{1 + \frac{331}{9}e^{-7(7/12)}} \approx 420$ yeast cells

9. (a) We will assume that the difference in birth and death rates is 20 million/year. Let $t = 0$ correspond to the year 2000. Thus, $k \approx \dfrac{1}{P}\dfrac{dP}{dt} = \dfrac{1}{6.1 \text{ billion}}\left(\dfrac{20 \text{ million}}{\text{year}}\right) = \dfrac{1}{305}$, and $\dfrac{dP}{dt} = kP\left(1 - \dfrac{P}{M}\right) = \dfrac{1}{305}P\left(1 - \dfrac{P}{20}\right)$ with P in billions.

(b) $A = \dfrac{M - P_0}{P_0} = \dfrac{20 - 6.1}{6.1} = \dfrac{139}{61} \approx 2.2787$. $P(t) = \dfrac{M}{1 + Ae^{-kt}} = \dfrac{20}{1 + \frac{139}{61}e^{-t/305}}$, so

$P(10) = \dfrac{20}{1 + \frac{139}{61}e^{-10/305}} \approx 6.24$ billion, which underestimates the actual 2010 population of 6.9 billion.

(c) The years 2100 and 2500 correspond to $t = 100$ and $t = 500$, respectively. $P(100) = \dfrac{20}{1 + \frac{139}{61}e^{-100/305}} \approx 7.57$ billion and $P(500) = \dfrac{20}{1 + \frac{139}{61}e^{-500/305}} \approx 13.87$ billion.

10. (a) Let $t = 0$ correspond to the year 2000. $A = \dfrac{M - P_0}{P_0} = \dfrac{800 - 282}{282} = \dfrac{259}{141} \approx 1.8369$.

$P(t) = \dfrac{M}{1 + Ae^{-kt}} = \dfrac{800}{1 + \frac{259}{141}e^{-kt}}$ with P in millions.

(b) $P(10) = 309 \quad \Leftrightarrow \quad \dfrac{800}{1 + \frac{259}{141}e^{-10k}} = 309 \quad \Leftrightarrow \quad \dfrac{800}{309} = 1 + \dfrac{259}{141}e^{-10k} \quad \Leftrightarrow \quad \dfrac{491}{309} = \dfrac{259}{141}e^{-10k} \quad \Leftrightarrow$

$\dfrac{491 \cdot 141}{309 \cdot 259} = e^{-10k} \quad \Leftrightarrow \quad -10k = \ln \dfrac{491 \cdot 47}{103 \cdot 259} \quad \Leftrightarrow \quad k = -\dfrac{1}{10} \ln \dfrac{23{,}077}{26{,}677} \approx 0.0145$.

(c) The years 2100 and 2200 correspond to $t = 100$ and $t = 200$, respectively. $P(100) = \dfrac{800}{1 + \frac{259}{141}e^{-100k}} \approx 559$ million and

$P(200) = \dfrac{800}{1 + \frac{259}{141}e^{-200k}} \approx 727$ million.

(d) $P(t) = 500 \quad \Leftrightarrow \quad \dfrac{800}{1 + \frac{259}{141}e^{-kt}} = 500 \quad \Leftrightarrow \quad \dfrac{800}{500} = 1 + \dfrac{259}{141}e^{-kt} \quad \Leftrightarrow \quad \dfrac{3}{5} = \dfrac{259}{141}e^{-kt} \quad \Leftrightarrow \quad \dfrac{3 \cdot 141}{5 \cdot 259} = e^{-kt} \quad \Leftrightarrow$

$-kt = \ln \dfrac{423}{1295} \quad \Leftrightarrow \quad t = 10\, \dfrac{\ln(423/1295)}{\ln(23{,}077/26{,}677)} \approx 77.18$ years. Our logistic model predicts that the US population will exceed 500 million in 77.18 years; that is, in the year 2077.

11. (a) Our assumption is that $\dfrac{dy}{dt} = ky(1 - y)$, where y is the fraction of the population that has heard the rumor.

(b) Using the logistic equation (4), $\dfrac{dP}{dt} = kP\left(1 - \dfrac{P}{M}\right)$, we substitute $y = \dfrac{P}{M}$, $P = My$, and $\dfrac{dP}{dt} = M\,\dfrac{dy}{dt}$,

to obtain $M\,\dfrac{dy}{dt} = k(My)(1 - y) \quad \Leftrightarrow \quad \dfrac{dy}{dt} = ky(1 - y)$, our equation in part (a).

Now the solution to (4) is $P(t) = \dfrac{M}{1 + Ae^{-kt}}$, where $A = \dfrac{M - P_0}{P_0}$.

We use the same substitution to obtain $My = \dfrac{M}{1 + \dfrac{M - My_0}{My_0}e^{-kt}} \quad \Rightarrow \quad y = \dfrac{y_0}{y_0 + (1 - y_0)e^{-kt}}$.

Alternatively, we could use the same steps as outlined in the solution of Equation 4.

(c) Let t be the number of hours since 8 AM. Then $y_0 = y(0) = \frac{80}{1000} = 0.08$ and $y(4) = \frac{1}{2}$, so

$\dfrac{1}{2} = y(4) = \dfrac{0.08}{0.08 + 0.92e^{-4k}}$. Thus, $0.08 + 0.92e^{-4k} = 0.16$, $e^{-4k} = \frac{0.08}{0.92} = \frac{2}{23}$, and $e^{-k} = \left(\frac{2}{23}\right)^{1/4}$,

so $y = \dfrac{0.08}{0.08 + 0.92(2/23)^{t/4}} = \dfrac{2}{2 + 23(2/23)^{t/4}}$. Solving this equation for t, we get

$$2y + 23y\left(\frac{2}{23}\right)^{t/4} = 2 \quad \Rightarrow \quad \left(\frac{2}{23}\right)^{t/4} = \frac{2 - 2y}{23y} \quad \Rightarrow \quad \left(\frac{2}{23}\right)^{t/4} = \frac{2}{23} \cdot \frac{1 - y}{y} \quad \Rightarrow \quad \left(\frac{2}{23}\right)^{t/4 - 1} = \frac{1 - y}{y}.$$

It follows that $\dfrac{t}{4} - 1 = \dfrac{\ln[(1 - y)/y]}{\ln \frac{2}{23}}$, so $t = 4\left[1 + \dfrac{\ln((1 - y)/y)}{\ln \frac{2}{23}}\right]$.

When $y = 0.9$, $\dfrac{1 - y}{y} = \frac{1}{9}$, so $t = 4\left(1 - \dfrac{\ln 9}{\ln \frac{2}{23}}\right) \approx 7.6$ h or 7 h 36 min. Thus, 90% of the population will have heard the rumor by 3:36 PM.

12. (a) $P(0) = P_0 = 400$, $P(1) = 1200$ and $M = 10{,}000$. From the solution to the logistic differential equation

$$P(t) = \frac{P_0 M}{P_0 + (M - P_0)e^{-kt}}, \text{ we get } P = \frac{400\,(10{,}000)}{400 + (9600)e^{-kt}} = \frac{10{,}000}{1 + 24e^{-kt}}. \quad P(1) = 1200 \quad \Rightarrow$$

$$1 + 24e^{-k} = \tfrac{100}{12} \quad \Rightarrow \quad e^k = \tfrac{288}{88} \quad \Rightarrow \quad k = \ln\tfrac{36}{11}. \text{ So } P = \frac{10{,}000}{1 + 24e^{-t\ln(36/11)}} = \frac{10{,}000}{1 + 24\cdot(11/36)^t}.$$

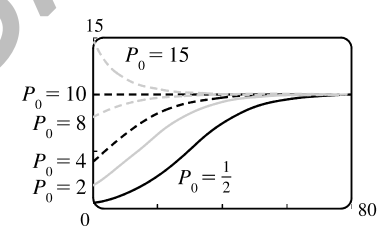
(b) $5000 = \dfrac{10{,}000}{1 + 24(11/36)^t} \quad \Rightarrow \quad 24\left(\tfrac{11}{36}\right)^t = 1 \quad \Rightarrow \quad t\ln\tfrac{11}{36} = \ln\tfrac{1}{24} \quad \Rightarrow \quad t \approx 2.68$ years.

13. (a) $\dfrac{dP}{dt} = kP\left(1 - \dfrac{P}{M}\right) \quad \Rightarrow \quad \dfrac{d^2P}{dt^2} = k\left[P\left(-\dfrac{1}{M}\dfrac{dP}{dt}\right) + \left(1 - \dfrac{P}{M}\right)\dfrac{dP}{dt}\right] = k\dfrac{dP}{dt}\left(-\dfrac{P}{M} + 1 - \dfrac{P}{M}\right)$

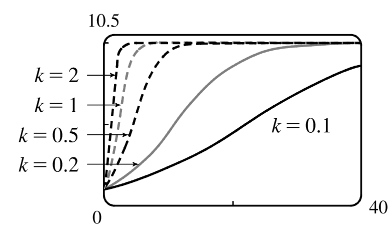
$$= k\left[kP\left(1 - \frac{P}{M}\right)\right]\left(1 - \frac{2P}{M}\right) = k^2P\left(1 - \frac{P}{M}\right)\left(1 - \frac{2P}{M}\right)$$

(b) P grows fastest when P' has a maximum, that is, when $P'' = 0$. From part (a), $P'' = 0 \quad \Leftrightarrow \quad P = 0, P = M$, or $P = M/2$. Since $0 < P < M$, we see that $P'' = 0 \quad \Leftrightarrow \quad P = M/2$.

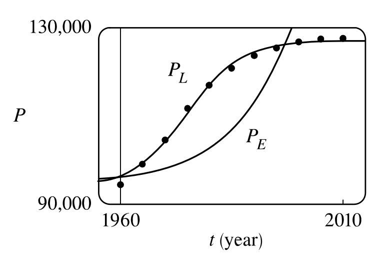
14. First we keep k constant (at 0.1, say) and change P_0 in the function $P = \dfrac{10P_0}{P_0 + (10 - P_0)e^{-0.1t}}$. (Notice that P_0 is the P-intercept.) If $P_0 = 0$, the function is 0 everywhere. For $0 < P_0 < 5$, the curve has an inflection point, which moves to the right as P_0 decreases. If $5 < P_0 < 10$, the graph is concave down everywhere. (We are considering only $t \geq 0$.) If $P_0 = 10$, the function is the constant function $P = 10$, and if $P_0 > 10$, the function decreases. For all $P_0 \neq 0$, $\lim\limits_{t\to\infty} P = 10$.



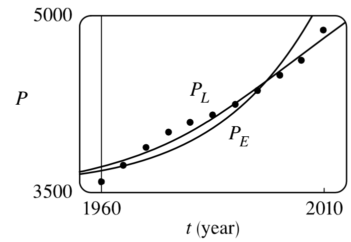
Now we instead keep P_0 constant (at $P_0 = 1$) and change k in the function $P = \dfrac{10}{1 + 9e^{-kt}}$. It seems that as k increases, the graph approaches the line $P = 10$ more and more quickly. (Note that the only difference in the shape of the curves is in the horizontal scaling; if we choose suitable x-scales, the graphs all look the same.)



15. Following the hint, we choose $t = 0$ to correspond to 1960 and subtract 94,000 from each of the population figures. We then use a calculator to obtain the models and add 94,000 to get the exponential function $P_E(t) = 1909.7761(1.0796)^t + 94{,}000$ and the logistic function $P_L(t) = \dfrac{33{,}086.4394}{1 + 12.3428e^{-0.1657t}} + 94{,}000$. P_L is a reasonably accurate model, while P_E is not, since an exponential model would only be used for the first few data points.



16. Following the hint, we choose $t = 0$ to correspond to 1960 and subtract 3500 from each of the population figures. We then use a calculator to obtain the models and add 3500 to get the exponential function $P_E(t) = 180.9934(1.0445)^t + 3500$ and the logistic function $P_L(t) = \dfrac{1348.9650}{1 + 6.2784e^{-0.0721t}} + 3500$. P_L is a reasonably accurate



accurate model, while P_E is not, since an exponential model would only be used for the first few data points.

17. (a) $\dfrac{dP}{dt} = kP - m = k\Big(P - \dfrac{m}{k}\Big)$. Let $y = P - \dfrac{m}{k}$, so $\dfrac{dy}{dt} = \dfrac{dP}{dt}$ and the differential equation becomes $\dfrac{dy}{dt} = ky$.

The solution is $y = y_0 e^{kt} \quad \Rightarrow \quad P - \dfrac{m}{k} = \Big(P_0 - \dfrac{m}{k}\Big)e^{kt} \quad \Rightarrow \quad P(t) = \dfrac{m}{k} + \Big(P_0 - \dfrac{m}{k}\Big)e^{kt}$.

(b) Since $k > 0$, there will be an exponential expansion $\Leftrightarrow \quad P_0 - \dfrac{m}{k} > 0 \quad \Leftrightarrow \quad m < kP_0$.

(c) The population will be constant if $P_0 - \dfrac{m}{k} = 0 \quad \Leftrightarrow \quad m = kP_0$. It will decline if $P_0 - \dfrac{m}{k} < 0 \quad \Leftrightarrow \quad m > kP_0$.

(d) $P_0 = 8{,}000{,}000$, $k = \alpha - \beta = 0.016$, $m = 210{,}000 \quad \Rightarrow \quad m > kP_0$ $(= 128{,}000)$, so by part (c), the population was declining.

18. (a) $\dfrac{dy}{dt} = ky^{1+c} \quad \Rightarrow \quad y^{-1-c}\,dy = k\,dt \quad \Rightarrow \quad \dfrac{y^{-c}}{-c} = kt + C$. Since $y(0) = y_0$, we have $C = \dfrac{y_0^{-c}}{-c}$. Thus,

$\dfrac{y^{-c}}{-c} = kt + \dfrac{y_0^{-c}}{-c}$, or $y^{-c} = y_0^{-c} - ckt$. So $y^c = \dfrac{1}{y_0^{-c} - ckt} = \dfrac{y_0^c}{1 - cy_0^c kt}$ and $y(t) = \dfrac{y_0}{(1 - cy_0^c kt)^{1/c}}$.

(b) $y(t) \to \infty$ as $1 - cy_0^c kt \to 0$, that is, as $t \to \dfrac{1}{cy_0^c k}$. Define $T = \dfrac{1}{cy_0^c k}$. Then $\lim\limits_{t \to T^-} y(t) = \infty$.

(c) According to the data given, we have $c = 0.01$, $y(0) = 2$, and $y(3) = 16$, where the time t is given in months. Thus,

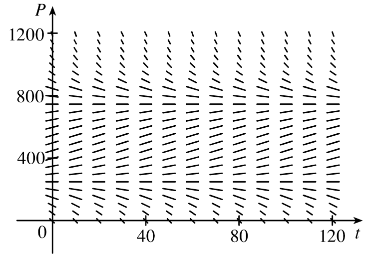
$y_0 = 2$ and $16 = y(3) = \dfrac{y_0}{(1 - cy_0^c k \cdot 3)^{1/c}}$. Since $T = \dfrac{1}{cy_0^c k}$, we will solve for $cy_0^c k$. $\quad 16 = \dfrac{2}{(1 - 3cy_0^c k)^{100}} \quad \Rightarrow$

$1 - 3cy_0^c k = \left(\frac{1}{8}\right)^{0.01} = 8^{-0.01} \quad \Rightarrow \quad cy_0^c k = \frac{1}{3}\left(1 - 8^{-0.01}\right)$. Thus, doomsday occurs when

$t = T = \dfrac{1}{cy_0^c k} = \dfrac{3}{1 - 8^{-0.01}} \approx 145.77$ months or 12.15 years.

19. (a) The term -15 represents a harvesting of fish at a constant rate—in this case, 15 fish/week. This is the rate at which fish are caught.

(b)



(c) From the graph in part (b), it appears that $P(t) = 250$ and $P(t) = 750$ are the equilibrium solutions. We confirm this analytically by solving the equation $dP/dt = 0$ as follows: $0.08P(1 - P/1000) - 15 = 0 \quad \Rightarrow$

$0.08P - 0.00008P^2 - 15 = 0 \quad \Rightarrow$

$-0.00008(P^2 - 1000P + 187{,}500) = 0 \quad \Rightarrow$

$(P - 250)(P - 750) = 0 \quad \Rightarrow \quad P = 250$ or 750.

(d) 
For $0 < P_0 < 250$, $P(t)$ decreases to 0. For $P_0 = 250$, $P(t)$ remains constant. For $250 < P_0 < 750$, $P(t)$ increases and approaches 750. For $P_0 = 750$, $P(t)$ remains constant. For $P_0 > 750$, $P(t)$ decreases and approaches 750.

(e) $\dfrac{dP}{dt} = 0.08P\left(1 - \dfrac{P}{1000}\right) - 15 \quad\Leftrightarrow\quad -\dfrac{100{,}000}{8} \cdot \dfrac{dP}{dt} = (0.08P - 0.00008P^2 - 15) \cdot \left(-\dfrac{100{,}000}{8}\right) \quad\Leftrightarrow$

$$-12{,}500\,\frac{dP}{dt} = P^2 - 1000P + 187{,}500 \quad\Leftrightarrow\quad \frac{dP}{(P-250)(P-750)} = -\frac{1}{12{,}500}\,dt \quad\Leftrightarrow$$

$$\int\left(\frac{-1/500}{P-250} + \frac{1/500}{P-750}\right)dP = -\frac{1}{12{,}500}\,dt \quad\Leftrightarrow\quad \int\left(\frac{1}{P-250} - \frac{1}{P-750}\right)dP = \tfrac{1}{25}\,dt \quad\Leftrightarrow$$

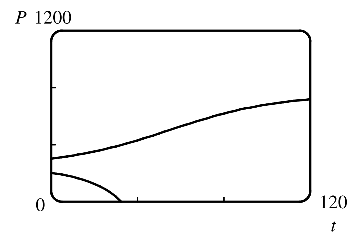
$$\ln|P-250| - \ln|P-750| = \tfrac{1}{25}t + C \quad\Leftrightarrow\quad \ln\left|\frac{P-250}{P-750}\right| = \tfrac{1}{25}t + C \quad\Leftrightarrow\quad \left|\frac{P-250}{P-750}\right| = e^{t/25+C} = ke^{t/25} \quad\Leftrightarrow$$

$$\frac{P-250}{P-750} = ke^{t/25} \quad\Leftrightarrow\quad P - 250 = Pke^{t/25} - 750ke^{t/25} \quad\Leftrightarrow\quad P - Pke^{t/25} = 250 - 750ke^{t/25} \quad\Leftrightarrow$$

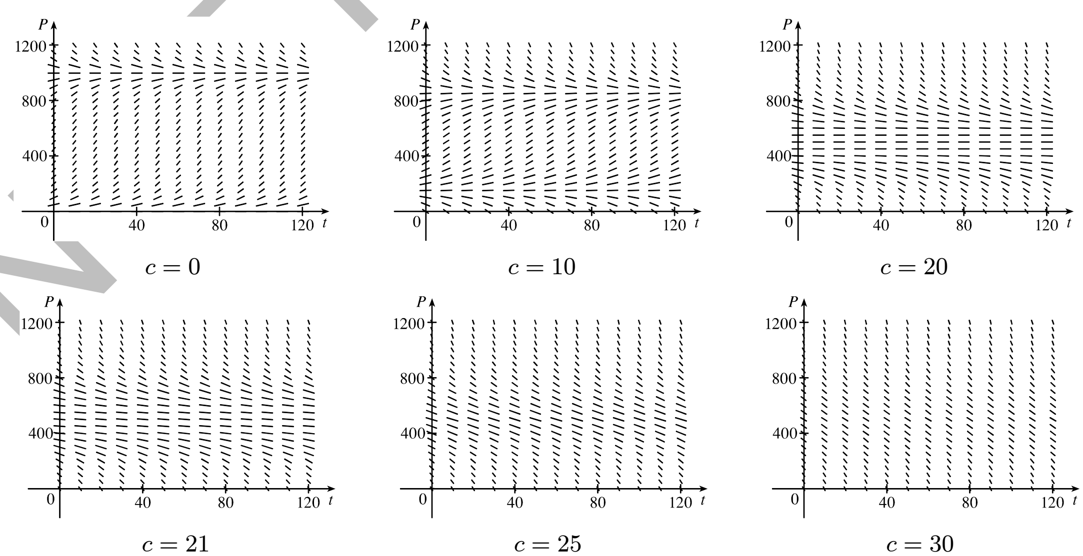
$P(t) = \dfrac{250 - 750ke^{t/25}}{1 - ke^{t/25}}$. If $t = 0$ and $P = 200$, then $200 = \dfrac{250 - 750k}{1-k} \quad\Leftrightarrow\quad 200 - 200k = 250 - 750k \quad\Leftrightarrow$

$550k = 50 \quad\Leftrightarrow\quad k = \frac{1}{11}$. Similarly, if $t = 0$ and $P = 300$, then $k = -\frac{1}{9}$. Simplifying P with these two values of k gives us

$P(t) = \dfrac{250(3e^{t/25} - 11)}{e^{t/25} - 11}$ and $P(t) = \dfrac{750(e^{t/25} + 3)}{e^{t/25} + 9}$.



20. (a)



(b) For $0 \le c \le 20$, there is at least one equilibrium solution. For $c > 20$, the population always dies out.

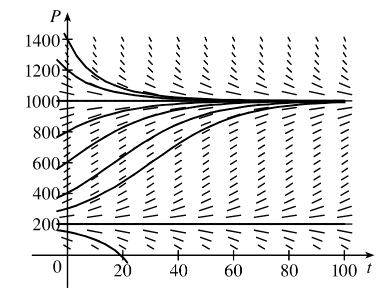
(c) $\dfrac{dP}{dt} = 0.08P - 0.00008P^2 - c$. $\dfrac{dP}{dt} = 0 \quad\Leftrightarrow\quad P = \dfrac{-0.08 \pm \sqrt{(0.08)^2 - 4(-0.00008)(-c)}}{2(-0.00008)}$, which has at least one solution when the discriminant is nonnegative $\Rightarrow$ $0.0064 - 0.00032c \geq 0 \quad\Leftrightarrow\quad c \leq 20$. For $0 \leq c \leq 20$, there is at least one value of P such that $dP/dt = 0$ and hence, at least one equilibrium solution. For $c > 20$, $dP/dt < 0$ and the population always dies out.

(d) The weekly catch should be less than 20 fish per week.

21. (a) $\dfrac{dP}{dt} = (kP)\left(1 - \dfrac{P}{M}\right)\left(1 - \dfrac{m}{P}\right)$. If $m < P < M$, then $dP/dt = (+)(+)(+) = + \quad\Rightarrow\quad P$ is increasing.

If $0 < P < m$, then $dP/dt = (+)(+)(-) = - \quad\Rightarrow\quad P$ is decreasing.

(b)



$k = 0.08$, $M = 1000$, and $m = 200 \quad\Rightarrow$

$$\frac{dP}{dt} = 0.08P\left(1 - \frac{P}{1000}\right)\left(1 - \frac{200}{P}\right)$$

For $0 < P_0 < 200$, the population dies out. For $P_0 = 200$, the population is steady. For $200 < P_0 < 1000$, the population increases and approaches 1000. For $P_0 > 1000$, the population decreases and approaches 1000.

The equilibrium solutions are $P(t) = 200$ and $P(t) = 1000$.

(c) $\dfrac{dP}{dt} = kP\left(1 - \dfrac{P}{M}\right)\left(1 - \dfrac{m}{P}\right) = kP\left(\dfrac{M-P}{M}\right)\left(\dfrac{P-m}{P}\right) = \dfrac{k}{M}(M-P)(P-m) \quad\Leftrightarrow$

$\displaystyle\int \frac{dP}{(M-P)(P-m)} = \int \frac{k}{M}\,dt$. By partial fractions, $\dfrac{1}{(M-P)(P-m)} = \dfrac{A}{M-P} + \dfrac{B}{P-m}$, so $A(P-m) + B(M-P) = 1$.

If $P = m$, $B = \dfrac{1}{M-m}$; if $P = M$, $A = \dfrac{1}{M-m}$, so $\displaystyle\frac{1}{M-m}\int\left(\frac{1}{M-P} + \frac{1}{P-m}\right)dP = \int \frac{k}{M}\,dt \quad\Rightarrow$

$\dfrac{1}{M-m}\left(-\ln|M-P| + \ln|P-m|\right) = \dfrac{k}{M}t + C \quad\Rightarrow\quad \dfrac{1}{M-m}\ln\left|\dfrac{P-m}{M-P}\right| = \dfrac{k}{M}t + C \quad\Rightarrow$

$\ln\left|\dfrac{P-m}{M-P}\right| = (M-m)\dfrac{k}{M}t + C_1 \quad\Leftrightarrow\quad \dfrac{P-m}{M-P} = De^{(M-m)(k/M)t} \quad [D = \pm e^{C_1}]$.

Let $t = 0$: $\dfrac{P_0 - m}{M - P_0} = D$. So $\dfrac{P-m}{M-P} = \dfrac{P_0 - m}{M - P_0}e^{(M-m)(k/M)t}$.

Solving for P, we get $P(t) = \dfrac{m(M-P_0) + M(P_0 - m)e^{(M-m)(k/M)t}}{M - P_0 + (P_0 - m)e^{(M-m)(k/M)t}}$.

(d) If $P_0 < m$, then $P_0 - m < 0$. Let $N(t)$ be the numerator of the expression for $P(t)$ in part (c). Then $N(0) = P_0(M-m) > 0$, and $P_0 - m < 0 \quad\Leftrightarrow\quad \displaystyle\lim_{t\to\infty} M(P_0 - m)e^{(M-m)(k/M)t} = -\infty \quad\Rightarrow\quad \lim_{t\to\infty} N(t) = -\infty$.

Since N is continuous, there is a number t such that $N(t) = 0$ and thus $P(t) = 0$. So the species will become extinct.

22. (a) $\dfrac{dP}{dt} = c\ln\left(\dfrac{M}{P}\right)P \quad\Rightarrow\quad \displaystyle\int \frac{dP}{P\ln(M/P)} = \int c\,dt$. Let $u = \ln\left(\dfrac{M}{P}\right) = \ln M - \ln P \quad\Rightarrow\quad du = -\dfrac{dP}{P} \quad\Rightarrow$

$\displaystyle\int -\frac{du}{u} = ct + D \quad\Rightarrow\quad \ln|u| = -ct - D \quad\Rightarrow\quad |u| = e^{-(ct+D)} \quad\Rightarrow\quad |\ln(M/P)| = e^{-(ct+D)} \quad\Rightarrow$

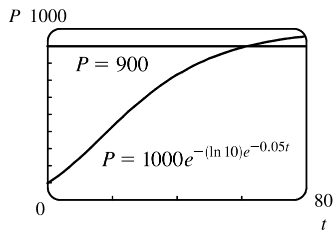
$\ln(M/P) = \pm e^{-(ct+D)}$. Letting $t = 0$, we get $\ln(M/P_0) = \pm e^{-D}$, so

$\ln(M/P) = \pm e^{-ct-D} = \pm e^{-ct}e^{-D} = \ln(M/P_0)e^{-ct} \quad \Rightarrow \quad M/P = e^{\ln(M/P_0)e^{-ct}} \quad \Rightarrow$

$P(t) = Me^{-\ln(M/P_0)e^{-ct}}$, $c \neq 0$.

(b) $\lim\limits_{t\to\infty} P(t) = \lim\limits_{t\to\infty} Me^{-\ln(M/P_0)e^{-ct}} = Me^{-\ln(M/P_0)\cdot 0} = Me^0 = M$

(c)



The graphs look very similar. For the Gompertz function, $P(40) \approx 732$, nearly the same as the logistic function. The Gompertz function reaches $P = 900$ at $t \approx 61.7$ and its value at $t = 80$ is about 959, so it doesn't increase quite as fast as the logistic curve.

(d) $\dfrac{dP}{dt} = c\ln\left(\dfrac{M}{P}\right)P = cP(\ln M - \ln P) \quad \Rightarrow$

$$\begin{aligned}\frac{d^2P}{dt^2} &= c\left[P\left(-\frac{1}{P}\frac{dP}{dt}\right) + (\ln M - \ln P)\frac{dP}{dt}\right] = c\,\frac{dP}{dt}\left[-1 + \ln\left(\frac{M}{P}\right)\right] \\ &= c[c\ln(M/P)P][\ln(M/P) - 1] = c^2P\ln(M/P)\,[\ln(M/P) - 1]\end{aligned}$$

Since $0 < P < M$, $P'' = 0 \quad \Leftrightarrow \quad \ln(M/P) = 1 \quad \Leftrightarrow \quad M/P = e \quad \Leftrightarrow \quad P = M/e$. $\;P'' > 0$ for $0 < P < M/e$ and $P'' < 0$ for $M/e < P < M$, so P' is a maximum (and P grows fastest) when $P = M/e$.

Note: If $P > M$, then $\ln(M/P) < 0$, so $P''(t) > 0$.

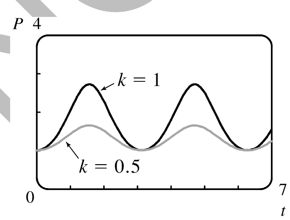
23. (a) $dP/dt = kP\cos(rt - \phi) \quad \Rightarrow \quad (dP)/P = k\cos(rt - \phi)\,dt \quad \Rightarrow \quad \int (dP)/P = k\int \cos(rt - \phi)\,dt \quad \Rightarrow$

$\ln P = (k/r)\sin(rt - \phi) + C$. (Since this is a growth model, $P > 0$ and we can write $\ln P$ instead of $\ln|P|$.) Since $P(0) = P_0$, we obtain $\ln P_0 = (k/r)\sin(-\phi) + C = -(k/r)\sin\phi + C \quad \Rightarrow \quad C = \ln P_0 + (k/r)\sin\phi$. Thus, $\ln P = (k/r)\sin(rt - \phi) + \ln P_0 + (k/r)\sin\phi$, which we can rewrite as $\ln(P/P_0) = (k/r)[\sin(rt - \phi) + \sin\phi]$ or, after exponentiation, $P(t) = P_0e^{(k/r)[\sin(rt-\phi)+\sin\phi]}$.

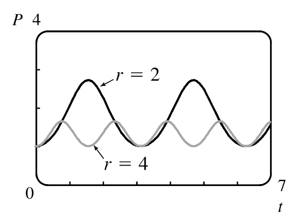
(b) As k increases, the amplitude increases, but the minimum value stays the same.

As r increases, the amplitude and the period decrease.

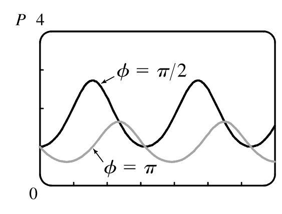
A change in ϕ produces slight adjustments in the phase shift and amplitude.



Comparing values of k with $P_0 = 1$, $r = 2$, and $\phi = \pi/2$



Comparing values of r with $P_0 = 1$, $k = 1$, and $\phi = \pi/2$



Comparing values of ϕ with $P_0 = 1$, $k = 1$, and $r = 2$

$P(t)$ oscillates between $P_0e^{(k/r)(1+\sin\phi)}$ and $P_0e^{(k/r)(-1+\sin\phi)}$ (the extreme values are attained when $rt - \phi$ is an odd multiple of $\frac{\pi}{2}$), so $\lim\limits_{t\to\infty} P(t)$ does not exist.

24. (a) $dP/dt = kP\cos^2(rt-\phi) \;\Rightarrow\; (dP)/P = k\cos^2(rt-\phi)\,dt \;\Rightarrow\; \int (dP)/P = k\int \cos^2(rt-\phi)\,dt \;\Rightarrow$

$\ln P = k\int \dfrac{1+\cos(2(rt-\phi))}{2}\,dt = \dfrac{k}{2}t + \dfrac{k}{4r}\sin(2(rt-\phi)) + C$. From $P(0)=P_0$, we get

$\ln P_0 = \dfrac{k}{4r}\sin(-2\phi) + C = C - \dfrac{k}{4r}\sin 2\phi$, so $C = \ln P_0 + \dfrac{k}{4r}\sin 2\phi$ and

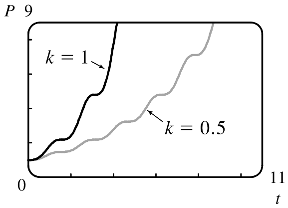
$\ln P = \dfrac{k}{2}t + \dfrac{k}{4r}\sin(2(rt-\phi)) + \ln P_0 + \dfrac{k}{4r}\sin 2\phi$. Simplifying, we get

$\ln \dfrac{P}{P_0} = \dfrac{k}{2}t + \dfrac{k}{4r}\left[\sin(2(rt-\phi)) + \sin 2\phi\right] = f(t)$, or $P(t) = P_0 e^{f(t)}$.

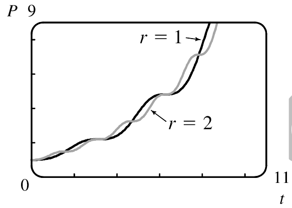
(b) An increase in k stretches the graph of P vertically while maintaining $P(0)=P_0$.

An increase in r compresses the graph of P horizontally—similar to changing the period in Exercise 19.

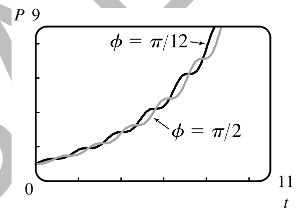
As in Exercise 23, a change in ϕ only makes slight adjustments in the growth of P, as shown in the figure.



Comparing values of k with $P_0 = 1$, $r = 2$, and $\phi = \pi/2$



Comparing values of r with $P_0 = 1$, $k = 0.5$, and $\phi = \pi/2$



Comparing values of ϕ with $P_0 = 1$, $k = 0.5$, and $r = 2$

$f'(t) = k/2 + [k/(4r)][2r\cos(2(rt-\phi))] = (k/2)[1+\cos(2(rt-\phi))] \geq 0$. Since $P(t) = P_0 e^{f(t)}$, we have $P'(t) = P_0 f'(t) e^{f(t)} \geq 0$, with equality only when $\cos(2(rt-\phi)) = -1$; that is, when $rt-\phi$ is an odd multiple of $\frac{\pi}{2}$. Therefore, $P(t)$ is an increasing function on $(0,\infty)$. P can also be written as $P(t) = P_0 e^{kt/2} e^{(k/4r)[\sin(2(rt-\phi))+\sin 2\phi]}$. The second exponential oscillates between $e^{(k/4r)(1+\sin 2\phi)}$ and $e^{(k/4r)(-1+\sin 2\phi)}$, while the first one, $e^{kt/2}$, grows without bound. So $\lim\limits_{t\to\infty} P(t) = \infty$.

25. By Equation 7, $P(t) = \dfrac{K}{1+Ae^{-kt}}$. By comparison, if $c = (\ln A)/k$ and $u = \frac{1}{2}k(t-c)$, then

$$1+\tanh u = 1 + \frac{e^u-e^{-u}}{e^u+e^{-u}} = \frac{e^u+e^{-u}}{e^u+e^{-u}} + \frac{e^u-e^{-u}}{e^u+e^{-u}} = \frac{2e^u}{e^u+e^{-u}}\cdot\frac{e^{-u}}{e^{-u}} = \frac{2}{1+e^{-2u}}$$

and $e^{-2u} = e^{-k(t-c)} = e^{kc}e^{-kt} = e^{\ln A}e^{-kt} = Ae^{-kt}$, so

$$\tfrac{1}{2}K\left[1+\tanh\left(\tfrac{1}{2}k(t-c)\right)\right] = \frac{K}{2}[1+\tanh u] = \frac{K}{2}\cdot\frac{2}{1+e^{-2u}} = \frac{K}{1+e^{-2u}} = \frac{K}{1+Ae^{-kt}} = P(t).$$

9.5 Linear Equations

1. $y' + x\sqrt{y} = x^2$ is not linear since it cannot be put into the standard form (1), $y' + P(x)\,y = Q(x)$.

2. $y' - x = y\tan x \;\Leftrightarrow\; y' + (-\tan x)y = x$ is linear since it can be put into the standard form (1), $y' + P(x)\,y = Q(x)$.

3. $ue^t = t + \sqrt{t}\,\dfrac{du}{dt} \;\Leftrightarrow\; \sqrt{t}\,u' - e^t u = -t \;\Leftrightarrow\; u' - \dfrac{e^t}{\sqrt{t}}u = -\sqrt{t}$ is linear since it can be put into the standard form, $u' + P(t)\,u = Q(t)$.

4. $\dfrac{dR}{dt} + t\cos R = e^{-t} \quad \Leftrightarrow \quad R' + t\cos R = e^{-t}$ is not linear since it cannot be put into the standard form $R' + P(t)\,R = Q(t)$.

5. Comparing the given equation, $y' + y = 1$, with the general form, $y' + P(x)\,y = Q(x)$, we see that $P(x) = 1$ and the integrating factor is $I(x) = e^{\int P(x)\,dx} = e^{\int 1\,dx} = e^x$. Multiplying the differential equation by $I(x)$ gives

$$e^x y' + e^x y = e^x \quad \Rightarrow \quad (e^x y)' = e^x \quad \Rightarrow \quad e^x y = \int e^x\,dx \quad \Rightarrow \quad e^x y = e^x + C \quad \Rightarrow \quad \frac{e^x y}{e^x} = \frac{e^x}{e^x} + \frac{C}{e^x} \quad \Rightarrow$$

$$y = 1 + Ce^{-x}.$$

6. $y' - y = e^x \quad \Leftrightarrow \quad y' + (-1)y = e^x \quad \Rightarrow \quad P(x) = -1. \quad I(x) = e^{\int P(x)\,dx} = e^{\int -1\,dx} = e^{-x}$. Multiplying the original differential equation by $I(x)$ gives $e^{-x}y' - e^{-x}y = e^0 \quad \Rightarrow \quad (e^{-x}y)' = 1 \quad \Rightarrow \quad e^{-x}y = \int 1\,dx \quad \Rightarrow$

$$e^{-x}y = x + C \quad \Rightarrow \quad y = \frac{x + C}{e^{-x}} \quad \Rightarrow \quad y = xe^x + Ce^x.$$

7. $y' = x - y \quad \Rightarrow \quad y' + y = x \ (\star)$. $I(x) = e^{\int P(x)\,dx} = e^{\int 1\,dx} = e^x$. Multiplying the differential equation $(\star)$ by $I(x)$ gives $e^x y' + e^x y = xe^x \quad \Rightarrow \quad (e^x y)' = xe^x \quad \Rightarrow \quad e^x y = \int xe^x\,dx \quad \Rightarrow \quad e^x y = xe^x - e^x + C$ [by parts] $\Rightarrow$ $y = x - 1 + Ce^{-x}$ [divide by e^x].

8. $4x^3 y + x^4 y' = \sin^3 x \quad \Rightarrow \quad (x^4 y)' = \sin^3 x \quad \Rightarrow \quad x^4 y = \int \sin^3 x\,dx \quad \Rightarrow$

$$x^4 y = \int \sin x\,(1 - \cos^2 x)\,dx = \int (1 - u^2)(-du) \quad \begin{bmatrix} u = \cos x, \\ du = -\sin x\,dx \end{bmatrix}$$

$$= \int (u^2 - 1)\,du = \tfrac{1}{3}u^3 - u + C = \tfrac{1}{3}u(u^2 - 3) + C = \tfrac{1}{3}\cos x\,(\cos^2 x - 3) + C \quad \Rightarrow$$

$$y = \frac{1}{3x^4}\cos x\,(\cos^2 x - 3) + \frac{C}{x^4}$$

9. Since $P(x)$ is the derivative of the coefficient of y' [$P(x) = 1$ and the coefficient is x], we can write the differential equation $xy' + y = \sqrt{x}$ in the easily integrable form $(xy)' = \sqrt{x} \quad \Rightarrow \quad xy = \frac{2}{3}x^{3/2} + C \quad \Rightarrow \quad y = \frac{2}{3}\sqrt{x} + C/x$.

10. $2xy' + y = 2\sqrt{x} \quad \Rightarrow \quad y' + \dfrac{1}{2x}\,y = \dfrac{1}{\sqrt{x}} \quad [x > 0] \quad \Rightarrow \quad P(x) = \dfrac{1}{2x}$.

$I(x) = e^{\int P(x)\,dx} = e^{\int 1/(2x)\,dx} = e^{(1/2)\ln|x|} = (e^{\ln x})^{1/2} = \sqrt{x}$. Multiplying the differential equation by $I(x)$ gives

$$\sqrt{x}\,y' + \frac{1}{2\sqrt{x}}\,y = 1 \quad \Rightarrow \quad (\sqrt{x}\,y)' = 1 \quad \Rightarrow \quad \sqrt{x}\,y = \int 1\,dx \quad \Rightarrow \quad \sqrt{x}\,y = x + C \quad \Rightarrow \quad y = \frac{x + C}{\sqrt{x}}.$$

11. $xy' - 2y = x^2 \quad \Rightarrow \quad y' - \dfrac{2}{x}\,y = x \quad \Rightarrow \quad P(x) = -\dfrac{2}{x}$.

$I(x) = e^{\int P(x)\,dx} = e^{\int -2/x\,dx} = e^{-2\ln x} \quad [x > 0] \quad = x^{-2} = \dfrac{1}{x^2}$. Multiplying the differential equation by $I(x)$ gives

$$\frac{1}{x^2}\,y' - \frac{2}{x^3}\,y = \frac{1}{x} \quad \Rightarrow \quad \left(\frac{1}{x^2}\,y\right)' = \frac{1}{x} \quad \Rightarrow \quad \frac{1}{x^2}\,y = \int \frac{1}{x}\,dx \quad \Rightarrow \quad \frac{1}{x^2}\,y = \ln x + C \quad \Rightarrow \quad y = x^2(\ln x + C).$$

12. $y' + 2xy = 1 \quad \Rightarrow \quad P(x) = 2x. \quad I(x) = e^{\int P(x)\,dx} = e^{\int 2x\,dx} = e^{x^2}$. Multiplying the differential equation by $I(x)$ gives $e^{x^2}y' + 2xe^{x^2}y = e^{x^2} \quad \Rightarrow \quad \left(e^{x^2}y\right)' = e^{x^2} \quad \Rightarrow \quad e^{x^2}y = \int_0^x e^{t^2}\,dt + C$ [see page 507] $\Rightarrow$

$$y = e^{-x^2}\int_0^x e^{t^2}\,dt + Ce^{-x^2}.$$

13. $t^2\,\dfrac{dy}{dt}+3ty=\sqrt{1+t^2} \quad\Rightarrow\quad y'+\dfrac{3}{t}\,y=\dfrac{\sqrt{1+t^2}}{t^2} \quad\Rightarrow\quad P(t)=\dfrac{3}{t}$.

$I(t)=e^{\int P(t)\,dt}=e^{\int 3/t\,dt}=e^{3\ln t}\quad [t>0]\quad =t^3$. Multiplying by t^3 gives $t^3y'+3t^2y=t\sqrt{1+t^2} \quad\Rightarrow$

$(t^3y)'=t\sqrt{1+t^2} \quad\Rightarrow\quad t^3y=\int t\sqrt{1+t^2}\,dt \quad\Rightarrow\quad t^3y=\frac{1}{3}(1+t^2)^{3/2}+C \quad\Rightarrow\quad y=\frac{1}{3}t^{-3}(1+t^2)^{3/2}+Ct^{-3}$.

14. $t\ln t\,\dfrac{dr}{dt}+r=te^t \quad\Rightarrow\quad \dfrac{dr}{dt}+\dfrac{1}{t\ln t}\,r=\dfrac{e^t}{\ln t}$. $\quad I(t)=e^{\int dt/(t\ln t)}=e^{\ln(\ln t)}=\ln t$. Multiplying by $\ln t$ gives

$\ln t\,\dfrac{dr}{dt}+\dfrac{1}{t}\,r=e^t \quad\Rightarrow\quad [(\ln t)r]'=e^t \quad\Rightarrow\quad (\ln t)r=e^t+C \quad\Rightarrow\quad r=\dfrac{e^t+C}{\ln t}$.

15. $x^2y'+2xy=\ln x \quad\Rightarrow\quad (x^2y)'=\ln x \quad\Rightarrow\quad x^2y=\int\ln x\,dx \quad\Rightarrow\quad x^2y=x\ln x-x+C$ [by parts]. Since $y(1)=2$,

$1^2(2)=1\ln 1-1+C \quad\Rightarrow\quad 2=-1+C \quad\Rightarrow\quad C=3$, so $x^2y=x\ln x-x+3$, or $y=\dfrac{1}{x}\ln x-\dfrac{1}{x}+\dfrac{3}{x^2}$.

16. $t^3\,\dfrac{dy}{dt}+3t^2y=\cos t \quad\Rightarrow\quad (t^3y)'=\cos t \quad\Rightarrow\quad t^3y=\int\cos t\,dt \quad\Rightarrow\quad t^3y=\sin t+C$. Since $y(\pi)=0$,

$\pi^3(0)=\sin\pi+C \quad\Rightarrow\quad C=0$, so $t^3y=\sin t$, or $y=\dfrac{\sin t}{t^3}$.

17. $t\,\dfrac{du}{dt}=t^2+3u \quad\Rightarrow\quad u'-\dfrac{3}{t}u=t\ (\star)$. $\quad I(t)=e^{\int -3/t\,dt}=e^{-3\ln|t|}=(e^{\ln|t|})^{-3}=t^{-3}\quad [t>0]\ =\dfrac{1}{t^3}$. Multiplying $(\star)$

by $I(t)$ gives $\dfrac{1}{t^3}\,u'-\dfrac{3}{t^4}u=\dfrac{1}{t^2} \quad\Rightarrow\quad \left(\dfrac{1}{t^3}u\right)'=\dfrac{1}{t^2} \quad\Rightarrow\quad \dfrac{1}{t^3}\,u=\displaystyle\int\dfrac{1}{t^2}\,dt \quad\Rightarrow\quad \dfrac{1}{t^3}\,u=-\dfrac{1}{t}+C$. Since $u(2)=4$,

$\dfrac{1}{2^3}(4)=-\dfrac{1}{2}+C \quad\Rightarrow\quad C=1$, so $\dfrac{1}{t^3}\,u=-\dfrac{1}{t}+1$, or $u=-t^2+t^3$.

18. $xy'+y=x\ln x \quad\Rightarrow\quad (x\,y)'=x\ln x \quad\Rightarrow\quad xy=\int x\ln x\,dx \quad\Rightarrow\quad xy=\frac{1}{2}x^2\ln x-\frac{1}{4}x^2+C \quad \left[\begin{matrix}\text{by parts}\\ \text{with } u=\ln x\end{matrix}\right] \quad\Rightarrow$

$y=\dfrac{1}{2}x\ln x-\dfrac{1}{4}x+\dfrac{C}{x}$. $\quad y(1)=0 \quad\Rightarrow\quad 0=0-\dfrac{1}{4}+C \quad\Rightarrow\quad C=\dfrac{1}{4}$, so $y=\dfrac{1}{2}x\ln x-\dfrac{1}{4}x+\dfrac{1}{4x}$.

19. $xy'=y+x^2\sin x \quad\Rightarrow\quad y'-\dfrac{1}{x}\,y=x\sin x$. $\quad I(x)=e^{\int(-1/x)\,dx}=e^{-\ln x}=e^{\ln x^{-1}}=\dfrac{1}{x}$.

Multiplying by $\dfrac{1}{x}$ gives $\dfrac{1}{x}\,y'-\dfrac{1}{x^2}\,y=\sin x \quad\Rightarrow\quad \left(\dfrac{1}{x}\,y\right)'=\sin x \quad\Rightarrow\quad \dfrac{1}{x}\,y=-\cos x+C \quad\Rightarrow\quad y=-x\cos x+Cx$.

$y(\pi)=0 \quad\Rightarrow\quad -\pi\cdot(-1)+C\pi=0 \quad\Rightarrow\quad C=-1$, so $y=-x\cos x-x$.

20. $(x^2+1)\,\dfrac{dy}{dx}+3x(y-1)=0 \quad\Rightarrow\quad (x^2+1)\,y'+3xy=3x \quad\Rightarrow\quad y'+\dfrac{3x}{x^2+1}\,y=\dfrac{3x}{x^2+1}$.

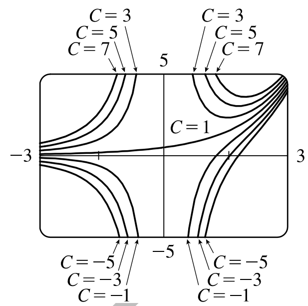
$I(x)=e^{\int 3x/(x^2+1)\,dx}=e^{(3/2)\ln\left|x^2+1\right|}=\left(e^{\ln(x^2+1)}\right)^{3/2}=(x^2+1)^{3/2}$. Multiplying by $(x^2+1)^{3/2}$ gives

$(x^2+1)^{3/2}\,y'+3x(x^2+1)^{1/2}\,y=3x(x^2+1)^{1/2} \quad\Rightarrow\quad \left[(x^2+1)^{3/2}y\right]'=3x(x^2+1)^{1/2} \quad\Rightarrow$

$(x^2+1)^{3/2}\,y=\int 3x(x^2+1)^{1/2}\,dx=(x^2+1)^{3/2}+C \quad\Rightarrow\quad y=1+C(x^2+1)^{-3/2}$. Since $y(0)=2$, we have

$2=1+C(1) \quad\Rightarrow\quad C=1$ and hence, $y=1+(x^2+1)^{-3/2}$.

21. $xy' + 2y = e^x \quad\Rightarrow\quad y' + \dfrac{2}{x}\,y = \dfrac{e^x}{x}$.



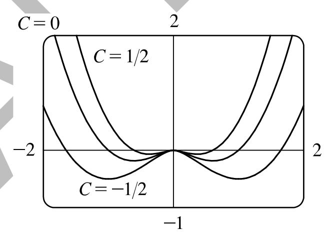
$I(x) = e^{\int (2/x)\,dx} = e^{2\ln|x|} = \left(e^{\ln|x|}\right)^2 = |x|^2 = x^2$.

Multiplying by $I(x)$ gives $x^2\,y' + 2xy = xe^x \quad\Rightarrow\quad (x^2y)' = xe^x \quad\Rightarrow$

$x^2y = \int xe^x\,dx = (x-1)e^x + C$ [by parts] $\Rightarrow$

$y = [(x-1)e^x + C]/x^2$. The graphs for $C = -5, -3, -1, 1, 3, 5$, and 7 are shown. $C = 1$ is a transitional value. For $C < 1$, there is an inflection point and for $C > 1$, there is a local minimum. As $|C|$ gets larger, the "branches" get further from the origin.

22. $xy' = x^2 + 2y \quad\Leftrightarrow\quad xy' - 2y = x^2 \quad\Leftrightarrow\quad y' - \dfrac{2}{x}\,y = x$.



$I(x) = e^{\int -2/x\,dx} = e^{-2\ln|x|} = (e^{\ln|x|})^{-2} = |x|^{-2} = \dfrac{1}{x^2}$. Multiplying by

$I(x)$ gives $\dfrac{1}{x^2}\,y' - \dfrac{2}{x^3}\,y = \dfrac{1}{x} \quad\Rightarrow\quad \left(\dfrac{1}{x^2}\,y\right)' = \dfrac{1}{x} \;\Rightarrow\; \dfrac{1}{x^2}\,y = \displaystyle\int \dfrac{1}{x}\,dx \quad\Rightarrow$

$\dfrac{1}{x^2}\,y = \ln|x| + C \quad\Rightarrow\quad y = (\ln|x| + C)x^2$. For all values of C, as $|x| \to 0$, $y \to 0$, and as $|x| \to \infty$, $y \to \infty$. As $|x|$ increases from 0, the function decreases and attains an absolute minimum. The inflection points, absolute minimums, and x-intercepts all move farther from the origin as C decreases.

23. Setting $u = y^{1-n}$, $\dfrac{du}{dx} = (1-n)\,y^{-n}\dfrac{dy}{dx}$ or $\dfrac{dy}{dx} = \dfrac{y^n}{1-n}\dfrac{du}{dx} = \dfrac{u^{n/(1-n)}}{1-n}\dfrac{du}{dx}$. Then the Bernoulli differential equation becomes $\dfrac{u^{n/(1-n)}}{1-n}\dfrac{du}{dx} + P(x)u^{1/(1-n)} = Q(x)u^{n/(1-n)}$ or $\dfrac{du}{dx} + (1-n)P(x)u = Q(x)(1-n)$.

24. Here $xy' + y = -xy^2 \quad\Rightarrow\quad y' + \dfrac{y}{x} = -y^2$, so $n = 2$, $P(x) = \dfrac{1}{x}$ and $Q(x) = -1$. Setting $u = y^{-1}$, u satisfies $u' - \dfrac{1}{x}u = 1$. Then $I(x) = e^{\int(-1/x)dx} = \dfrac{1}{x}$ (for $x > 0$) and $u = x\left(\displaystyle\int \dfrac{1}{x}\,dx + C\right) = x(\ln|x| + C)$. Thus, $y = \dfrac{1}{x(C + \ln|x|)}$.

25. Here $y' + \dfrac{2}{x}\,y = \dfrac{y^3}{x^2}$, so $n = 3$, $P(x) = \dfrac{2}{x}$ and $Q(x) = \dfrac{1}{x^2}$. Setting $u = y^{-2}$, u satisfies $u' - \dfrac{4u}{x} = -\dfrac{2}{x^2}$.

Then $I(x) = e^{\int(-4/x)\,dx} = x^{-4}$ and $u = x^4\left(\displaystyle\int -\dfrac{2}{x^6}\,dx + C\right) = x^4\left(\dfrac{2}{5x^5} + C\right) = Cx^4 + \dfrac{2}{5x}$.

Thus, $y = \pm\left(Cx^4 + \dfrac{2}{5x}\right)^{-1/2}$.

26. $xy'' + 2y' = 12x^2$ and $u = y' \quad\Rightarrow\quad xu' + 2u = 12x^2 \quad\Rightarrow\quad u' + \dfrac{2}{x}\,u = 12x$.

$I(x) = e^{\int (2/x)\,dx} = e^{2\ln|x|} = \left(e^{\ln|x|}\right)^2 = |x|^2 = x^2$. Multiplying the last differential equation by x^2 gives

$x^2u' + 2xu = 12x^3 \;\Rightarrow\; (x^2u)' = 12x^3 \;\Rightarrow\; x^2u = \int 12x^3\,dx = 3x^4 + C \;\Rightarrow\; u = 3x^2 + C/x^2 \;\Rightarrow$

$y' = 3x^2 + C/x^2 \;\Rightarrow\; y = x^3 - C/x + D.$

27. (a) $2\,\dfrac{dI}{dt} + 10I = 40$ or $\dfrac{dI}{dt} + 5I = 20$. Then the integrating factor is $e^{\int 5\,dt} = e^{5t}$. Multiplying the differential equation by the integrating factor gives $e^{5t}\,\dfrac{dI}{dt} + 5Ie^{5t} = 20e^{5t} \;\Rightarrow\; (e^{5t}I)' = 20e^{5t} \;\Rightarrow$

$I(t) = e^{-5t}\left[\int 20e^{5t}\,dt + C\right] = 4 + Ce^{-5t}$. But $0 = I(0) = 4 + C$, so $I(t) = 4 - 4e^{-5t}$.

(b) $I(0.1) = 4 - 4e^{-0.5} \approx 1.57$ A

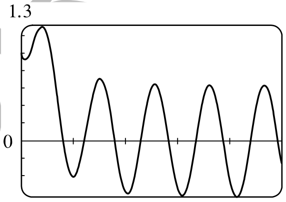
28. (a) $\dfrac{dI}{dt} + 20I = 40\sin 60t$, so the integrating factor is e^{20t}. Multiplying the differential equation by the integrating factor gives $e^{20t}\,\dfrac{dI}{dt} + 20Ie^{20t} = 40e^{20t}\sin 60t \;\Rightarrow\; (e^{20t}I)' = 40e^{20t}\sin 60t \;\Rightarrow$

$$I(t) = e^{-20t}\left[\int 40e^{20t}\sin 60t\,dt + C\right] = e^{-20t}\left[40e^{20t}\left(\tfrac{1}{4000}\right)(20\sin 60t - 60\cos 60t)\right] + Ce^{-20t}$$
$$= \frac{\sin 60t - 3\cos 60t}{5} + Ce^{-20t}$$

But $1 = I(0) = -\frac{3}{5} + C$, so $I(t) = \dfrac{\sin 60t - 3\cos 60t\; + 8e^{-20t}}{5}$.

(b) $I(0.1) = \dfrac{\sin 6 - 3\cos 6 + 8e^{-2}}{5} \approx -0.42$ A

(c)



29. $5\,\dfrac{dQ}{dt} + 20Q = 60$ with $Q(0) = 0$ C. Then the integrating factor is $e^{\int 4\,dt} = e^{4t}$, and multiplying the differential equation by the integrating factor gives $e^{4t}\,\dfrac{dQ}{dt} + 4e^{4t}Q = 12e^{4t} \;\Rightarrow\; (e^{4t}Q)' = 12e^{4t} \;\Rightarrow$

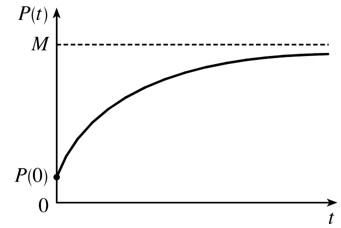
$Q(t) = e^{-4t}\left[\int 12e^{4t}\,dt + C\right] = 3 + Ce^{-4t}$. But $0 = Q(0) = 3 + C$ so $Q(t) = 3(1 - e^{-4t})$ is the charge at time t and $I = dQ/dt = 12e^{-4t}$ is the current at time t.

30. $2\,\dfrac{dQ}{dt} + 100Q = 10\sin 60t$ or $\dfrac{dQ}{dt} + 50Q = 5\sin 60t$. Then the integrating factor is $e^{\int 50\,dt} = e^{50t}$, and multiplying the differential equation by the integrating factor gives $e^{50t}\,\dfrac{dQ}{dt} + 50e^{50t}Q = 5e^{50t}\sin 60t \;\Rightarrow\; (e^{50t}Q)' = 5e^{50t}\sin 60t \;\Rightarrow$

$$Q(t) = e^{-50t}\left[\int 5e^{50t}\sin 60t\,dt + C\right] = e^{-50t}\left[5e^{50t}\left(\tfrac{1}{6100}\right)(50\sin 60t - 60\cos 60t)\right] + Ce^{-50t}$$
$$= \tfrac{1}{122}(5\sin 60t - 6\cos 60t) + Ce^{-50t}$$

But $0 = Q(0) = -\frac{6}{122} + C$ so $C = \frac{3}{61}$ and $Q(t) = \dfrac{5\sin 60t - 6\cos 60t}{122} + \dfrac{3e^{-50t}}{61}$ is the charge at time t, while the current is $I(t) = \dfrac{dQ}{dt} = \dfrac{150\cos 60t + 180\sin 60t - 150e^{-50t}}{61}$.

31. $\dfrac{dP}{dt} + kP = kM$, so $I(t) = e^{\int k\,dt} = e^{kt}$. Multiplying the differential equation by $I(t)$ gives $e^{kt}\,\dfrac{dP}{dt} + kPe^{kt} = kMe^{kt} \;\Rightarrow\; (e^{kt}P)' = kMe^{kt} \;\Rightarrow$ $P(t) = e^{-kt}\left(\int kMe^{kt}dt + C\right) = M + Ce^{-kt}$, $k > 0$. Furthermore, it is reasonable to assume that $0 \le P(0) \le M$, so $-M \le C \le 0$.



32. Since $P(0) = 0$, we have $P(t) = M(1 - e^{-kt})$. If $P_1(t)$ is Jim's learning curve, then $P_1(1) = 25$ and $P_1(2) = 45$. Hence, $25 = M_1(1 - e^{-k})$ and $45 = M_1(1 - e^{-2k})$, so $1 - 25/M_1 = e^{-k}$ or $k = -\ln\left(1 - \dfrac{25}{M_1}\right) = \ln\left(\dfrac{M_1}{M_1 - 25}\right)$. But $45 = M_1(1 - e^{-2k})$ so $45 = M_1\left[1 - \left(\dfrac{M_1 - 25}{M_1}\right)^2\right]$ or $45 = \dfrac{50M_1 - 625}{M_1}$. Thus, $M_1 = 125$ is the maximum number of units per hour Jim is capable of processing. Similarly, if $P_2(t)$ is Mark's learning curve, then $P_2(1) = 35$ and $P_2(2) = 50$. So $k = \ln\left(\dfrac{M_2}{M_2 - 35}\right)$ and $50 = M_2\left[1 - \left(\dfrac{M_2 - 35}{M_2}\right)^2\right]$ or $M_2 = 61.25$. Hence the maximum number of units per hour for Mark is approximately 61. Another approach would be to use the midpoints of the intervals so that $P_1(0.5) = 25$ and $P_1(1.5) = 45$. Doing so gives us $M_1 \approx 52.6$ and $M_2 \approx 51.8$.

33. $y(0) = 0$ kg. Salt is added at a rate of $\left(0.4\,\dfrac{\text{kg}}{\text{L}}\right)\left(5\,\dfrac{\text{L}}{\text{min}}\right) = 2\,\dfrac{\text{kg}}{\text{min}}$. Since solution is drained from the tank at a rate of 3 L/min, but salt solution is added at a rate of 5 L/min, the tank, which starts out with 100 L of water, contains $(100 + 2t)$ L of liquid after t min. Thus, the salt concentration at time t is $\dfrac{y(t)}{100 + 2t}\,\dfrac{\text{kg}}{\text{L}}$. Salt therefore leaves the tank at a rate of $\left(\dfrac{y(t)}{100 + 2t}\,\dfrac{\text{kg}}{\text{L}}\right)\left(3\,\dfrac{\text{L}}{\text{min}}\right) = \dfrac{3y}{100 + 2t}\,\dfrac{\text{kg}}{\text{min}}$. Combining the rates at which salt enters and leaves the tank, we get $\dfrac{dy}{dt} = 2 - \dfrac{3y}{100 + 2t}$. Rewriting this equation as $\dfrac{dy}{dt} + \left(\dfrac{3}{100 + 2t}\right)y = 2$, we see that it is linear.

$$I(t) = \exp\left(\int \frac{3\,dt}{100 + 2t}\right) = \exp\left(\tfrac{3}{2}\ln(100 + 2t)\right) = (100 + 2t)^{3/2}$$

Multiplying the differential equation by $I(t)$ gives $(100 + 2t)^{3/2}\,\dfrac{dy}{dt} + 3(100 + 2t)^{1/2}y = 2(100 + 2t)^{3/2} \;\Rightarrow$ $[(100 + 2t)^{3/2}y]' = 2(100 + 2t)^{3/2} \;\Rightarrow\; (100 + 2t)^{3/2}y = \frac{2}{5}(100 + 2t)^{5/2} + C \;\Rightarrow$ $y = \frac{2}{5}(100 + 2t) + C(100 + 2t)^{-3/2}$. Now $0 = y(0) = \frac{2}{5}(100) + C \cdot 100^{-3/2} = 40 + \frac{1}{1000}C \;\Rightarrow\; C = -40{,}000$, so $y = \left[\frac{2}{5}(100 + 2t) - 40{,}000(100 + 2t)^{-3/2}\right]$ kg. From this solution (no pun intended), we calculate the salt concentration at time t to be $C(t) = \dfrac{y(t)}{100 + 2t} = \left[\dfrac{-40{,}000}{(100 + 2t)^{5/2}} + \dfrac{2}{5}\right]\dfrac{\text{kg}}{\text{L}}$. In particular, $C(20) = \dfrac{-40{,}000}{140^{5/2}} + \dfrac{2}{5} \approx 0.2275\,\dfrac{\text{kg}}{\text{L}}$ and $y(20) = \frac{2}{5}(140) - 40{,}000(140)^{-3/2} \approx 31.85$ kg.

34. Let $y(t)$ denote the amount of chlorine in the tank at time t (in seconds). $y(0) = (0.05 \text{ g/L})(400 \text{ L}) = 20$ g. The amount of liquid in the tank at time t is $(400 - 6t)$ L since 4 L of water enters the tank each second and 10 L of liquid leaves the tank each second. Thus, the concentration of chlorine at time t is $\dfrac{y(t)}{400-6t}\,\dfrac{\text{g}}{\text{L}}$. Chlorine doesn't enter the tank, but it leaves at a rate of $\left[\dfrac{y(t)}{400-6t}\,\dfrac{\text{g}}{\text{L}}\right]\left[10\,\dfrac{\text{L}}{\text{s}}\right] = \dfrac{10\,y(t)}{400-6t}\,\dfrac{\text{g}}{\text{s}} = \dfrac{5\,y(t)}{200-3t}\,\dfrac{\text{g}}{\text{s}}$. Therefore, $\dfrac{dy}{dt} = -\dfrac{5y}{200-3t} \Rightarrow \displaystyle\int \frac{dy}{y} = \int \frac{-5\,dt}{200-3t} \Rightarrow$ $\ln y = \frac{5}{3}\ln(200-3t) + C \Rightarrow y = \exp\left(\frac{5}{3}\ln(200-3t)+C\right) = e^C(200-3t)^{5/3}$. Now $20 = y(0) = e^C \cdot 200^{5/3} \Rightarrow$ $e^C = \dfrac{20}{200^{5/3}}$, so $y(t) = 20\dfrac{(200-3t)^{5/3}}{200^{5/3}} = 20(1-0.015t)^{5/3}$ g for $0 \le t \le 66\frac{2}{3}$ s, at which time the tank is empty.

35. (a) $\dfrac{dv}{dt} + \dfrac{c}{m}v = g$ and $I(t) = e^{\int (c/m)\,dt} = e^{(c/m)t}$, and multiplying the differential equation by $I(t)$ gives $e^{(c/m)t}\dfrac{dv}{dt} + \dfrac{vce^{(c/m)t}}{m} = ge^{(c/m)t} \Rightarrow \left[e^{(c/m)t}v\right]' = ge^{(c/m)t}$. Hence, $v(t) = e^{-(c/m)t}\left[\int ge^{(c/m)t}\,dt + K\right] = mg/c + Ke^{-(c/m)t}$. But the object is dropped from rest, so $v(0) = 0$ and $K = -mg/c$. Thus, the velocity at time t is $v(t) = (mg/c)[1 - e^{-(c/m)t}]$.

(b) $\lim\limits_{t\to\infty} v(t) = mg/c$

(c) $s(t) = \int v(t)\,dt = (mg/c)[t + (m/c)e^{-(c/m)t}] + c_1$ where $c_1 = s(0) - m^2g/c^2$.
$s(0)$ is the initial position, so $s(0) = 0$ and $s(t) = (mg/c)[t + (m/c)e^{-(c/m)t}] - m^2g/c^2$.

36. $v = (mg/c)(1 - e^{-ct/m}) \Rightarrow$

$$\frac{dv}{dm} = \frac{mg}{c}\left(0 - e^{-ct/m}\cdot\frac{ct}{m^2}\right) + \frac{g}{c}\left(1 - e^{-ct/m}\right)\cdot 1 = -\frac{gt}{m}e^{-ct/m} + \frac{g}{c} - \frac{g}{c}e^{-ct/m}$$
$$= \frac{g}{c}\left(1 - e^{-ct/m} - \frac{ct}{m}e^{-ct/m}\right) \Rightarrow$$

$\dfrac{c}{g}\dfrac{dv}{dm} = 1 - \left(1 + \dfrac{ct}{m}\right)e^{-ct/m} = 1 - \dfrac{1+ct/m}{e^{ct/m}} = 1 - \dfrac{1+Q}{e^Q}$, where $Q = \dfrac{ct}{m} \ge 0$. Since $e^Q > 1 + Q$ for all $Q > 0$, it follows that $dv/dm > 0$ for $t > 0$. In other words, for all $t > 0$, v increases as m increases.

37. (a) $z = \dfrac{1}{P} \Rightarrow P = \dfrac{1}{z} \Rightarrow P' = -\dfrac{z'}{z^2}$. Substituting into $P' = kP(1 - P/M)$ gives us $-\dfrac{z'}{z^2} = k\dfrac{1}{z}\left(1 - \dfrac{1}{zM}\right) \Rightarrow$ $z' = -kz\left(1 - \dfrac{1}{zM}\right) \Rightarrow z' = -kz + \dfrac{k}{M} \Rightarrow z' + kz = \dfrac{k}{M}$ $(\star)$.

(b) The integrating factor is $e^{\int k\,dt} = e^{kt}$. Multiplying $(\star)$ by e^{kt} gives $e^{kt}z' + ke^{kt}z = \dfrac{ke^{kt}}{M} \Rightarrow (e^{kt}z)' = \dfrac{k}{M}e^{kt} \Rightarrow$ $e^{kt}z = \displaystyle\int \frac{k}{M}e^{kt}\,dt \Rightarrow e^{kt}z = \frac{1}{M}e^{kt} + C \Rightarrow z = \frac{1}{M} + Ce^{-kt}$. Since $P = \dfrac{1}{z}$, we have $P = \dfrac{1}{\frac{1}{M} + Ce^{-kt}} \Rightarrow P = \dfrac{M}{1 + MCe^{-kt}}$, which agrees with Equation 9.4.7, $P = \dfrac{M}{1 + Ae^{-kt}}$, when $MC = A$.

38. (a) $z = \frac{1}{P} \Rightarrow P = \frac{1}{z} \Rightarrow P' = \frac{-z'}{z^2}$. Substituting into $\frac{dP}{dt} = k(t)P\left(1 - \frac{P}{M(t)}\right)$ gives us

$$-\frac{z'}{z^2} = \frac{k(t)}{z}\left(1 - \frac{1}{M(t)z}\right) \Rightarrow z' = -k(t)z\left(1 - \frac{1}{M(t)z}\right) \Rightarrow z' = -k(t)z + \frac{k(t)}{M(t)} \Rightarrow$$

$$\frac{dz}{dt} + k(t)z = \frac{k(t)}{M(t)} \quad (\star).$$

(b) The integrating factor is $e^{K(t)}$, where $K(t) = \int_0^t k(s)\,ds$, so that $K'(t) = k(t)$. Multiplying $(\star)$ by

$e^{K(t)}$ gives $e^{K(t)}\frac{dz}{dt} + e^{K(t)}k(t)z = \frac{e^{K(t)}k(t)}{M(t)} \Rightarrow (e^{K(t)}z)' = \frac{K'(t)e^{K(t)}}{M(t)} \Rightarrow$

$e^{K(t)}z = \int_0^t \frac{K'(s)e^{K(s)}}{M(s)}\,ds + C$, so $P = \frac{1}{z} = \dfrac{e^{K(t)}}{\int_0^t \frac{K'(s)e^{K(s)}}{M(s)}\,ds + C}$. Now suppose that M is a constant. Then

$P(t) = \dfrac{Me^{K(t)}}{\int_0^t K'(s)e^{K(s)}\,ds + CM} = \dfrac{Me^{K(t)}}{e^{K(t)} + CM} = \dfrac{M}{1 + CMe^{-K(t)}}$. If $\int_0^\infty k(t)\,dt = \infty$, then $\lim_{t\to\infty} K(t) = \infty$, so

$$\lim_{t\to\infty} P(t) = \frac{M}{1 + CM\lim_{t\to\infty} e^{-K(t)}} = \frac{M}{1 + CM \cdot 0} = M.$$

(c) If k is constant, but M varies, then $K(t) = kt$ and we get $e^{kt}z = \int_0^t \frac{ke^{ks}}{M(s)}\,ds + C \Rightarrow$

$z(t) = \dfrac{\int_0^t \frac{ke^{ks}}{M(s)}\,ds + C}{e^{kt}} \Rightarrow z(t) = e^{-kt}\int_0^t \frac{ke^{ks}}{M(s)}\,ds + Ce^{-kt}$. Suppose $M(t)$ has a limit as $t \to \infty$,

say $\lim_{t\to\infty} M(t) = L$. Then

$$\lim_{t\to\infty} P(t) = \lim_{t\to\infty} \frac{1}{z(t)} = \lim_{t\to\infty} \frac{e^{kt}}{\int_0^t \frac{ke^{ks}}{M(s)}\,ds + C} = \lim_{t\to\infty} \frac{ke^{kt}}{\frac{ke^{kt}}{M(t)} + 0} \quad \left[\begin{array}{c}\text{l'Hospital's}\\ \text{and FTC 1}\end{array}\right] = \lim_{t\to\infty} M(t) = L.$$

9.6 Predator-Prey Systems

1. (a) $dx/dt = -0.05x + 0.0001xy$. If $y = 0$, we have $dx/dt = -0.05x$, which indicates that in the absence of y, x declines at a rate proportional to itself. So x represents the predator population and y represents the prey population. The growth of the prey population, $0.1y$ (from $dy/dt = 0.1y - 0.005xy$), is restricted only by encounters with predators (the term $-0.005xy$). The predator population increases only through the term $0.0001xy$; that is, by encounters with the prey and not through additional food sources.

(b) $dy/dt = -0.015y + 0.00008xy$. If $x = 0$, we have $dy/dt = -0.015y$, which indicates that in the absence of x, y would decline at a rate proportional to itself. So y represents the predator population and x represents the prey population. The growth of the prey population, $0.2x$ (from $dx/dt = 0.2x - 0.0002x^2 - 0.006xy = 0.2x(1 - 0.001x) - 0.006xy$), is restricted by a carrying capacity of 1000 [from the term $1 - 0.001x = 1 - x/1000$] and by encounters with predators (the term $-0.006xy$). The predator population increases only through the term $0.00008xy$; that is, by encounters with the prey and not through additional food sources.

2. (a) $dx/dt = 0.12x - 0.0006x^2 + 0.00001xy$. $dy/dt = 0.08y + 0.00004xy$.

The xy terms represent encounters between the two species x and y. An increase in y makes dx/dt (the growth rate of x) larger due to the positive term $0.00001xy$. An increase in x makes dy/dt (the growth rate of y) larger due to the positive term $0.00004xy$. Hence, the system describes a cooperation model.

(b) $dx/dt = 0.15x - 0.0002x^2 - 0.0006xy = 0.15x(1 - x/750) - 0.0006xy$.

$dy/dt = 0.2y - 0.00008y^2 - 0.0002xy = 0.2y(1 - y/2500) - 0.0002xy$.

The system shows that x and y have carrying capacities of 750 and 2500. An increase in x reduces the growth rate of y due to the negative term $-0.0002xy$. An increase in y reduces the growth rate of x due to the negative term $-0.0006xy$. Hence, the system describes a competition model.

3. (a) $dx/dt = 0.5x - 0.004x^2 - 0.001xy = 0.5x(1 - x/125) - 0.001xy$.
$dy/dt = 0.4y - 0.001y^2 - 0.002xy = 0.4y(1 - y/400) - 0.002xy$.

The system shows that x and y have carrying capacities of 125 and 400. An increase in x reduces the growth rate of y due to the negative term $-0.002xy$. An increase in y reduces the growth rate of x due to the negative term $-0.001xy$. Hence the system describes a competition model.

(b) $dx/dt = 0 \quad\Rightarrow\quad x(0.5 - 0.004x - 0.001y) = 0 \quad\Rightarrow\quad x(500 - 4x - y) = 0$ **(1)** and $dy/dt = 0 \quad\Rightarrow$
$y(0.4 - 0.001y - 0.002x) = 0 \quad\Rightarrow\quad y(400 - y - 2x) = 0$ **(2).**

From **(1)** and **(2)**, we get four equilibrium solutions.

(i) $x = 0$ and $y = 0$: If the populations are zero, there is no change.

(ii) $x = 0$ and $400 - y - 2x = 0 \quad\Rightarrow\quad x = 0$ and $y = 400$: In the absence of an x-population, the y-population stabilizes at 400.

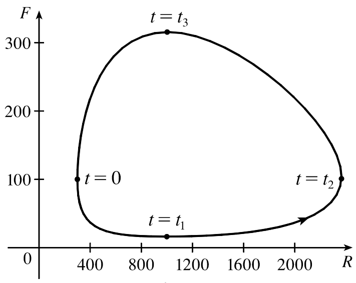
(iii) $500 - 4x - y = 0$ and $y = 0 \quad\Rightarrow\quad x = 125$ and $y = 0$: In the absence of y-population, the x-population stabilizes at 125.

(iv) $500 - 4x - y = 0$ and $400 - y - 2x = 0 \quad\Rightarrow\quad y = 500 - 4x$ and $y = 400 - 2x \quad\Rightarrow\quad 500 - 4x = 400 - 2x \quad\Rightarrow$ $100 = 2x \quad\Rightarrow\quad x = 50$ and $y = 300$: A y-population of 300 is just enough to support a constant x-population of 50.

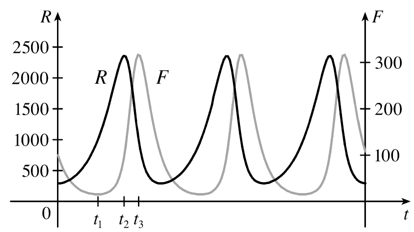
4. Let $L(t)$, $H(t)$, and $W(t)$ represent the populations of lynx, hares, and willows at time t. Let the k_i's and the c_i's denote positive constants, so that a plus sign means an increase and a minus sign means a decrease in the corresponding growth rate. "In the absence of hares, the willow population will grow exponentially and the lynx population will decay exponentially" gives us $dW/dt = +k_1 W$ and $dL/dt = -k_2 L$. "In the absence of lynx and willow, the hare population will decay exponentially" gives us $dH/dt = -k_3 H$. "Lynx eat snowshoe hares and snowshoe hares eat woody plants like willows" gives us encounters that lynx win, hares lose and win, and willows lose. In terms of growth rates, this means that $dL/dt = +c_1 LH$, $dH/dt = -c_2 LH + c_3 HW$, and $dW/dt = -c_4 HW$. Putting this information together gives us the following system of differential equations.

$$\begin{aligned} dL/dt &= -k_2 L \quad + c_1 LH \\ dH/dt &= -k_3 H \quad - c_2 LH + c_3 HW \\ dW/dt &= +k_1 W \qquad\qquad\quad - c_4 HW \end{aligned}$$

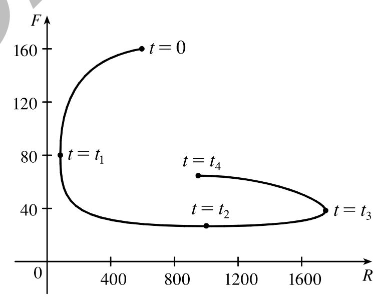
5. (a) At $t = 0$, there are about 300 rabbits and 100 foxes. At $t = t_1$, the number of foxes reaches a minimum of about 20 while the number of rabbits is about 1000. At $t = t_2$, the number of rabbits reaches a maximum of about 2400, while the number of foxes rebounds to 100. At $t = t_3$, the number of rabbits decreases to about 1000 and the number of foxes reaches a maximum of about 315. As t increases, the number of foxes decreases greatly to 100, and the number of rabbits decreases to 300 (the initial populations), and the cycle starts again.



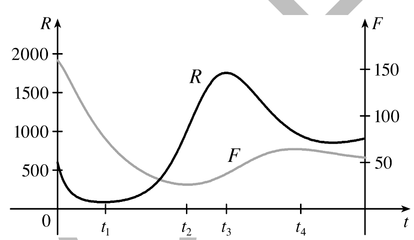
(b)



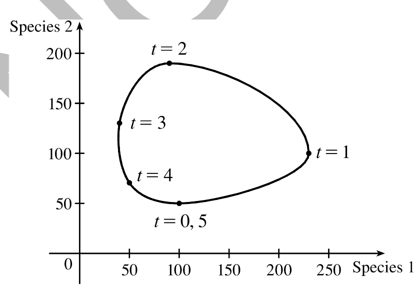
6. (a) At $t = 0$, there are about 600 rabbits and 160 foxes. At $t = t_1$, the number of rabbits reaches a minimum of about 80 and the number of foxes is also 80. At $t = t_2$, the number of foxes reaches a minimum of about 25 while the number of rabbits rebounds to 1000. At $t = t_3$, the number of foxes has increased to 40 and the rabbit population has reached a maximum of about 1750. The curve ends at $t = t_4$, where the number of foxes has increased to 65 and the number of rabbits has decreased to about 950.



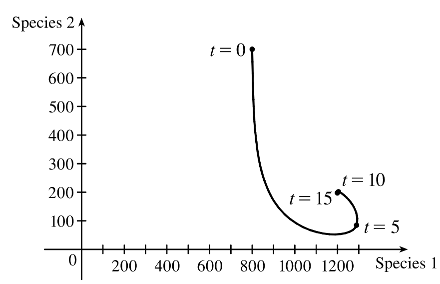
(b)



7.



8.



9. $$\frac{dW}{dR} = \frac{-0.02W + 0.00002RW}{0.08R - 0.001RW} \quad\Leftrightarrow\quad (0.08 - 0.001W)R\,dW = (-0.02 + 0.00002R)W\,dR \quad\Leftrightarrow$$

$$\frac{0.08 - 0.001W}{W}\,dW = \frac{-0.02 + 0.00002R}{R}\,dR \quad\Leftrightarrow\quad \int\left(\frac{0.08}{W} - 0.001\right)dW = \int\left(-\frac{0.02}{R} + 0.00002\right)dR \quad\Leftrightarrow$$

$0.08\ \ln|W| - 0.001W = -0.02\ \ln|R| + 0.00002R + K \quad\Leftrightarrow\quad 0.08\ \ln W + 0.02\ \ln R = 0.001W + 0.00002R + K \quad\Leftrightarrow$

$\ln\left(W^{0.08}R^{0.02}\right) = 0.00002R + 0.001W + K \quad\Leftrightarrow\quad W^{0.08}R^{0.02} = e^{0.00002R+0.001W+K} \quad\Leftrightarrow$

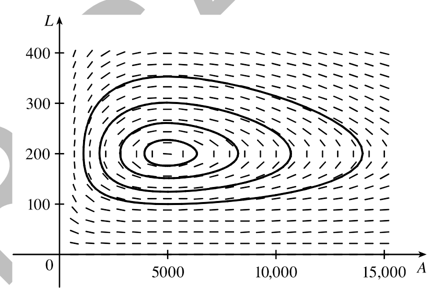
$R^{0.02}W^{0.08} = Ce^{0.00002R}e^{0.001W} \quad\Leftrightarrow\quad \dfrac{R^{0.02}W^{0.08}}{e^{0.00002R}e^{0.001W}} = C$. In general, if $\dfrac{dy}{dx} = \dfrac{-ry+bxy}{kx-axy}$, then $C = \dfrac{x^r y^k}{e^{bx}e^{ay}}$.

10. (a) A and L are constant $\Rightarrow$ $A' = 0$ and $L' = 0$ $\Rightarrow$ $\left\{\begin{matrix} 0 = 2A - 0.01AL \\ 0 = -0.5L + 0.0001AL \end{matrix}\right\} \Rightarrow \left\{\begin{matrix} 0 = A(2 - 0.01L) \\ 0 = L(-0.5 + 0.0001A) \end{matrix}\right.$

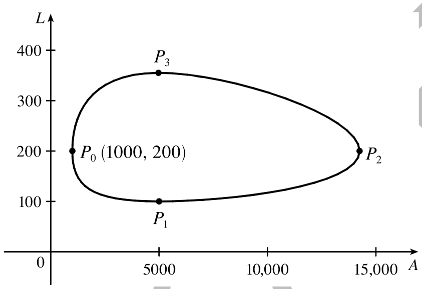
So either $A = L = 0$ or $L = \frac{2}{0.01} = 200$ and $A = \frac{0.5}{0.0001} = 5000$. The trivial solution $A = L = 0$ just says that if there aren't any aphids or ladybugs, then the populations will not change. The non-trivial solution, $L = 200$ and $A = 5000$, indicates the population sizes needed so that there are no changes in either the number of aphids or the number of ladybugs.

(b) $\dfrac{dL}{dA} = \dfrac{dL/dt}{dA/dt} = \dfrac{-0.5L + 0.0001AL}{2A - 0.01AL}$

(c) The solution curves (phase trajectories) are all closed curves that have the equilibrium point $(5000, 200)$ inside them.



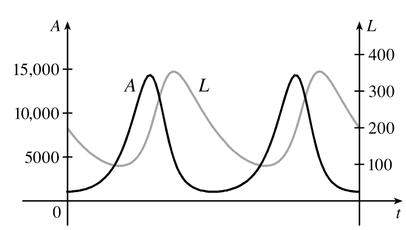
(d)



At $P_0(1000, 200)$, $dA/dt = 0$ and $dL/dt = -80 < 0$, so the number of ladybugs is decreasing and hence, we are proceeding in a counterclockwise direction. At P_0, there aren't enough aphids to support the ladybug population, so the number of ladybugs decreases and the number of aphids begins to increase. The ladybug population reaches a minimum at $P_1(5000, 100)$ while the aphid population increases in a dramatic way, reaching its maximum at $P_2(14, 250, 200)$.

Meanwhile, the ladybug population is increasing from P_1 to $P_3(5000, 355)$, and as we pass through P_2, the increasing number of ladybugs starts to deplete the aphid population. At P_3 the ladybugs reach a maximum population, and start to decrease due to the reduced aphid population. Both populations then decrease until P_0, where the cycle starts over again.

(e) Both graphs have the same period and the graph of L peaks about a quarter of a cycle after the graph of A.



11. (a) Letting $W = 0$ gives us $dR/dt = 0.08R(1 - 0.0002R)$. $dR/dt = 0 \Leftrightarrow R = 0$ or 5000. Since $dR/dt > 0$ for $0 < R < 5000$, we would expect the rabbit population to *increase* to 5000 for these values of R. Since $dR/dt < 0$ for $R > 5000$, we would expect the rabbit population to *decrease* to 5000 for these values of R. Hence, in the absence of wolves, we would expect the rabbit population to stabilize at 5000.

(b) R and W are constant $\Rightarrow$ $R' = 0$ and $W' = 0$ $\Rightarrow$

$$\left.\begin{cases} 0 = 0.08R(1 - 0.0002R) - 0.001RW \\ 0 = -0.02W + 0.00002RW \end{cases}\right\} \Rightarrow \begin{cases} 0 = R[0.08(1 - 0.0002R) - 0.001W] \\ 0 = W(-0.02 + 0.00002R) \end{cases}$$

The second equation is true if $W = 0$ or $R = \frac{0.02}{0.00002} = 1000$. If $W = 0$ in the first equation, then either $R = 0$ or $R = \frac{1}{0.0002} = 5000$ [as in part (a)]. If $R = 1000$, then $0 = 1000[0.08(1 - 0.0002 \cdot 1000) - 0.001W]$ $\Leftrightarrow$ $0 = 80(1 - 0.2) - W$ $\Leftrightarrow$ $W = 64$.

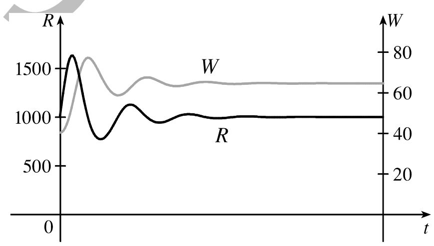
Case (i): $W = 0$, $R = 0$: both populations are zero

Case (ii): $W = 0$, $R = 5000$: see part (a)

Case (iii): $R = 1000$, $W = 64$: the predator/prey interaction balances and the populations are stable.

(c) The populations of wolves and rabbits fluctuate around 64 and 1000, respectively, and eventually stabilize at those values.

(d)



12. (a) If $L = 0$, $dA/dt = 2A\,(1 - 0.0001A)$, so $dA/dt = 0$ $\Leftrightarrow$ $A = 0$ or $A = \frac{1}{0.0001} = 10{,}000$. Since $dA/dt > 0$ for $0 < A < 10{,}000$, we expect the aphid population to *increase* to 10,000 for these values of A. Since $dA/dt < 0$ for $A > 10{,}000$, we expect the aphid population to *decrease* to 10,000 for these values of A. Hence, in the absence of ladybugs we expect the aphid population to stabilize at 10,000.

(b) A and L are constant $\Rightarrow$ $A' = 0$ and $L' = 0$ $\Rightarrow$

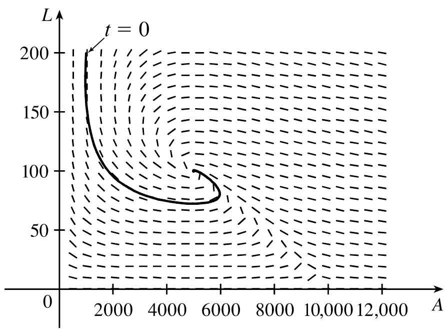
$$\left.\begin{cases} 0 = 2A(1 - 0.0001A) - 0.01AL \\ 0 = -0.5L + 0.0001AL \end{cases}\right\} \Rightarrow \begin{cases} 0 = A[2(1 - 0.0001A) - 0.01L] \\ 0 = L(-0.5 + 0.0001A) \end{cases}$$

The second equation is true if $L = 0$ or $A = \frac{0.5}{0.0001} = 5000$. If $L = 0$ in the first equation, then either $A = 0$ or $A = \frac{1}{0.0001} = 10{,}000$. If $A = 5000$, then $0 = 5000[2(1 - 0.0001 \cdot 5000) - 0.01L]$ $\Leftrightarrow$ $0 = 10{,}000(1 - 0.5) - 50L$ $\Leftrightarrow$ $50L = 5000$ $\Leftrightarrow$ $L = 100$.

The equilibrium solutions are: (i) $L = 0, A = 0$ (ii) $L = 0, A = 10{,}000$ (iii) $A = 5000, L = 100$

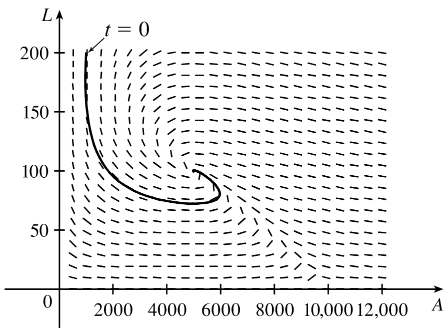
(c) $\dfrac{dL}{dA} = \dfrac{dL/dt}{dA/dt} = \dfrac{-0.5L + 0.0001AL}{2A(1 - 0.0001A) - 0.01AL}$

(d)



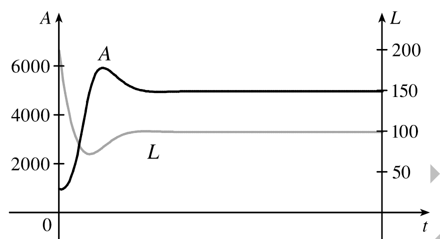
All of the phase trajectories spiral tightly around the equilibrium solution $(5000, 100)$.

(e)



At $t = 0$, the ladybug population decreases rapidly and the aphid population decreases slightly before beginning to increase. As the aphid population continues to increase, the ladybug population reaches a minimum at about $(5000, 75)$. The ladybug population starts to increase and quickly stabilizes at 100, while the aphid population stabilizes at 5000.

(f)



The graph of A peaks just after the graph of L has a minimum.

9 Review

TRUE-FALSE QUIZ

1. True. Since $y^4 \geq 0$, $y' = -1 - y^4 < 0$ and the solutions are decreasing functions.

2. True. $f(x) = y = \dfrac{\ln x}{x} \quad \Rightarrow \quad y' = \dfrac{1 - \ln x}{x^2}$.

LHS $= x^2 y' + xy = x^2 \cdot \dfrac{1 - \ln x}{x^2} + x \cdot \dfrac{\ln x}{x} = (1 - \ln x) + \ln x = 1 =$ RHS, so $y = \dfrac{\ln x}{x}$ is a solution of $x^2 y' + xy = 1$.

3. False. $x + y$ cannot be written in the form $g(x) f(y)$.

4. True. $y' = 3y - 2x + 6xy - 1 = 6xy - 2x + 3y - 1 = 2x(3y - 1) + 1(3y - 1) = (2x + 1)(3y - 1)$, so y' can be written in the form $g(x) f(y)$, and hence, is separable.

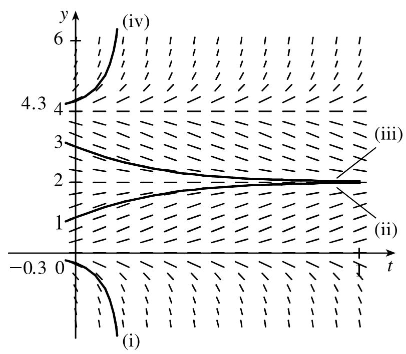
5. True. $e^x y' = y \Rightarrow y' = e^{-x} y \Rightarrow y' + (-e^{-x})y = 0$, which is of the form $y' + P(x)\,y = Q(x)$, so the equation is linear.

6. False. $y' + xy = e^y$ cannot be put in the form $y' + P(x)\,y = Q(x)$, so it is not linear.

7. True. By comparing $\dfrac{dy}{dt} = 2y\left(1 - \dfrac{y}{5}\right)$ with the logistic differential equation (9.4.4), we see that the carrying capacity is 5; that is, $\lim\limits_{t\to\infty} y = 5$.

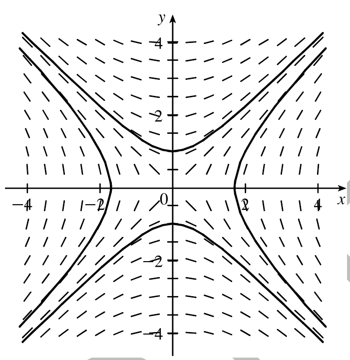
EXERCISES

1. (a)



(b) $\lim\limits_{t\to\infty} y(t)$ appears to be finite for $0 \le c \le 4$. In fact $\lim\limits_{t\to\infty} y(t) = 4$ for $c = 4$, $\lim\limits_{t\to\infty} y(t) = 2$ for $0 < c < 4$, and $\lim\limits_{t\to\infty} y(t) = 0$ for $c = 0$. The equilibrium solutions are $y(t) = 0$, $y(t) = 2$, and $y(t) = 4$.

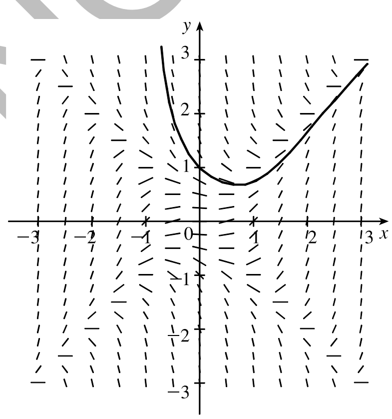
2. (a)



We sketch the direction field and four solution curves, as shown. Note that the slope $y' = x/y$ is not defined on the line $y = 0$.

(b) $y' = x/y \Leftrightarrow y\,dy = x\,dx \Leftrightarrow y^2 = x^2 + C$. For $C = 0$, this is the pair of lines $y = \pm x$. For $C \neq 0$, it is the hyperbola $x^2 - y^2 = -C$.

3. (a)



We estimate that when $x = 0.3$, $y = 0.8$, so $y(0.3) \approx 0.8$.

(b) $h = 0.1$, $x_0 = 0$, $y_0 = 1$ and $F(x,y) = x^2 - y^2$. So $y_n = y_{n-1} + 0.1\left(x_{n-1}^2 - y_{n-1}^2\right)$. Thus,

$y_1 = 1 + 0.1\left(0^2 - 1^2\right) = 0.9$, $y_2 = 0.9 + 0.1\left(0.1^2 - 0.9^2\right) = 0.82$, $y_3 = 0.82 + 0.1\left(0.2^2 - 0.82^2\right) = 0.75676$.

This is close to our graphical estimate of $y(0.3) \approx 0.8$.

(c) The centers of the horizontal line segments of the direction field are located on the lines $y = x$ and $y = -x$. When a solution curve crosses one of these lines, it has a local maximum or minimum.

4. (a) $h = 0.2$, $x_0 = 0$, $y_0 = 1$ and $F(x,y) = 2xy^2$. We need y_2.

$y_1 = 1 + 0.2(2 \cdot 0 \cdot 1^2) = 1$, $y_2 = 1 + 0.2(2 \cdot 0.2 \cdot 1^2) = 1.08 \approx y(0.4)$.

(b) $h = 0.1$ now, so $y_1 = 1 + 0.1(2 \cdot 0 \cdot 1^2) = 1$, $y_2 = 1 + 0.1(2 \cdot 0.1 \cdot 1^2) = 1.02$,

$y_3 = 1.02 + 0.1(2 \cdot 0.2 \cdot 1.02^2) \approx 1.06162$, $y_4 = 1.06162 + 0.1(2 \cdot 0.3 \cdot 1.06162^2) \approx 1.1292 \approx y(0.4)$.

(c) The equation is separable, so we write $\dfrac{dy}{y^2} = 2x\,dx \;\Rightarrow\; \displaystyle\int \frac{dy}{y^2} = \int 2x\,dx \;\Leftrightarrow\; -\frac{1}{y} = x^2 + C$, but $y(0) = 1$, so $C = -1$ and $y(x) = \dfrac{1}{1 - x^2} \;\Leftrightarrow\; y(0.4) = \dfrac{1}{1 - 0.16} \approx 1.1905$. From this we see that the approximation was greatly improved by increasing the number of steps, but the approximations were still far off.

5. $y' = xe^{-\sin x} - y\cos x \;\Rightarrow\; y' + (\cos x)\,y = xe^{-\sin x}$ $(\star)$. This is a linear equation and the integrating factor is $I(x) = e^{\int \cos x\,dx} = e^{\sin x}$. Multiplying $(\star)$ by $e^{\sin x}$ gives $e^{\sin x}\,y' + e^{\sin x}(\cos x)\,y = x \;\Rightarrow\; (e^{\sin x}\,y)' = x \;\Rightarrow\; e^{\sin x}\,y = \frac{1}{2}x^2 + C \;\Rightarrow\; y = \left(\frac{1}{2}x^2 + C\right)e^{-\sin x}$.

6. $\dfrac{dx}{dt} = 1 - t + x - tx = 1(1-t) + x(1-t) = (1+x)(1-t) \;\Rightarrow\; \dfrac{dx}{1+x} = (1-t)\,dt \;\Rightarrow$

$\displaystyle\int \frac{dx}{1+x} = \int (1-t)\,dt \;\Rightarrow\; \ln|1+x| = t - \tfrac{1}{2}t^2 + C \;\Rightarrow\; |1+x| = e^{t - t^2/2 + C} \;\Rightarrow$

$1 + x = \pm e^{t - t^2/2} \cdot e^C \;\Rightarrow\; x = -1 + Ke^{t - t^2/2}$, where K is any nonzero constant.

7. $2ye^{y^2}y' = 2x + 3\sqrt{x} \;\Rightarrow\; 2ye^{y^2}\dfrac{dy}{dx} = 2x + 3\sqrt{x} \;\Rightarrow\; 2ye^{y^2}\,dy = \left(2x + 3\sqrt{x}\right)dx \;\Rightarrow$

$\int 2ye^{y^2}\,dy = \int \left(2x + 3\sqrt{x}\right)dx \;\Rightarrow\; e^{y^2} = x^2 + 2x^{3/2} + C \;\Rightarrow\; y^2 = \ln(x^2 + 2x^{3/2} + C) \;\Rightarrow$

$y = \pm\sqrt{\ln(x^2 + 2x^{3/2} + C)}$

8. $x^2y' - y = 2x^3e^{-1/x} \;\Rightarrow\; y' - \dfrac{1}{x^2}\,y = 2xe^{-1/x}$ $(\star)$. This is a linear equation and the integrating factor is $I(x) = e^{\int(-1/x^2)\,dx} = e^{1/x}$. Multiplying $(\star)$ by $e^{1/x}$ gives $e^{1/x}\,y' - e^{1/x} \cdot \dfrac{1}{x^2}\,y = 2x \;\Rightarrow\; (e^{1/x}\,y)' = 2x \;\Rightarrow$

$e^{1/x}\,y = x^2 + C \;\Rightarrow\; y = e^{-1/x}(x^2 + C)$.

9. $\dfrac{dr}{dt} + 2tr = r \;\Rightarrow\; \dfrac{dr}{dt} = r - 2tr = r(1-2t) \;\Rightarrow\; \displaystyle\int \frac{dr}{r} = \int (1-2t)\,dt \;\Rightarrow\; \ln|r| = t - t^2 + C \;\Rightarrow$

$|r| = e^{t - t^2 + C} = ke^{t - t^2}$. Since $r(0) = 5$, $5 = ke^0 = k$. Thus, $r(t) = 5e^{t - t^2}$.

10. $(1 + \cos x)y' = (1 + e^{-y}) \sin x \quad \Rightarrow \quad \dfrac{dy}{1 + e^{-y}} = \dfrac{\sin x\, dx}{1 + \cos x} \quad \Rightarrow \quad \displaystyle\int \frac{dy}{1 + 1/e^y} = \int \frac{\sin x\, dx}{1 + \cos x} \quad \Rightarrow$

$\displaystyle\int \frac{e^y\, dy}{1 + e^y} = \int \frac{\sin x\, dx}{1 + \cos x} \quad \Rightarrow \quad \ln|1 + e^y| = -\ln|1 + \cos x| + C \quad \Rightarrow \quad \ln(1 + e^y) = -\ln(1 + \cos x) + C \quad \Rightarrow$

$1 + e^y = e^{-\ln(1+\cos x)} \cdot e^C \quad \Rightarrow \quad e^y = ke^{-\ln(1+\cos x)} - 1 \quad \Rightarrow \quad y = \ln[ke^{-\ln(1+\cos x)} - 1]$. Since $y(0) = 0$,

$0 = \ln[ke^{-\ln 2} - 1] \quad \Rightarrow \quad e^0 = k\left(\frac{1}{2}\right) - 1 \quad \Rightarrow \quad k = 4$. Thus, $y(x) = \ln[4e^{-\ln(1+\cos x)} - 1]$. An equivalent form

is $y(x) = \ln \dfrac{3 - \cos x}{1 + \cos x}$.

11. $xy' - y = x \ln x \quad \Rightarrow \quad y' - \dfrac{1}{x}\, y = \ln x$. $\quad I(x) = e^{\int(-1/x)\, dx} = e^{-\ln|x|} = \left(e^{\ln|x|}\right)^{-1} = |x|^{-1} = 1/x$ since the condition

$y(1) = 2$ implies that we want a solution with $x > 0$. Multiplying the last differential equation by $I(x)$ gives

$\dfrac{1}{x}\, y' - \dfrac{1}{x^2}\, y = \dfrac{1}{x} \ln x \quad \Rightarrow \quad \left(\dfrac{1}{x}\, y\right)' = \dfrac{1}{x} \ln x \quad \Rightarrow \quad \dfrac{1}{x}\, y = \displaystyle\int \frac{\ln x}{x}\, dx \quad \Rightarrow \quad \dfrac{1}{x}\, y = \frac{1}{2}(\ln x)^2 + C \quad \Rightarrow$

$y = \frac{1}{2}x(\ln x)^2 + Cx$. Now $y(1) = 2 \quad \Rightarrow \quad 2 = 0 + C \quad \Rightarrow \quad C = 2$, so $y = \frac{1}{2}x(\ln x)^2 + 2x$.

12. $y' = 3x^2 e^y \quad \Rightarrow \quad \dfrac{dy}{dx} = 3x^2 e^y \quad \Rightarrow \quad e^{-y}\, dy = 3x^2\, dx \quad \Rightarrow$

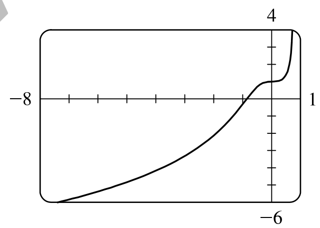
$\int e^{-y}\, dy = \int 3x^2\, dx \quad \Rightarrow \quad -e^{-y} = x^3 + C$. Now $y(0) = 1 \quad \Rightarrow$

$-e^{-1} = C$, so $-e^{-y} = x^3 - e^{-1} \quad \Rightarrow \quad e^{-y} = -x^3 + e^{-1} \quad \Rightarrow$

$-y = \ln(-x^3 + e^{-1}) \quad \Rightarrow \quad y = -\ln(-x^3 + e^{-1})$. To find the domain,

solve $-x^3 + e^{-1} > 0 \quad \Rightarrow \quad x^3 < e^{-1} \quad \Rightarrow \quad x < e^{-1/3}$, so the domain is

$(-\infty, e^{-1/3})$ and $x = e^{-1/3}$ $[\approx 0.72]$ is a vertical asymptote.



13. $\dfrac{d}{dx}(y) = \dfrac{d}{dx}(ke^x) \quad \Rightarrow \quad y' = ke^x = y$, so the orthogonal trajectories must have $y' = -\dfrac{1}{y} \quad \Rightarrow \quad \dfrac{dy}{dx} = -\dfrac{1}{y} \quad \Rightarrow$

$y\, dy = -dx \quad \Rightarrow \quad \int y\, dy = -\int dx \quad \Rightarrow \quad \frac{1}{2}y^2 = -x + C \quad \Rightarrow \quad x = C - \frac{1}{2}y^2$, which are parabolas with a horizontal axis.

14. $\dfrac{d}{dx}(y) = \dfrac{d}{dx}(e^{kx}) \quad \Rightarrow \quad y' = ke^{kx} = ky = \dfrac{\ln y}{x} \cdot y$, so the orthogonal trajectories must have $y' = -\dfrac{x}{y \ln y} \quad \Rightarrow$

$\dfrac{dy}{dx} = -\dfrac{x}{y \ln y} \quad \Rightarrow \quad y \ln y\, dy = -x\, dx \quad \Rightarrow \quad \int y \ln y\, dy = -\int x\, dx \quad \Rightarrow \quad \frac{1}{2}y^2 \ln y - \frac{1}{4}y^2$ [parts with $u = \ln y$,

$dv = y\, dy$] $= -\frac{1}{2}x^2 + C_1 \quad \Rightarrow \quad 2y^2 \ln y - y^2 = C - 2x^2$.

15. (a) Using (4) and (7) in Section 9.4, we see that for $\dfrac{dP}{dt} = 0.1P\left(1 - \dfrac{P}{2000}\right)$ with $P(0) = 100$, we have $k = 0.1$,

$M = 2000$, $P_0 = 100$, and $A = \dfrac{2000 - 100}{100} = 19$. Thus, the solution of the initial-value problem is

$P(t) = \dfrac{2000}{1 + 19e^{-0.1t}}$ and $P(20) = \dfrac{2000}{1 + 19e^{-2}} \approx 560$.

(b) $P = 1200 \quad \Leftrightarrow \quad 1200 = \dfrac{2000}{1 + 19e^{-0.1t}} \quad \Leftrightarrow \quad 1 + 19e^{-0.1t} = \dfrac{2000}{1200} \quad \Leftrightarrow \quad 19e^{-0.1t} = \dfrac{5}{3} - 1 \quad \Leftrightarrow$

$e^{-0.1t} = \left(\frac{2}{3}\right)/19 \quad \Leftrightarrow \quad -0.1t = \ln \frac{2}{57} \quad \Leftrightarrow \quad t = -10 \ln \frac{2}{57} \approx 33.5$.

16. (a) Let $t = 0$ correspond to the year 2000. An exponential model is $P(t) = ae^{kt}$. $P(0) = 6.1$, so $P(t) = 6.1e^{kt}$.

$P(10) = 6.1e^{10k}$ and $P(10) = 6.9$, so $6.1e^{10k} = 6.9 \quad \Leftrightarrow \quad \dfrac{6.9}{6.1} = e^{10k} \quad \Rightarrow \quad 10k = \ln \dfrac{69}{61} \quad \Rightarrow$

$k = \dfrac{1}{10} \ln \dfrac{69}{61} \approx 0.0123$. Thus, $P(t) = 6.1e^{kt}$ and $P(20) = 6.1e^{20k} \approx 7.8$. Our model predicts that the world population in the year 2020 will be 7.8 billion.

(b) $P(t) = 10 \quad \Leftrightarrow \quad 6.1e^{kt} = 10 \quad \Leftrightarrow \quad e^{kt} = \dfrac{10}{6.1} \quad \Leftrightarrow \quad kt = \ln \dfrac{10}{6.1} \quad \Leftrightarrow \quad t = 10 \dfrac{\ln(10/6.1)}{\ln(69/61)} \approx 40.11$ years. Our exponential model predicts that the world population will exceed 10 billion in 40.11 years; that is, in the year 2040.

(c) $A = \dfrac{M - P_0}{P_0} = \dfrac{20 - 6.1}{6.1} = \dfrac{139}{61}$ and from part (a) , $k = \dfrac{1}{10} \ln \dfrac{69}{61}$, so $P(t) = \dfrac{M}{1 + Ae^{-kt}} = \dfrac{20}{1 + \frac{139}{61} e^{-kt}}$. Thus,

$P(20) = \dfrac{20}{1 + \frac{139}{61} e^{-20k}} \approx 7.2$ billion, which is less than our prediction of 7.8 billion from the exponential model in part (a).

(d) $P(t) = 10 \quad \Leftrightarrow \quad \dfrac{20}{1 + \frac{139}{61} e^{-kt}} = 10 \quad \Leftrightarrow \quad \dfrac{20}{10} = 1 + \dfrac{139}{61} e^{-kt} \quad \Leftrightarrow \quad 1 = \dfrac{139}{61} e^{-kt} \quad \Leftrightarrow \quad \dfrac{61}{139} = e^{-kt} \quad \Leftrightarrow$

$\ln \dfrac{61}{139} = -kt \quad \Leftrightarrow \quad t = -10 \dfrac{\ln(61/139)}{\ln(69/61)} \approx 66.83$ years. Our logistic model predicts that the world population will exceed 10 billion in 66.83 years; that is, in the year 2066, which is considerably later than our prediction of 2040 from the exponential model in part (b).

17. (a) $\dfrac{dL}{dt} \propto L_\infty - L \quad \Rightarrow \quad \dfrac{dL}{dt} = k(L_\infty - L) \quad \Rightarrow \quad \displaystyle\int \frac{dL}{L_\infty - L} = \int k\,dt \quad \Rightarrow \quad -\ln |L_\infty - L| = kt + C \quad \Rightarrow$

$\ln |L_\infty - L| = -kt - C \quad \Rightarrow \quad |L_\infty - L| = e^{-kt-C} \quad \Rightarrow \quad L_\infty - L = Ae^{-kt} \quad \Rightarrow \quad L = L_\infty - Ae^{-kt}$.

At $t = 0$, $L = L(0) = L_\infty - A \quad \Rightarrow \quad A = L_\infty - L(0) \quad \Rightarrow \quad L(t) = L_\infty - [L_\infty - L(0)]e^{-kt}$.

(b) $L_\infty = 53$ cm, $L(0) = 10$ cm, and $k = 0.2 \quad \Rightarrow \quad L(t) = 53 - (53 - 10)e^{-0.2t} = 53 - 43e^{-0.2t}$.

18. Denote the amount of salt in the tank (in kg) by y. $y(0) = 0$ since initially there is only water in the tank.

The rate at which y increases is equal to the rate at which salt flows into the tank minus the rate at which it flows out.

That rate is $\dfrac{dy}{dt} = 0.1 \dfrac{\text{kg}}{\text{L}} \times 10 \dfrac{\text{L}}{\text{min}} - \dfrac{y}{100} \dfrac{\text{kg}}{\text{L}} \times 10 \dfrac{\text{L}}{\text{min}} = 1 - \dfrac{y}{10} \dfrac{\text{kg}}{\text{min}} \quad \Rightarrow \quad \displaystyle\int \frac{dy}{10 - y} = \int \frac{1}{10}\,dt \quad \Rightarrow$

$-\ln |10 - y| = \frac{1}{10} t + C \quad \Rightarrow \quad 10 - y = Ae^{-t/10}$. $y(0) = 0 \quad \Rightarrow \quad 10 = A \quad \Rightarrow \quad y = 10(1 - e^{-t/10})$.

At $t = 6$ minutes, $y = 10(1 - e^{-6/10}) \approx 4.512$ kg.

19. Let P represent the population and I the number of infected people. The rate of spread dI/dt is jointly proportional to I and to $P - I$, so for some constant k, $\dfrac{dI}{dt} = kI(P - I) \quad \Rightarrow \quad I(t) = \dfrac{I_0 P}{I_0 + (P - I_0)e^{-kPt}}$ [from the discussion of logistic growth in Section 9.4].

Now, measuring t in days, we substitute $t = 7$, $P = 5000$, $I_0 = 160$ and $I(7) = 1200$ to find k:

$$1200 = \frac{160 \cdot 5000}{160 + (5000 - 160)e^{-5000 \cdot 7 \cdot k}} \Leftrightarrow 3 = \frac{2000}{160 + 4840e^{-35{,}000k}} \Leftrightarrow 480 + 14{,}520e^{-35{,}000k} = 2000 \Leftrightarrow$$

$$e^{-35{,}000k} = \frac{2000 - 480}{14{,}520} \Leftrightarrow -35{,}000k = \ln\frac{38}{363} \Leftrightarrow k = \frac{-1}{35{,}000}\ln\frac{38}{363} \approx 0.00006448.$$ Next, let

$I = 5000 \times 80\% = 4000$, and solve for t: $4000 = \dfrac{160 \cdot 5000}{160 + (5000 - 160)e^{-k \cdot 5000 \cdot t}} \Leftrightarrow 1 = \dfrac{200}{160 + 4840e^{-5000kt}} \Leftrightarrow$

$$160 + 4840e^{-5000kt} = 200 \Leftrightarrow e^{-5000kt} = \frac{200 - 160}{4840} \Leftrightarrow -5000kt = \ln\frac{1}{121} \Leftrightarrow$$

$t = \dfrac{-1}{5000k}\ln\dfrac{1}{121} = \dfrac{1}{\frac{1}{7}\ln\frac{38}{363}} \cdot \ln\dfrac{1}{121} = 7 \cdot \dfrac{\ln 121}{\ln\frac{363}{38}} \approx 14.875$. So it takes about 15 days for 80% of the population to be infected.

20. $\dfrac{1}{R}\dfrac{dR}{dt} = \dfrac{k}{S}\dfrac{dS}{dt} \Rightarrow \dfrac{d}{dt}(\ln R) = \dfrac{d}{dt}(k \ln S) \Rightarrow \ln R = k \ln S + C \Rightarrow$

$R = e^{k \ln S + C} = e^C\left(e^{\ln S}\right)^k \Rightarrow R = AS^k$, where $A = e^C$ is a positive constant.

21. $\dfrac{dh}{dt} = -\dfrac{R}{V}\left(\dfrac{h}{k+h}\right) \Rightarrow \displaystyle\int \frac{k+h}{h}\,dh = \int\left(-\frac{R}{V}\right)dt \Rightarrow \int\left(1 + \frac{k}{h}\right)dh = -\frac{R}{V}\int 1\,dt \Rightarrow$

$h + k \ln h = -\dfrac{R}{V}t + C$. This equation gives a relationship between h and t, but it is not possible to isolate h and express it in terms of t.

22. $dx/dt = 0.4x - 0.002xy$, $dy/dt = -0.2y + 0.000008xy$

(a) The xy terms represent encounters between the birds and the insects. Since the y-population increases from these terms and the x-population decreases, we expect y to represent the birds and x the insects.

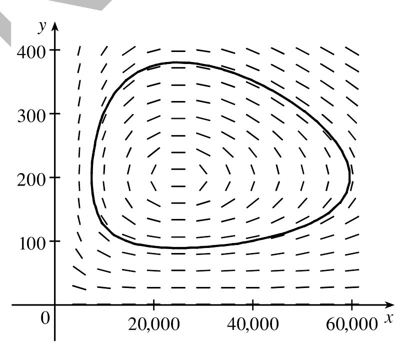
(b) x and y are constant $\Rightarrow x' = 0$ and $y' = 0 \Rightarrow$

$$\left\{\begin{array}{l} 0 = 0.4x - 0.002xy \\ 0 = -0.2y + 0.000008xy \end{array}\right\} \Rightarrow \left\{\begin{array}{l} 0 = 0.4x(1 - 0.005y) \\ 0 = -0.2y(1 - 0.00004x) \end{array}\right. \Rightarrow y = 0 \text{ and } x = 0 \text{ (zero populations)}$$

or $y = \frac{1}{0.005} = 200$ and $x = \frac{1}{0.00004} = 25{,}000$. The non-trivial solution represents the population sizes needed so that there are no changes in either the number of birds or the number of insects.

(c) $\dfrac{dy}{dx} = \dfrac{dy/dt}{dx/dt} = \dfrac{-0.2y + 0.000008xy}{0.4x - 0.002xy}$

(d)



At $(x, y) = (40{,}000, 100)$, $dx/dt = 8000 > 0$, so as t increases we are proceeding in a counterclockwise direction. The populations increase to approximately $(59{,}646, 200)$, at which point the insect population starts to decrease. The birds attain a maximum population of about 380 when the insect population is 25,000. The populations decrease to about $(7370, 200)$, at which point the insect population starts to increase. The birds attain a minimum population of about 88 when the insect population is 25,000, and then the cycle repeats.

(e) 
Both graphs have the same period and the bird population peaks about a quarter-cycle after the insect population.

23. (a) $dx/dt = 0.4x(1 - 0.000005x) - 0.002xy$, $dy/dt = -0.2y + 0.000008xy$. If $y = 0$, then $dx/dt = 0.4x(1 - 0.000005x)$, so $dx/dt = 0 \quad \Leftrightarrow \quad x = 0$ or $x = 200{,}000$, which shows that the insect population increases logistically with a carrying capacity of 200,000. Since $dx/dt > 0$ for $0 < x < 200{,}000$ and $dx/dt < 0$ for $x > 200{,}000$, we expect the insect population to stabilize at 200,000.

(b) x and y are constant $\Rightarrow \quad x' = 0$ and $y' = 0 \quad \Rightarrow$

$$\left\{\begin{array}{l} 0 = 0.4x(1 - 0.000005x) - 0.002xy \\ 0 = -0.2y + 0.000008xy \end{array}\right\} \Rightarrow \left\{\begin{array}{l} 0 = 0.4x[(1 - 0.000005x) - 0.005y] \\ 0 = y(-0.2 + 0.000008x) \end{array}\right.$$

The second equation is true if $y = 0$ or $x = \frac{0.2}{0.000008} = 25{,}000$. If $y = 0$ in the first equation, then either $x = 0$ or $x = \frac{1}{0.000005} = 200{,}000$. If $x = 25{,}000$, then $0 = 0.4(25{,}000)[(1 - 0.000005 \cdot 25{,}000) - 0.005y] \quad \Rightarrow$ $0 = 10{,}000[(1 - 0.125) - 0.005y] \quad \Rightarrow \quad 0 = 8750 - 50y \quad \Rightarrow \quad y = 175$.

Case (i): $y = 0$, $x = 0$: Zero populations

Case (ii): $y = 0$, $x = 200{,}000$: In the absence of birds, the insect population is always 200,000.

Case (iii): $x = 25{,}000$, $y = 175$: The predator/prey interaction balances and the populations are stable.

(c) The populations of the birds and insects fluctuate around 175 and 25,000, respectively, and eventually stabilize at those values.

(d) 
24. First note that, in this question, "weighs" is used in the informal sense, so what we really require is Barbara's mass m in kg as a function of t. Barbara's net intake of calories per day at time t (measured in days) is $c(t) = 1600 - 850 - 15m(t) = 750 - 15m(t)$, where $m(t)$ is her mass at time t. We are given that $m(0) = 60$ kg and $\dfrac{dm}{dt} = \dfrac{c(t)}{10{,}000}$, so $\dfrac{dm}{dt} = \dfrac{750 - 15m}{10{,}000} = \dfrac{150 - 3m}{2000} = \dfrac{-3(m - 50)}{2000}$ with $m(0) = 60$. From $\displaystyle\int \frac{dm}{m - 50} = \int \frac{-3\,dt}{2000}$, we get $\ln|m - 50| = -\frac{3}{2000}t + C$. Since $m(0) = 60$, $C = \ln 10$. Now $\ln \dfrac{|m - 50|}{10} = -\dfrac{3t}{2000}$, so $|m - 50| = 10e^{-3t/2000}$. The quantity $m - 50$ is continuous, initially positive, and the right-hand side is never zero. Thus, $m - 50$ is positive for all t, and $m(t) = 50 + 10e^{-3t/2000}$ kg. As $t \to \infty$, $m(t) \to 50$ kg. Thus, Barbara's mass gradually settles down to 50 kg.

PROBLEMS PLUS

1. We use the Fundamental Theorem of Calculus to differentiate the given equation:

$[f(x)]^2 = 100 + \int_0^x \left\{[f(t)]^2 + [f'(t)]^2\right\} dt \quad\Rightarrow\quad 2f(x)f'(x) = [f(x)]^2 + [f'(x)]^2 \quad\Rightarrow$

$[f(x)]^2 + [f'(x)]^2 - 2f(x)f'(x) = 0 \quad\Rightarrow\quad [f(x) - f'(x)]^2 = 0 \quad\Leftrightarrow\quad f(x) = f'(x)$. We can solve this as a separable equation, or else use Theorem 9.4.2 with $k = 1$, which says that the solutions are $f(x) = Ce^x$. Now $[f(0)]^2 = 100$, so $f(0) = C = \pm 10$, and hence $f(x) = \pm 10e^x$ are the only functions satisfying the given equation.

2. $(fg)' = f'g'$, where $f(x) = e^{x^2} \quad\Rightarrow\quad \left(e^{x^2} g\right)' = 2xe^{x^2} g'$. Since the student's mistake did not affect the answer,

$\left(e^{x^2} g\right)' = e^{x^2} g' + 2xe^{x^2} g = 2xe^{x^2} g'$. So $(2x - 1)g' = 2xg$, or $\dfrac{g'}{g} = \dfrac{2x}{2x - 1} = 1 + \dfrac{1}{2x - 1} \quad\Rightarrow$

$\ln|g(x)| = x + \frac{1}{2}\ln(2x - 1) + C \quad\Rightarrow\quad g(x) = Ae^x\sqrt{2x - 1}$.

3. $f'(x) = \lim\limits_{h\to 0} \dfrac{f(x + h) - f(x)}{h} = \lim\limits_{h\to 0} \dfrac{f(x)\,[f(h) - 1]}{h} \quad$ [since $f(x + h) = f(x)f(h)$]

$$= f(x) \lim_{h\to 0} \frac{f(h) - 1}{h} = f(x) \lim_{h\to 0} \frac{f(h) - f(0)}{h - 0} = f(x)f'(0) = f(x)$$

Therefore, $f'(x) = f(x)$ for all x and from Theorem 9.4.2 we get $f(x) = Ae^x$.

Now $f(0) = 1 \quad\Rightarrow\quad A = 1 \quad\Rightarrow\quad f(x) = e^x$.

4. $\left(\displaystyle\int f(x)\,dx\right)\left(\displaystyle\int \frac{dx}{f(x)}\right) = -1 \quad\Rightarrow\quad \displaystyle\int \frac{dx}{f(x)} = \frac{-1}{\int f(x)\,dx} \quad\Rightarrow\quad \frac{1}{f(x)} = \frac{f(x)}{\left[\int f(x)\,dx\right]^2}$ [after differentiating] $\Rightarrow$

$\int f(x)\,dx = \pm f(x)$ [after taking square roots] $\Rightarrow\quad f(x) = \pm f'(x)$ [after differentiating again] $\Rightarrow\quad y = Ae^x$ or $y = Ae^{-x}$ by Theorem 9.4.2. Therefore, $f(x) = Ae^x$ or $f(x) = Ae^{-x}$, for all nonzero constants A, are the functions satisfying the original equation.

5. "The area under the graph of f from 0 to x is proportional to the $(n + 1)$st power of $f(x)$" translates to

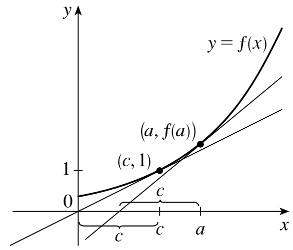
$\int_0^x f(t)\,dt = k[f(x)]^{n+1}$ for some constant k. By FTC1, $\dfrac{d}{dx}\displaystyle\int_0^x f(t)\,dt = \dfrac{d}{dx}\left\{k[f(x)]^{n+1}\right\} \quad\Rightarrow$

$f(x) = k(n + 1)[f(x)]^n f'(x) \quad\Rightarrow\quad 1 = k(n + 1)[f(x)]^{n-1} f'(x) \quad\Rightarrow\quad 1 = k(n + 1)y^{n-1}\dfrac{dy}{dx} \quad\Rightarrow$

$k(n + 1)y^{n-1}\,dy = dx \quad\Rightarrow\quad \int k(n + 1)y^{n-1}\,dy = \int dx \quad\Rightarrow\quad k(n + 1)\dfrac{1}{n}y^n = x + C$.

Now $f(0) = 0 \quad\Rightarrow\quad 0 = 0 + C \quad\Rightarrow\quad C = 0$ and then $f(1) = 1 \quad\Rightarrow\quad k(n + 1)\dfrac{1}{n} = 1 \quad\Rightarrow\quad k = \dfrac{n}{n + 1}$,

so $y^n = x$ and $y = f(x) = x^{1/n}$.



6. Let $y = f(x)$ be a curve that passes through the point $(c, 1)$ and whose subtangents all have length c. The tangent line at $x = a$ has equation $y - f(a) = f'(a)(x - a)$. Assuming $f(a) \neq 0$ and $f'(a) \neq 0$, it has x-intercept $a - \dfrac{f(a)}{f'(a)}$ [let $y = 0$ and solve for x]. Thus, the length of the subtangent is c, so $\left|a - \left(a - \dfrac{f(a)}{f'(a)}\right)\right| = \left|\dfrac{f(a)}{f'(a)}\right| = c \;\Rightarrow\; \dfrac{f'(a)}{f(a)} = \pm\dfrac{1}{c}$.

Now $\dfrac{f'(x)}{f(x)} = \pm\dfrac{1}{c} \;\Rightarrow\; f'(x) = \pm\dfrac{1}{c}f(x) \;\Rightarrow\; \dfrac{dy}{dx} = \pm\dfrac{1}{c}y \;\Rightarrow\; \dfrac{dy}{y} = \pm\dfrac{1}{c}\,dx \;\Rightarrow\; \displaystyle\int \frac{1}{y}\,dy = \pm\frac{1}{c}\int dx \;\Rightarrow$ $\ln|y| = \pm\dfrac{1}{c}x + K$. Since $f(c) = 1$, $\ln 1 = \pm 1 + K \;\Rightarrow\; K = \mp 1$. Thus, $y = e^{\pm x/c \mp 1}$, or $y = e^{\pm(x/c-1)}$. One curve is an increasing exponential (as shown in the figure) and the other curve is its reflection about the line $x = c$.

7. Let $y(t)$ denote the temperature of the peach pie t minutes after 5:00 PM and R the temperature of the room. Newton's Law of Cooling gives us $dy/dt = k(y - R)$. Solving for y we get $\dfrac{dy}{y - R} = k\,dt \;\Rightarrow\; \ln|y - R| = kt + C \;\Rightarrow$ $|y - R| = e^{kt+C} \;\Rightarrow\; y - R = \pm e^{kt}\cdot e^{C} \;\Rightarrow\; y = Me^{kt} + R$, where M is a nonzero constant. We are given temperatures at three times.

$$y(0) = 100 \;\Rightarrow\; 100 = M + R \;\Rightarrow\; R = 100 - M$$
$$y(10) = 80 \;\Rightarrow\; 80 = Me^{10k} + R \qquad \textbf{(1)}$$
$$y(20) = 65 \;\Rightarrow\; 65 = Me^{20k} + R \qquad \textbf{(2)}$$

Substituting $100 - M$ for R in **(1)** and **(2)** gives us

$$-20 = Me^{10k} - M \;\textbf{(3)} \quad \text{and} \quad -35 = Me^{20k} - M \;\textbf{(4)}$$

Dividing **(3)** by **(4)** gives us $\dfrac{-20}{-35} = \dfrac{M(e^{10k} - 1)}{M(e^{20k} - 1)} \;\Rightarrow\; \dfrac{4}{7} = \dfrac{e^{10k} - 1}{e^{20k} - 1} \;\Rightarrow\; 4e^{20k} - 4 = 7e^{10k} - 7 \;\Rightarrow$ $4e^{20k} - 7e^{10k} + 3 = 0$. This is a quadratic equation in e^{10k}. $\left(4e^{10k} - 3\right)\left(e^{10k} - 1\right) = 0 \;\Rightarrow\; e^{10k} = \frac{3}{4}$ or $1 \;\Rightarrow$ $10k = \ln\frac{3}{4}$ or $\ln 1 \;\Rightarrow\; k = \frac{1}{10}\ln\frac{3}{4}$ since k is a nonzero constant of proportionality. Substituting $\frac{3}{4}$ for e^{10k} in **(3)** gives us $-20 = M\cdot\frac{3}{4} - M \;\Rightarrow\; -20 = -\frac{1}{4}M \;\Rightarrow\; M = 80$. Now $R = 100 - M$ so $R = 20^\circ\text{C}$.

8. Let b be the number of hours before noon that it began to snow, t the time measured in hours after noon, and $x = x(t) =$ distance traveled by the plow at time t. Then $dx/dt =$ speed of plow. Since the snow falls steadily, the height at time t is $h(t) = k(t + b)$, where k is a constant. We are given that the rate of removal is constant, say R (in m^3/h). If the width of the path is w, then $R = \text{height} \times \text{width} \times \text{speed} = h(t) \times w \times \dfrac{dx}{dt} = k(t + b)w\,\dfrac{dx}{dt}$. Thus, $\dfrac{dx}{dt} = \dfrac{C}{t + b}$, where $C = \dfrac{R}{kw}$ is a constant. This is a separable equation. $\displaystyle\int dx = C\int \frac{dt}{t + b} \;\Rightarrow\; x(t) = C\ln(t + b) + K$.

Put $t = 0$: $0 = C\ln b + K \;\Rightarrow\; K = -C\ln b$, so $x(t) = C\ln(t + b) - C\ln b = C\ln(1 + t/b)$.

Put $t = 1$: $6000 = C\ln(1 + 1/b)$ $[x = 6\text{ km}]$.

Put $t = 2$: $9000 = C\ln(1 + 2/b)$ $[x = (6 + 3)\text{ km}]$.

Solve for b: $\dfrac{\ln(1+1/b)}{6000} = \dfrac{\ln(1+2/b)}{9000} \Rightarrow 3\ln\left(1+\dfrac{1}{b}\right) = 2\ln\left(1+\dfrac{2}{b}\right) \Rightarrow \left(1+\dfrac{1}{b}\right)^3 = \left(1+\dfrac{2}{b}\right)^2 \Rightarrow$

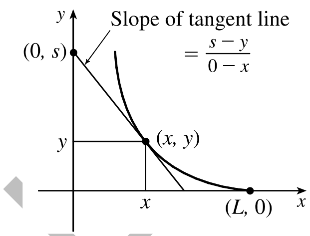
$1+\dfrac{3}{b}+\dfrac{3}{b^2}+\dfrac{1}{b^3} = 1+\dfrac{4}{b}+\dfrac{4}{b^2} \Rightarrow \dfrac{1}{b}+\dfrac{1}{b^2}-\dfrac{1}{b^3} = 0 \Rightarrow b^2+b-1=0 \Rightarrow b = \frac{-1\pm\sqrt{5}}{2}$.

But $b>0$, so $b = \frac{-1+\sqrt{5}}{2} \approx 0.618$ h ≈ 37 min. The snow began to fall $\frac{\sqrt{5}-1}{2}$ hours before noon; that is, at about 11:23 AM.

9. (a) While running from $(L,0)$ to (x,y), the dog travels a distance

$s = \int_x^L \sqrt{1+(dy/dx)^2}\,dx = -\int_L^x \sqrt{1+(dy/dx)^2}\,dx$, so

$\dfrac{ds}{dx} = -\sqrt{1+(dy/dx)^2}$. The dog and rabbit run at the same speed, so the rabbit's position when the dog has traveled a distance s is $(0,s)$. Since the dog runs straight for the rabbit, $\dfrac{dy}{dx} = \dfrac{s-y}{0-x}$ (see the figure).



Thus, $s = y - x\dfrac{dy}{dx} \Rightarrow \dfrac{ds}{dx} = \dfrac{dy}{dx} - \left(x\dfrac{d^2y}{dx^2} + 1\dfrac{dy}{dx}\right) = -x\dfrac{d^2y}{dx^2}$. Equating the two expressions for $\dfrac{ds}{dx}$ gives us $x\dfrac{d^2y}{dx^2} = \sqrt{1+\left(\dfrac{dy}{dx}\right)^2}$, as claimed.

(b) Letting $z = \dfrac{dy}{dx}$, we obtain the differential equation $x\dfrac{dz}{dx} = \sqrt{1+z^2}$, or $\dfrac{dz}{\sqrt{1+z^2}} = \dfrac{dx}{x}$. Integrating:

$\ln x = \displaystyle\int \frac{dz}{\sqrt{1+z^2}} \overset{25}{=} \ln\left(z+\sqrt{1+z^2}\right) + C$. When $x=L$, $z = dy/dx = 0$, so $\ln L = \ln 1 + C$. Therefore,

$C = \ln L$, so $\ln x = \ln\left(\sqrt{1+z^2}+z\right) + \ln L = \ln\left[L\left(\sqrt{1+z^2}+z\right)\right] \Rightarrow x = L\left(\sqrt{1+z^2}+z\right) \Rightarrow$

$\sqrt{1+z^2} = \dfrac{x}{L} - z \Rightarrow 1+z^2 = \left(\dfrac{x}{L}\right)^2 - \dfrac{2xz}{L} + z^2 \Rightarrow \left(\dfrac{x}{L}\right)^2 - 2z\left(\dfrac{x}{L}\right) - 1 = 0 \Rightarrow$

$z = \dfrac{(x/L)^2-1}{2(x/L)} = \dfrac{x^2-L^2}{2Lx} = \dfrac{x}{2L} - \dfrac{L}{2}\dfrac{1}{x}$ [for $x>0$]. Since $z = \dfrac{dy}{dx}$, $y = \dfrac{x^2}{4L} - \dfrac{L}{2}\ln x + C_1$.

Since $y=0$ when $x=L$, $0 = \dfrac{L}{4} - \dfrac{L}{2}\ln L + C_1 \Rightarrow C_1 = \dfrac{L}{2}\ln L - \dfrac{L}{4}$. Thus,

$y = \dfrac{x^2}{4L} - \dfrac{L}{2}\ln x + \dfrac{L}{2}\ln L - \dfrac{L}{4} = \dfrac{x^2-L^2}{4L} - \dfrac{L}{2}\ln\left(\dfrac{x}{L}\right)$.

(c) As $x \to 0^+$, $y \to \infty$, so the dog never catches the rabbit.

10. (a) If the dog runs twice as fast as the rabbit, then the rabbit's position when the dog has traveled a distance s is $(0, s/2)$.

Since the dog runs straight toward the rabbit, the tangent line to the dog's path has slope $\dfrac{dy}{dx} = \dfrac{s/2-y}{0-x}$.

Thus, $s = 2y - 2x\dfrac{dy}{dx} \Rightarrow \dfrac{ds}{dx} = 2\dfrac{dy}{dx} - \left(2x\dfrac{d^2y}{dx^2} + 2\dfrac{dy}{dx}\right) = -2x\dfrac{d^2y}{dx^2}$.

From Problem 9(a), $\dfrac{ds}{dx} = -\sqrt{1+\left(\dfrac{dy}{dx}\right)^2}$, so $2x\dfrac{d^2y}{dx^2} = \sqrt{1+\left(\dfrac{dy}{dx}\right)^2}$.

Letting $z = \dfrac{dy}{dx}$, we obtain the differential equation $2x\dfrac{dz}{dx} = \sqrt{1+z^2}$, or $\dfrac{2\,dz}{\sqrt{1+z^2}} = \dfrac{dx}{x}$. Integrating, we get

$\ln x = \displaystyle\int \frac{2\,dz}{\sqrt{1+z^2}} = 2\ln\left(\sqrt{1+z^2}+z\right)+C$. [See Problem 9(b).] When $x = L$, $z = dy/dx = 0$, so $\ln L = 2\ln 1 + C = C$. Thus,

$$\ln x = 2\ln\left(\sqrt{1+z^2}+z\right)+\ln L = \ln\left(L\left(\sqrt{1+z^2}+z\right)^2\right) \quad\Rightarrow\quad x = L\left(\sqrt{1+z^2}+z\right)^2 \quad\Rightarrow$$

$$\sqrt{1+z^2} = \sqrt{\frac{x}{L}} - z \quad\Rightarrow\quad 1+z^2 = \frac{x}{L} - 2\sqrt{\frac{x}{L}}\,z + z^2 \quad\Rightarrow\quad 2\sqrt{\frac{x}{L}}\,z = \frac{x}{L} - 1 \quad\Rightarrow$$

$$\frac{dy}{dx} = z = \frac{1}{2}\sqrt{\frac{x}{L}} - \frac{1}{2\sqrt{x/L}} = \frac{1}{2\sqrt{L}}\,x^{1/2} - \frac{\sqrt{L}}{2}\,x^{-1/2} \quad\Rightarrow\quad y = \frac{1}{3\sqrt{L}}\,x^{3/2} - \sqrt{L}\,x^{1/2} + C_1.$$

When $x = L$, $y = 0$, so $0 = \dfrac{1}{3\sqrt{L}}L^{3/2} - \sqrt{L}\,L^{1/2} + C_1 = \dfrac{L}{3} - L + C_1 = C_1 - \frac{2}{3}L$. Therefore, $C_1 = \frac{2}{3}L$ and

$y = \dfrac{x^{3/2}}{3\sqrt{L}} - \sqrt{L}\,x^{1/2} + \frac{2}{3}L$. As $x \to 0$, $y \to \frac{2}{3}L$, so the dog catches the rabbit when the rabbit is at $\left(0, \frac{2}{3}L\right)$.

(At that point, the dog has traveled a distance of $\frac{4}{3}L$, twice as far as the rabbit has run.)

(b) As in the solutions to part (a) and Problem 9, we get $z = \dfrac{dy}{dx} = \dfrac{x^2}{2L^2} - \dfrac{L^2}{2x^2}$ and hence $y = \dfrac{x^3}{6L^2} + \dfrac{L^2}{2x} - \frac{2}{3}L$.

We want to minimize the distance D from the dog at (x, y) to the rabbit at $(0, 2s)$. Now $s = \frac{1}{2}y - \frac{1}{2}x\dfrac{dy}{dx} \quad\Rightarrow$

$2s = y - xz \quad\Rightarrow\quad y - 2s = xz = x\left(\dfrac{x^2}{2L^2} - \dfrac{L^2}{2x^2}\right) = \dfrac{x^3}{2L^2} - \dfrac{L^2}{2x}$, so

$$D = \sqrt{(x-0)^2 + (y-2s)^2} = \sqrt{x^2 + \left(\frac{x^3}{2L^2} - \frac{L^2}{2x}\right)^2} = \sqrt{\frac{x^6}{4L^4} + \frac{x^2}{2} + \frac{L^4}{4x^2}} = \sqrt{\left(\frac{x^3}{2L^2} + \frac{L^2}{2x}\right)^2}$$
$$= \frac{x^3}{2L^2} + \frac{L^2}{2x}$$

$$D' = 0 \quad\Leftrightarrow\quad \frac{3x^2}{2L^2} - \frac{L^2}{2x^2} = 0 \quad\Leftrightarrow\quad \frac{3x^2}{2L^2} = \frac{L^2}{2x^2} \quad\Leftrightarrow\quad x^4 = \frac{L^4}{3} \quad\Leftrightarrow\quad x = \frac{L}{\sqrt[4]{3}},\ x > 0,\ L > 0.$$

Since $D''(x) = \dfrac{3x}{L^2} + \dfrac{L^2}{x^3} > 0$ for all $x > 0$, we know that $D\left(\dfrac{L}{\sqrt[4]{3}}\right) = \dfrac{(L\cdot 3^{-1/4})^3}{2L^2} + \dfrac{L^2}{2L\cdot 3^{-1/4})} = \dfrac{2L}{3^{3/4}}$ is the minimum value of D, that is, the closest the dog gets to the rabbit. The positions at this distance are

$$\text{Dog: } (x, y) = \left(\frac{L}{\sqrt[4]{3}}, \left(\frac{5}{3^{7/4}} - \frac{2}{3}\right)L\right) = \left(\frac{L}{\sqrt[4]{3}}, \frac{5\sqrt[4]{3} - 6}{9}L\right)$$

$$\text{Rabbit: } (0, 2s) = \left(0, \frac{8\sqrt[4]{3}L}{9} - \frac{2L}{3}\right) = \left(0, \frac{8\sqrt[4]{3} - 6}{9}L\right)$$

11. (a) We are given that $V = \frac{1}{3}\pi r^2 h$, $dV/dt = 60{,}000\pi$ ft^3/h, and $r = 1.5h = \frac{3}{2}h$. So $V = \frac{1}{3}\pi\left(\frac{3}{2}h\right)^2 h = \frac{3}{4}\pi h^3 \quad\Rightarrow$

$\dfrac{dV}{dt} = \frac{3}{4}\pi\cdot 3h^2\dfrac{dh}{dt} = \frac{9}{4}\pi h^2\dfrac{dh}{dt}$. Therefore, $\dfrac{dh}{dt} = \dfrac{4(dV/dt)}{9\pi h^2} = \dfrac{240{,}000\pi}{9\pi h^2} = \dfrac{80{,}000}{3h^2}$ $(\star)$ $\Rightarrow$

$\int 3h^2\,dh = \int 80{,}000\,dt \quad\Rightarrow\quad h^3 = 80{,}000t + C$. When $t = 0$, $h = 60$. Thus, $C = 60^3 = 216{,}000$, so

$h^3 = 80{,}000t + 216{,}000$. Let $h = 100$. Then $100^3 = 1{,}000{,}000 = 80{,}000t + 216{,}000 \Rightarrow$
$80{,}000t = 784{,}000 \Rightarrow t = 9.8$, so the time required is 9.8 hours.

(b) The floor area of the silo is $F = \pi \cdot 200^2 = 40{,}000\pi$ ft^2, and the area of the base of the pile is
$A = \pi r^2 = \pi\left(\frac{3}{2}h\right)^2 = \frac{9\pi}{4}h^2$. So the area of the floor which is not covered when $h = 60$ is
$F - A = 40{,}000\pi - 8100\pi = 31{,}900\pi \approx 100{,}217$ ft^2. Now $A = \frac{9\pi}{4}h^2 \Rightarrow dA/dt = \frac{9\pi}{4} \cdot 2h\,(dh/dt)$,
and from ($\star$) in part (a) we know that when $h = 60$, $dh/dt = \frac{80{,}000}{3(60)^2} = \frac{200}{27}$ ft/h. Therefore,
$dA/dt = \frac{9\pi}{4}(2)(60)\left(\frac{200}{27}\right) = 2000\pi \approx 6283$ ft^2/h.

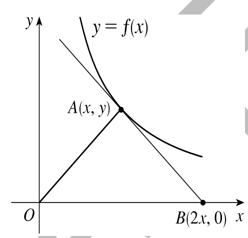
(c) At $h = 90$ ft, $dV/dt = 60{,}000\pi - 20{,}000\pi = 40{,}000\pi$ ft^3/h. From ($\star$) in part (a),
$\dfrac{dh}{dt} = \dfrac{4(dV/dt)}{9\pi h^2} = \dfrac{4(40{,}000\pi)}{9\pi h^2} = \dfrac{160{,}000}{9h^2} \Rightarrow \int 9h^2\,dh = \int 160{,}000\,dt \Rightarrow 3h^3 = 160{,}000t + C$. When $t = 0$,
$h = 90$; therefore, $C = 3 \cdot 729{,}000 = 2{,}187{,}000$. So $3h^3 = 160{,}000t + 2{,}187{,}000$. At the top, $h = 100 \Rightarrow$
$3(100)^3 = 160{,}000t + 2{,}187{,}000 \Rightarrow t = \frac{813{,}000}{160{,}000} \approx 5.1$. The pile reaches the top after about 5.1 h.

12. Let $P(a, b)$ be any first-quadrant point on the curve $y = f(x)$. The tangent line at P has equation $y - b = f'(a)(x - a)$, or equivalently, $y = mx + b - ma$, where $m = f'(a)$. If $Q(0, c)$ is the y-intercept, then $c = b - am$. If $R(k, 0)$ is the x-intercept, then $k = \dfrac{am - b}{m} = a - \dfrac{b}{m}$. Since the tangent line is bisected at P, we know that $|PQ| = |PR|$; that is,
$\sqrt{(a-0)^2 + [b - (b - am)]^2} = \sqrt{[a - (a - b/m)]^2 + (b - 0)^2}$. Squaring and simplifying gives us
$a^2 + a^2m^2 = b^2/m^2 + b^2 \Rightarrow a^2m^2 + a^2m^4 = b^2 + b^2m^2 \Rightarrow a^2m^4 + \left(a^2 - b^2\right)m^2 - b^2 = 0 \Rightarrow$
$\left(a^2m^2 - b^2\right)\left(m^2 + 1\right) = 0 \Rightarrow m^2 = b^2/a^2$. Since m is the slope of the line from a positive y-intercept to a positive x-intercept, m must be negative. Since a and b are positive, we have $m = -b/a$, so we will solve the equivalent differential equation $\dfrac{dy}{dx} = -\dfrac{y}{x} \Rightarrow \dfrac{dy}{y} = -\dfrac{dx}{x} \Rightarrow \displaystyle\int \frac{dy}{y} = -\int \frac{dx}{x} \Rightarrow \ln y = -\ln x + C\ [x, y > 0] \Rightarrow$
$y = e^{-\ln x + C} = e^{\ln x^{-1}} \cdot e^C = x^{-1} \cdot A \Rightarrow y = A/x$. Since the point $(3, 2)$ is on the curve, $3 = A/2 \Rightarrow A = 6$ and the curve is $y = 6/x$ with $x > 0$.

13. Let $P(a, b)$ be any point on the curve. If m is the slope of the tangent line at P, then $m = y'(a)$, and an equation of the normal line at P is $y - b = -\dfrac{1}{m}(x - a)$, or equivalently, $y = -\dfrac{1}{m}x + b + \dfrac{a}{m}$. The y-intercept is always 6, so
$b + \dfrac{a}{m} = 6 \Rightarrow \dfrac{a}{m} = 6 - b \Rightarrow m = \dfrac{a}{6 - b}$. We will solve the equivalent differential equation $\dfrac{dy}{dx} = \dfrac{x}{6 - y} \Rightarrow$
$(6 - y)\,dy = x\,dx \Rightarrow \displaystyle\int (6 - y)\,dy = \int x\,dx \Rightarrow 6y - \frac{1}{2}y^2 = \frac{1}{2}x^2 + C \Rightarrow 12y - y^2 = x^2 + K$.
Since $(3, 2)$ is on the curve, $12(2) - 2^2 = 3^2 + K \Rightarrow K = 11$. So the curve is given by $12y - y^2 = x^2 + 11 \Rightarrow$
$x^2 + y^2 - 12y + 36 = -11 + 36 \Rightarrow x^2 + (y - 6)^2 = 25$, a circle with center $(0, 6)$ and radius 5.

14. Let $P(x_0, y_0)$ be a point on the curve. Since the midpoint of the line segment determined by the normal line from (x_0, y_0) to its intersection with the x-axis has x-coordinate 0, the x-coordinate of the point of intersection with the x-axis must be $-x_0$. Hence, the normal line has slope $\dfrac{y_0 - 0}{x_0 - (-x_0)} = \dfrac{y_0}{2x_0}$. So the tangent line has slope $-\dfrac{2x_0}{y_0}$. This gives the differential equation $y' = -\dfrac{2x}{y} \Rightarrow y\,dy = -2x\,dx \Rightarrow \int y\,dy = \int(-2x)\,dx \Rightarrow \frac{1}{2}y^2 = -x^2 + C \Rightarrow x^2 + \frac{1}{2}y^2 = C$ $[C > 0]$. This is a family of ellipses.

15. From the figure, slope $OA = \dfrac{y}{x}$. If triangle OAB is isosceles, then slope AB must be $-\dfrac{y}{x}$, the negative of slope OA. This slope is also equal to $f'(x)$, so we have $\dfrac{dy}{dx} = -\dfrac{y}{x} \Rightarrow \displaystyle\int \frac{dy}{y} = -\int \frac{dx}{x} \Rightarrow$
$\ln|y| = -\ln|x| + C \Rightarrow |y| = e^{-\ln|x|+C} \Rightarrow$
$|y| = (e^{\ln|x|})^{-1}e^C \Rightarrow |y| = \dfrac{1}{|x|}e^C \Rightarrow y = \dfrac{K}{x}, K \neq 0.$

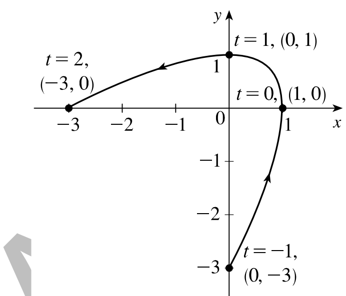


10 □ PARAMETRIC EQUATIONS AND POLAR COORDINATES

10.1 Curves Defined by Parametric Equations

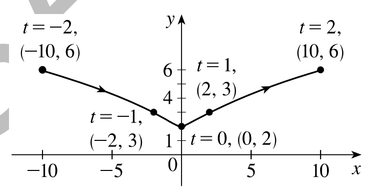
1. $x = 1 - t^2, \quad y = 2t - t^2, \quad -1 \le t \le 2$

t	-1	0	1	2
x	0	1	0	-3
y	-3	0	1	0



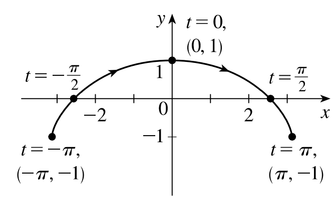
2. $x = t^3 + t, \quad y = t^2 + 2, \quad -2 \le t \le 2$

t	-2	-1	0	1	2
x	-10	-2	0	2	10
y	6	3	2	3	6



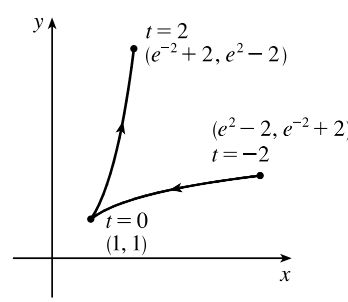
3. $x = t + \sin t, \quad y = \cos t, \quad -\pi \le t \le \pi$

t	$-\pi$	$-\pi/2$	0	$\pi/2$	π
x	$-\pi$	$-\pi/2+1$	0	$\pi/2+1$	π
y	-1	0	1	0	-1



4. $x = e^{-t} + t, \quad y = e^t - t, \quad -2 \le t \le 2$

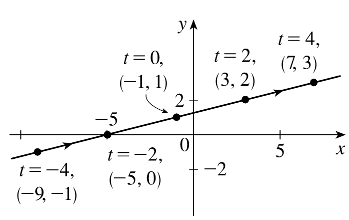
t	-2	-1	0	1	2
x	$e^2 - 2$ 5.39	$e - 1$ 1.72	1	$e^{-1} + 1$ 1.37	$e^{-2} + 2$ 2.14
y	$e^{-2} + 2$ 2.14	$e^{-1} + 1$ 1.37	1	$e - 1$ 1.72	$e^2 - 2$ 5.39



5. $x = 2t - 1, \quad y = \frac{1}{2}t + 1$

(a)

t	-4	-2	0	2	4
x	-9	-5	-1	3	7
y	-1	0	1	2	3



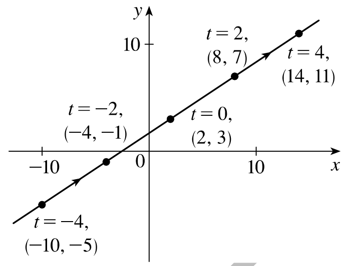
(b) $x = 2t - 1 \quad \Rightarrow \quad 2t = x + 1 \quad \Rightarrow \quad t = \frac{1}{2}x + \frac{1}{2}$, so

$$y = \tfrac{1}{2}t + 1 = \tfrac{1}{2}\left(\tfrac{1}{2}x + \tfrac{1}{2}\right) + 1 = \tfrac{1}{4}x + \tfrac{1}{4} + 1 \quad \Rightarrow \quad y = \tfrac{1}{4}x + \tfrac{5}{4}$$

6. $x = 3t + 2, \quad y = 2t + 3$

(a)

t	-4	-2	0	2	4
x	-10	-4	2	8	14
y	-5	-1	3	7	11



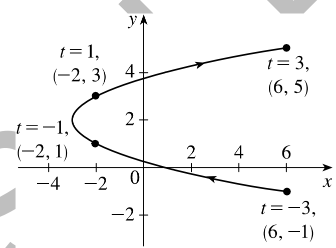
(b) $x = 3t + 2 \quad \Rightarrow \quad 3t = x - 2 \quad \Rightarrow \quad t = \frac{1}{3}x - \frac{2}{3}$, so

$y = 2t + 3 = 2\left(\frac{1}{3}x - \frac{2}{3}\right) + 3 = \frac{2}{3}x - \frac{4}{3} + 3 \quad \Rightarrow \quad y = \frac{2}{3}x + \frac{5}{3}$

7. $x = t^2 - 3, \quad y = t + 2, \quad -3 \le t \le 3$

(a)

t	-3	-1	1	3
x	6	-2	-2	6
y	-1	1	3	5



(b) $y = t + 2 \quad \Rightarrow \quad t = y - 2$, so

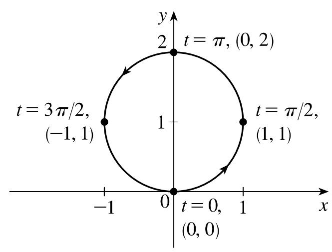
$x = t^2 - 3 = (y - 2)^2 - 3 = y^2 - 4y + 4 - 3 \quad \Rightarrow$

$x = y^2 - 4y + 1, -1 \le y \le 5$

8. $x = \sin t, \quad y = 1 - \cos t, \quad 0 \le t \le 2\pi$

(a)

t	0	$\pi/2$	π	$3\pi/2$	2π
x	0	1	0	-1	0
y	0	1	2	1	0



(b) $x = \sin t, y = 1 - \cos t \quad [\text{or } y - 1 = -\cos t] \quad \Rightarrow$

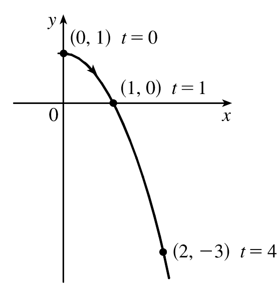
$x^2 + (y - 1)^2 = (\sin t)^2 + (-\cos t)^2 \quad \Rightarrow \quad x^2 + (y - 1)^2 = 1.$

As t varies from 0 to 2π, the circle with center $(0, 1)$ and radius 1 is traced out.

9. $x = \sqrt{t}, \ y = 1 - t$

(a)

t	0	1	2	3	4
x	0	1	1.414	1.732	2
y	1	0	-1	-2	-3



(b) $x = \sqrt{t} \quad \Rightarrow \quad t = x^2 \quad \Rightarrow \quad y = 1 - t = 1 - x^2$. Since $t \ge 0$, $x \ge 0$.

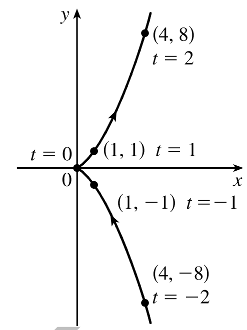
So the curve is the right half of the parabola $y = 1 - x^2$.

10. $x = t^2$, $y = t^3$

(a)

t	-2	-1	0	1	2
x	4	1	0	1	4
y	-8	-1	0	1	8

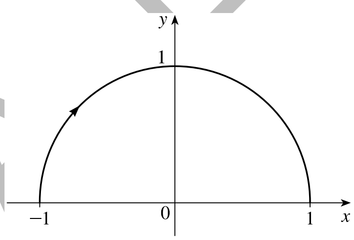
(b) $y = t^3 \;\Rightarrow\; t = \sqrt[3]{y} \;\Rightarrow\; x = t^2 = \left(\sqrt[3]{y}\right)^2 = y^{2/3}$. $t \in \mathbb{R}, y \in \mathbb{R}, x \geq 0$.



11. (a) $x = \sin \frac{1}{2}\theta$, $y = \cos \frac{1}{2}\theta$, $-\pi \leq \theta \leq \pi$.

$x^2 + y^2 = \sin^2 \frac{1}{2}\theta + \cos^2 \frac{1}{2}\theta = 1$. For $-\pi \leq \theta \leq 0$, we have $-1 \leq x \leq 0$ and $0 \leq y \leq 1$. For $0 < \theta \leq \pi$, we have $0 < x \leq 1$ and $1 > y \geq 0$. The graph is a semicircle.

(b)

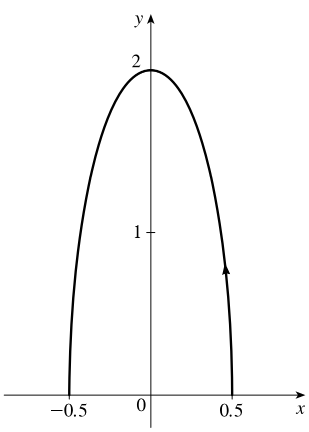


12. (a) $x = \frac{1}{2}\cos\theta$, $y = 2\sin\theta$, $0 \leq \theta \leq \pi$.

$(2x)^2 + \left(\frac{1}{2}y\right)^2 = \cos^2\theta + \sin^2\theta = 1 \;\Rightarrow\; 4x^2 + \frac{1}{4}y^2 = 1 \;\Rightarrow$

$\dfrac{x^2}{(1/2)^2} + \dfrac{y^2}{2^2} = 1$, which is an equation of an ellipse with x-intercepts $\pm\frac{1}{2}$ and y-intercepts ± 2. For $0 \leq \theta \leq \pi/2$, we have $\frac{1}{2} \geq x \geq 0$ and $0 \leq y \leq 2$. For $\pi/2 < \theta \leq \pi$, we have $0 > x \geq -\frac{1}{2}$ and $2 > y \geq 0$. So the graph is the top half of the ellipse.

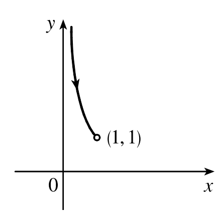
(b)



13. (a) $x = \sin t$, $y = \csc t$, $0 < t < \frac{\pi}{2}$. $y = \csc t = \dfrac{1}{\sin t} = \dfrac{1}{x}$.

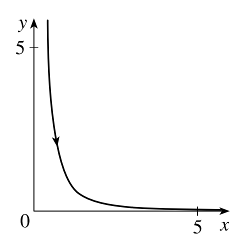
For $0 < t < \frac{\pi}{2}$, we have $0 < x < 1$ and $y > 1$. Thus, the curve is the portion of the hyperbola $y = 1/x$ with $y > 1$.

(b)



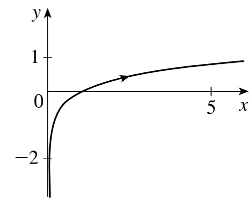
14. (a) $y = e^{-2t} = (e^t)^{-2} = x^{-2} = 1/x^2$ for $x > 0$ since $x = e^t$.

(b)



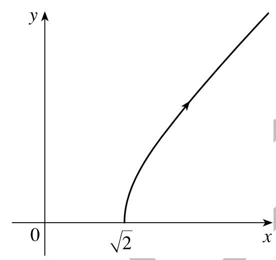
15. (a) $y = \ln t \quad \Rightarrow \quad t = e^y$, so $x = t^2 = (e^y)^2 = e^{2y}$.

(b)



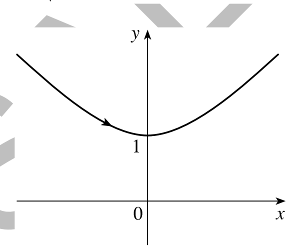
16. (a) $x = \sqrt{t+1} \quad \Rightarrow \quad x^2 = t+1 \quad \Rightarrow \quad t = x^2 - 1$.
$y = \sqrt{t-1} = \sqrt{(x^2-1)-1} = \sqrt{x^2-2}$. The curve is the part of the hyperbola $x^2 - y^2 = 2$ with $x \geq \sqrt{2}$ and $y \geq 0$.

(b)



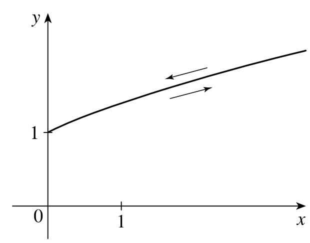
17. (a) $x = \sinh t, y = \cosh t \quad \Rightarrow \quad y^2 - x^2 = \cosh^2 t - \sinh^2 t = 1$.
Since $y = \cosh t \geq 1$, we have the upper branch of the hyperbola $y^2 - x^2 = 1$.

(b)



18. (a) $x = \tan^2 \theta, y = \sec \theta, -\pi/2 < \theta < \pi/2$.
$1 + \tan^2 \theta = \sec^2 \theta \quad \Rightarrow \quad 1 + x = y^2 \quad \Rightarrow \quad x = y^2 - 1$. For $-\pi/2 < \theta \leq 0$, we have $x \geq 0$ and $y \geq 1$. For $0 < \theta < \pi/2$, we have $0 < x$ and $1 < y$. Thus, the curve is the portion of the parabola $x = y^2 - 1$ in the first quadrant. As θ increases from $-\pi/2$ to 0, the point (x, y) approaches $(0, 1)$ along the parabola. As θ increases from 0 to $\pi/2$, the point (x, y) retreats from $(0, 1)$ along the parabola.

(b)



19. $x = 5 + 2\cos \pi t, y = 3 + 2\sin \pi t \quad \Rightarrow \quad \cos \pi t = \dfrac{x-5}{2}, \sin \pi t = \dfrac{y-3}{2}. \quad \cos^2(\pi t) + \sin^2(\pi t) = 1 \quad \Rightarrow$

$\left(\dfrac{x-5}{2}\right)^2 + \left(\dfrac{y-3}{2}\right)^2 = 1$. The motion of the particle takes place on a circle centered at $(5, 3)$ with a radius 2. As t goes from 1 to 2, the particle starts at the point $(3, 3)$ and moves counterclockwise along the circle $\left(\dfrac{x-5}{2}\right)^2 + \left(\dfrac{y-3}{2}\right)^2 = 1$ to $(7, 3)$ [one-half of a circle].

20. $x = 2 + \sin t, y = 1 + 3\cos t \quad \Rightarrow \quad \sin t = x - 2, \cos t = \dfrac{y-1}{3}. \quad \sin^2 t + \cos^2 t = 1 \quad \Rightarrow \quad (x-2)^2 + \left(\dfrac{y-1}{3}\right)^2 = 1.$

The motion of the particle takes place on an ellipse centered at $(2, 1)$. As t goes from $\pi/2$ to 2π, the particle starts at the point $(3, 1)$ and moves counterclockwise three-fourths of the way around the ellipse to $(2, 4)$.

21. $x = 5\sin t$, $y = 2\cos t \Rightarrow \sin t = \dfrac{x}{5}$, $\cos t = \dfrac{y}{2}$. $\sin^2 t + \cos^2 t = 1 \Rightarrow \left(\dfrac{x}{5}\right)^2 + \left(\dfrac{y}{2}\right)^2 = 1$. The motion of the particle takes place on an ellipse centered at $(0, 0)$. As t goes from $-\pi$ to 5π, the particle starts at the point $(0, -2)$ and moves clockwise around the ellipse 3 times.

22. $y = \cos^2 t = 1 - \sin^2 t = 1 - x^2$. The motion of the particle takes place on the parabola $y = 1 - x^2$. As t goes from -2π to $-\pi$, the particle starts at the point $(0, 1)$, moves to $(1, 0)$, and goes back to $(0, 1)$. As t goes from $-\pi$ to 0, the particle moves to $(-1, 0)$ and goes back to $(0, 1)$. The particle repeats this motion as t goes from 0 to 2π.

23. We must have $1 \le x \le 4$ and $2 \le y \le 3$. So the graph of the curve must be contained in the rectangle $[1, 4]$ by $[2, 3]$.

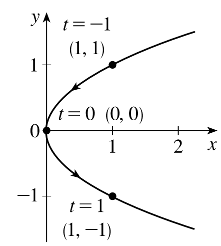
24. (a) From the first graph, we have $1 \le x \le 2$. From the second graph, we have $-1 \le y \le 1$. The only choice that satisfies either of those conditions is III.

(b) From the first graph, the values of x cycle through the values from -2 to 2 four times. From the second graph, the values of y cycle through the values from -2 to 2 six times. Choice I satisfies these conditions.

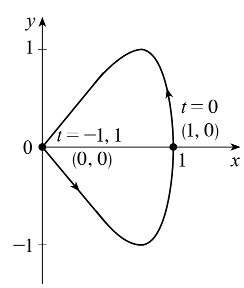
(c) From the first graph, the values of x cycle through the values from -2 to 2 three times. From the second graph, we have $0 \le y \le 2$. Choice IV satisfies these conditions.

(d) From the first graph, the values of x cycle through the values from -2 to 2 two times. From the second graph, the values of y do the same thing. Choice II satisfies these conditions.

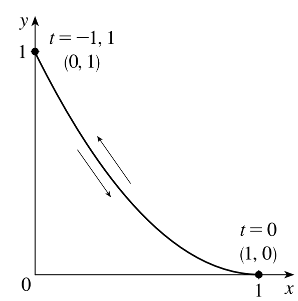
25. When $t = -1$, $(x, y) = (1, 1)$. As t increases to 0, x and y both decrease to 0. As t increases from 0 to 1, x increases from 0 to 1 and y decreases from 0 to -1. As t increases beyond 1, x continues to increase and y continues to decrease. For $t < -1$, x and y are both positive and decreasing. We could achieve greater accuracy by estimating x- and y-values for selected values of t from the given graphs and plotting the corresponding points.



26. When $t = -1$, $(x, y) = (0, 0)$. As t increases to 0, x increases from 0 to 1, while y first decreases to -1 and then increases to 0. As t increases from 0 to 1, x decreases from 1 to 0, while y first increases to 1 and then decreases to 0. We could achieve greater accuracy by estimating x- and y-values for selected values of t from the given graphs and plotting the corresponding points.



27. When $t = -1$, $(x, y) = (0, 1)$. As t increases to 0, x increases from 0 to 1 and y decreases from 1 to 0. As t increases from 0 to 1, the curve is retraced in the opposite direction with x decreasing from 1 to 0 and y increasing from 0 to 1. We could achieve greater accuracy by estimating x- and y-values for selected values of t from the given graphs and plotting the corresponding points.



28. (a) $x = t^4 - t + 1 = (t^4 + 1) - t > 0$ [think of the graphs of $y = t^4 + 1$ and $y = t$] and $y = t^2 \geq 0$, so these equations are matched with graph V.

(b) $y = \sqrt{t} \geq 0$. $x = t^2 - 2t = t(t - 2)$ is negative for $0 < t < 2$, so these equations are matched with graph I.

(c) $x = \sin 2t$ has period $2\pi/2 = \pi$. Note that

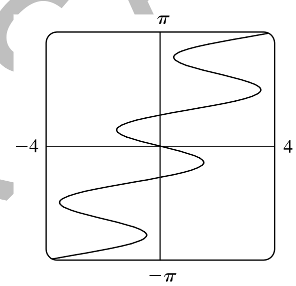
$y(t + 2\pi) = \sin[t + 2\pi + \sin 2(t + 2\pi)] = \sin(t + 2\pi + \sin 2t) = \sin(t + \sin 2t) = y(t)$, so y has period 2π. These equations match graph II since x cycles through the values -1 to 1 twice as y cycles through those values once.

(d) $x = \cos 5t$ has period $2\pi/5$ and $y = \sin 2t$ has period π, so x will take on the values -1 to 1, and then 1 to -1, before y takes on the values -1 to 1. Note that when $t = 0$, $(x, y) = (1, 0)$. These equations are matched with graph VI.

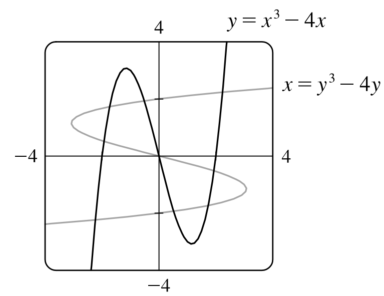
(e) $x = t + \sin 4t,\ y = t^2 + \cos 3t$. As t becomes large, t and t^2 become the dominant terms in the expressions for x and y, so the graph will look like the graph of $y = x^2$, but with oscillations. These equations are matched with graph IV.

(f) $x = \dfrac{\sin 2t}{4 + t^2},\ y = \dfrac{\cos 2t}{4 + t^2}$. As $t \to \infty$, x and y both approach 0. These equations are matched with graph III.

29. Use $y = t$ and $x = t - 2\sin \pi t$ with a t-interval of $[-\pi, \pi]$.



30. Use $x_1 = t$, $y_1 = t^3 - 4t$ and $x_2 = t^3 - 4t$, $y_2 = t$ with a t-interval of $[-3, 3]$. There are 9 points of intersection; $(0, 0)$ is fairly obvious. The point in quadrant I is approximately $(2.2, 2.2)$, and by symmetry, the point in quadrant III is approximately $(-2.2, -2.2)$. The other six points are approximately $(\mp 1.9, \pm 0.5)$, $(\mp 1.7, \pm 1.7)$, and $(\mp 0.5, \pm 1.9)$.



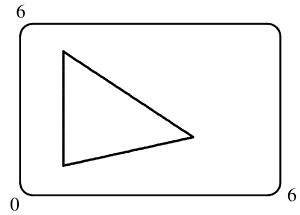
31. (a) $x = x_1 + (x_2 - x_1)t$, $y = y_1 + (y_2 - y_1)t$, $0 \leq t \leq 1$. Clearly the curve passes through $P_1(x_1, y_1)$ when $t = 0$ and through $P_2(x_2, y_2)$ when $t = 1$. For $0 < t < 1$, x is strictly between x_1 and x_2 and y is strictly between y_1 and y_2. For every value of t, x and y satisfy the relation $y - y_1 = \dfrac{y_2 - y_1}{x_2 - x_1}(x - x_1)$, which is the equation of the line through $P_1(x_1, y_1)$ and $P_2(x_2, y_2)$.

Finally, any point (x, y) on that line satisfies $\dfrac{y - y_1}{y_2 - y_1} = \dfrac{x - x_1}{x_2 - x_1}$; if we call that common value t, then the given parametric equations yield the point (x, y); and any (x, y) on the line between $P_1(x_1, y_1)$ and $P_2(x_2, y_2)$ yields a value of t in $[0, 1]$. So the given parametric equations exactly specify the line segment from $P_1(x_1, y_1)$ to $P_2(x_2, y_2)$.

(b) $x = -2 + [3 - (-2)]t = -2 + 5t$ and $y = 7 + (-1 - 7)t = 7 - 8t$ for $0 \leq t \leq 1$.

32. For the side of the triangle from A to B, use $(x_1, y_1) = (1, 1)$ and $(x_2, y_2) = (4, 2)$. Hence, the equations are

$$x = x_1 + (x_2 - x_1)\,t = 1 + (4 - 1)\,t = 1 + 3t,$$
$$y = y_1 + (y_2 - y_1)\,t = 1 + (2 - 1)\,t = 1 + t.$$



Graphing $x = 1 + 3t$ and $y = 1 + t$ with $0 \le t \le 1$ gives us the side of the triangle from A to B. Similarly, for the side BC we use $x = 4 - 3t$ and $y = 2 + 3t$, and for the side AC we use $x = 1$ and $y = 1 + 4t$.

33. The circle $x^2 + (y - 1)^2 = 4$ has center $(0, 1)$ and radius 2, so by Example 4 it can be represented by $x = 2\cos t$, $y = 1 + 2\sin t$, $0 \le t \le 2\pi$. This representation gives us the circle with a counterclockwise orientation starting at $(2, 1)$.

(a) To get a clockwise orientation, we could change the equations to $x = 2\cos t$, $y = 1 - 2\sin t$, $0 \le t \le 2\pi$.

(b) To get three times around in the counterclockwise direction, we use the original equations $x = 2\cos t$, $y = 1 + 2\sin t$ with the domain expanded to $0 \le t \le 6\pi$.

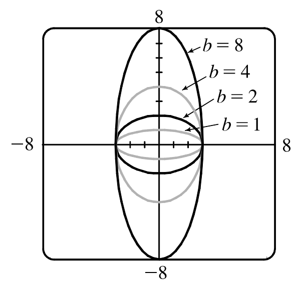
(c) To start at $(0, 3)$ using the original equations, we must have $x_1 = 0$; that is, $2\cos t = 0$. Hence, $t = \frac{\pi}{2}$. So we use $x = 2\cos t$, $y = 1 + 2\sin t$, $\frac{\pi}{2} \le t \le \frac{3\pi}{2}$.

Alternatively, if we want t to start at 0, we could change the equations of the curve. For example, we could use $x = -2\sin t$, $y = 1 + 2\cos t$, $0 \le t \le \pi$.

34. (a) Let $x^2/a^2 = \sin^2 t$ and $y^2/b^2 = \cos^2 t$ to obtain $x = a\sin t$ and $y = b\cos t$ with $0 \le t \le 2\pi$ as possible parametric equations for the ellipse $x^2/a^2 + y^2/b^2 = 1$.

(b) The equations are $x = 3\sin t$ and $y = b\cos t$ for $b \in \{1, 2, 4, 8\}$.

(c) As b increases, the ellipse stretches vertically.



35. *Big circle:* It's centered at $(2, 2)$ with a radius of 2, so by Example 4, parametric equations are

$$x = 2 + 2\cos t, \qquad y = 2 + 2\sin t, \qquad 0 \le t \le 2\pi$$

Small circles: They are centered at $(1, 3)$ and $(3, 3)$ with a radius of 0.1. By Example 4, parametric equations are

	(left)	$x = 1 + 0.1\cos t,$	$y = 3 + 0.1\sin t,$	$0 \le t \le 2\pi$
and	*(right)*	$x = 3 + 0.1\cos t,$	$y = 3 + 0.1\sin t,$	$0 \le t \le 2\pi$

Semicircle: It's the lower half of a circle centered at $(2, 2)$ with radius 1. By Example 4, parametric equations are

$$x = 2 + 1\cos t, \qquad y = 2 + 1\sin t, \qquad \pi \le t \le 2\pi$$

To get all four graphs on the same screen with a typical graphing calculator, we need to change the last t-interval to$[0, 2\pi]$ in order to match the others. We can do this by changing t to $0.5t$. This change gives us the upper half. There are several ways to get the lower half—one is to change the "+" to a "−" in the y-assignment, giving us

$$x = 2 + 1\cos(0.5t), \qquad y = 2 - 1\sin(0.5t), \qquad 0 \le t \le 2\pi$$

36. If you are using a calculator or computer that can overlay graphs (using multiple t-intervals), the following is appropriate.

Left side: $x = 1$ and y goes from 1.5 to 4, so use

$$x = 1, \qquad y = t, \qquad 1.5 \le t \le 4$$

Right side: $x = 10$ and y goes from 1.5 to 4, so use

$$x = 10, \qquad y = t, \qquad 1.5 \le t \le 4$$

Bottom: x goes from 1 to 10 and $y = 1.5$, so use

$$x = t, \qquad y = 1.5, \qquad 1 \le t \le 10$$

Handle: It starts at $(10, 4)$ and ends at $(13, 7)$, so use

$$x = 10 + t, \qquad y = 4 + t, \qquad 0 \le t \le 3$$

Left wheel: It's centered at $(3, 1)$, has a radius of 1, and appears to go about $30°$ above the horizontal, so use

$$x = 3 + 1\cos t, \qquad y = 1 + 1\sin t, \qquad \tfrac{5\pi}{6} \le t \le \tfrac{13\pi}{6}$$

Right wheel: Similar to the left wheel with center $(8, 1)$, so use

$$x = 8 + 1\cos t, \qquad y = 1 + 1\sin t, \qquad \tfrac{5\pi}{6} \le t \le \tfrac{13\pi}{6}$$

If you are using a calculator or computer that cannot overlay graphs (using one t-interval), the following is appropriate. We'll start by picking the t-interval $[0, 2.5]$ since it easily matches the t-values for the two sides. We now need to find parametric equations for all graphs with $0 \le t \le 2.5$.

Left side: $x = 1$ and y goes from 1.5 to 4, so use

$$x = 1, \qquad y = 1.5 + t, \qquad 0 \le t \le 2.5$$

Right side: $x = 10$ and y goes from 1.5 to 4, so use

$$x = 10, \qquad y = 1.5 + t, \qquad 0 \le t \le 2.5$$

Bottom: x goes from 1 to 10 and $y = 1.5$, so use

$$x = 1 + 3.6t, \qquad y = 1.5, \qquad 0 \le t \le 2.5$$

To get the x-assignment, think of creating a linear function such that when $t = 0$, $x = 1$ and when $t = 2.5$, $x = 10$. We can use the point-slope form of a line with $(t_1, x_1) = (0, 1)$ and $(t_2, x_2) = (2.5, 10)$.

$x - 1 = \dfrac{10 - 1}{2.5 - 0}(t - 0) \quad \Rightarrow \quad x = 1 + 3.6t.$

Handle: It starts at $(10, 4)$ and ends at $(13, 7)$, so use

$$x = 10 + 1.2t, \qquad y = 4 + 1.2t, \qquad 0 \le t \le 2.5$$

$(t_1, x_1) = (0, 10)$ and $(t_2, x_2) = (2.5, 13)$ gives us $x - 10 = \dfrac{13 - 10}{2.5 - 0}(t - 0) \quad \Rightarrow \quad x = 10 + 1.2t.$

$(t_1, y_1) = (0, 4)$ and $(t_2, y_2) = (2.5, 7)$ gives us $y - 4 = \dfrac{7 - 4}{2.5 - 0}(t - 0) \quad \Rightarrow \quad y = 4 + 1.2t.$

Left wheel: It's centered at $(3, 1)$, has a radius of 1, and appears to go about $30°$ above the horizontal, so use

$$x = 3 + 1\cos\left(\tfrac{8\pi}{15}t + \tfrac{5\pi}{6}\right), \qquad y = 1 + 1\sin\left(\tfrac{8\pi}{15}t + \tfrac{5\pi}{6}\right), \qquad 0 \le t \le 2.5$$

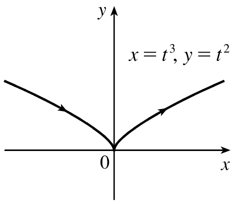
$(t_1, \theta_1) = \left(0, \frac{5\pi}{6}\right)$ and $(t_2, \theta_2) = \left(\frac{5}{2}, \frac{13\pi}{6}\right)$ gives us $\theta - \frac{5\pi}{6} = \dfrac{\frac{13\pi}{6} - \frac{5\pi}{6}}{\frac{5}{2} - 0}(t - 0) \;\Rightarrow\; \theta = \frac{5\pi}{6} + \frac{8\pi}{15}t$.

Right wheel: Similar to the left wheel with center $(8, 1)$, so use

$$x = 8 + 1\cos\left(\tfrac{8\pi}{15}t + \tfrac{5\pi}{6}\right), \qquad y = 1 + 1\sin\left(\tfrac{8\pi}{15}t + \tfrac{5\pi}{6}\right), \qquad 0 \le t \le 2.5$$

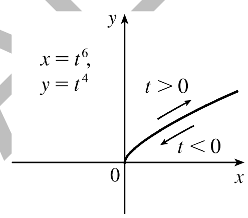
37. (a) $x = t^3 \;\Rightarrow\; t = x^{1/3}$, so $y = t^2 = x^{2/3}$.

We get the entire curve $y = x^{2/3}$ traversed in a left to right direction.



(b) $x = t^6 \;\Rightarrow\; t = x^{1/6}$, so $y = t^4 = x^{4/6} = x^{2/3}$.

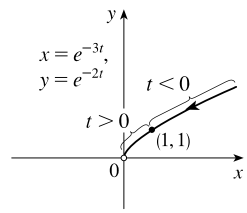
Since $x = t^6 \ge 0$, we only get the right half of the curve $y = x^{2/3}$.



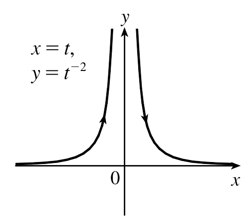
(c) $x = e^{-3t} = (e^{-t})^3$ [so $e^{-t} = x^{1/3}$],

$y = e^{-2t} = (e^{-t})^2 = (x^{1/3})^2 = x^{2/3}$.

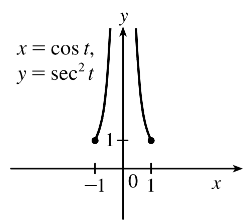
If $t < 0$, then x and y are both larger than 1. If $t > 0$, then x and y are between 0 and 1. Since $x > 0$ and $y > 0$, the curve never quite reaches the origin.



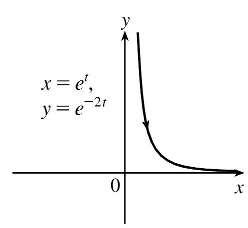
38. (a) $x = t$, so $y = t^{-2} = x^{-2}$. We get the entire curve $y = 1/x^2$ traversed in a left-to-right direction.



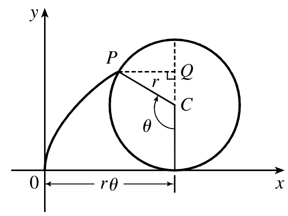
(b) $x = \cos t$, $y = \sec^2 t = \dfrac{1}{\cos^2 t} = \dfrac{1}{x^2}$. Since $\sec t \ge 1$, we only get the parts of the curve $y = 1/x^2$ with $y \ge 1$. We get the first quadrant portion of the curve when $x > 0$, that is, $\cos t > 0$, and we get the second quadrant portion of the curve when $x < 0$, that is, $\cos t < 0$.



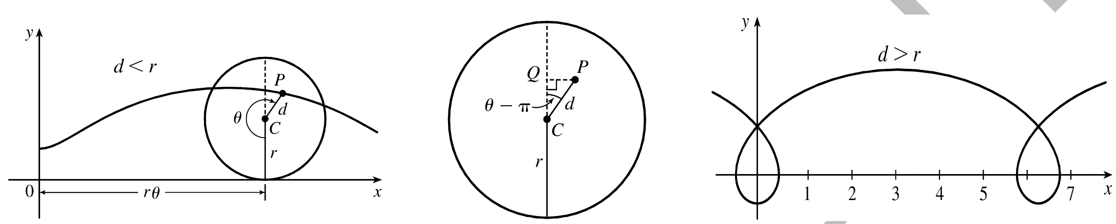
(c) $x = e^t$, $y = e^{-2t} = (e^t)^{-2} = x^{-2}$. Since e^t and e^{-2t} are both positive, we only get the first quadrant portion of the curve $y = 1/x^2$.



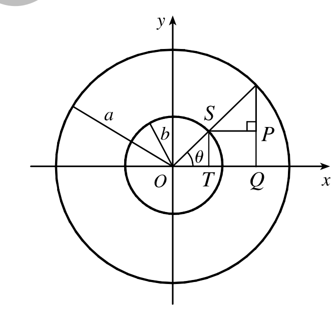
39. The case $\frac{\pi}{2} < \theta < \pi$ is illustrated. C has coordinates $(r\theta, r)$ as in Example 7, and Q has coordinates $(r\theta, r + r\cos(\pi - \theta)) = (r\theta, r(1 - \cos\theta))$ [since $\cos(\pi - \alpha) = \cos\pi\cos\alpha + \sin\pi\sin\alpha = -\cos\alpha$], so P has coordinates $(r\theta - r\sin(\pi - \theta), r(1 - \cos\theta)) = (r(\theta - \sin\theta), r(1 - \cos\theta))$ [since $\sin(\pi - \alpha) = \sin\pi\cos\alpha - \cos\pi\sin\alpha = \sin\alpha$]. Again we have the parametric equations $x = r(\theta - \sin\theta)$, $y = r(1 - \cos\theta)$.



40. The first two diagrams depict the case $\pi < \theta < \frac{3\pi}{2}$, $d < r$. As in Example 7, C has coordinates $(r\theta, r)$. Now Q (in the second diagram) has coordinates $(r\theta, r + d\cos(\theta - \pi)) = (r\theta, r - d\cos\theta)$, so a typical point P of the trochoid has coordinates $(r\theta + d\sin(\theta - \pi), r - d\cos\theta)$. That is, P has coordinates (x, y), where $x = r\theta - d\sin\theta$ and $y = r - d\cos\theta$. When $d = r$, these equations agree with those of the cycloid.

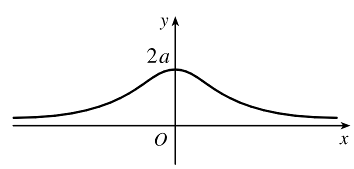


41. It is apparent that $x = |OQ|$ and $y = |QP| = |ST|$. From the diagram, $x = |OQ| = a\cos\theta$ and $y = |ST| = b\sin\theta$. Thus, the parametric equations are $x = a\cos\theta$ and $y = b\sin\theta$. To eliminate θ we rearrange: $\sin\theta = y/b \Rightarrow \sin^2\theta = (y/b)^2$ and $\cos\theta = x/a \Rightarrow \cos^2\theta = (x/a)^2$. Adding the two equations: $\sin^2\theta + \cos^2\theta = 1 = x^2/a^2 + y^2/b^2$. Thus, we have an ellipse.



42. A has coordinates $(a\cos\theta, a\sin\theta)$. Since OA is perpendicular to AB, ΔOAB is a right triangle and B has coordinates $(a\sec\theta, 0)$. It follows that P has coordinates $(a\sec\theta, b\sin\theta)$. Thus, the parametric equations are $x = a\sec\theta$, $y = b\sin\theta$.

43. $C = (2a\cot\theta, 2a)$, so the x-coordinate of P is $x = 2a\cot\theta$. Let $B = (0, 2a)$. Then $\angle OAB$ is a right angle and $\angle OBA = \theta$, so $|OA| = 2a\sin\theta$ and $A = ((2a\sin\theta)\cos\theta, (2a\sin\theta)\sin\theta)$. Thus, the y-coordinate of P is $y = 2a\sin^2\theta$.



44. (a) Let θ be the angle of inclination of segment OP. Then $|OB| = \dfrac{2a}{\cos\theta}$.

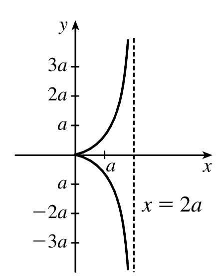
Let $C = (2a, 0)$. Then by use of right triangle OAC we see that $|OA| = 2a\cos\theta$.

Now

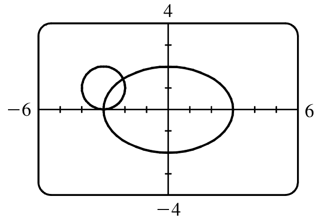
$$\begin{aligned} |OP| &= |AB| = |OB| - |OA| \\ &= 2a\left(\frac{1}{\cos\theta} - \cos\theta\right) = 2a\,\frac{1 - \cos^2\theta}{\cos\theta} = 2a\,\frac{\sin^2\theta}{\cos\theta} = 2a\sin\theta\,\tan\theta \end{aligned}$$

So P has coordinates $x = 2a\sin\theta\,\tan\theta\cdot\cos\theta = 2a\sin^2\theta$ and $y = 2a\sin\theta\,\tan\theta\cdot\sin\theta = 2a\sin^2\theta\,\tan\theta$.

(b)



45. (a)



There are 2 points of intersection:

$(-3, 0)$ and approximately $(-2.1, 1.4)$.

(b) A collision point occurs when $x_1 = x_2$ and $y_1 = y_2$ for the same t. So solve the equations:

$$3\sin t = -3 + \cos t \quad \textbf{(1)}$$
$$2\cos t = 1 + \sin t \quad \textbf{(2)}$$

From **(2)**, $\sin t = 2\cos t - 1$. Substituting into **(1)**, we get $3(2\cos t - 1) = -3 + \cos t \Rightarrow 5\cos t = 0 \ (\star) \Rightarrow \cos t = 0 \Rightarrow t = \frac{\pi}{2}$ or $\frac{3\pi}{2}$. We check that $t = \frac{3\pi}{2}$ satisfies **(1)** and **(2)** but $t = \frac{\pi}{2}$ does not. So the only collision point occurs when $t = \frac{3\pi}{2}$, and this gives the point $(-3, 0)$. [We could check our work by graphing x_1 and x_2 together as functions of t and, on another plot, y_1 and y_2 as functions of t. If we do so, we see that the only value of t for which *both* pairs of graphs intersect is $t = \frac{3\pi}{2}$.]

(c) The circle is centered at $(3, 1)$ instead of $(-3, 1)$. There are still 2 intersection points: $(3, 0)$ and $(2.1, 1.4)$, but there are no collision points, since $(\star)$ in part (b) becomes $5\cos t = 6 \Rightarrow \cos t = \frac{6}{5} > 1$.

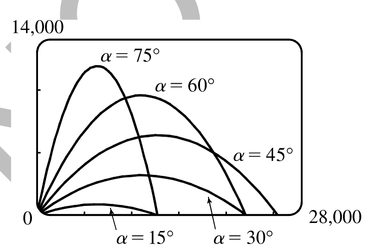
46. (a) If $\alpha = 30°$ and $v_0 = 500$ m/s, then the equations become $x = (500\cos 30°)t = 250\sqrt{3}t$ and $y = (500\sin 30°)t - \frac{1}{2}(9.8)t^2 = 250t - 4.9t^2$. $y = 0$ when $t = 0$ (when the gun is fired) and again when $t = \frac{250}{4.9} \approx 51$ s. Then $x = \left(250\sqrt{3}\right)\left(\frac{250}{4.9}\right) \approx 22{,}092$ m, so the bullet hits the ground about 22 km from the gun.

The formula for y is quadratic in t. To find the maximum y-value, we will complete the square:

$$y = -4.9\left(t^2 - \tfrac{250}{4.9}t\right) = -4.9\left[t^2 - \tfrac{250}{4.9}t + \left(\tfrac{125}{4.9}\right)^2\right] + \tfrac{125^2}{4.9} = -4.9\left(t - \tfrac{125}{4.9}\right)^2 + \tfrac{125^2}{4.9} \le \tfrac{125^2}{4.9}$$

with equality when $t = \frac{125}{4.9}$ s, so the maximum height attained is $\frac{125^2}{4.9} \approx 3189$ m.

(b)



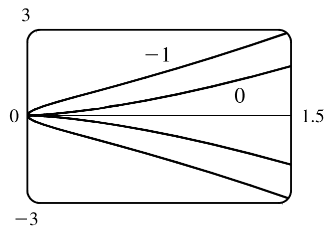
As α ($0° < \alpha < 90°$) increases up to $45°$, the projectile attains a greater height and a greater range. As α increases past $45°$, the projectile attains a greater height, but its range decreases.

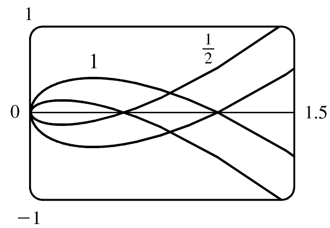
(c) $x = (v_0\cos\alpha)t \Rightarrow t = \dfrac{x}{v_0\cos\alpha}$.

$$y = (v_0\sin\alpha)t - \tfrac{1}{2}gt^2 \Rightarrow y = (v_0\sin\alpha)\frac{x}{v_0\cos\alpha} - \frac{g}{2}\left(\frac{x}{v_0\cos\alpha}\right)^2 = (\tan\alpha)x - \left(\frac{g}{2v_0^2\cos^2\alpha}\right)x^2,$$

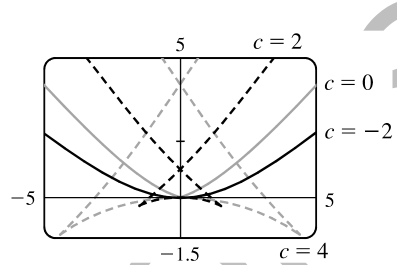
which is the equation of a parabola (quadratic in x).

47. $x = t^2, y = t^3 - ct$. We use a graphing device to produce the graphs for various values of c with $-\pi \leq t \leq \pi$. Note that all the members of the family are symmetric about the x-axis. For $c < 0$, the graph does not cross itself, but for $c = 0$ it has a cusp at $(0, 0)$ and for $c > 0$ the graph crosses itself at $x = c$, so the loop grows larger as c increases.

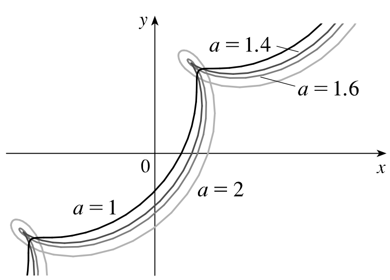




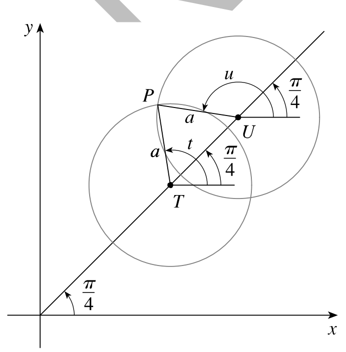
48. $x = 2ct - 4t^3, y = -ct^2 + 3t^4$. We use a graphing device to produce the graphs for various values of c with $-\pi \leq t \leq \pi$. Note that all the members of the family are symmetric about the y-axis. When $c < 0$, the graph resembles that of a polynomial of even degree, but when $c = 0$ there is a corner at the origin, and when $c > 0$, the graph crosses itself at the origin, and has two cusps below the x-axis. The size of the "swallowtail" increases as c increases.



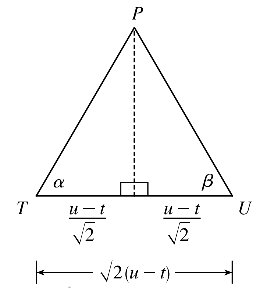
49. $x = t + a\cos t, y = t + a\sin t, a > 0$. From the first figure, we see that curves roughly follow the line $y = x$, and they start having loops when a is between 1.4 and 1.6. The loops increase in size as a increases.



While not required, the following is a solution to determine the *exact* values for which the curve has a loop, that is, we seek the values of a for which there exist parameter values t and u such that $t < u$ and $(t + a\cos t, t + a\sin t) = (u + a\cos u, u + a\sin u)$.



In the diagram at the left, T denotes the point (t, t), U the point (u, u), and P the point $(t + a\cos t, t + a\sin t) = (u + a\cos u, u + a\sin u)$. Since $\overline{PT} = \overline{PU} = a$, the triangle PTU is isosceles. Therefore its base angles, $\alpha = \angle PTU$ and $\beta = \angle PUT$ are equal. Since $\alpha = t - \frac{\pi}{4}$ and $\beta = 2\pi - \frac{3\pi}{4} - u = \frac{5\pi}{4} - u$, the relation $\alpha = \beta$ implies that $u + t = \frac{3\pi}{2}$ **(1)**.



Since $\overline{TU} = \text{distance}((t,t),(u,u)) = \sqrt{2(u-t)^2} = \sqrt{2}\,(u-t)$, we see that

$\cos\alpha = \dfrac{\frac{1}{2}\overline{TU}}{\overline{PT}} = \dfrac{(u-t)/\sqrt{2}}{a}$, so $u - t = \sqrt{2}\,a\cos\alpha$, that is,

$u - t = \sqrt{2}\,a\cos\left(t - \frac{\pi}{4}\right)$ **(2)**. Now $\cos\left(t - \frac{\pi}{4}\right) = \sin\left[\frac{\pi}{2} - \left(t - \frac{\pi}{4}\right)\right] = \sin\left(\frac{3\pi}{4} - t\right)$,

so we can rewrite **(2)** as $u - t = \sqrt{2}\,a\sin\left(\frac{3\pi}{4} - t\right)$ **(2′)**. Subtracting **(2′)** from **(1)** and

dividing by 2, we obtain $t = \frac{3\pi}{4} - \frac{\sqrt{2}}{2}a\sin\left(\frac{3\pi}{4} - t\right)$, or $\frac{3\pi}{4} - t = \frac{a}{\sqrt{2}}\sin\left(\frac{3\pi}{4} - t\right)$ **(3)**.

Since $a > 0$ and $t < u$, it follows from **(2′)** that $\sin\left(\frac{3\pi}{4} - t\right) > 0$. Thus from **(3)** we see that $t < \frac{3\pi}{4}$. [We have implicitly assumed that $0 < t < \pi$ by the way we drew our diagram, but we lost no generality by doing so since replacing t by $t + 2\pi$ merely increases x and y by 2π. The curve's basic shape repeats every time we change t by 2π.] Solving for a in **(3)**, we get $a = \dfrac{\sqrt{2}\left(\frac{3\pi}{4} - t\right)}{\sin\left(\frac{3\pi}{4} - t\right)}$. Write $z = \frac{3\pi}{4} - t$. Then $a = \dfrac{\sqrt{2}\,z}{\sin z}$, where $z > 0$. Now $\sin z < z$ for $z > 0$, so $a > \sqrt{2}$.

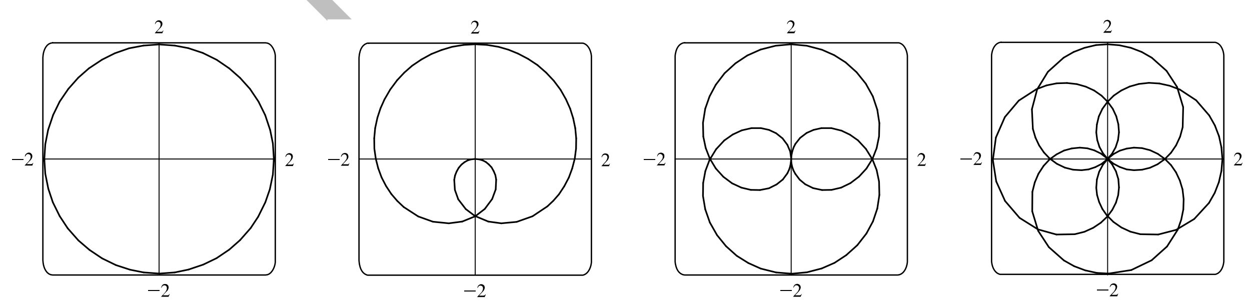
$\left[\text{As } z \to 0^+, \text{ that is, as } t \to \left(\frac{3\pi}{4}\right)^-, a \to \sqrt{2}\right]$.

50. Consider the curves $x = \sin t + \sin nt$, $y = \cos t + \cos nt$, where n is a positive integer. For $n = 1$, we get a circle of radius 2 centered at the origin. For $n > 1$, we get a curve lying on or inside that circle that traces out $n - 1$ loops as t ranges from 0 to 2π.

Note:

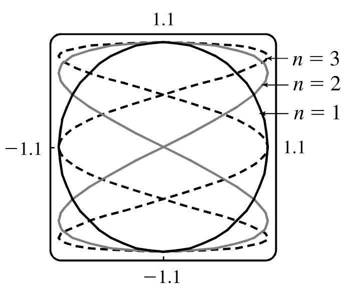
$$\begin{aligned} x^2 + y^2 &= (\sin t + \sin nt)^2 + (\cos t + \cos nt)^2 \\ &= \sin^2 t + 2\sin t\,\sin nt + \sin^2 nt + \cos^2 t + 2\cos t\,\cos nt + \cos^2 nt \\ &= (\sin^2 t + \cos^2 t) + (\sin^2 nt + \cos^2 nt) + 2(\cos t\,\cos nt + \sin t\,\sin nt) \\ &= 1 + 1 + 2\cos(t - nt) = 2 + 2\cos((1-n)t) \le 4 = 2^2, \end{aligned}$$

with equality for $n = 1$. This shows that each curve lies on or inside the curve for $n = 1$, which is a circle of radius 2 centered at the origin.

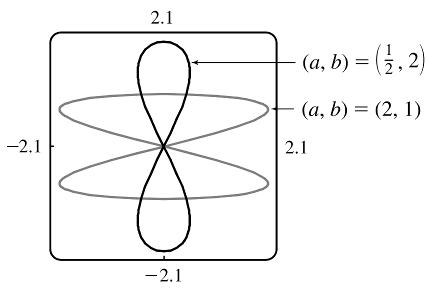


$n = 1$ $n = 2$ $n = 3$ $n = 5$

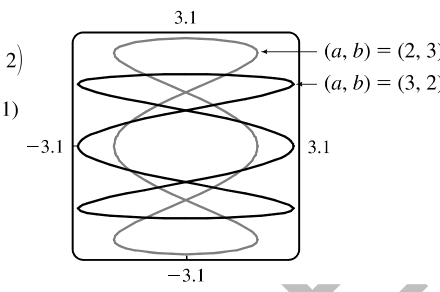
51. Note that all the Lissajous figures are symmetric about the x-axis. The parameters a and b simply stretch the graph in the x- and y-directions respectively. For $a = b = n = 1$ the graph is simply a circle with radius 1. For $n = 2$ the graph crosses itself at the origin and there are loops above and below the x-axis. In general, the figures have $n - 1$ points of intersection, all of which are on the y-axis, and a total of n closed loops.



$a = b = 1$

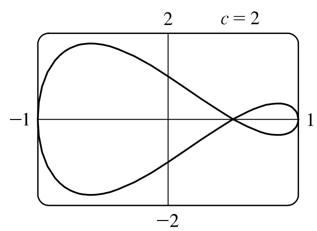


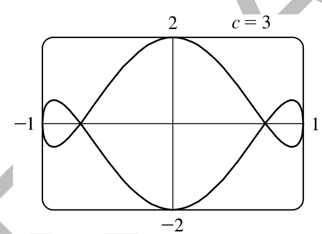
$n = 2$

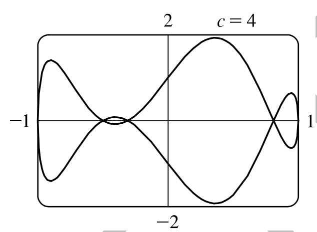


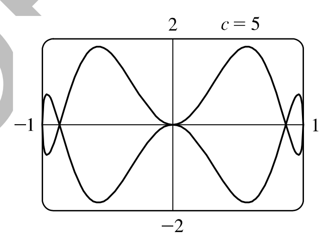
$n = 3$

52. $x = \cos t$, $y = \sin t - \sin ct$. If $c = 1$, then $y = 0$, and the curve is simply the line segment from $(-1, 0)$ to $(1, 0)$. The graphs are shown for $c = 2, 3, 4$ and 5.

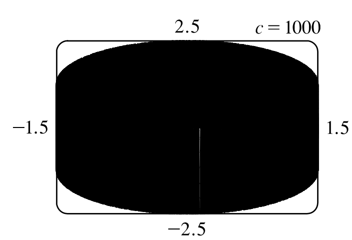




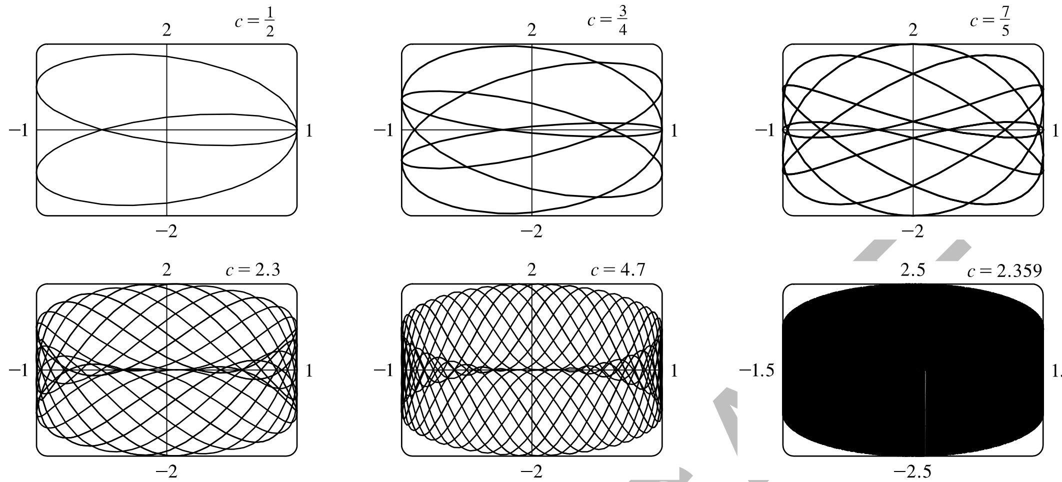




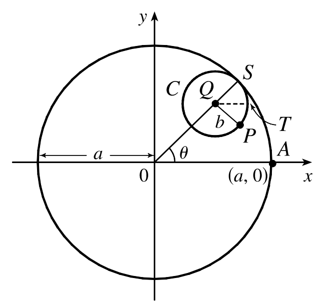
It is easy to see that all the curves lie in the rectangle $[-1, 1]$ by $[-2, 2]$. When c is an integer, $x(t + 2\pi) = x(t)$ and $y(t + 2\pi) = y(t)$, so the curve is closed. When c is a positive integer greater than 1, the curve intersects the x-axis $c + 1$ times and has c loops (one of which degenerates to a tangency at the origin when c is an odd integer of the form $4k + 1$). As c increases, the curve's loops become thinner, but stay in the region bounded by the semicircles $y = \pm\left(1 + \sqrt{1 - x^2}\,\right)$ and the line segments from $(-1, -1)$ to $(-1, 1)$ and from $(1, -1)$ to $(1, 1)$. This is true because $|y| = |\sin t - \sin ct| \le |\sin t| + |\sin ct| \le \sqrt{1 - x^2} + 1$. This curve appears to fill the entire region when c is very large, as shown in the figure for $c = 1000$.



When c is a fraction, we get a variety of shapes with multiple loops, but always within the same region. For some fractional values, such as $c = 2.359$, the curve again appears to fill the region.



LABORATORY PROJECT Running Circles Around Circles

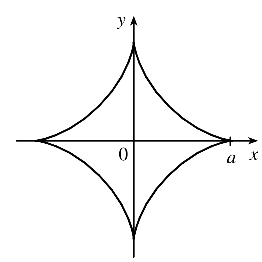


1. The center Q of the smaller circle has coordinates $((a-b)\cos\theta, (a-b)\sin\theta)$. Arc PS on circle C has length $a\theta$ since it is equal in length to arc AS (the smaller circle rolls without slipping against the larger.)

Thus, $\angle PQS = \dfrac{a}{b}\theta$ and $\angle PQT = \dfrac{a}{b}\theta - \theta$, so P has coordinates

$$x = (a-b)\cos\theta + b\cos(\angle PQT) = (a-b)\cos\theta + b\cos\left(\frac{a-b}{b}\theta\right)$$

and $$y = (a-b)\sin\theta - b\sin(\angle PQT) = (a-b)\sin\theta - b\sin\left(\frac{a-b}{b}\theta\right).$$

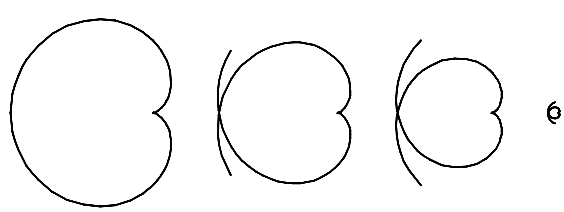


2. With $b = 1$ and a a positive integer greater than 2, we obtain a hypocycloid of a cusps. Shown in the figure is the graph for $a = 4$. Let $a = 4$ and $b = 1$. Using the sum identities to expand $\cos 3\theta$ and $\sin 3\theta$, we obtain

$$x = 3\cos\theta + \cos 3\theta = 3\cos\theta + \left(4\cos^3\theta - 3\cos\theta\right) = 4\cos^3\theta$$

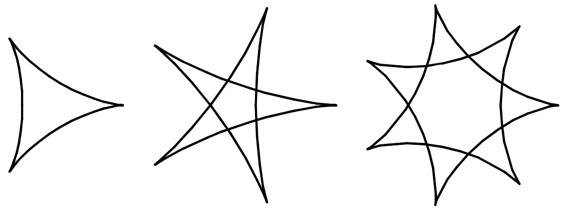
and $$y = 3\sin\theta - \sin 3\theta = 3\sin\theta - \left(3\sin\theta - 4\sin^3\theta\right) = 4\sin^3\theta.$$

3. The graphs at the right are obtained with $b = 1$ and $a = \frac{1}{2}, \frac{1}{3}, \frac{1}{4}$, and $\frac{1}{10}$ with $-2\pi \le \theta \le 2\pi$. We conclude that as the denominator d increases, the graph gets smaller, but maintains the basic shape shown.

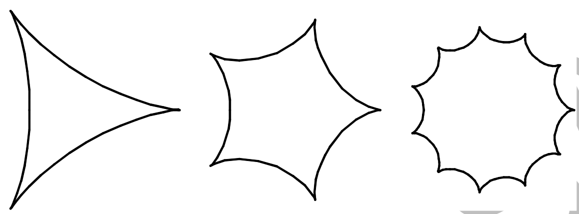


[continued]

Letting $d = 2$ and $n = 3$, 5, and 7 with $-2\pi \le \theta \le 2\pi$ gives us the following:



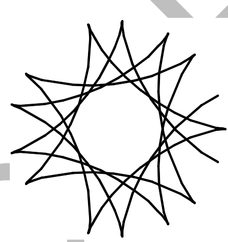
So if d is held constant and n varies, we get a graph with n cusps (assuming n/d is in lowest form). When $n = d + 1$, we obtain a hypocycloid of n cusps. As n increases, we must expand the range of θ in order to get a closed curve. The following graphs have $a = \frac{3}{2}$, $\frac{5}{4}$, and $\frac{11}{10}$.



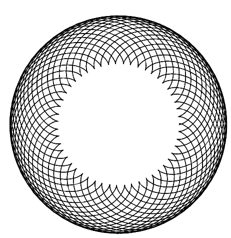
4. If $b = 1$, the equations for the hypocycloid are

$$x = (a-1)\cos\theta + \cos((a-1)\theta) \qquad y = (a-1)\sin\theta - \sin((a-1)\theta)$$

which is a hypocycloid of a cusps (from Problem 2). In general, if $a > 1$, we get a figure with cusps on the "outside ring" and if $a < 1$, the cusps are on the "inside ring". In any case, as the values of θ get larger, we get a figure that looks more and more like a washer. If we were to graph the hypocycloid for all values of θ, every point on the washer would eventually be arbitrarily close to a point on the curve.

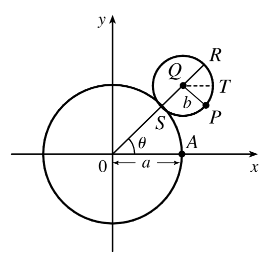


$a = \sqrt{2}, \quad -10\pi \le \theta \le 10\pi$



$a = e - 2, \quad 0 \le \theta \le 446$

5. The center Q of the smaller circle has coordinates $((a+b)\cos\theta, (a+b)\sin\theta)$.



Arc PS has length $a\theta$ (as in Problem 1), so that $\angle PQS = \dfrac{a\theta}{b}$, $\angle PQR = \pi - \dfrac{a\theta}{b}$,

and $\angle PQT = \pi - \dfrac{a\theta}{b} - \theta = \pi - \left(\dfrac{a+b}{b}\right)\theta$ since $\angle RQT = \theta$.

Thus, the coordinates of P are

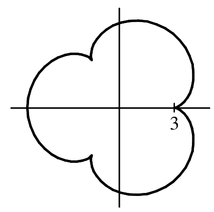
$$x = (a+b)\cos\theta + b\cos\left(\pi - \frac{a+b}{b}\theta\right) = (a+b)\cos\theta - b\cos\left(\frac{a+b}{b}\theta\right)$$

and $$y = (a+b)\sin\theta - b\sin\left(\pi - \frac{a+b}{b}\theta\right) = (a+b)\sin\theta - b\sin\left(\frac{a+b}{b}\theta\right).$$

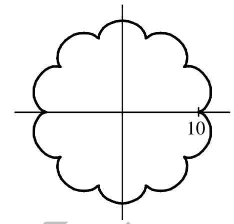
6. Let $b = 1$ and the equations become

$$x = (a+1)\cos\theta - \cos((a+1)\theta) \qquad y = (a+1)\sin\theta - \sin((a+1)\theta)$$

If $a = 1$, we have a cardioid. If a is a positive integer greater than 1, we get the graph of an "a-leafed clover", with cusps that are a units from the origin. (Some of the pairs of figures are not to scale.)

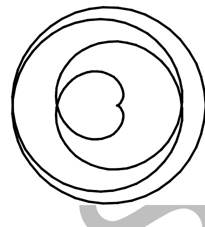


$a = 3, -2\pi \le \theta \le 2\pi$

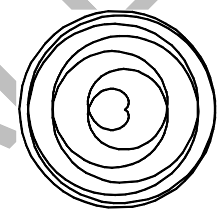


$a = 10, -2\pi \le \theta \le 2\pi$

If $a = n/d$ with $n = 1$, we obtain a figure that does not increase in size and requires $-d\pi \le \theta \le d\pi$ to be a closed curve traced exactly once.

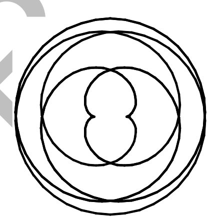


$a = \frac{1}{4}, -4\pi \le \theta \le 4\pi$

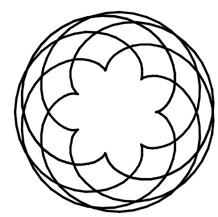


$a = \frac{1}{7}, -7\pi \le \theta \le 7\pi$

Next, we keep d constant and let n vary. As n increases, so does the size of the figure. There is an n-pointed star in the middle.

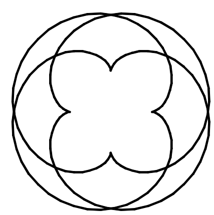


$a = \frac{2}{5}, -5\pi \le \theta \le 5\pi$

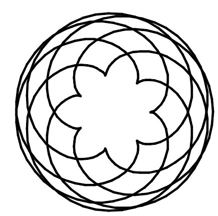


$a = \frac{7}{5}, -5\pi \le \theta \le 5\pi$

Now if $n = d + 1$ we obtain figures similar to the previous ones, but the size of the figure does not increase.

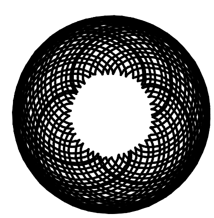


$a = \frac{4}{3}, -3\pi \le \theta \le 3\pi$

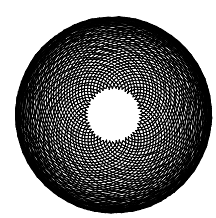


$a = \frac{7}{6}, -6\pi \le \theta \le 6\pi$

If a is irrational, we get washers that increase in size as a increases.



$a = \sqrt{2}, 0 \le \theta \le 200$



$a = e - 2, 0 \le \theta \le 446$

10.2 Calculus with Parametric Curves

1. $x = \dfrac{t}{1+t},\ y = \sqrt{1+t} \quad\Rightarrow\quad \dfrac{dy}{dt} = \dfrac{1}{2}(1+t)^{-1/2} = \dfrac{1}{2\sqrt{1+t}},\ \dfrac{dx}{dt} = \dfrac{(1+t)(1) - t(1)}{(1+t)^2} = \dfrac{1}{(1+t)^2}$, and

$\dfrac{dy}{dx} = \dfrac{dy/dt}{dx/dt} = \dfrac{1/(2\sqrt{1+t}\,)}{1/(1+t)^2} = \dfrac{(1+t)^2}{2\sqrt{1+t}} = \dfrac{1}{2}(1+t)^{3/2}$.

2. $x = te^t,\ y = t + \sin t \quad\Rightarrow\quad \dfrac{dy}{dt} = 1 + \cos t,\ \dfrac{dx}{dt} = te^t + e^t = e^t(t+1)$, and $\dfrac{dy}{dx} = \dfrac{dy/dt}{dx/dt} = \dfrac{1+\cos t}{e^t(t+1)}$.

3. $x = t^3 + 1,\ y = t^4 + t;\quad t = -1.\ \dfrac{dy}{dt} = 4t^3 + 1,\ \dfrac{dx}{dt} = 3t^2$, and $\dfrac{dy}{dx} = \dfrac{dy/dt}{dx/dt} = \dfrac{4t^3+1}{3t^2}$. When $t = -1$, $(x, y) = (0, 0)$ and $dy/dx = -3/3 = -1$, so an equation of the tangent to the curve at the point corresponding to $t = -1$ is $y - 0 = -1(x - 0)$, or $y = -x$.

4. $x = \sqrt{t},\ y = t^2 - 2t;\quad t = 4.\ \dfrac{dy}{dt} = 2t - 2,\ \dfrac{dx}{dt} = \dfrac{1}{2\sqrt{t}}$, and $\dfrac{dy}{dx} = \dfrac{dy/dt}{dx/dt} = (2t-2)2\sqrt{t} = 4(t-1)\sqrt{t}$. When $t = 4$, $(x, y) = (2, 8)$ and $dy/dx = 4(3)(2) = 24$, so an equation of the tangent to the curve at the point corresponding to $t = 4$ is $y - 8 = 24(x - 2)$, or $y = 24x - 40$.

5. $x = t\cos t,\ y = t\sin t;\ t = \pi.\quad \dfrac{dy}{dt} = t\cos t + \sin t,\ \dfrac{dx}{dt} = t(-\sin t) + \cos t$, and $\dfrac{dy}{dx} = \dfrac{dy/dt}{dx/dt} = \dfrac{t\cos t + \sin t}{-t\sin t + \cos t}$. When $t = \pi$, $(x, y) = (-\pi, 0)$ and $dy/dx = -\pi/(-1) = \pi$, so an equation of the tangent to the curve at the point corresponding to $t = \pi$ is $y - 0 = \pi[x - (-\pi)]$, or $y = \pi x + \pi^2$.

6. $x = e^t \sin \pi t,\ y = e^{2t};\quad t = 0.\ \dfrac{dy}{dt} = 2e^{2t},\ \dfrac{dx}{dt} = e^t(\pi\cos\pi t) + (\sin\pi t)e^t = e^t(\pi\cos\pi t + \sin\pi t)$, and

$\dfrac{dy}{dx} = \dfrac{dy/dt}{dx/dt} = \dfrac{2e^{2t}}{e^t(\pi\cos\pi t + \sin\pi t)} = \dfrac{2e^t}{\pi\cos\pi t + \sin\pi t}$. When $t = 0$, $(x, y) = (0, 1)$ and $dy/dx = 2/\pi$, so an equation of the tangent to the curve at the point corresponding to $t = 0$ is $y - 1 = \frac{2}{\pi}(x - 0)$, or $y = \frac{2}{\pi}x + 1$.

7. (a) $x = 1 + \ln t,\ y = t^2 + 2;\ (1, 3).\quad \dfrac{dy}{dt} = 2t,\ \dfrac{dx}{dt} = \dfrac{1}{t}$, and $\dfrac{dy}{dx} = \dfrac{dy/dt}{dx/dt} = \dfrac{2t}{1/t} = 2t^2$. At $(1, 3)$,

$x = 1 + \ln t = 1 \quad\Rightarrow\quad \ln t = 0 \quad\Rightarrow\quad t = 1$ and $\dfrac{dy}{dx} = 2$, so an equation of the tangent is $y - 3 = 2(x - 1)$, or $y = 2x + 1$.

(b) $x = 1 + \ln t \quad\Rightarrow\quad \ln t = x - 1 \quad\Rightarrow\quad t = e^{x-1}$, so $y = t^2 + 2 = (e^{x-1})^2 + 2 = e^{2x-2} + 2$, and $y' = e^{2x-2}\cdot 2$. At $(1, 3)$, $y' = e^{2(1)-2}\cdot 2 = 2$, so an equation of the tangent is $y - 3 = 2(x - 1)$, or $y = 2x + 1$.

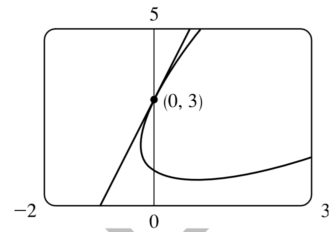
8. (a) $x = 1 + \sqrt{t},\ y = e^{t^2};\ (2, e).\quad \dfrac{dy}{dt} = e^{t^2}\cdot 2t,\ \dfrac{dx}{dt} = \dfrac{1}{2\sqrt{t}}$, and $\dfrac{dy}{dx} = \dfrac{dy/dt}{dx/dt} = \dfrac{2te^{t^2}}{1/(2\sqrt{t}\,)} = 4t^{3/2}e^{t^2}$. At $(2, e)$,

$x = 1 + \sqrt{t} = 2 \quad\Rightarrow\quad \sqrt{t} = 1 \quad\Rightarrow\quad t = 1$ and $\dfrac{dy}{dx} = 4e$, so an equation of the tangent is $y - e = 4e(x - 2)$, or $y = 4ex - 7e$.

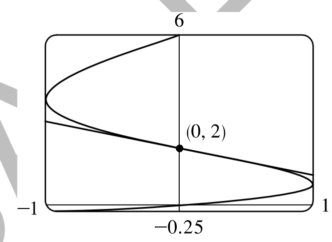
(b) $x = 1 + \sqrt{t} \quad \Rightarrow \quad \sqrt{t} = x - 1 \quad \Rightarrow \quad t = (x-1)^2$, so $y = e^{t^2} = e^{(x-1)^4}$, and $y' = e^{(x-1)^4} \cdot 4(x-1)^3$.

At $(2, e)$, $y' = e \cdot 4 = 4e$, so an equation of the tangent is $y - e = 4e(x - 2)$, or $y = 4ex - 7e$.

9. $x = t^2 - t, \; y = t^2 + t + 1; \; (0, 3)$. $\dfrac{dy}{dx} = \dfrac{dy/dt}{dx/dt} = \dfrac{2t+1}{2t-1}$. To find the value of t corresponding to the point $(0, 3)$, solve $x = 0 \quad \Rightarrow$ $t^2 - t = 0 \quad \Rightarrow \quad t(t-1) = 0 \quad \Rightarrow \quad t = 0$ or $t = 1$. Only $t = 1$ gives $y = 3$. With $t = 1$, $dy/dx = 3$, and an equation of the tangent is $y - 3 = 3(x - 0)$, or $y = 3x + 3$.



10. $x = \sin \pi t, \; y = t^2 + t; \; (0, 2)$. $\dfrac{dy}{dx} = \dfrac{dy/dt}{dx/dt} = \dfrac{2t+1}{\pi \cos \pi t}$. To find the value of t corresponding to the point $(0, 2)$, solve $y = 2 \quad \Rightarrow$ $t^2 + t - 2 = 0 \quad \Rightarrow \quad (t+2)(t-1) = 0 \quad \Rightarrow \quad t = -2$ or $t = 1$. Either value gives $dy/dx = -3/\pi$, so an equation of the tangent is $y - 2 = -\frac{3}{\pi}(x - 0)$, or $y = -\frac{3}{\pi}x + 2$.



11. $x = t^2 + 1, \; y = t^2 + t \quad \Rightarrow \quad \dfrac{dy}{dx} = \dfrac{dy/dt}{dx/dt} = \dfrac{2t+1}{2t} = 1 + \dfrac{1}{2t} \quad \Rightarrow \quad \dfrac{d^2y}{dx^2} = \dfrac{\frac{d}{dt}\left(\frac{dy}{dx}\right)}{dx/dt} = \dfrac{-1/(2t^2)}{2t} = -\dfrac{1}{4t^3}$.

The curve is CU when $\dfrac{d^2y}{dx^2} > 0$, that is, when $t < 0$.

12. $x = t^3 + 1, \; y = t^2 - t \quad \Rightarrow \quad \dfrac{dy}{dx} = \dfrac{dy/dt}{dx/dt} = \dfrac{2t-1}{3t^2} = \dfrac{2}{3t} - \dfrac{1}{3t^2} \quad \Rightarrow$

$$\frac{d^2y}{dx^2} = \frac{\frac{d}{dt}\left(\frac{dy}{dx}\right)}{dx/dt} = \frac{-\frac{2}{3t^2} + \frac{2}{3t^3}}{3t^2} = \frac{\frac{2-2t}{3t^3}}{3t^2} = \frac{2(1-t)}{9t^5}.$$ The curve is CU when $\dfrac{d^2y}{dx^2} > 0$, that is, when $0 < t < 1$.

13. $x = e^t, \; y = te^{-t} \quad \Rightarrow \quad \dfrac{dy}{dx} = \dfrac{dy/dt}{dx/dt} = \dfrac{-te^{-t} + e^{-t}}{e^t} = \dfrac{e^{-t}(1-t)}{e^t} = e^{-2t}(1-t) \quad \Rightarrow$

$$\frac{d^2y}{dx^2} = \frac{\frac{d}{dt}\left(\frac{dy}{dx}\right)}{dx/dt} = \frac{e^{-2t}(-1) + (1-t)(-2e^{-2t})}{e^t} = \frac{e^{-2t}(-1-2+2t)}{e^t} = e^{-3t}(2t-3).$$ The curve is CU when $\dfrac{d^2y}{dx^2} > 0$, that is, when $t > \frac{3}{2}$.

14. $x = t^2 + 1, \; y = e^t - 1 \quad \Rightarrow \quad \dfrac{dy}{dx} = \dfrac{dy/dt}{dx/dt} = \dfrac{e^t}{2t} \quad \Rightarrow \quad \dfrac{d^2y}{dx^2} = \dfrac{\frac{d}{dt}\left(\frac{dy}{dx}\right)}{dx/dt} = \dfrac{\frac{2te^t - e^t \cdot 2}{(2t)^2}}{2t} = \dfrac{2e^t(t-1)}{(2t)^3} = \dfrac{e^t(t-1)}{4t^3}$.

The curve is CU when $\dfrac{d^2y}{dx^2} > 0$, that is, when $t < 0$ or $t > 1$.

15. $x = t - \ln t,\ y = t + \ln t$ [note that $t > 0$] $\Rightarrow$ $\dfrac{dy}{dx} = \dfrac{dy/dt}{dx/dt} = \dfrac{1 + 1/t}{1 - 1/t} = \dfrac{t+1}{t-1}$ $\Rightarrow$

$$\frac{d^2y}{dx^2} = \frac{\frac{d}{dt}\left(\frac{dy}{dx}\right)}{dx/dt} = \frac{\frac{(t-1)(1) - (t+1)(1)}{(t-1)^2}}{(t-1)/t} = \frac{-2t}{(t-1)^3}.$$ The curve is CU when $\dfrac{d^2y}{dx^2} > 0$, that is, when $0 < t < 1$.

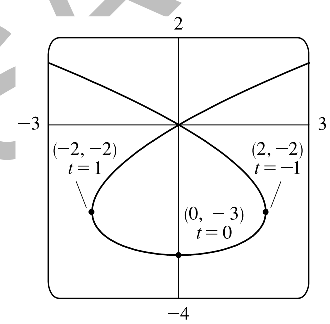
16. $x = \cos t,\ y = \sin 2t,\ 0 < t < \pi$ $\Rightarrow$ $\dfrac{dy}{dx} = \dfrac{dy/dt}{dx/dt} = \dfrac{2\cos 2t}{-\sin t}$ $\Rightarrow$

$$\frac{d^2y}{dx^2} = \frac{\frac{d}{dt}\left(\frac{dy}{dx}\right)}{dx/dt} = \frac{\frac{(-\sin t)(-4\sin 2t) - (2\cos 2t)(-\cos t)}{(-\sin t)^2}}{-\sin t} = \frac{(\sin t)(8\sin t\,\cos t) + [2(1 - 2\sin^2 t)](\cos t)}{(-\sin t)\sin^2 t}$$

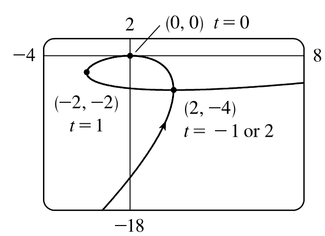
$$= \frac{(\cos t)(8\sin^2 t + 2 - 4\sin^2 t)}{(-\sin t)\sin^2 t} = -\frac{\cos t}{\sin t}\cdot\frac{4\sin^2 t + 2}{\sin^2 t} \quad [\,(-\cot t)\cdot \text{positive expression}]$$

The curve is CU when $\dfrac{d^2y}{dx^2} > 0$, that is, when $-\cot t > 0$ $\Leftrightarrow$ $\cot t < 0$ $\Leftrightarrow$ $\frac{\pi}{2} < t < \pi$.

17. $x = t^3 - 3t,\ y = t^2 - 3$. $\dfrac{dy}{dt} = 2t$, so $\dfrac{dy}{dt} = 0$ $\Leftrightarrow$ $t = 0$ $\Leftrightarrow$ $(x, y) = (0, -3)$. $\dfrac{dx}{dt} = 3t^2 - 3 = 3(t+1)(t-1)$, so $\dfrac{dx}{dt} = 0$ $\Leftrightarrow$ $t = -1$ or 1 $\Leftrightarrow$ $(x, y) = (2, -2)$ or $(-2, -2)$. The curve has a horizontal tangent at $(0, -3)$ and vertical tangents at $(2, -2)$ and $(-2, -2)$.



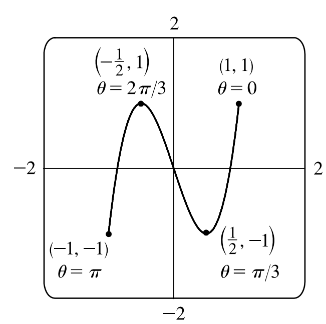
18. $x = t^3 - 3t,\ y = t^3 - 3t^2$. $\dfrac{dy}{dt} = 3t^2 - 6t = 3t(t-2)$, so $\dfrac{dy}{dt} = 0$ $\Leftrightarrow$ $t = 0$ or 2 $\Leftrightarrow$ $(x, y) = (0, 0)$ or $(2, -4)$. $\dfrac{dx}{dt} = 3t^2 - 3 = 3(t+1)(t-1)$, so $\dfrac{dx}{dt} = 0$ $\Leftrightarrow$ $t = -1$ or 1 $\Leftrightarrow$ $(x, y) = (2, -4)$ or $(-2, -2)$. The curve has horizontal tangents at $(0, 0)$ and $(2, -4)$, and vertical tangents at $(2, -4)$ and $(-2, -2)$.



19. $x = \cos\theta,\ y = \cos 3\theta$. The whole curve is traced out for $0 \le \theta \le \pi$.

$\dfrac{dy}{d\theta} = -3\sin 3\theta$, so $\dfrac{dy}{d\theta} = 0$ $\Leftrightarrow$ $\sin 3\theta = 0$ $\Leftrightarrow$ $3\theta = 0, \pi, 2\pi$, or 3π $\Leftrightarrow$ $\theta = 0, \frac{\pi}{3}, \frac{2\pi}{3}$, or π $\Leftrightarrow$ $(x, y) = (1, 1), \left(\frac{1}{2}, -1\right), \left(-\frac{1}{2}, 1\right)$, or $(-1, -1)$.

$\dfrac{dx}{d\theta} = -\sin\theta$, so $\dfrac{dx}{d\theta} = 0$ $\Leftrightarrow$ $\sin\theta = 0$ $\Leftrightarrow$ $\theta = 0$ or π $\Leftrightarrow$ $(x, y) = (1, 1)$ or $(-1, -1)$. Both $\dfrac{dy}{d\theta}$ and $\dfrac{dx}{d\theta}$ equal 0 when $\theta = 0$ and π.



To find the slope when $\theta = 0$, we find $\displaystyle\lim_{\theta\to 0}\frac{dy}{dx} = \lim_{\theta\to 0}\frac{-3\sin 3\theta}{-\sin\theta} \overset{\text{H}}{=} \lim_{\theta\to 0}\frac{-9\cos 3\theta}{-\cos\theta} = 9$, which is the same slope when $\theta = \pi$.

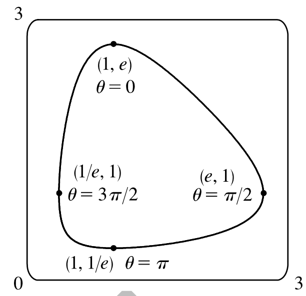
Thus, the curve has horizontal tangents at $\left(\frac{1}{2}, -1\right)$ and $\left(-\frac{1}{2}, 1\right)$, and there are no vertical tangents.

20. $x = e^{\sin\theta}$, $y = e^{\cos\theta}$. The whole curve is traced out for $0 \le \theta < 2\pi$.

$\dfrac{dy}{d\theta} = -\sin\theta\, e^{\cos\theta}$, so $\dfrac{dy}{d\theta} = \theta \iff \sin\theta = 0 \iff \theta = 0$ or $\pi \iff$

$(x, y) = (1, e)$ or $(1, 1/e)$. $\dfrac{dx}{d\theta} = \cos\theta\, e^{\sin\theta}$, so $\dfrac{dx}{d\theta} = 0 \iff \cos\theta = 0 \iff$

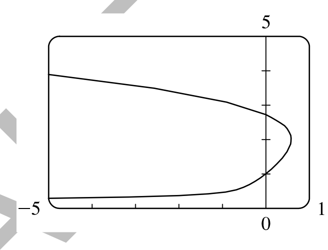
$\theta = \frac{\pi}{2}$ or $\frac{3\pi}{2} \iff (x, y) = (e, 1)$ or $(1/e, 1)$. The curve has horizontal tangents at $(1, e)$ and $(1, 1/e)$, and vertical tangents at $(e, 1)$ and $(1/e, 1)$.



21. From the graph, it appears that the rightmost point on the curve $x = t - t^6$, $y = e^t$ is about $(0.6, 2)$. To find the exact coordinates, we find the value of t for which the graph has a vertical tangent, that is, $0 = dx/dt = 1 - 6t^5 \iff t = 1/\sqrt[5]{6}$.

Hence, the rightmost point is

$$\left(1/\sqrt[5]{6} - 1/\left(6\sqrt[5]{6}\right), e^{1/\sqrt[5]{6}}\right) = \left(5 \cdot 6^{-6/5}, e^{6^{-1/5}}\right) \approx (0.58, 2.01).$$



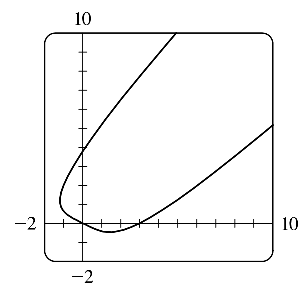
22. From the graph, it appears that the lowest point and the leftmost point on the curve $x = t^4 - 2t$, $y = t + t^4$ are $(1.5, -0.5)$ and $(-1.2, 1.2)$, respectively. To find the exact coordinates, we solve $dy/dt = 0$ (horizontal tangents) and $dx/dt = 0$ (vertical tangents).

$\dfrac{dy}{dt} = 0 \iff 1 + 4t^3 = 0 \iff t = -\dfrac{1}{\sqrt[3]{4}}$, so the lowest point is

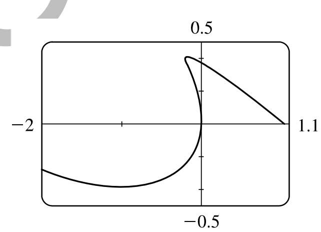
$$\left(\frac{1}{\sqrt[3]{256}} + \frac{2}{\sqrt[3]{4}}, -\frac{1}{\sqrt[3]{4}} + \frac{1}{\sqrt[3]{256}}\right) = \left(\frac{9}{\sqrt[3]{256}}, -\frac{3}{\sqrt[3]{256}}\right) \approx (1.42, -0.47).$$

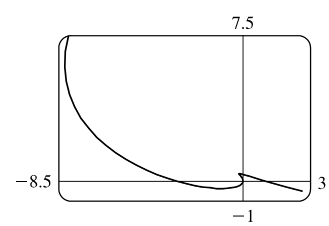
$\dfrac{dx}{dt} = 0 \iff 4t^3 - 2 = 0 \iff t = \dfrac{1}{\sqrt[3]{2}}$, so the leftmost point is

$$\left(\frac{1}{\sqrt[3]{16}} - \frac{2}{\sqrt[3]{2}}, \frac{1}{\sqrt[3]{2}} + \frac{1}{\sqrt[3]{16}}\right) = \left(-\frac{3}{\sqrt[3]{16}}, \frac{3}{\sqrt[3]{16}}\right) \approx (-1.19, 1.19).$$



23. We graph the curve $x = t^4 - 2t^3 - 2t^2$, $y = t^3 - t$ in the viewing rectangle $[-2, 1.1]$ by $[-0.5, 0.5]$. This rectangle corresponds approximately to $t \in [-1, 0.8]$.

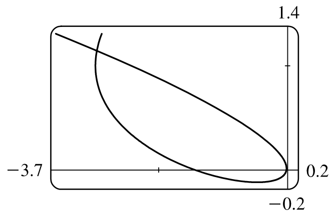


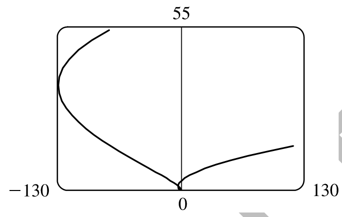


We estimate that the curve has horizontal tangents at about $(-1, -0.4)$ and $(-0.17, 0.39)$ and vertical tangents at about $(0, 0)$ and $(-0.19, 0.37)$. We calculate $\dfrac{dy}{dx} = \dfrac{dy/dt}{dx/dt} = \dfrac{3t^2 - 1}{4t^3 - 6t^2 - 4t}$. The horizontal tangents occur when $dy/dt = 3t^2 - 1 = 0 \iff t = \pm\frac{1}{\sqrt{3}}$, so both horizontal tangents are shown in our graph. The vertical tangents occur when

$dx/dt = 2t(2t^2 - 3t - 2) = 0 \quad\Leftrightarrow\quad 2t(2t+1)(t-2) = 0 \quad\Leftrightarrow\quad t = 0, -\frac{1}{2}$ or 2. It seems that we have missed one vertical tangent, and indeed if we plot the curve on the t-interval $[-1.2, 2.2]$ we see that there is another vertical tangent at $(-8, 6)$.

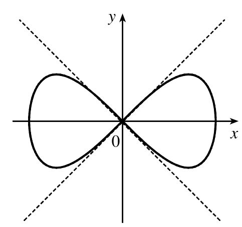
24. We graph the curve $x = t^4 + 4t^3 - 8t^2$, $y = 2t^2 - t$ in the viewing rectangle $[-3.7, 0.2]$ by $[-0.2, 1.4]$. It appears that there is a horizontal tangent at about $(-0.4, -0.1)$, and vertical tangents at about $(-3, 1)$ and $(0, 0)$.



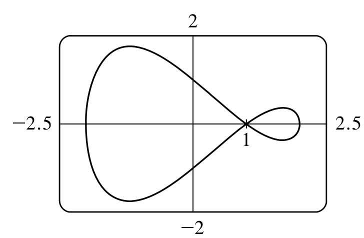


We calculate $\dfrac{dy}{dx} = \dfrac{dy/dt}{dx/dt} = \dfrac{4t-1}{4t^3 + 12t^2 - 16t}$, so there is a horizontal tangent where $dy/dt = 4t - 1 = 0 \quad\Leftrightarrow\quad t = \frac{1}{4}$. This point (the lowest point) is shown in the first graph. There are vertical tangents where $dx/dt = 4t^3 + 12t^2 - 16t = 0 \quad\Leftrightarrow$ $4t(t^2 + 3t - 4) = 0 \quad\Leftrightarrow\quad 4t(t+4)(t-1) = 0$. We have missed one vertical tangent corresponding to $t = -4$, and if we plot the graph for $t \in [-5, 3]$, we see that the curve has another vertical tangent line at approximately $(-128, 36)$.

25. $x = \cos t,\ y = \sin t \cos t.\quad dx/dt = -\sin t,$ $dy/dt = -\sin^2 t + \cos^2 t = \cos 2t.\ (x, y) = (0, 0) \quad\Leftrightarrow\quad \cos t = 0 \quad\Leftrightarrow\quad t$ is an odd multiple of $\frac{\pi}{2}$. When $t = \frac{\pi}{2}$, $dx/dt = -1$ and $dy/dt = -1$, so $dy/dx = 1$. When $t = \frac{3\pi}{2}$, $dx/dt = 1$ and $dy/dt = -1$. So $dy/dx = -1$. Thus, $y = x$ and $y = -x$ are both tangent to the curve at $(0, 0)$.



26. $x = -2\cos t,\ y = \sin t + \sin 2t$. From the graph, it appears that the curve crosses itself at the point $(1, 0)$. If this is true, then $x = 1 \quad\Leftrightarrow$ $-2\cos t = 1 \quad\Leftrightarrow\quad \cos t = -\frac{1}{2} \quad\Leftrightarrow\quad t = \frac{2\pi}{3}$ or $\frac{4\pi}{3}$ for $0 \le t \le 2\pi$. Substituting either value of t into y gives $y = 0$, confirming that $(1, 0)$ is the point where the curve crosses itself. $\dfrac{dy}{dx} = \dfrac{dy/dt}{dx/dt} = \dfrac{\cos t + 2\cos 2t}{2\sin t}$.



When $t = \dfrac{2\pi}{3}$, $\dfrac{dy}{dx} = \dfrac{-1/2 + 2(-1/2)}{2(\sqrt{3}/2)} = \dfrac{-3/2}{\sqrt{3}} = -\dfrac{\sqrt{3}}{2}$, so an equation of the tangent line is $y - 0 = -\dfrac{\sqrt{3}}{2}(x - 1)$, or $y = -\dfrac{\sqrt{3}}{2}x + \dfrac{\sqrt{3}}{2}$. Similarly, when $t = \dfrac{4\pi}{3}$, an equation of the tangent line is $y = \dfrac{\sqrt{3}}{2}x - \dfrac{\sqrt{3}}{2}$.

27. $x = r\theta - d\sin\theta,\ y = r - d\cos\theta$.

(a) $\dfrac{dx}{d\theta} = r - d\cos\theta$, $\dfrac{dy}{d\theta} = d\sin\theta$, so $\dfrac{dy}{dx} = \dfrac{d\sin\theta}{r - d\cos\theta}$.

(b) If $0 < d < r$, then $|d\cos\theta| \le d < r$, so $r - d\cos\theta \ge r - d > 0$. This shows that $dx/d\theta$ never vanishes, so the trochoid can have no vertical tangent if $d < r$.

28. $x = a\cos^3\theta,\ y = a\sin^3\theta.$

(a) $\dfrac{dx}{d\theta} = -3a\cos^2\theta\sin\theta,\ \dfrac{dy}{d\theta} = 3a\sin^2\theta\cos\theta$, so $\dfrac{dy}{dx} = -\dfrac{\sin\theta}{\cos\theta} = -\tan\theta.$

(b) The tangent is horizontal $\Leftrightarrow$ $dy/dx = 0$ $\Leftrightarrow$ $\tan\theta = 0$ $\Leftrightarrow$ $\theta = n\pi$ $\Leftrightarrow$ $(x, y) = (\pm a, 0).$

The tangent is vertical $\Leftrightarrow$ $\cos\theta = 0$ $\Leftrightarrow$ θ is an odd multiple of $\frac{\pi}{2}$ $\Leftrightarrow$ $(x, y) = (0, \pm a)$.

(c) $dy/dx = \pm 1$ $\Leftrightarrow$ $\tan\theta = \pm 1$ $\Leftrightarrow$ θ is an odd multiple of $\frac{\pi}{4}$ $\Leftrightarrow$ $(x, y) = \left(\pm\frac{\sqrt{2}}{4}a, \pm\frac{\sqrt{2}}{4}a\right)$

[All sign choices are valid.]

29. $x = 3t^2 + 1,\ y = t^3 - 1$ $\Rightarrow$ $\dfrac{dy}{dx} = \dfrac{dy/dt}{dx/dt} = \dfrac{3t^2}{6t} = \dfrac{t}{2}$. The tangent line has slope $\dfrac{1}{2}$ when $\dfrac{t}{2} = \dfrac{1}{2}$ $\Leftrightarrow$ $t = 1$, so the point is $(4, 0)$.

30. $x = 3t^2 + 1, y = 2t^3 + 1, \dfrac{dx}{dt} = 6t, \dfrac{dy}{dt} = 6t^2$, so $\dfrac{dy}{dx} = \dfrac{6t^2}{6t} = t$ [even where $t = 0$].

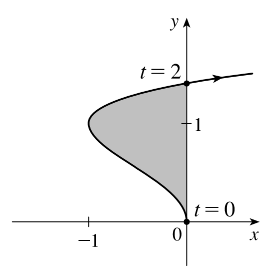
So at the point corresponding to parameter value t, an equation of the tangent line is $y - (2t^3 + 1) = t[x - (3t^2 + 1)]$.

If this line is to pass through $(4, 3)$, we must have $3 - (2t^3 + 1) = t[4 - (3t^2 + 1)]$ $\Leftrightarrow$ $2t^3 - 2 = 3t^3 - 3t$ $\Leftrightarrow$ $t^3 - 3t + 2 = 0$ $\Leftrightarrow$ $(t-1)^2(t+2) = 0$ $\Leftrightarrow$ $t = 1$ or -2. Hence, the desired equations are $y - 3 = x - 4$, or $y = x - 1$, tangent to the curve at $(4, 3)$, and $y - (-15) = -2(x - 13)$, or $y = -2x + 11$, tangent to the curve at $(13, -15)$.

31. By symmetry of the ellipse about the x- and y-axes,

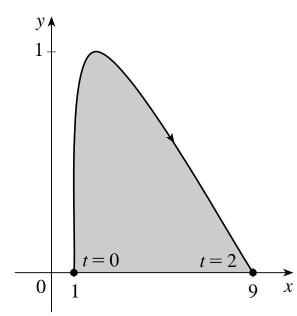
$$\begin{aligned} A &= 4\int_0^a y\,dx = 4\int_{\pi/2}^0 b\sin\theta\,(-a\sin\theta)\,d\theta = 4ab\int_0^{\pi/2}\sin^2\theta\,d\theta = 4ab\int_0^{\pi/2}\tfrac{1}{2}(1 - \cos 2\theta)\,d\theta \\ &= 2ab\left[\theta - \tfrac{1}{2}\sin 2\theta\right]_0^{\pi/2} = 2ab\left(\tfrac{\pi}{2}\right) = \pi ab \end{aligned}$$

32. The curve $x = t^2 - 2t = t(t-2),\ y = \sqrt{t}$ intersects the y-axis when $x = 0$, that is, when $t = 0$ and $t = 2$. The corresponding values of y are 0 and $\sqrt{2}$. The shaded area is given by



$$\begin{aligned} \int_{y=0}^{y=\sqrt{2}} (x_R - x_L)\,dy &= \int_{t=0}^{t=2} [0 - x(t)]\,y'(t)\,dt = -\int_0^2 (t^2 - 2t)\left(\frac{1}{2\sqrt{t}}\,dt\right) \\ &= -\int_0^2\left(\tfrac{1}{2}t^{3/2} - t^{1/2}\right)dt = -\left[\tfrac{1}{5}t^{5/2} - \tfrac{2}{3}t^{3/2}\right]_0^2 \\ &= -\left(\tfrac{1}{5}\cdot 2^{5/2} - \tfrac{2}{3}\cdot 2^{3/2}\right) = -2^{1/2}\left(\tfrac{4}{5} - \tfrac{4}{3}\right) \\ &= -\sqrt{2}\left(-\tfrac{8}{15}\right) = \tfrac{8}{15}\sqrt{2} \end{aligned}$$

33. The curve $x = t^3 + 1, y = 2t - t^2 = t(2 - t)$ intersects the x-axis when $y = 0$, that is, when $t = 0$ and $t = 2$. The corresponding values of x are 1 and 9. The shaded area is given by



$$\begin{aligned} \int_{x=1}^{x=9} (y_T - y_B)\,dx &= \int_{t=0}^{t=2} [y(t) - 0]\,x'(t)\,dt = \int_0^2 (2t - t^2)(3t^2)\,dt \\ &= 3\int_0^2 (2t^3 - t^4)\,dt = 3\left[\tfrac{1}{2}t^4 - \tfrac{1}{5}t^5\right]_0^2 = 3\left(8 - \tfrac{32}{5}\right) = \tfrac{24}{5} \end{aligned}$$

34. By symmetry, $A = 4\int_0^a y\,dx = 4\int_{\pi/2}^0 a\sin^3\theta(-3a\cos^2\theta\,\sin\theta)\,d\theta = 12a^2\int_0^{\pi/2}\sin^4\theta\,\cos^2\theta\,d\theta$. Now

$$\begin{aligned}\int \sin^4\theta\,\cos^2\theta\,d\theta &= \int \sin^2\theta\left(\tfrac{1}{4}\sin^2 2\theta\right)d\theta = \tfrac{1}{8}\int(1-\cos 2\theta)\sin^2 2\theta\,d\theta \\ &= \tfrac{1}{8}\int\left[\tfrac{1}{2}(1-\cos 4\theta) - \sin^2 2\theta\,\cos 2\theta\right]d\theta = \tfrac{1}{16}\theta - \tfrac{1}{64}\sin 4\theta - \tfrac{1}{48}\sin^3 2\theta + C\end{aligned}$$

so $\int_0^{\pi/2}\sin^4\theta\,\cos^2\theta\,d\theta = \left[\frac{1}{16}\theta - \frac{1}{64}\sin 4\theta - \frac{1}{48}\sin^3 2\theta\right]_0^{\pi/2} = \frac{\pi}{32}$. Thus, $A = 12a^2\left(\frac{\pi}{32}\right) = \frac{3}{8}\pi a^2$.

35. $x = r\theta - d\sin\theta,\ y = r - d\cos\theta$.

$$\begin{aligned}A &= \int_0^{2\pi r} y\,dx = \int_0^{2\pi}(r - d\cos\theta)(r - d\cos\theta)\,d\theta = \int_0^{2\pi}(r^2 - 2dr\cos\theta + d^2\cos^2\theta)\,d\theta \\ &= \left[r^2\theta - 2dr\sin\theta + \tfrac{1}{2}d^2\left(\theta + \tfrac{1}{2}\sin 2\theta\right)\right]_0^{2\pi} = 2\pi r^2 + \pi d^2\end{aligned}$$

36. (a) By symmetry, the area of $\mathscr{R}$ is twice the area inside $\mathscr{R}$ above the x-axis. The top half of the loop is described by $x = t^2$, $y = t^3 - 3t$, $-\sqrt{3} \le t \le 0$, so, using the Substitution Rule with $y = t^3 - 3t$ and $dx = 2t\,dt$, we find that

$$\begin{aligned}\text{area} &= 2\int_0^3 y\,dx = 2\int_0^{-\sqrt{3}}(t^3 - 3t)2t\,dt = 2\int_0^{-\sqrt{3}}(2t^4 - 6t^2)\,dt = 2\left[\tfrac{2}{5}t^5 - 2t^3\right]_0^{-\sqrt{3}} \\ &= 2\left[\tfrac{2}{5}(-3^{1/2})^5 - 2(-3^{1/2})^3\right] = 2\left[\tfrac{2}{5}(-9\sqrt{3}) - 2(-3\sqrt{3})\right] = \tfrac{24}{5}\sqrt{3}\end{aligned}$$

(b) Here we use the formula for disks and use the Substitution Rule as in part (a):

$$\begin{aligned}\text{volume} &= \pi\int_0^3 y^2\,dx = \pi\int_0^{-\sqrt{3}}(t^3 - 3t)^2 2t\,dt = 2\pi\int_0^{-\sqrt{3}}(t^6 - 6t^4 + 9t^2)t\,dt = 2\pi\left[\tfrac{1}{8}t^8 - t^6 + \tfrac{9}{4}t^4\right]_0^{-\sqrt{3}} \\ &= 2\pi\left[\tfrac{1}{8}(-3^{1/2})^8 - (-3^{1/2})^6 + \tfrac{9}{4}(-3^{1/2})^4\right] = 2\pi\left[\tfrac{81}{8} - 27 + \tfrac{81}{4}\right] = \tfrac{27}{4}\pi\end{aligned}$$

(c) By symmetry, the y-coordinate of the centroid is 0. To find the x-coordinate, we note that it is the same as the x-coordinate of the centroid of the top half of $\mathscr{R}$, the area of which is $\frac{1}{2}\cdot\frac{24}{5}\sqrt{3} = \frac{12}{5}\sqrt{3}$. So, using Formula 8.3.8 with $A = \frac{12}{5}\sqrt{3}$, we get

$$\begin{aligned}\overline{x} &= \tfrac{5}{12\sqrt{3}}\int_0^3 xy\,dx = \tfrac{5}{12\sqrt{3}}\int_0^{-\sqrt{3}} t^2(t^3 - 3t)2t\,dt = \tfrac{5}{6\sqrt{3}}\left[\tfrac{1}{7}t^7 - \tfrac{3}{5}t^5\right]_0^{-\sqrt{3}} \\ &= \tfrac{5}{6\sqrt{3}}\left[\tfrac{1}{7}(-3^{1/2})^7 - \tfrac{3}{5}(-3^{1/2})^5\right] = \tfrac{5}{6\sqrt{3}}\left[-\tfrac{27}{7}\sqrt{3} + \tfrac{27}{5}\sqrt{3}\right] = \tfrac{9}{7}\end{aligned}$$

So the coordinates of the centroid of $\mathscr{R}$ are $(x, y) = \left(\frac{9}{7}, 0\right)$.

37. $x = t + e^{-t},\ y = t - e^{-t},\ 0 \le t \le 2.$ $dx/dt = 1 - e^{-t}$ and $dy/dt = 1 + e^{-t}$, so $(dx/dt)^2 + (dy/dt)^2 = (1 - e^{-t})^2 + (1 + e^{-t})^2 = 1 - 2e^{-t} + e^{-2t} + 1 + 2e^{-t} + e^{-2t} = 2 + 2e^{-2t}$.
Thus, $L = \int_a^b\sqrt{(dx/dt)^2 + (dy/dt)^2}\,dt = \int_0^2\sqrt{2 + 2e^{-2t}}\,dt \approx 3.1416$.

38. $x = t^2 - t,\ y = t^4,\ 1 \le t \le 4.$ $dx/dt = 2t - 1$ and $dy/dt = 4t^3$, so $(dx/dt)^2 + (dy/dt)^2 = (2t - 1)^2 + (4t^3)^2 = 4t^2 - 4t + 1 + 16t^6$.
Thus, $L = \int_a^b\sqrt{(dx/dt)^2 + (dy/dt)^2}\,dt = \int_1^4\sqrt{16t^6 + 4t^2 - 4t + 1}\,dt \approx 255.3756$.

39. $x = t - 2\sin t,\ y = 1 - 2\cos t,\ 0 \le t \le 4\pi.$ $dx/dt = 1 - 2\cos t$ and $dy/dt = 2\sin t$, so $(dx/dt)^2 + (dy/dt)^2 = (1 - 2\cos t)^2 + (2\sin t)^2 = 1 - 4\cos t + 4\cos^2 t + 4\sin^2 t = 5 - 4\cos t$.
Thus, $L = \int_a^b\sqrt{(dx/dt)^2 + (dy/dt)^2}\,dt = \int_0^{4\pi}\sqrt{5 - 4\cos t}\,dt \approx 26.7298$.

40. $x = t + \sqrt{t},\ y = t - \sqrt{t},\ 0 \le t \le 1.$ $\dfrac{dx}{dt} = 1 + \dfrac{1}{2\sqrt{t}}$ and $\dfrac{dy}{dt} = 1 - \dfrac{1}{2\sqrt{t}}$, so

$$\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2 = \left(1 + \frac{1}{2\sqrt{t}}\right)^2 + \left(1 - \frac{1}{2\sqrt{t}}\right)^2 = 1 + \frac{1}{\sqrt{t}} + \frac{1}{4t} + 1 - \frac{1}{\sqrt{t}} + \frac{1}{4t} = 2 + \frac{1}{2t}.$$

Thus, $L = \int_a^b \sqrt{(dx/dt)^2 + (dy/dt)^2}\,dt = \int_0^1 \sqrt{2 + \frac{1}{2t}}\,dt = \lim\limits_{t \to 0^+} \int_t^1 \sqrt{2 + \frac{1}{2t}}\,dt \approx 2.0915.$

41. $x = 1 + 3t^2,\ \ y = 4 + 2t^3,\ \ 0 \le t \le 1.$ $dx/dt = 6t$ and $dy/dt = 6t^2$, so $(dx/dt)^2 + (dy/dt)^2 = 36t^2 + 36t^4$.

Thus, $L = \int_0^1 \sqrt{36t^2 + 36t^4}\,dt = \int_0^1 6t\sqrt{1 + t^2}\,dt = 6\int_1^2 \sqrt{u}\,\left(\frac{1}{2}\,du\right)$ $[u = 1 + t^2,\ du = 2t\,dt]$

$= 3\left[\frac{2}{3}u^{3/2}\right]_1^2 = 2(2^{3/2} - 1) = 2\left(2\sqrt{2} - 1\right)$

42. $x = e^t - t,\ y = 4e^{t/2},\ 0 \le t \le 2.$ $dx/dt = e^t - 1$ and $dy/dt = 2e^{t/2}$, so

$(dx/dt)^2 + (dy/dt)^2 = (e^t - 1)^2 + (2e^{t/2})^2 = e^{2t} - 2e^t + 1 + 4e^t = e^{2t} + 2e^t + 1 = (e^t + 1)^2$. Thus,

$$L = \int_0^2 \sqrt{(e^t + 1)^2}\,dt = \int_0^2 \left|e^t + 1\right|\,dt = \int_0^2 (e^t + 1)\,dt = \left[e^t + t\right]_0^2 = (e^2 + 2) - (1 + 0) = e^2 + 1.$$

43. $x = t\sin t,\ y = t\cos t,\ 0 \le t \le 1.$ $\dfrac{dx}{dt} = t\cos t + \sin t$ and $\dfrac{dy}{dt} = -t\sin t + \cos t$, so

$$\begin{aligned}\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2 &= t^2\cos^2 t + 2t\sin t\,\cos t + \sin^2 t + t^2\sin^2 t - 2t\sin t\,\cos t + \cos^2 t \\ &= t^2(\cos^2 t + \sin^2 t) + \sin^2 t + \cos^2 t = t^2 + 1.\end{aligned}$$

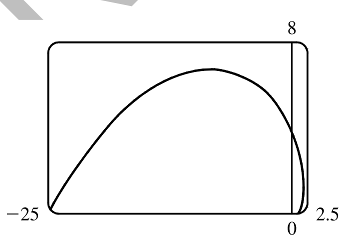
Thus, $L = \int_0^1 \sqrt{t^2 + 1}\,dt \overset{21}{=} \left[\frac{1}{2}t\sqrt{t^2 + 1} + \frac{1}{2}\ln\left(t + \sqrt{t^2 + 1}\right)\right]_0^1 = \frac{1}{2}\sqrt{2} + \frac{1}{2}\ln\left(1 + \sqrt{2}\right).$

44. $x = 3\cos t - \cos 3t,\ y = 3\sin t - \sin 3t,\ 0 \le t \le \pi.$ $\dfrac{dx}{dt} = -3\sin t + 3\sin 3t$ and $\dfrac{dy}{dt} = 3\cos t - 3\cos 3t$, so

$$\begin{aligned}\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2 &= 9\sin^2 t - 18\sin t\,\sin 3t + 9\sin^2(3t) + 9\cos^2 t - 18\cos t\,\cos 3t + 9\cos^2(3t) \\ &= 9(\cos^2 t + \sin^2 t) - 18(\cos t\,\cos 3t + \sin t\,\sin 3t) + 9[\cos^2(3t) + \sin^2(3t)] \\ &= 9(1) - 18\cos(t - 3t) + 9(1) = 18 - 18\cos(-2t) = 18(1 - \cos 2t) \\ &= 18[1 - (1 - 2\sin^2 t)] = 36\sin^2 t.\end{aligned}$$

Thus, $L = \int_0^\pi \sqrt{36\sin^2 t}\,dt = 6\int_0^\pi |\sin t|\,dt = 6\int_0^\pi \sin t\,dt = -6\left[\cos t\right]_0^\pi = -6\,(-1 - 1) = 12.$

45.



$x = e^t\cos t,\ y = e^t\sin t,\ 0 \le t \le \pi.$

$$\begin{aligned}\left(\tfrac{dx}{dt}\right)^2 + \left(\tfrac{dy}{dt}\right)^2 &= [e^t(\cos t - \sin t)]^2 + [e^t(\sin t + \cos t)]^2 \\ &= (e^t)^2(\cos^2 t - 2\cos t\,\sin t + \sin^2 t) \\ &\quad + (e^t)^2(\sin^2 t + 2\sin t\,\cos t + \cos^2 t \\ &= e^{2t}(2\cos^2 t + 2\sin^2 t) = 2e^{2t}\end{aligned}$$

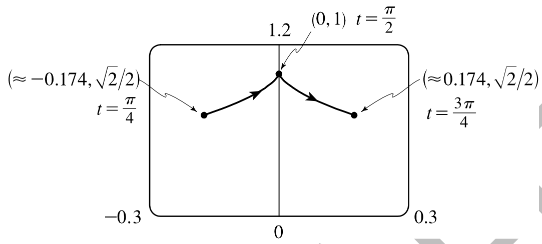
Thus, $L = \int_0^\pi \sqrt{2e^{2t}}\,dt = \int_0^\pi \sqrt{2}\,e^t\,dt = \sqrt{2}\,\left[\,e^t\,\right]_0^\pi = \sqrt{2}\,(e^\pi - 1).$

46. $x = \cos t + \ln(\tan \frac{1}{2}t)$, $\quad y = \sin t$, $\quad \pi/4 \le t \le 3\pi/4$.

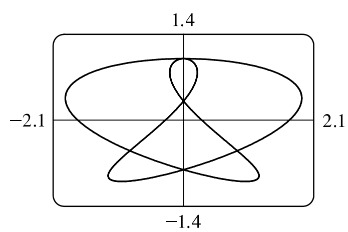
$$\frac{dx}{dt} = -\sin t + \frac{\frac{1}{2}\sec^2(t/2)}{\tan(t/2)} = -\sin t + \frac{1}{2\sin(t/2)\,\cos(t/2)} = -\sin t + \frac{1}{\sin t} \text{ and } \frac{dy}{dt} = \cos t \text{, so}$$

$$\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2 = \sin^2 t - 2 + \frac{1}{\sin^2 t} + \cos^2 t = 1 - 2 + \csc^2 t = \cot^2 t. \text{ Thus,}$$

$$L = \int_{\pi/4}^{3\pi/4} |\cot t|\, dt = 2\int_{\pi/4}^{\pi/2} \cot t\, dt$$
$$= 2\Big[\ln|\sin t|\Big]_{\pi/4}^{\pi/2} = 2\left(\ln 1 - \ln \frac{1}{\sqrt{2}}\right)$$
$$= 2\big(0 + \ln\sqrt{2}\big) = 2\big(\tfrac{1}{2}\ln 2\big) = \ln 2.$$



47.



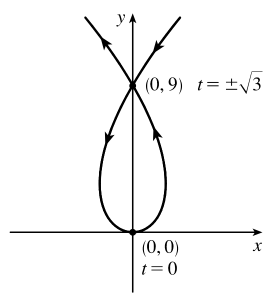
The figure shows the curve $x = \sin t + \sin 1.5t$, $y = \cos t$ for $0 \le t \le 4\pi$.
$dx/dt = \cos t + 1.5\cos 1.5t$ and $dy/dt = -\sin t$, so
$(dx/dt)^2 + (dy/dt)^2 = \cos^2 t + 3\cos t\,\cos 1.5t + 2.25\cos^2 1.5t + \sin^2 t$.
Thus, $L = \int_0^{4\pi} \sqrt{1 + 3\cos t\,\cos 1.5t + 2.25\cos^2 1.5t}\, dt \approx 16.7102$.

48. $x = 3t - t^3$, $y = 3t^2$. $\quad dx/dt = 3 - 3t^2$ and $dy/dt = 6t$, so

$$\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2 = (3 - 3t^2)^2 + (6t)^2 = (3 + 3t^2)^2$$

and the length of the loop is given by

$$L = \int_{-\sqrt{3}}^{\sqrt{3}} (3 + 3t^2)\, dt = 2\int_0^{\sqrt{3}} (3 + 3t^2)\, dt = 2\left[3t + t^3\right]_0^{\sqrt{3}}$$
$$= 2\big(3\sqrt{3} + 3\sqrt{3}\big) = 12\sqrt{3}$$



49. $x = t - e^t$, $y = t + e^t$, $-6 \le t \le 6$.

$\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2 = (1 - e^t)^2 + (1 + e^t)^2 = (1 - 2e^t + e^{2t}) + (1 + 2e^t + e^{2t}) = 2 + 2e^{2t}$, so $L = \int_{-6}^{6} \sqrt{2 + 2e^{2t}}\, dt$.

Set $f(t) = \sqrt{2 + 2e^{2t}}$. Then by Simpson's Rule with $n = 6$ and $\Delta t = \frac{6-(-6)}{6} = 2$, we get

$L \approx \frac{2}{3}[f(-6) + 4f(-4) + 2f(-2) + 4f(0) + 2f(2) + 4f(4) + f(6)] \approx 612.3053$.

50. $x = 2a\cot\theta \;\Rightarrow\; dx/dt = -2a\csc^2\theta$ and $y = 2a\sin^2\theta \;\Rightarrow\; dy/dt = 4a\sin\theta\,\cos\theta = 2a\sin 2\theta$.

So $L = \int_{\pi/4}^{\pi/2} \sqrt{4a^2\csc^4\theta + 4a^2\sin^2 2\theta}\, d\theta = 2a\int_{\pi/4}^{\pi/2} \sqrt{\csc^4\theta + \sin^2 2\theta}\, d\theta$. Using Simpson's Rule with

$n = 4$, $\Delta\theta = \frac{\pi/2 - \pi/4}{4} = \frac{\pi}{16}$, and $f(\theta) = \sqrt{\csc^4\theta + \sin^2 2\theta}$, we get

$L \approx 2a \cdot S_4 = (2a)\,\frac{\pi}{16\cdot 3}\left[f\left(\frac{\pi}{4}\right) + 4f\left(\frac{5\pi}{16}\right) + 2f\left(\frac{3\pi}{8}\right) + 4f\left(\frac{7\pi}{16}\right) + f\left(\frac{\pi}{2}\right)\right] \approx 2.2605a$.

51. $x = \sin^2 t$, $y = \cos^2 t$, $0 \le t \le 3\pi$.

$(dx/dt)^2 + (dy/dt)^2 = (2\sin t\,\cos t)^2 + (-2\cos t\sin t)^2 = 8\sin^2 t\cos^2 t = 2\sin^2 2t \quad\Rightarrow$

Distance $= \int_0^{3\pi} \sqrt{2}\,|\sin 2t|\; dt = 6\sqrt{2}\int_0^{\pi/2} \sin 2t\, dt$ [by symmetry] $= -3\sqrt{2}\Big[\cos 2t\Big]_0^{\pi/2} = -3\sqrt{2}\,(-1-1) = 6\sqrt{2}.$

The full curve is traversed as t goes from 0 to $\frac{\pi}{2}$, because the curve is the segment of $x + y = 1$ that lies in the first quadrant (since $x, y \geq 0$), and this segment is completely traversed as t goes from 0 to $\frac{\pi}{2}$. Thus, $L = \int_0^{\pi/2} \sin 2t\, dt = \sqrt{2}$, as above.

52. $x = \cos^2 t,\ y = \cos t,\ 0 \leq t \leq 4\pi.$ $\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2 = (-2\cos t \sin t)^2 + (-\sin t)^2 = \sin^2 t\,(4\cos^2 t + 1)$

$$\begin{aligned} \text{Distance } &= \int_0^{4\pi} |\sin t|\,\sqrt{4\cos^2 t + 1}\,dt = 4\int_0^{\pi} \sin t\,\sqrt{4\cos^2 t + 1}\,dt \\ &= -4\int_1^{-1} \sqrt{4u^2 + 1}\,du \quad [u = \cos t,\ du = -\sin t\,dt] \quad = 4\int_{-1}^{1} \sqrt{4u^2 + 1}\,du \\ &= 8\int_0^1 \sqrt{4u^2 + 1}\,du = 8\int_0^{\tan^{-1} 2} \sec\theta \cdot \tfrac{1}{2}\sec^2\theta\,d\theta \qquad [2u = \tan\theta,\ 2\,du = \sec^2\theta\,d\theta] \\ &= 4\int_0^{\tan^{-1} 2} \sec^3\theta\,d\theta \overset{71}{=} \Big[2\sec\theta\tan\theta + 2\ln|\sec\theta + \tan\theta|\Big]_0^{\tan^{-1} 2} = 4\sqrt{5} + 2\ln\big(\sqrt{5} + 2\big) \end{aligned}$$

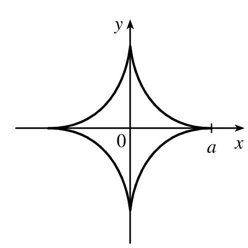
Thus, $L = \int_0^{\pi} |\sin t|\,\sqrt{4\cos^2 t + 1}\,dt = \sqrt{5} + \frac{1}{2}\ln\big(\sqrt{5} + 2\big)$.

53. $x = a\sin\theta,\ y = b\cos\theta,\ 0 \leq \theta \leq 2\pi.$

$$\begin{aligned} \left(\tfrac{dx}{dt}\right)^2 + \left(\tfrac{dy}{dt}\right)^2 &= (a\cos\theta)^2 + (-b\sin\theta)^2 = a^2\cos^2\theta + b^2\sin^2\theta = a^2(1 - \sin^2\theta) + b^2\sin^2\theta \\ &= a^2 - (a^2 - b^2)\sin^2\theta = a^2 - c^2\sin^2\theta = a^2\left(1 - \frac{c^2}{a^2}\sin^2\theta\right) = a^2(1 - e^2\sin^2\theta) \end{aligned}$$

So $L = 4\int_0^{\pi/2} \sqrt{a^2\left(1 - e^2\sin^2\theta\right)}\,d\theta$ [by symmetry] $= 4a\int_0^{\pi/2} \sqrt{1 - e^2\sin^2\theta}\,d\theta$.

54. $x = a\cos^3\theta,\ y = a\sin^3\theta.$

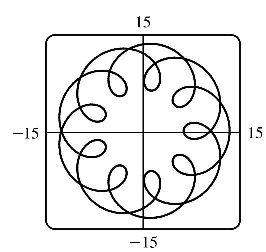


$$\begin{aligned} \left(\tfrac{dx}{dt}\right)^2 + \left(\tfrac{dy}{dt}\right)^2 &= (-3a\cos^2\theta\,\sin\theta)^2 + (3a\sin^2\theta\,\cos\theta)^2 \\ &= 9a^2\cos^4\theta\,\sin^2\theta + 9a^2\sin^4\theta\,\cos^2\theta \\ &= 9a^2\sin^2\theta\,\cos^2\theta(\cos^2\theta + \sin^2\theta) = 9a^2\sin^2\theta\,\cos^2\theta. \end{aligned}$$

The graph has four-fold symmetry and the curve in the first quadrant corresponds to $0 \leq \theta \leq \pi/2$. Thus,

$$\begin{aligned} L &= 4\int_0^{\pi/2} 3a\sin\theta\,\cos\theta\,d\theta \qquad [\text{since } a > 0 \text{ and } \sin\theta \text{ and } \cos\theta \text{ are positive for } 0 \leq \theta \leq \pi/2] \\ &= 12a\Big[\tfrac{1}{2}\sin^2\theta\Big]_0^{\pi/2} = 12a\big(\tfrac{1}{2} - 0\big) = 6a \end{aligned}$$

55. (a) $x = 11\cos t - 4\cos(11t/2),\ y = 11\sin t - 4\sin(11t/2).$

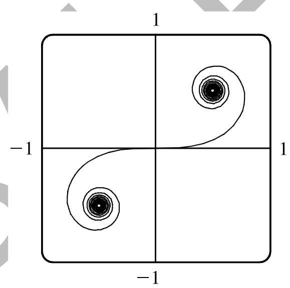


Notice that $0 \leq t \leq 2\pi$ does not give the complete curve because $x(0) \neq x(2\pi)$. In fact, we must take $t \in [0, 4\pi]$ in order to obtain the complete curve, since the first term in each of the parametric equations has period 2π and the second has period $\frac{2\pi}{11/2} = \frac{4\pi}{11}$, and the least common integer multiple of these two numbers is 4π.

(b) We use the CAS to find the derivatives dx/dt and dy/dt, and then use Theorem 5 to find the arc length. Recent versions of Maple express the integral $\int_0^{4\pi} \sqrt{(dx/dt)^2 + (dy/dt)^2}\, dt$ as $88E(2\sqrt{2}\, i)$, where $E(x)$ is the elliptic integral $\int_0^1 \frac{\sqrt{1 - x^2 t^2}}{\sqrt{1 - t^2}}\, dt$ and i is the imaginary number $\sqrt{-1}$.

Some earlier versions of Maple (as well as Mathematica) cannot do the integral exactly, so we use the command `evalf(Int(sqrt(diff(x,t)^2+diff(y,t)^2),t=0..4*Pi));` to estimate the length, and find that the arc length is approximately 294.03. Derive's `Para_arc_length` function in the utility file `Int_apps` simplifies the integral to $11 \int_0^{4\pi} \sqrt{-4\cos t\, \cos\left(\frac{11t}{2}\right) - 4\sin t\, \sin\left(\frac{11t}{2}\right) + 5}\, dt$.

56. (a) It appears that as $t \to \infty$, $(x, y) \to \left(\frac{1}{2}, \frac{1}{2}\right)$, and as $t \to -\infty$, $(x, y) \to \left(-\frac{1}{2}, -\frac{1}{2}\right)$.



(b) By the Fundamental Theorem of Calculus, $dx/dt = \cos\left(\frac{\pi}{2}t^2\right)$ and $dy/dt = \sin\left(\frac{\pi}{2}t^2\right)$, so by Theorem 5, the length of the curve from the origin to the point with parameter value t is

$$L = \int_0^t \sqrt{\left(\frac{dx}{du}\right)^2 + \left(\frac{dy}{du}\right)^2}\, du = \int_0^t \sqrt{\cos^2\left(\frac{\pi}{2}u^2\right) + \sin^2\left(\frac{\pi}{2}u^2\right)}\, du$$
$$= \int_0^t 1\, du = t \qquad [\text{or } -t \text{ if } t < 0]$$

We have used u as the dummy variable so as not to confuse it with the upper limit of integration.

57. $x = t\sin t,\ y = t\cos t,\ 0 \le t \le \pi/2$. $dx/dt = t\cos t + \sin t$ and $dy/dt = -t\sin t + \cos t$, so

$$\begin{aligned}(dx/dt)^2 + (dy/dt)^2 &= t^2\cos^2 t + 2t\sin t\, \cos t + \sin^2 t + t^2\sin^2 t - 2t\sin t\, \cos t + \cos^2 t \\ &= t^2(\cos^2 t + \sin^2 t) + \sin^2 t + \cos^2 t = t^2 + 1\end{aligned}$$

$S = \int 2\pi y\, ds = \int_0^{\pi/2} 2\pi t\cos t\sqrt{t^2 + 1}\, dt \approx 4.7394$.

58. $x = \sin t,\ y = \sin 2t,\ 0 \le t \le \pi/2$. $dx/dt = \cos t$ and $dy/dt = 2\cos 2t$, so $(dx/dt)^2 + (dy/dt)^2 = \cos^2 t + 4\cos^2 2t$.

$S = \int 2\pi y\, ds = \int_0^{\pi/2} 2\pi\sin 2t\sqrt{\cos^2 t + 4\cos^2 2t}\, dt \approx 8.0285$.

59. $x = t + e^t,\ y = e^{-t},\ 0 \le t \le 1$.

$dx/dt = 1 + e^t$ and $dy/dt = -e^{-t}$, so $(dx/dt)^2 + (dy/dt)^2 = (1 + e^t)^2 + (-e^{-t})^2 = 1 + 2e^t + e^{2t} + e^{-2t}$.

$S = \int 2\pi y\, ds = \int_0^1 2\pi e^{-t}\sqrt{1 + 2e^t + e^{2t} + e^{-2t}}\, dt \approx 10.6705$.

60. $x = t^2 - t^3,\ y = t + t^4,\ 0 \le t \le 1$.

$(dx/dt)^2 + (dy/dt)^2 = (2t - 3t^2)^2 + (1 + 4t^3)^2 = 4t^2 - 12t^3 + 9t^4 + 1 + 8t^3 + 16t^6$, so

$S = \int 2\pi y\, ds = \int_0^1 2\pi(t + t^4)\sqrt{16t^6 + 9t^4 - 4t^3 + 4t^2 + 1}\, dt \approx 12.7176$.

61. $x = t^3,\ y = t^2,\ 0 \le t \le 1.\quad \left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2 = \left(3t^2\right)^2 + (2t)^2 = 9t^4 + 4t^2.$

$$S = \int_0^1 2\pi y\sqrt{\left(\tfrac{dx}{dt}\right)^2 + \left(\tfrac{dy}{dt}\right)^2}\,dt = \int_0^1 2\pi t^2\sqrt{9t^4 + 4t^2}\,dt = 2\pi\int_0^1 t^2\sqrt{t^2(9t^2+4)}\,dt$$

$$= 2\pi\int_4^{13}\left(\frac{u-4}{9}\right)\sqrt{u}\left(\tfrac{1}{18}\,du\right)\quad\left[\begin{array}{l}u = 9t^2+4,\ t^2 = (u-4)/9,\\ du = 18t\,dt,\text{ so } t\,dt = \frac{1}{18}\,du\end{array}\right]\quad = \frac{2\pi}{9\cdot 18}\int_4^{13}(u^{3/2} - 4u^{1/2})\,du$$

$$= \tfrac{\pi}{81}\left[\tfrac{2}{5}u^{5/2} - \tfrac{8}{3}u^{3/2}\right]_4^{13} = \tfrac{\pi}{81}\cdot\tfrac{2}{15}\left[3u^{5/2} - 20u^{3/2}\right]_4^{13}$$

$$= \tfrac{2\pi}{1215}\left[\left(3\cdot 13^2\sqrt{13} - 20\cdot 13\sqrt{13}\right) - (3\cdot 32 - 20\cdot 8)\right] = \tfrac{2\pi}{1215}\left(247\sqrt{13} + 64\right)$$

62. $x = 2t^2 + 1/t,\ y = 8\sqrt{t},\ 1 \le t \le 3.$

$$\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2 = \left(4t - \frac{1}{t^2}\right)^2 + \left(\frac{4}{\sqrt{t}}\right)^2 = 16t^2 - \frac{8}{t} + \frac{1}{t^4} + \frac{16}{t} = 16t^2 + \frac{8}{t} + \frac{1}{t^4} = \left(4t + \frac{1}{t^2}\right)^2.$$

$$S = \int_1^3 2\pi y\sqrt{\left(\tfrac{dx}{dt}\right)^2 + \left(\tfrac{dy}{dt}\right)^2}\,dt = \int_1^3 2\pi\left(8\sqrt{t}\right)\sqrt{\left(4t + \frac{1}{t^2}\right)^2}\,dt = 16\pi\int_1^3 t^{1/2}(4t + t^{-2})\,dt$$

$$= 16\pi\int_1^3 (4t^{3/2} + t^{-3/2})\,dt = 16\pi\left[\tfrac{8}{5}t^{5/2} - 2t^{-1/2}\right]_1^3 = 16\pi\left[\left(\tfrac{72}{5}\sqrt{3} - \tfrac{2}{3}\sqrt{3}\right) - \left(\tfrac{8}{5} - 2\right)\right]$$

$$= 16\pi\left(\tfrac{206}{15}\sqrt{3} + \tfrac{6}{15}\right) = \tfrac{32\pi}{15}\left(103\sqrt{3} + 3\right)$$

63. $x = a\cos^3\theta,\ y = a\sin^3\theta,\ 0 \le \theta \le \frac{\pi}{2}.\quad \left(\frac{dx}{d\theta}\right)^2 + \left(\frac{dy}{d\theta}\right)^2 = (-3a\cos^2\theta\,\sin\theta)^2 + (3a\sin^2\theta\,\cos\theta)^2 = 9a^2\sin^2\theta\,\cos^2\theta.$

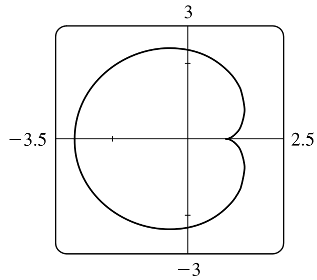
$$S = \int_0^{\pi/2} 2\pi\cdot a\sin^3\theta\cdot 3a\sin\theta\,\cos\theta\,d\theta = 6\pi a^2\int_0^{\pi/2}\sin^4\theta\,\cos\theta\,d\theta = \tfrac{6}{5}\pi a^2\left[\sin^5\theta\right]_0^{\pi/2} = \tfrac{6}{5}\pi a^2$$

64. $x = 2\cos\theta - \cos 2\theta,\ y = 2\sin\theta - \sin 2\theta\quad\Rightarrow$

$$\left(\tfrac{dx}{d\theta}\right)^2 + \left(\tfrac{dy}{d\theta}\right)^2 = (-2\sin\theta + 2\sin 2\theta)^2 + (2\cos\theta - 2\cos 2\theta)^2$$

$$= 4[(\sin^2\theta - 2\sin\theta\,\sin 2\theta + \sin^2 2\theta) + (\cos^2\theta - 2\cos\theta\,\cos 2\theta + \cos^2 2\theta)]$$

$$= 4[1 + 1 - 2(\cos 2\theta\cos\theta + \sin 2\theta\sin\theta)] = 8[1 - \cos(2\theta - \theta)] = 8(1 - \cos\theta)$$



We plot the graph with parameter interval $[0, 2\pi]$, and see that we should only integrate between 0 and π. (If the interval $[0, 2\pi]$ were taken, the surface of revolution would be generated twice.) Also note that $y = 2\sin\theta - \sin 2\theta = 2\sin\theta(1 - \cos\theta)$. So

$$S = \int_0^{\pi} 2\pi\cdot 2\sin\theta(1 - \cos\theta)\,2\sqrt{2}\sqrt{1 - \cos\theta}\,d\theta$$

$$= 8\sqrt{2}\pi\int_0^{\pi}(1 - \cos\theta)^{3/2}\sin\theta\,d\theta = 8\sqrt{2}\pi\int_0^2\sqrt{u^3}\,du\quad\left[\begin{array}{l}u = 1 - \cos\theta,\\ du = \sin\theta\,d\theta\end{array}\right]$$

$$= 8\sqrt{2}\pi\left[\left(\tfrac{2}{5}\right)u^{5/2}\right]_0^2 = \tfrac{16}{5}\sqrt{2}\pi(2^{5/2}) = \tfrac{128}{5}\pi$$

65. $x = 3t^2,\ y = 2t^3,\ 0 \le t \le 5\quad\Rightarrow\quad\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2 = (6t)^2 + (6t^2)^2 = 36t^2(1 + t^2)\quad\Rightarrow$

$$S = \int_0^5 2\pi x\sqrt{(dx/dt)^2 + (dy/dt)^2}\,dt = \int_0^5 2\pi(3t^2)6t\sqrt{1 + t^2}\,dt = 18\pi\int_0^5 t^2\sqrt{1 + t^2}\,2t\,dt$$

$$= 18\pi\int_1^{26}(u - 1)\sqrt{u}\,du\quad\left[\begin{array}{l}u = 1 + t^2,\\ du = 2t\,dt\end{array}\right]\quad = 18\pi\int_1^{26}(u^{3/2} - u^{1/2})\,du = 18\pi\left[\tfrac{2}{5}u^{5/2} - \tfrac{2}{3}u^{3/2}\right]_1^{26}$$

$$= 18\pi\left[\left(\tfrac{2}{5}\cdot 676\sqrt{26} - \tfrac{2}{3}\cdot 26\sqrt{26}\right) - \left(\tfrac{2}{5} - \tfrac{2}{3}\right)\right] = \tfrac{24}{5}\pi\left(949\sqrt{26} + 1\right)$$

66. $x = e^t - t, y = 4e^{t/2}, 0 \le t \le 1$. $\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2 = (e^t - 1)^2 + (2e^{t/2})^2 = e^{2t} + 2e^t + 1 = (e^t + 1)^2$.

$$S = \int_0^1 2\pi(e^t - t)\sqrt{(e^t - 1)^2 + (2e^{t/2})^2}\,dt = \int_0^1 2\pi(e^t - t)(e^t + 1)d$$
$$= 2\pi\left[\tfrac{1}{2}e^{2t} + e^t - (t-1)e^t - \tfrac{1}{2}t^2\right]_0^1 = \pi(e^2 + 2e - 6)$$

67. If f' is continuous and $f'(t) \ne 0$ for $a \le t \le b$, then either $f'(t) > 0$ for all t in $[a, b]$ or $f'(t) < 0$ for all t in $[a, b]$. Thus, f is monotonic (in fact, strictly increasing or strictly decreasing) on $[a, b]$. It follows that f has an inverse. Set $F = g \circ f^{-1}$, that is, define F by $F(x) = g(f^{-1}(x))$. Then $x = f(t) \Rightarrow f^{-1}(x) = t$, so $y = g(t) = g(f^{-1}(x)) = F(x)$.

68. By Formula 8.2.5 with $y = F(x)$, $S = \int_a^b 2\pi F(x)\sqrt{1 + [F'(x)]^2}\,dx$. But by Formula 10.2.1,

$1 + [F'(x)]^2 = 1 + \left(\dfrac{dy}{dx}\right)^2 = 1 + \left(\dfrac{dy/dt}{dx/dt}\right)^2 = \dfrac{(dx/dt)^2 + (dy/dt)^2}{(dx/dt)^2}$. Using the Substitution Rule with $x = x(t)$,

where $a = x(\alpha)$ and $b = x(\beta)$, we have $\left[\text{since } dx = \dfrac{dx}{dt}\,dt\right]$

$$S = \int_\alpha^\beta 2\pi\,F(x(t))\sqrt{\frac{(dx/dt)^2 + (dy/dt)^2}{(dx/dt)^2}}\,\frac{dx}{dt}\,dt = \int_\alpha^\beta 2\pi y\sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2}\,dt,$$ which is Formula 10.2.6.

69. (a) $\phi = \tan^{-1}\left(\dfrac{dy}{dx}\right) \Rightarrow \dfrac{d\phi}{dt} = \dfrac{d}{dt}\tan^{-1}\left(\dfrac{dy}{dx}\right) = \dfrac{1}{1 + (dy/dx)^2}\left[\dfrac{d}{dt}\left(\dfrac{dy}{dx}\right)\right]$. But $\dfrac{dy}{dx} = \dfrac{dy/dt}{dx/dt} = \dfrac{\dot{y}}{\dot{x}} \Rightarrow$

$\dfrac{d}{dt}\left(\dfrac{dy}{dx}\right) = \dfrac{d}{dt}\left(\dfrac{\dot{y}}{\dot{x}}\right) = \dfrac{\ddot{y}\dot{x} - \ddot{x}\dot{y}}{\dot{x}^2} \Rightarrow \dfrac{d\phi}{dt} = \dfrac{1}{1 + (\dot{y}/\dot{x})^2}\left(\dfrac{\ddot{y}\dot{x} - \ddot{x}\dot{y}}{\dot{x}^2}\right) = \dfrac{\dot{x}\ddot{y} - \ddot{x}\dot{y}}{\dot{x}^2 + \dot{y}^2}$. Using the Chain Rule, and the

fact that $s = \displaystyle\int_0^t \sqrt{\left(\tfrac{dx}{dt}\right)^2 + \left(\tfrac{dy}{dt}\right)^2}\,dt \Rightarrow \tfrac{ds}{dt} = \sqrt{\left(\tfrac{dx}{dt}\right)^2 + \left(\tfrac{dy}{dt}\right)^2} = \left(\dot{x}^2 + \dot{y}^2\right)^{1/2}$, we have that

$\dfrac{d\phi}{ds} = \dfrac{d\phi/dt}{ds/dt} = \left(\dfrac{\dot{x}\ddot{y} - \ddot{x}\dot{y}}{\dot{x}^2 + \dot{y}^2}\right)\dfrac{1}{(\dot{x}^2 + \dot{y}^2)^{1/2}} = \dfrac{\dot{x}\ddot{y} - \ddot{x}\dot{y}}{(\dot{x}^2 + \dot{y}^2)^{3/2}}$. So $\kappa = \left|\dfrac{d\phi}{ds}\right| = \left|\dfrac{\dot{x}\ddot{y} - \ddot{x}\dot{y}}{(\dot{x}^2 + \dot{y}^2)^{3/2}}\right| = \dfrac{|\dot{x}\ddot{y} - \ddot{x}\dot{y}|}{(\dot{x}^2 + \dot{y}^2)^{3/2}}$.

(b) $x = x$ and $y = f(x) \Rightarrow \dot{x} = 1, \ddot{x} = 0$ and $\dot{y} = \dfrac{dy}{dx}, \ddot{y} = \dfrac{d^2y}{dx^2}$.

So $\kappa = \dfrac{\left|1 \cdot (d^2y/dx^2) - 0 \cdot (dy/dx)\right|}{[1 + (dy/dx)^2]^{3/2}} = \dfrac{\left|d^2y/dx^2\right|}{[1 + (dy/dx)^2]^{3/2}}$.

70. (a) $y = x^2 \Rightarrow \dfrac{dy}{dx} = 2x \Rightarrow \dfrac{d^2y}{dx^2} = 2$. So $\kappa = \dfrac{\left|d^2y/dx^2\right|}{[1 + (dy/dx)^2]^{3/2}} = \dfrac{2}{(1 + 4x^2)^{3/2}}$, and at $(1, 1)$,

$\kappa = \dfrac{2}{5^{3/2}} = \dfrac{2}{5\sqrt{5}}$.

(b) $\kappa' = \dfrac{d\kappa}{dx} = -3(1 + 4x^2)^{-5/2}(8x) = 0 \Leftrightarrow x = 0 \Rightarrow y = 0$. This is a maximum since $\kappa' > 0$ for $x < 0$ and $\kappa' < 0$ for $x > 0$. So the parabola $y = x^2$ has maximum curvature at the origin.

71. $x = \theta - \sin\theta \Rightarrow \dot{x} = 1 - \cos\theta \Rightarrow \ddot{x} = \sin\theta$, and $y = 1 - \cos\theta \Rightarrow \dot{y} = \sin\theta \Rightarrow \ddot{y} = \cos\theta$. Therefore,

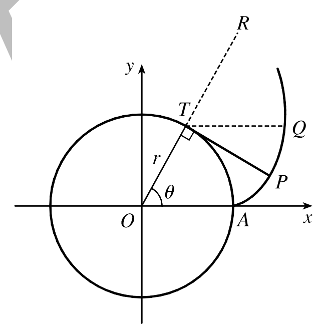
$\kappa = \dfrac{\left|\cos\theta - \cos^2\theta - \sin^2\theta\right|}{[(1 - \cos\theta)^2 + \sin^2\theta]^{3/2}} = \dfrac{\left|\cos\theta - (\cos^2\theta + \sin^2\theta)\right|}{(1 - 2\cos\theta + \cos^2\theta + \sin^2\theta)^{3/2}} = \dfrac{|\cos\theta - 1|}{(2 - 2\cos\theta)^{3/2}}$. The top of the arch is characterized by a horizontal tangent, and from Example 2(b) in Section 10.2, the tangent is horizontal when $\theta = (2n-1)\pi$, so take $n = 1$ and substitute $\theta = \pi$ into the expression for κ: $\kappa = \dfrac{|\cos\pi - 1|}{(2 - 2\cos\pi)^{3/2}} = \dfrac{|-1-1|}{[2-2(-1)]^{3/2}} = \dfrac{1}{4}$.

72. (a) Every straight line has parametrizations of the form $x = a + vt$, $y = b + wt$, where a, b are arbitrary and $v, w \neq 0$. For example, a straight line passing through distinct points (a,b) and (c,d) can be described as the parametrized curve $x = a + (c-a)t$, $y = b + (d-b)t$. Starting with $x = a + vt$, $y = b + wt$, we compute $\dot{x} = v$, $\dot{y} = w$, $\ddot{x} = \ddot{y} = 0$, and $\kappa = \dfrac{|v\cdot 0 - w\cdot 0|}{(v^2+w^2)^{3/2}} = 0$.

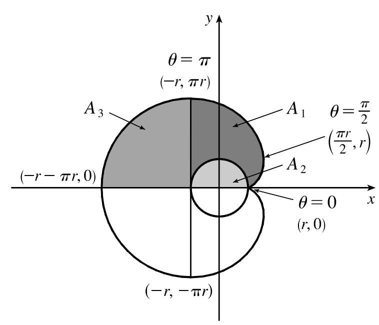
(b) Parametric equations for a circle of radius r are $x = r\cos\theta$ and $y = r\sin\theta$. We can take the center to be the origin. So $\dot{x} = -r\sin\theta \;\Rightarrow\; \ddot{x} = -r\cos\theta$ and $\dot{y} = r\cos\theta \;\Rightarrow\; \ddot{y} = -r\sin\theta$. Therefore,

$$\kappa = \frac{\left|r^2\sin^2\theta + r^2\cos^2\theta\right|}{(r^2\sin^2\theta + r^2\cos^2\theta)^{3/2}} = \frac{r^2}{r^3} = \frac{1}{r}.$$ And so for any θ (and thus any point), $\kappa = \dfrac{1}{r}$.

73. The coordinates of T are $(r\cos\theta, r\sin\theta)$. Since TP was unwound from arc TA, TP has length $r\theta$. Also $\angle PTQ = \angle PTR - \angle QTR = \frac{1}{2}\pi - \theta$, so P has coordinates $x = r\cos\theta + r\theta\cos\left(\frac{1}{2}\pi - \theta\right) = r(\cos\theta + \theta\sin\theta)$, $y = r\sin\theta - r\theta\sin\left(\frac{1}{2}\pi - \theta\right) = r(\sin\theta - \theta\cos\theta)$.



74. If the cow walks with the rope taut, it traces out the portion of the involute in Exercise 73 corresponding to the range $0 \leq \theta \leq \pi$, arriving at the point $(-r, \pi r)$ when $\theta = \pi$. With the rope now fully extended, the cow walks in a semicircle of radius πr, arriving at $(-r, -\pi r)$. Finally, the cow traces out another portion of the involute, namely the reflection about the x-axis of the initial involute path. (This corresponds to the range $-\pi \leq \theta \leq 0$.) Referring to the figure, we see that the total grazing area is $2(A_1 + A_3)$. A_3 is one-quarter of the area of a circle of radius πr, so $A_3 = \frac{1}{4}\pi(\pi r)^2 = \frac{1}{4}\pi^3 r^2$. We will compute $A_1 + A_2$ and then subtract $A_2 = \frac{1}{2}\pi r^2$ to obtain A_1.



To find $A_1 + A_2$, first note that the rightmost point of the involute is $\left(\frac{\pi}{2}r, r\right)$. [To see this, note that $dx/d\theta = 0$ when $\theta = 0$ or $\frac{\pi}{2}$. $\theta = 0$ corresponds to the cusp at $(r, 0)$ and $\theta = \frac{\pi}{2}$ corresponds to $\left(\frac{\pi}{2}r, r\right)$.] The leftmost point of the involute is $(-r, \pi r)$. Thus, $A_1 + A_2 = \int_{\theta=\pi}^{\pi/2} y\,dx - \int_{\theta=0}^{\pi/2} y\,dx = \int_{\theta=\pi}^{0} y\,dx$.

Now $y\,dx = r(\sin\theta - \theta\cos\theta)\,r\theta\cos\theta\,d\theta = r^2(\theta\sin\theta\,\cos\theta - \theta^2\cos^2\theta)d\theta$. Integrate:

$(1/r^2)\int y\,dx = -\theta\cos^2\theta - \frac{1}{2}\left(\theta^2 - 1\right)\sin\theta\,\cos\theta - \frac{1}{6}\theta^3 + \frac{1}{2}\theta + C$. This enables us to compute

$$A_1 + A_2 = r^2\left[-\theta\cos^2\theta - \tfrac{1}{2}(\theta^2-1)\,\sin\theta\,\cos\theta - \tfrac{1}{6}\theta^3 + \tfrac{1}{2}\theta\right]_{\pi}^{0} = r^2\left[0 - \left(-\pi - \frac{\pi^3}{6} + \frac{\pi}{2}\right)\right] = r^2\left(\frac{\pi}{2} + \frac{\pi^3}{6}\right)$$

Therefore, $A_1 = (A_1 + A_2) - A_2 = \frac{1}{6}\pi^3 r^2$, so the grazing area is $2(A_1 + A_3) = 2\left(\frac{1}{6}\pi^3 r^2 + \frac{1}{4}\pi^3 r^2\right) = \frac{5}{6}\pi^3 r^2$.

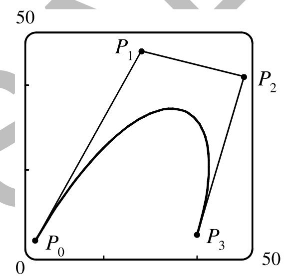
LABORATORY PROJECT Bézier Curves

1. The parametric equations for a cubic Bézier curve are

$$x = x_0(1-t)^3 + 3x_1 t(1-t)^2 + 3x_2 t^2(1-t) + x_3 t^3$$
$$y = y_0(1-t)^3 + 3y_1 t(1-t)^2 + 3y_2 t^2(1-t) + y_3 t^3$$

where $0 \le t \le 1$. We are given the points $P_0(x_0, y_0) = (4, 1)$, $P_1(x_1, y_1) = (28, 48)$, $P_2(x_2, y_2) = (50, 42)$, and $P_3(x_3, y_3) = (40, 5)$. The curve is then given by

$$x(t) = 4(1-t)^3 + 3\cdot 28t(1-t)^2 + 3\cdot 50t^2(1-t) + 40t^3$$
$$y(t) = 1(1-t)^3 + 3\cdot 48t(1-t)^2 + 3\cdot 42t^2(1-t) + 5t^3$$



where $0 \le t \le 1$. The line segments are of the form $x = x_0 + (x_1 - x_0)t$, $y = y_0 + (y_1 - y_0)t$:

P_0P_1	$x = 4 + 24t,$	$y = 1 + 47t$
P_1P_2	$x = 28 + 22t,$	$y = 48 - 6t$
P_2P_3	$x = 50 - 10t,$	$y = 42 - 37t$

2. It suffices to show that the slope of the tangent at P_0 is the same as that of line segment P_0P_1, namely $\dfrac{y_1 - y_0}{x_1 - x_0}$.

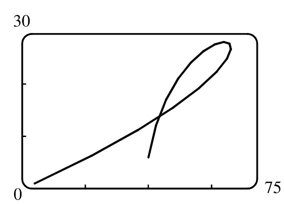
We calculate the slope of the tangent to the Bézier curve:

$$\frac{dy/dt}{dx/dt} = \frac{-3y_0(1-t)^2 + 3y_1\left[-2t(1-t) + (1-t)^2\right] + 3y_2\left[-t^2 + (2t)(1-t)\right] + 3y_3t^2}{-3x_0^2(1-t) + 3x_1[-2t(1-t) + (1-t)^2] + 3x_2[-t^2 + (2t)(1-t)] + 3x_3t^2}$$

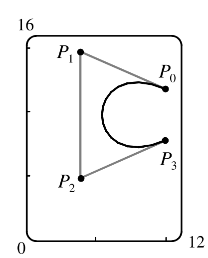
At point P_0, $t = 0$, so the slope of the tangent is $\dfrac{-3y_0 + 3y_1}{-3x_0 + 3x_1} = \dfrac{y_1 - y_0}{x_1 - x_0}$. So the tangent to the curve at P_0 passes through P_1. Similarly, the slope of the tangent at point P_3 [where $t = 1$] is $\dfrac{-3y_2 + 3y_3}{-3x_2 + 3x_3} = \dfrac{y_3 - y_2}{x_3 - x_2}$, which is also the slope of line P_2P_3.

3. It seems that if P_1 were to the right of P_2, a loop would appear.

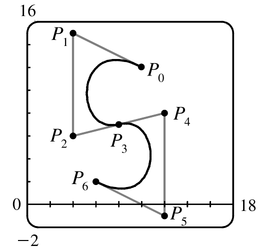
We try setting $P_1 = (110, 30)$, and the resulting curve does indeed have a loop.



4. Based on the behavior of the Bézier curve in Problems 1–3, we suspect that the four control points should be in an exaggerated C shape. We try $P_0(10, 12)$, $P_1(4, 15)$, $P_2(4, 5)$, and $P_3(10, 8)$, and these produce a decent C. If you are using a CAS, it may be necessary to instruct it to make the x- and y-scales the same so as not to distort the figure (this is called a "constrained projection" in Maple.)

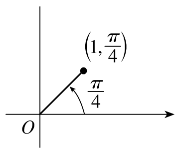


5. We use the same P_0 and P_1 as in Problem 4, and use part of our C as the top of an S. To prevent the center line from slanting up too much, we move P_2 up to $(4, 6)$ and P_3 down and to the left, to $(8, 7)$. In order to have a smooth joint between the top and bottom halves of the S (and a symmetric S), we determine points P_4, P_5, and P_6 by rotating points P_2, P_1, and P_0 about the center of the letter (point P_3). The points are therefore $P_4(12, 8)$, $P_5(12, -1)$, and $P_6(6, 2)$.



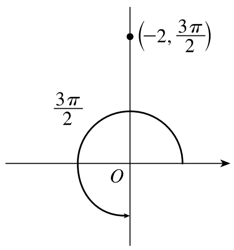
10.3 Polar Coordinates

1. (a) $\left(1, \frac{\pi}{4}\right)$



By adding 2π to $\frac{\pi}{4}$, we obtain the point $\left(1, \frac{9\pi}{4}\right)$, which satisfies the $r > 0$ requirement. The direction opposite $\frac{\pi}{4}$ is $\frac{5\pi}{4}$, so $\left(-1, \frac{5\pi}{4}\right)$ is a point that satisfies the $r < 0$ requirement.

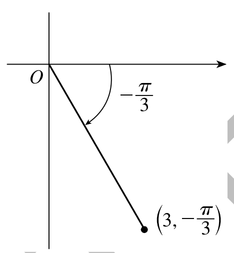
(b) $\left(-2, \frac{3\pi}{2}\right)$



$\boldsymbol{r} >$ **0:** $\left(-(-2), \frac{3\pi}{2} - \pi\right) = \left(2, \frac{\pi}{2}\right)$

$\boldsymbol{r} <$ **0:** $\left(-2, \frac{3\pi}{2} + 2\pi\right) = \left(-2, \frac{7\pi}{2}\right)$

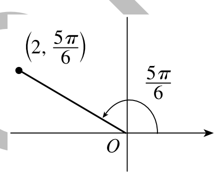
(c) $\left(3, -\frac{\pi}{3}\right)$



$\boldsymbol{r} >$ **0:** $\left(3, -\frac{\pi}{3} + 2\pi\right) = \left(3, \frac{5\pi}{3}\right)$

$\boldsymbol{r} <$ **0:** $\left(-3, -\frac{\pi}{3} + \pi\right) = \left(-3, \frac{2\pi}{3}\right)$

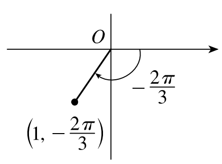
2. (a) $\left(2, \frac{5\pi}{6}\right)$



$\boldsymbol{r} >$ **0:** $\left(2, \frac{5\pi}{6} + 2\pi\right) = \left(2, \frac{17\pi}{6}\right)$

$\boldsymbol{r} <$ **0:** $\left(-2, \frac{5\pi}{6} - \pi\right) = \left(-2, -\frac{\pi}{6}\right)$

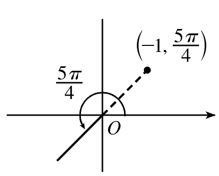
(b) $\left(1, -\frac{2\pi}{3}\right)$



$\boldsymbol{r} >$ **0:**$\left(1, -\frac{2\pi}{3} + 2\pi\right) = \left(1, \frac{4\pi}{3}\right)$

$\boldsymbol{r} <$ **0:** $\left(-1, -\frac{2\pi}{3} + \pi\right) = \left(-1, \frac{\pi}{3}\right)$

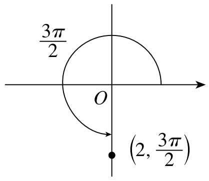
(c) $\left(-1, \frac{5\pi}{4}\right)$



$\boldsymbol{r} >$ **0:** $\left(-(-1), \frac{5\pi}{4} - \pi\right) = \left(1, \frac{\pi}{4}\right)$

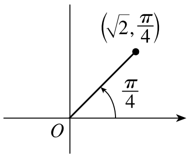
$\boldsymbol{r} <$ **0:** $\left(-1, \frac{5\pi}{4} - 2\pi\right) = \left(-1, -\frac{3\pi}{4}\right)$

3. (a)



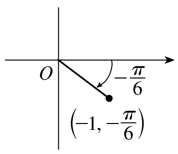
$x = 2\cos\frac{3\pi}{2} = 2(0) = 0$ and $y = 2\sin\frac{3\pi}{2} = 2(-1) = -2$ give us the Cartesian coordinates $(0, -2)$.

(b)



$x = \sqrt{2}\cos\dfrac{\pi}{4} = \sqrt{2}\left(\dfrac{1}{\sqrt{2}}\right) = 1$ and $y = \sqrt{2}\sin\dfrac{\pi}{4} = \sqrt{2}\left(\dfrac{1}{\sqrt{2}}\right) = 1$ give us the Cartesian coordinates $(1, 1)$.

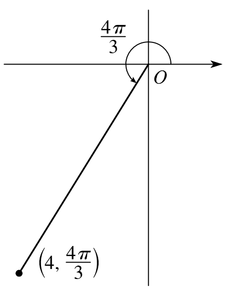
(c)



$x = -1\cos\left(-\dfrac{\pi}{6}\right) = -1\left(\dfrac{\sqrt{3}}{2}\right) = -\dfrac{\sqrt{3}}{2}$ and

$y = -1\sin\left(-\dfrac{\pi}{6}\right) = -1\left(-\dfrac{1}{2}\right) = \dfrac{1}{2}$ give us the Cartesian coordinates $\left(-\dfrac{\sqrt{3}}{2}, \dfrac{1}{2}\right)$.

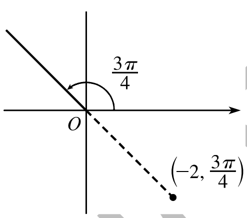
4. (a)



$x = 4\cos\dfrac{4\pi}{3} = 4\left(-\dfrac{1}{2}\right) = -2$ and

$y = 4\sin\dfrac{4\pi}{3} = 4\left(-\dfrac{\sqrt{3}}{2}\right) = -2\sqrt{3}$ give us the Cartesian coordinates $\left(-2, -2\sqrt{3}\right)$.

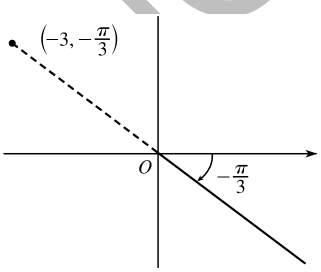
(b)



$x = -2\cos\dfrac{3\pi}{4} = -2\left(-\dfrac{\sqrt{2}}{2}\right) = \sqrt{2}$ and

$y = -2\sin\dfrac{3\pi}{4} = -2\left(\dfrac{\sqrt{2}}{2}\right) = -\sqrt{2}$ give us the Cartesian coordinates $\left(\sqrt{2}, -\sqrt{2}\right)$.

(c)



$x = -3\cos\left(-\dfrac{\pi}{3}\right) = -3\left(\dfrac{1}{2}\right) = -\dfrac{3}{2}$ and

$y = -3\sin\left(-\dfrac{\pi}{3}\right) = -3\left(-\dfrac{\sqrt{3}}{2}\right) = \dfrac{3\sqrt{3}}{2}$ give us the Cartesian coordinates $\left(-\dfrac{3}{2}, \dfrac{3\sqrt{3}}{2}\right)$.

5. (a) $x = -4$ and $y = 4 \quad \Rightarrow \quad r = \sqrt{(-4)^2 + 4^2} = 4\sqrt{2}$ and $\tan\theta = \frac{4}{-4} = -1 \quad [\theta = -\frac{\pi}{4} + n\pi]$. Since $(-4, 4)$ is in the second quadrant, the polar coordinates are (i) $\left(4\sqrt{2}, \frac{3\pi}{4}\right)$ and (ii) $\left(-4\sqrt{2}, \frac{7\pi}{4}\right)$.

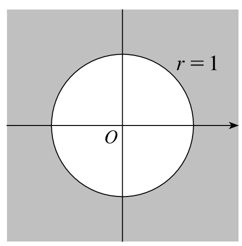
(b) $x = 3$ and $y = 3\sqrt{3} \quad \Rightarrow \quad r = \sqrt{3^2 + \left(3\sqrt{3}\right)^2} = \sqrt{9 + 27} = 6$ and $\tan\theta = \dfrac{3\sqrt{3}}{3} = \sqrt{3} \quad [\theta = \frac{\pi}{3} + n\pi]$.

Since $\left(3, 3\sqrt{3}\right)$ is in the first quadrant, the polar coordinates are (i) $\left(6, \frac{\pi}{3}\right)$ and (ii) $\left(-6, \frac{4\pi}{3}\right)$.

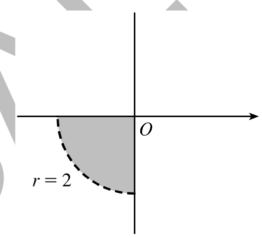
6. (a) $x = \sqrt{3}$ and $y = -1 \quad \Rightarrow \quad r = \sqrt{\left(\sqrt{3}\right)^2 + (-1)^2} = 2$ and $\tan\theta = \dfrac{-1}{\sqrt{3}} \quad [\theta = -\frac{\pi}{6} + n\pi]$. Since $\left(\sqrt{3}, -1\right)$ is in the fourth quadrant, the polar coordinates are (i) $\left(2, \frac{11\pi}{6}\right)$ and (ii) $\left(-2, \frac{5\pi}{6}\right)$.

(b) $x = -6$ and $y = 0 \quad \Rightarrow \quad r = \sqrt{(-6)^2 + 0^2} = 6$ and $\tan\theta = \frac{0}{-6} = 0 \quad [\theta = n\pi]$. Since $(-6, 0)$ is on the negative x-axis, the polar coordinates are (i) $(6, \pi)$ and (ii) $(-6, 0)$.

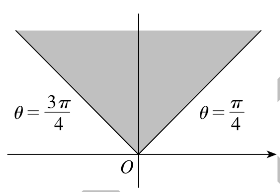
7. $r \geq 1$. The curve $r = 1$ represents a circle with center O and radius 1. So $r \geq 1$ represents the region on or outside the circle. Note that θ can take on any value.



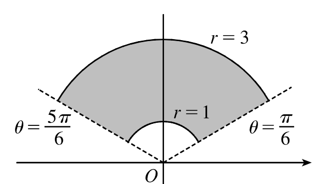
8. $0 \leq r < 2,\ \pi \leq \theta \leq 3\pi/2$. This is the region inside the circle $r = 2$ in the third quadrant.



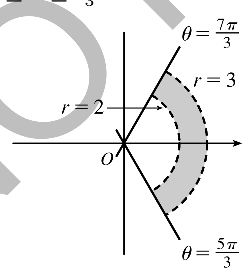
9. $r \geq 0,\ \pi/4 \leq \theta \leq 3\pi/4$.
$\theta = k$ represents a line through O.



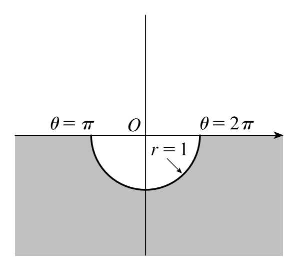
10. $1 \leq r \leq 3,\ \pi/6 < \theta < 5\pi/6$



11. $2 < r < 3,\ \frac{5\pi}{3} \leq \theta \leq \frac{7\pi}{3}$



12. $r \geq 1,\ \pi \leq \theta \leq 2\pi$



13. Converting the polar coordinates $\left(4, \frac{4\pi}{3}\right)$ and $\left(6, \frac{5\pi}{3}\right)$ to Cartesian coordinates gives us $\left(4\cos\frac{4\pi}{3}, 4\sin\frac{4\pi}{3}\right) = \left(-2, -2\sqrt{3}\right)$ and $\left(6\cos\frac{5\pi}{3}, 6\sin\frac{5\pi}{3}\right) = \left(3, -3\sqrt{3}\right)$. Now use the distance formula

$$\begin{aligned} d &= \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2} = \sqrt{[3 - (-2)]^2 + \left[-3\sqrt{3} - \left(-2\sqrt{3}\right)\right]^2} \\ &= \sqrt{5^2 + \left(-\sqrt{3}\right)^2} = \sqrt{25 + 3} = \sqrt{28} = 2\sqrt{7} \end{aligned}$$

14. The points (r_1, θ_1) and (r_2, θ_2) in Cartesian coordinates are $(r_1 \cos\theta_1, r_1 \sin\theta_1)$ and $(r_2 \cos\theta_2, r_2 \sin\theta_2)$, respectively. The *square* of the distance between them is

$$\begin{aligned}(r_2\cos\theta_2 - r_1\cos\theta_1)^2 + (r_2\sin\theta_2 - r_1\sin\theta_1)^2 \\ &= \left(r_2^2\cos^2\theta_2 - 2r_1r_2\cos\theta_1\cos\theta_2 + r_1^2\cos^2\theta_1\right) + \left(r_2^2\sin^2\theta_2 - 2r_1r_2\sin\theta_1\sin\theta_2 + r_1^2\sin^2\theta_1\right) \\ &= r_1^2\left(\sin^2\theta_1 + \cos^2\theta_1\right) + r_2^2\left(\sin^2\theta_2 + \cos^2\theta_2\right) - 2r_1r_2(\cos\theta_1\cos\theta_2 + \sin\theta_1\sin\theta_2) \\ &= r_1^2 - 2r_1r_2\cos(\theta_1 - \theta_2) + r_2^2,\end{aligned}$$

so the distance between them is $\sqrt{r_1^2 - 2r_1r_2\cos(\theta_1 - \theta_2) + r_2^2}$.

15. $r^2 = 5 \quad\Leftrightarrow\quad x^2 + y^2 = 5$, a circle of radius $\sqrt{5}$ centered at the origin.

16. $r = 4\sec\theta \quad\Leftrightarrow\quad \dfrac{r}{\sec\theta} = 4 \quad\Leftrightarrow\quad r\cos\theta = 4 \quad\Leftrightarrow\quad x = 4$, a vertical line.

17. $r = 5\cos\theta \quad\Rightarrow\quad r^2 = 5r\cos\theta \quad\Leftrightarrow\quad x^2 + y^2 = 5x \quad\Leftrightarrow\quad x^2 - 5x + \frac{25}{4} + y^2 = \frac{25}{4} \quad\Leftrightarrow\quad \left(x - \frac{5}{2}\right)^2 + y^2 = \frac{25}{4}$, a circle of radius $\frac{5}{2}$ centered at $\left(\frac{5}{2}, 0\right)$. The first two equations are actually equivalent since $r^2 = 5r\cos\theta \quad\Rightarrow$ $r(r - 5\cos\theta) = 0 \quad\Rightarrow\quad r = 0$ or $r = 5\cos\theta$. But $r = 5\cos\theta$ gives the point $r = 0$ (the pole) when $\theta = 0$. Thus, the equation $r = 5\cos\theta$ is equivalent to the compound condition ($r = 0$ or $r = 5\cos\theta$).

18. $\theta = \dfrac{\pi}{3} \quad\Rightarrow\quad \tan\theta = \tan\dfrac{\pi}{3} \quad\Rightarrow\quad \dfrac{y}{x} = \sqrt{3} \quad\Leftrightarrow\quad y = \sqrt{3}\,x$, a line through the origin.

19. $r^2\cos 2\theta = 1 \quad\Leftrightarrow\quad r^2(\cos^2\theta - \sin^2\theta) = 1 \quad\Leftrightarrow\quad (r\cos\theta)^2 - (r\sin\theta)^2 = 1 \quad\Leftrightarrow\quad x^2 - y^2 = 1$, a hyperbola centered at the origin with foci on the x-axis.

20. $r^2\sin 2\theta = 1 \quad\Leftrightarrow\quad r^2(2\sin\theta\,\cos\theta) = 1 \quad\Leftrightarrow\quad 2(r\cos\theta)(r\sin\theta) = 1 \quad\Leftrightarrow\quad 2xy = 1 \quad\Leftrightarrow\quad xy = \frac{1}{2}$, a hyperbola centered at the origin with foci on the line $y = x$.

21. $y = 2 \quad\Leftrightarrow\quad r\sin\theta = 2 \quad\Leftrightarrow\quad r = \dfrac{2}{\sin\theta} \quad\Leftrightarrow\quad r = 2\csc\theta$

22. $y = x \quad\Rightarrow\quad \dfrac{y}{x} = 1\ [x \neq 0] \quad\Rightarrow\quad \tan\theta = 1 \quad\Rightarrow\quad \theta = \tan^{-1} 1 \quad\Rightarrow\quad \theta = \dfrac{\pi}{4}$ or $\theta = \dfrac{5\pi}{4}$ [either includes the pole]

23. $y = 1 + 3x \quad\Leftrightarrow\quad r\sin\theta = 1 + 3r\cos\theta \quad\Leftrightarrow\quad r\sin\theta - 3r\cos\theta = 1 \quad\Leftrightarrow\quad r(\sin\theta - 3\cos\theta) = 1 \quad\Leftrightarrow$ $r = \dfrac{1}{\sin\theta - 3\cos\theta}$

24. $4y^2 = x \quad\Leftrightarrow\quad 4(r\sin\theta)^2 = r\cos\theta \quad\Leftrightarrow\quad 4r^2\sin^2\theta - r\cos\theta = 0 \quad\Leftrightarrow\quad r(4r\sin^2\theta - \cos\theta) = 0 \quad\Leftrightarrow\quad r = 0$ or $r = \dfrac{\cos\theta}{4\sin^2\theta} \quad\Leftrightarrow\quad r = 0$ or $r = \frac{1}{4}\cot\theta\,\csc\theta$. $r = 0$ is included in $r = \frac{1}{4}\cot\theta\,\csc\theta$ when $\theta = \frac{\pi}{2}$, so the curve is represented by the single equation $r = \frac{1}{4}\cot\theta\,\csc\theta$.

25. $x^2 + y^2 = 2cx \quad\Leftrightarrow\quad r^2 = 2cr\cos\theta \quad\Leftrightarrow\quad r^2 - 2cr\cos\theta = 0 \quad\Leftrightarrow\quad r(r - 2c\cos\theta) = 0 \quad\Leftrightarrow\quad r = 0$ or $r = 2c\cos\theta$. $r = 0$ is included in $r = 2c\cos\theta$ when $\theta = \frac{\pi}{2} + n\pi$, so the curve is represented by the single equation $r = 2c\cos\theta$.

26. $x^2 - y^2 = 4 \;\Leftrightarrow\; (r\cos\theta)^2 - (r\sin\theta)^2 = 4 \;\Leftrightarrow\; r^2\cos^2\theta - r^2\sin^2\theta = 4 \;\Leftrightarrow\; r^2(\cos^2\theta - \sin^2\theta) = 4 \;\Leftrightarrow$
$r^2\cos 2\theta = 4$

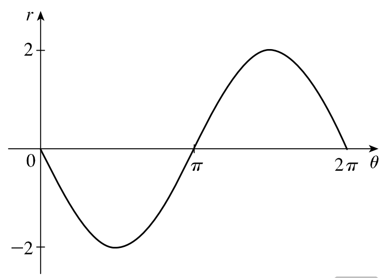
27. (a) The description leads immediately to the polar equation $\theta = \frac{\pi}{6}$, and the Cartesian equation $y = \tan\left(\frac{\pi}{6}\right)x = \frac{1}{\sqrt{3}}\,x$ is slightly more difficult to derive.

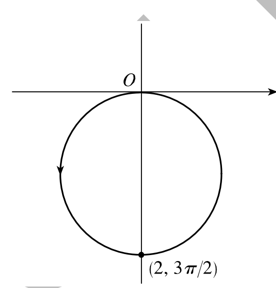
(b) The easier description here is the Cartesian equation $x = 3$.

28. (a) Because its center is not at the origin, it is more easily described by its Cartesian equation, $(x-2)^2 + (y-3)^2 = 5^2$.

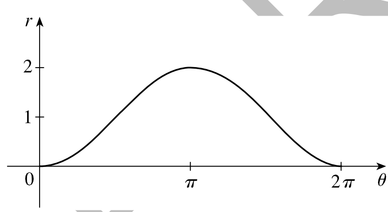
(b) This circle is more easily given in polar coordinates: $r = 4$. The Cartesian equation is also simple: $x^2 + y^2 = 16$.

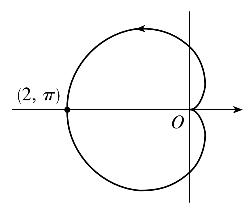
29. $r = -2\sin\theta$



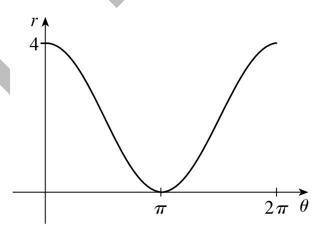


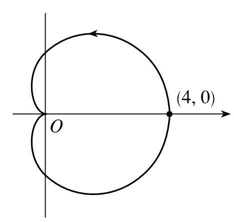
30. $r = 1 - \cos\theta$



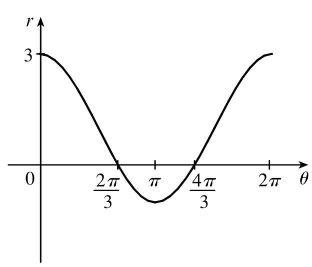


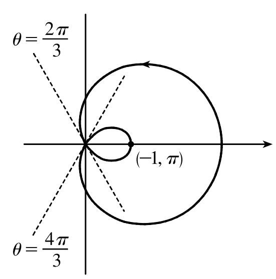
31. $r = 2(1 + \cos\theta)$



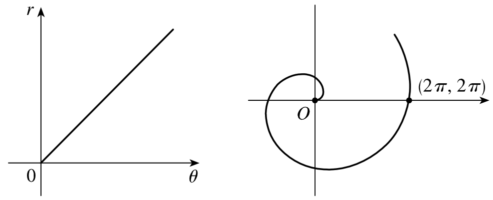


32. $r = 1 + 2\cos\theta$

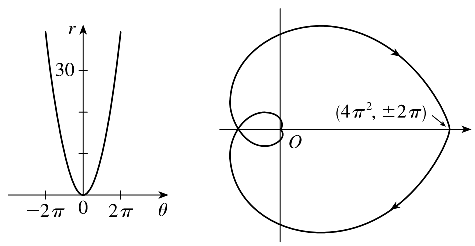




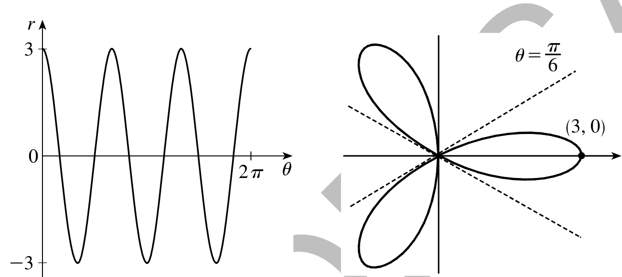
33. $r = \theta, \quad \theta \geq 0$



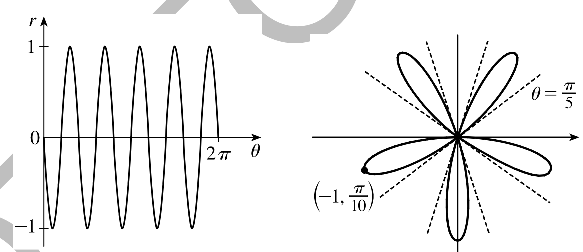
34. $r = \theta^2, \ -2\pi \leq \theta \leq 2\pi$



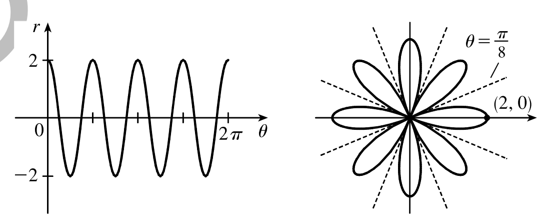
35. $r = 3\cos 3\theta$



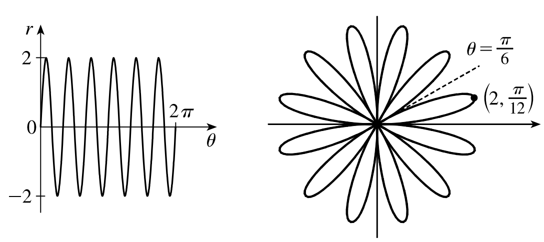
36. $r = -\sin 5\theta$



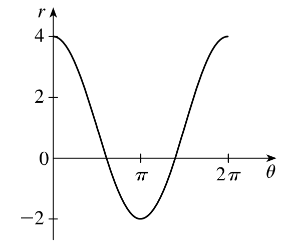
37. $r = 2\cos 4\theta$

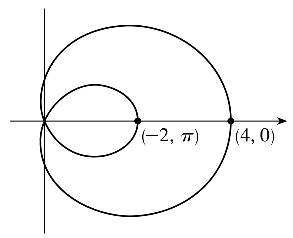


38. $r = 2\sin 6\theta$

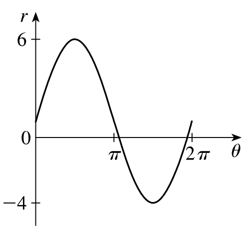


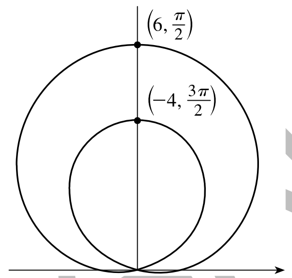
39. $r = 1 + 3\cos\theta$



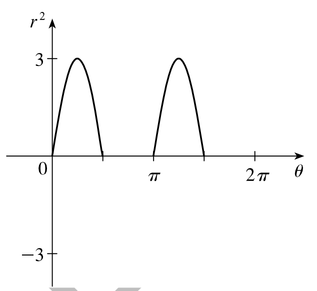


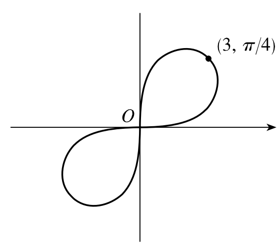
40. $r = 1 + 5\sin\theta$



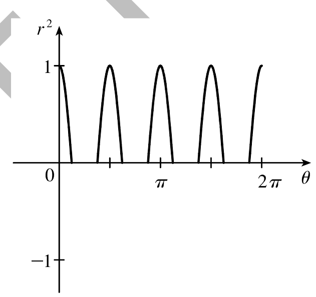


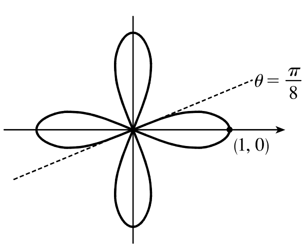
41. $r^2 = 9\sin 2\theta$



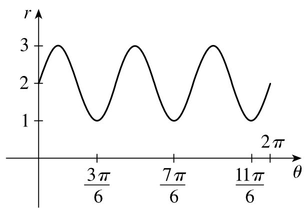


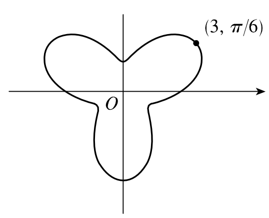
42. $r^2 = \cos 4\theta$



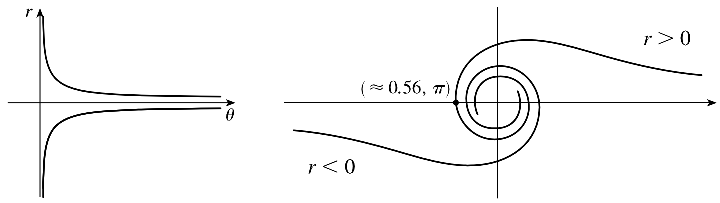


43. $r = 2 + \sin 3\theta$

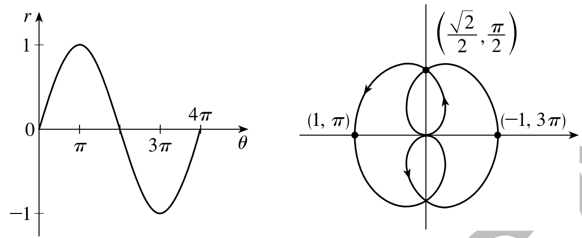




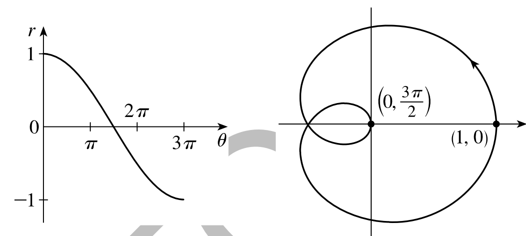
44. $r^2\theta = 1 \quad \Leftrightarrow \quad r = \pm 1/\sqrt{\theta}$ for $\theta > 0$



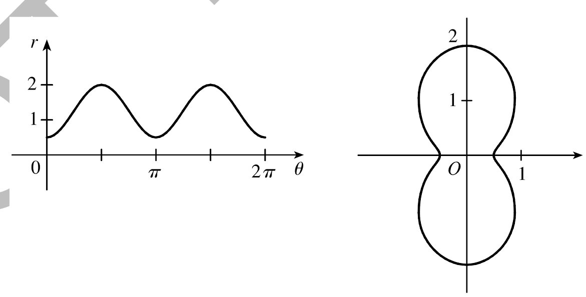
45. $r = \sin(\theta/2)$



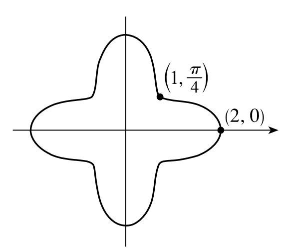
46. $r = \cos(\theta/3)$



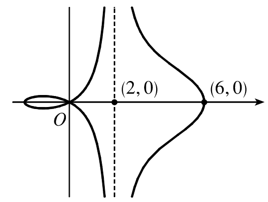
47. For $\theta = 0$, π, and 2π, r has its minimum value of about 0.5. For $\theta = \frac{\pi}{2}$ and $\frac{3\pi}{2}$, r attains its maximum value of 2. We see that the graph has a similar shape for $0 \le \theta \le \pi$ and $\pi \le \theta \le 2\pi$.



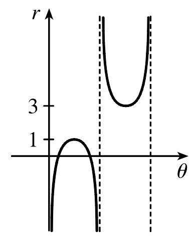
48. The given graph has a maximum of 2 for $\theta = 0$, a minimum of 1 for $\theta = \frac{\pi}{4}$, and then a maximum of 2 for $\theta = \frac{\pi}{2}$. This pattern is repeated 4 times for $0 \le \theta \le 2\pi$.

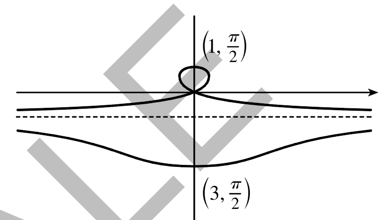


49. $x = r\cos\theta = (4 + 2\sec\theta)\cos\theta = 4\cos\theta + 2$. Now, $r \to \infty \;\Rightarrow$ $(4 + 2\sec\theta) \to \infty \;\Rightarrow\; \theta \to \left(\frac{\pi}{2}\right)^-$ or $\theta \to \left(\frac{3\pi}{2}\right)^+$ [since we need only consider $0 \le \theta < 2\pi$], so $\lim\limits_{r\to\infty} x = \lim\limits_{\theta\to\pi/2^-}(4\cos\theta + 2) = 2$. Also, $r \to -\infty \;\Rightarrow\; (4 + 2\sec\theta) \to -\infty \;\Rightarrow\; \theta \to \left(\frac{\pi}{2}\right)^+$ or $\theta \to \left(\frac{3\pi}{2}\right)^-$, so $\lim\limits_{r\to-\infty} x = \lim\limits_{\theta\to\pi/2^+}(4\cos\theta + 2) = 2$. Therefore, $\lim\limits_{r\to\pm\infty} x = 2 \;\Rightarrow\; x = 2$ is a vertical asymptote.



50. $y = r\sin\theta = 2\sin\theta - \csc\theta\sin\theta = 2\sin\theta - 1$.
$r \to \infty \;\Rightarrow\; (2 - \csc\theta) \to \infty \;\Rightarrow$ $\csc\theta \to -\infty \;\Rightarrow\; \theta \to \pi^+$ [since we need only consider $0 \le \theta < 2\pi$] and so $\lim\limits_{r\to\infty} y = \lim\limits_{\theta\to\pi^+} 2\sin\theta - 1 = -1$.



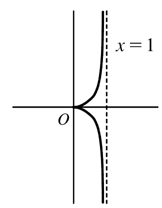


Also $r \to -\infty \;\Rightarrow\; (2 - \csc\theta) \to -\infty \;\Rightarrow\; \csc\theta \to \infty \;\Rightarrow\; \theta \to \pi^-$ and so $\lim\limits_{r\to-\infty} x = \lim\limits_{\theta\to\pi^-} 2\sin\theta - 1 = -1$.

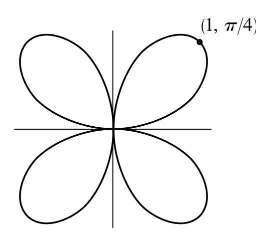
Therefore $\lim\limits_{r\to\pm\infty} y = -1 \;\Rightarrow\; y = -1$ is a horizontal asymptote.

51. To show that $x = 1$ is an asymptote we must prove $\lim\limits_{r\to\pm\infty} x = 1$.

$x = (r)\cos\theta = (\sin\theta\,\tan\theta)\cos\theta = \sin^2\theta$. Now, $r \to \infty \;\Rightarrow\; \sin\theta\,\tan\theta \to \infty \;\Rightarrow$ $\theta \to \left(\frac{\pi}{2}\right)^-$, so $\lim\limits_{r\to\infty} x = \lim\limits_{\theta\to\pi/2^-}\sin^2\theta = 1$. Also, $r \to -\infty \;\Rightarrow\; \sin\theta\,\tan\theta \to -\infty \;\Rightarrow$ $\theta \to \left(\frac{\pi}{2}\right)^+$, so $\lim\limits_{r\to-\infty} x = \lim\limits_{\theta\to\pi/2^+}\sin^2\theta = 1$. Therefore, $\lim\limits_{r\to\pm\infty} x = 1 \;\Rightarrow\; x = 1$ is a vertical asymptote. Also notice that $x = \sin^2\theta \ge 0$ for all θ, and $x = \sin^2\theta \le 1$ for all θ. And $x \ne 1$, since the curve is not defined at odd multiples of $\frac{\pi}{2}$. Therefore, the curve lies entirely within the vertical strip $0 \le x < 1$.



52. The equation is $(x^2 + y^2)^3 = 4x^2y^2$, but using polar coordinates we know that $x^2 + y^2 = r^2$ and $x = r\cos\theta$ and $y = r\sin\theta$. Substituting into the given equation: $r^6 = 4r^2\cos^2\theta\, r^2\sin^2\theta \;\Rightarrow\; r^2 = 4\cos^2\theta\,\sin^2\theta \;\Rightarrow$ $r = \pm 2\cos\theta\,\sin\theta = \pm\sin 2\theta$. $r = \pm\sin 2\theta$ is sketched at right.



53. (a) We see that the curve $r = 1 + c\sin\theta$ crosses itself at the origin, where $r = 0$ (in fact the inner loop corresponds to negative r-values,) so we solve the equation of the limaçon for $r = 0 \;\Leftrightarrow\; c\sin\theta = -1 \;\Leftrightarrow\; \sin\theta = -1/c$. Now if $|c| < 1$, then this equation has no solution and hence there is no inner loop. But if $c < -1$, then on the interval $(0, 2\pi)$ the equation has the two solutions $\theta = \sin^{-1}(-1/c)$ and $\theta = \pi - \sin^{-1}(-1/c)$, and if $c > 1$, the solutions are $\theta = \pi + \sin^{-1}(1/c)$ and $\theta = 2\pi - \sin^{-1}(1/c)$. In each case, $r < 0$ for θ between the two solutions, indicating a loop.

(b) For $0 < c < 1$, the dimple (if it exists) is characterized by the fact that y has a local maximum at $\theta = \frac{3\pi}{2}$. So we determine for what c-values $\dfrac{d^2y}{d\theta^2}$ is negative at $\theta = \frac{3\pi}{2}$, since by the Second Derivative Test this indicates a maximum:

$y = r\sin\theta = \sin\theta + c\sin^2\theta \quad\Rightarrow\quad \dfrac{dy}{d\theta} = \cos\theta + 2c\sin\theta\,\cos\theta = \cos\theta + c\sin 2\theta \quad\Rightarrow\quad \dfrac{d^2y}{d\theta^2} = -\sin\theta + 2c\cos 2\theta.$

At $\theta = \frac{3\pi}{2}$, this is equal to $-(-1) + 2c(-1) = 1 - 2c$, which is negative only for $c > \frac{1}{2}$. A similar argument shows that for $-1 < c < 0$, y only has a local minimum at $\theta = \frac{\pi}{2}$ (indicating a dimple) for $c < -\frac{1}{2}$.

54. (a) $r = \ln\theta,\ 1 \le \theta \le 6\pi$. r increases as θ increases and there are almost three full revolutions. The graph must be either III or VI. As θ increases, r grows slowly in VI and quickly in III. Since $r = \ln\theta$ grows slowly, its graph must be VI.

(b) $r = \theta^2,\ 0 \le \theta \le 8\pi$. See part (a). This is graph III.

(c) The graph of $r = \cos 3\theta$ is a three-leaved rose, which is graph II.

(d) Since $-1 \le \cos 3\theta \le 1$, $1 \le 2 + \cos 3\theta \le 3$, so $r = 2 + \cos 3\theta$ is never 0; that is, the curve never intersects the pole. The graph must be I or IV. For $0 \le \theta \le 2\pi$, the graph assumes its minimum r-value of 1 three times, at $\theta = \frac{\pi}{3}$, π, and $\frac{5\pi}{3}$, so it must be graph IV.

(e) $r = \cos(\theta/2)$. For $\theta = 0$, $r = 1$, and as θ increases to π, r decreases to 0. Only graph V satisfies those values.

(f) $r = 2 + \cos(3\theta/2)$. As in part (d), this graph never intersects the pole, so it must be graph I.

55. $r = 2\cos\theta \quad\Rightarrow\quad x = r\cos\theta = 2\cos^2\theta,\ y = r\sin\theta = 2\sin\theta\,\cos\theta = \sin 2\theta \quad\Rightarrow$

$$\frac{dy}{dx} = \frac{dy/d\theta}{dx/d\theta} = \frac{2\cos 2\theta}{2\cdot 2\cos\theta(-\sin\theta)} = \frac{\cos 2\theta}{-\sin 2\theta} = -\cot 2\theta$$

When $\theta = \dfrac{\pi}{3}$, $\dfrac{dy}{dx} = -\cot\left(2\cdot\dfrac{\pi}{3}\right) = \cot\dfrac{\pi}{3} = \dfrac{1}{\sqrt{3}}$. [*Another method:* Use Equation 3.]

56. $r = 2 + \sin 3\theta \quad\Rightarrow\quad x = r\cos\theta = (2 + \sin 3\theta)\cos\theta,\ y = r\sin\theta = (2 + \sin 3\theta)\sin\theta \quad\Rightarrow$

$$\frac{dy}{dx} = \frac{dy/d\theta}{dx/d\theta} = \frac{(2 + \sin 3\theta)\cos\theta + \sin\theta(3\cos 3\theta)}{(2 + \sin 3\theta)(-\sin\theta) + \cos\theta(3\cos 3\theta)}$$

When $\theta = \dfrac{\pi}{4}$, $\dfrac{dy}{dx} = \dfrac{\left(2 + \sin\frac{3\pi}{4}\right)\cos\frac{\pi}{4} + \sin\frac{\pi}{4}\left(3\cos\frac{3\pi}{4}\right)}{\left(2 + \sin\frac{3\pi}{4}\right)\left(-\sin\frac{\pi}{4}\right) + \cos\frac{\pi}{4}\left(3\cos\frac{3\pi}{4}\right)} = \dfrac{\left(2 + \frac{\sqrt{2}}{2}\right)\frac{\sqrt{2}}{2} + \frac{\sqrt{2}}{2}\cdot 3\left(-\frac{\sqrt{2}}{2}\right)}{\left(2 + \frac{\sqrt{2}}{2}\right)\left(-\frac{\sqrt{2}}{2}\right) + \frac{\sqrt{2}}{2}\cdot 3\left(-\frac{\sqrt{2}}{2}\right)}$

$$= \frac{\sqrt{2} + \frac{1}{2} - \frac{3}{2}}{-\sqrt{2} - \frac{1}{2} - \frac{3}{2}} = \frac{\sqrt{2} - 1}{-\sqrt{2} - 2}, \text{ or, equivalently, } 2 - \frac{3}{2}\sqrt{2}.$$

57. $r = 1/\theta \quad\Rightarrow\quad x = r\cos\theta = (\cos\theta)/\theta,\ y = r\sin\theta = (\sin\theta)/\theta \quad\Rightarrow$

$$\frac{dy}{dx} = \frac{dy/d\theta}{dx/d\theta} = \frac{\sin\theta(-1/\theta^2) + (1/\theta)\cos\theta}{\cos\theta(-1/\theta^2) - (1/\theta)\sin\theta}\cdot\frac{\theta^2}{\theta^2} = \frac{-\sin\theta + \theta\cos\theta}{-\cos\theta - \theta\sin\theta}$$

When $\theta = \pi$, $\dfrac{dy}{dx} = \dfrac{-0 + \pi(-1)}{-(-1) - \pi(0)} = \dfrac{-\pi}{1} = -\pi$.

58. $r = \cos(\theta/3) \quad\Rightarrow\quad x = r\cos\theta = \cos(\theta/3)\cos\theta,\ y = r\sin\theta = \cos(\theta/3)\sin\theta \quad\Rightarrow$

$$\frac{dy}{dx} = \frac{dy/d\theta}{dx/d\theta} = \frac{\cos(\theta/3)\cos\theta + \sin\theta\left(-\frac{1}{3}\sin(\theta/3)\right)}{\cos(\theta/3)(-\sin\theta) + \cos\theta\left(-\frac{1}{3}\sin(\theta/3)\right)}$$

When $\theta = \pi$, $\dfrac{dy}{dx} = \dfrac{\frac{1}{2}(-1) + (0)\left(-\sqrt{3}/6\right)}{\frac{1}{2}(0) + (-1)\left(-\sqrt{3}/6\right)} = \dfrac{-1/2}{\sqrt{3}/6} = -\dfrac{3}{\sqrt{3}} = -\sqrt{3}$.

59. $r = \cos 2\theta \quad\Rightarrow\quad x = r\cos\theta = \cos 2\theta\,\cos\theta,\, y = r\sin\theta = \cos 2\theta\,\sin\theta \quad\Rightarrow$

$$\frac{dy}{dx} = \frac{dy/d\theta}{dx/d\theta} = \frac{\cos 2\theta\,\cos\theta + \sin\theta\,(-2\sin 2\theta)}{\cos 2\theta\,(-\sin\theta) + \cos\theta\,(-2\sin 2\theta)}$$

When $\theta = \frac{\pi}{4}$, $\frac{dy}{dx} = \frac{0\big(\sqrt{2}/2\big) + \big(\sqrt{2}/2\big)(-2)}{0\big(-\sqrt{2}/2\big) + \big(\sqrt{2}/2\big)(-2)} = \frac{-\sqrt{2}}{-\sqrt{2}} = 1.$

60. $r = 1 + 2\cos\theta \quad\Rightarrow\quad x = r\cos\theta = (1 + 2\cos\theta)\cos\theta,\, y = r\sin\theta = (1 + 2\cos\theta)\sin\theta \quad\Rightarrow$

$$\frac{dy}{dx} = \frac{dy/d\theta}{dx/d\theta} = \frac{(1 + 2\cos\theta)\cos\theta + \sin\theta\,(-2\sin\theta)}{(1 + 2\cos\theta)(-\sin\theta) + \cos\theta\,(-2\sin\theta)}$$

When $\theta = \frac{\pi}{3}$, $\frac{dy}{dx} = \frac{2\big(\frac{1}{2}\big) + \big(\sqrt{3}/2\big)\big(-\sqrt{3}\,\big)}{2\big(-\sqrt{3}/2\big) + \frac{1}{2}\big(-\sqrt{3}\,\big)} \cdot \frac{2}{2} = \frac{2 - 3}{-2\sqrt{3} - \sqrt{3}} = \frac{-1}{-3\sqrt{3}} = \frac{\sqrt{3}}{9}.$

61. $r = 3\cos\theta \quad\Rightarrow\quad x = r\cos\theta = 3\cos\theta\,\cos\theta,\;\; y = r\sin\theta = 3\cos\theta\,\sin\theta \quad\Rightarrow$

$\frac{dy}{d\theta} = -3\sin^2\theta + 3\cos^2\theta = 3\cos 2\theta = 0 \quad\Rightarrow\quad 2\theta = \frac{\pi}{2}$ or $\frac{3\pi}{2} \quad\Leftrightarrow\quad \theta = \frac{\pi}{4}$ or $\frac{3\pi}{4}$.

So the tangent is horizontal at $\left(\frac{3}{\sqrt{2}}, \frac{\pi}{4}\right)$ and $\left(-\frac{3}{\sqrt{2}}, \frac{3\pi}{4}\right)$ $\left[\text{same as } \left(\frac{3}{\sqrt{2}}, -\frac{\pi}{4}\right)\right]$.

$\frac{dx}{d\theta} = -6\sin\theta\cos\theta = -3\sin 2\theta = 0 \quad\Rightarrow\quad 2\theta = 0$ or $\pi \quad\Leftrightarrow\quad \theta = 0$ or $\frac{\pi}{2}$. So the tangent is vertical at $(3, 0)$ and $\left(0, \frac{\pi}{2}\right)$.

62. $r = 1 - \sin\theta \quad\Rightarrow\quad x = r\cos\theta = \cos\theta\,(1 - \sin\theta),\;\; y = r\sin\theta = \sin\theta\,(1 - \sin\theta) \quad\Rightarrow$

$\frac{dy}{d\theta} = \sin\theta\,(-\cos\theta) + (1 - \sin\theta)\,\cos\theta = \cos\theta\,(1 - 2\sin\theta) = 0 \quad\Rightarrow\quad \cos\theta = 0$ or $\sin\theta = \frac{1}{2} \quad\Rightarrow$

$\theta = \frac{\pi}{6}, \frac{\pi}{2}, \frac{5\pi}{6}$, or $\frac{3\pi}{2} \quad\Rightarrow\quad$ horizontal tangent at $\left(\frac{1}{2}, \frac{\pi}{6}\right)$, $\left(\frac{1}{2}, \frac{5\pi}{6}\right)$, and $\left(2, \frac{3\pi}{2}\right)$.

$$\begin{aligned}\frac{dx}{d\theta} &= \cos\theta\,(-\cos\theta) + (1 - \sin\theta)(-\sin\theta) = -\cos^2\theta - \sin\theta + \sin^2\theta = 2\sin^2\theta - \sin\theta - 1 \\ &= (2\sin\theta + 1)(\sin\theta - 1) = 0 \quad\Rightarrow\end{aligned}$$

$\sin\theta = -\frac{1}{2}$ or $1 \quad\Rightarrow\quad \theta = \frac{7\pi}{6}, \frac{11\pi}{6}$, or $\frac{\pi}{2} \quad\Rightarrow\quad$ vertical tangent at $\left(\frac{3}{2}, \frac{7\pi}{6}\right)$, $\left(\frac{3}{2}, \frac{11\pi}{6}\right)$, and $\left(0, \frac{\pi}{2}\right)$.

Note that the tangent is vertical, not horizontal, when $\theta = \frac{\pi}{2}$, since

$$\lim_{\theta\to(\pi/2)^-} \frac{dy/d\theta}{dx/d\theta} = \lim_{\theta\to(\pi/2)^-} \frac{\cos\theta\,(1 - 2\sin\theta)}{(2\sin\theta + 1)(\sin\theta - 1)} = \infty \text{ and } \lim_{\theta\to(\pi/2)^+} \frac{dy/d\theta}{dx/d\theta} = -\infty.$$

63. $r = 1 + \cos\theta \quad\Rightarrow\quad x = r\cos\theta = \cos\theta\,(1 + \cos\theta),\;\; y = r\sin\theta = \sin\theta\,(1 + \cos\theta) \quad\Rightarrow$

$\frac{dy}{d\theta} = (1 + \cos\theta)\,\cos\theta - \sin^2\theta = 2\cos^2\theta + \cos\theta - 1 = (2\cos\theta - 1)(\cos\theta + 1) = 0 \quad\Rightarrow\quad \cos\theta = \frac{1}{2}$ or $-1 \quad\Rightarrow$

$\theta = \frac{\pi}{3}, \pi$, or $\frac{5\pi}{3} \quad\Rightarrow\quad$ horizontal tangent at $\left(\frac{3}{2}, \frac{\pi}{3}\right)$, $(0, \pi)$, and $\left(\frac{3}{2}, \frac{5\pi}{3}\right)$.

$\frac{dx}{d\theta} = -(1 + \cos\theta)\sin\theta - \cos\theta\sin\theta = -\sin\theta\,(1 + 2\cos\theta) = 0 \quad\Rightarrow\quad \sin\theta = 0$ or $\cos\theta = -\frac{1}{2} \quad\Rightarrow$

$\theta = 0, \pi, \frac{2\pi}{3}$, or $\frac{4\pi}{3} \quad\Rightarrow\quad$ vertical tangent at $(2, 0)$, $\left(\frac{1}{2}, \frac{2\pi}{3}\right)$, and $\left(\frac{1}{2}, \frac{4\pi}{3}\right)$.

Note that the tangent is horizontal, not vertical when $\theta = \pi$, since $\lim\limits_{\theta\to\pi} \frac{dy/d\theta}{dx/d\theta} = 0.$

64. $r = e^\theta \quad\Rightarrow\quad x = r\cos\theta = e^\theta\cos\theta,\;\; y = r\sin\theta = e^\theta\sin\theta \quad\Rightarrow$

$\frac{dy}{d\theta} = e^\theta\sin\theta + e^\theta\cos\theta = e^\theta(\sin\theta + \cos\theta) = 0 \quad\Rightarrow\quad \sin\theta = -\cos\theta \quad\Rightarrow\quad \tan\theta = -1 \quad\Rightarrow$

$\theta = -\frac{1}{4}\pi + n\pi$ [n any integer] $\Rightarrow$ horizontal tangents at $\left(e^{\pi(n-1/4)}, \pi\left(n - \frac{1}{4}\right)\right)$.

$\frac{dx}{d\theta} = e^\theta \cos\theta - e^\theta \sin\theta = e^\theta (\cos\theta - \sin\theta) = 0 \quad\Rightarrow\quad \sin\theta = \cos\theta \quad\Rightarrow\quad \tan\theta = 1 \quad\Rightarrow$

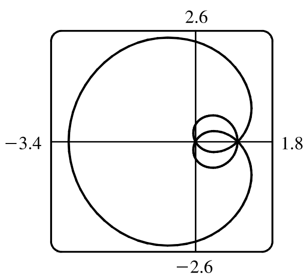
$\theta = \frac{1}{4}\pi + n\pi$ [n any integer] $\Rightarrow$ vertical tangents at $\left(e^{\pi(n+1/4)}, \pi\left(n + \frac{1}{4}\right)\right)$.

65. $r = a\sin\theta + b\cos\theta \quad\Rightarrow\quad r^2 = ar\sin\theta + br\cos\theta \quad\Rightarrow\quad x^2 + y^2 = ay + bx \quad\Rightarrow$

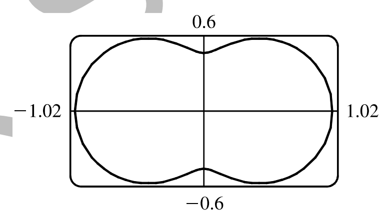
$x^2 - bx + \left(\frac{1}{2}b\right)^2 + y^2 - ay + \left(\frac{1}{2}a\right)^2 = \left(\frac{1}{2}b\right)^2 + \left(\frac{1}{2}a\right)^2 \quad\Rightarrow\quad \left(x - \frac{1}{2}b\right)^2 + \left(y - \frac{1}{2}a\right)^2 = \frac{1}{4}(a^2 + b^2)$, and this is a circle with center $\left(\frac{1}{2}b, \frac{1}{2}a\right)$ and radius $\frac{1}{2}\sqrt{a^2 + b^2}$.

66. These curves are circles which intersect at the origin and at $\left(\frac{1}{\sqrt{2}}\,a, \frac{\pi}{4}\right)$. At the origin, the first circle has a horizontal tangent and the second a vertical one, so the tangents are perpendicular here. For the first circle [$r = a\sin\theta$], $dy/d\theta = a\cos\theta\,\sin\theta + a\sin\theta\,\cos\theta = a\sin 2\theta = a$ at $\theta = \frac{\pi}{4}$ and $dx/d\theta = a\cos^2\theta - a\sin^2\theta = a\cos 2\theta = 0$ at $\theta = \frac{\pi}{4}$, so the tangent here is vertical. Similarly, for the second circle [$r = a\cos\theta$], $dy/d\theta = a\cos 2\theta = 0$ and $dx/d\theta = -a\sin 2\theta = -a$ at $\theta = \frac{\pi}{4}$, so the tangent is horizontal, and again the tangents are perpendicular.

67. $r = 1 + 2\sin(\theta/2)$. The parameter interval is $[0, 4\pi]$.

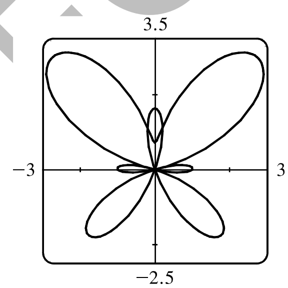


68. $r = \sqrt{1 - 0.8\sin^2\theta}$. The parameter interval is $[0, 2\pi]$.



69. $r = e^{\sin\theta} - 2\cos(4\theta)$.

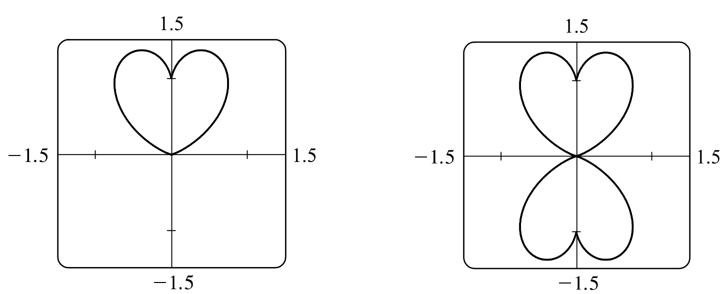
The parameter interval is $[0, 2\pi]$.



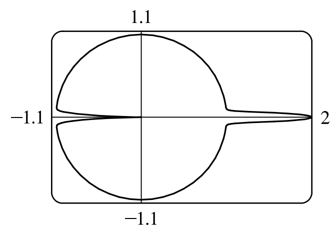
70. $r = |\tan\theta|^{|\cot\theta|}$.

The parameter interval $[0, \pi]$ produces the heart-shaped valentine curve shown in the first window.

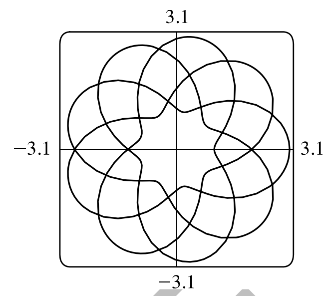
The complete curve, including the reflected heart, is produced by the parameter interval $[0, 2\pi]$, but perhaps you'll agree that the first curve is more appropriate.



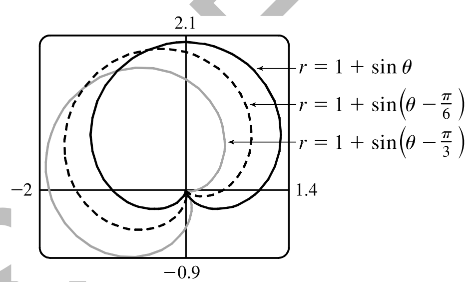
71. $r = 1 + \cos^{999}\theta$. The parameter interval is $[0, 2\pi]$.



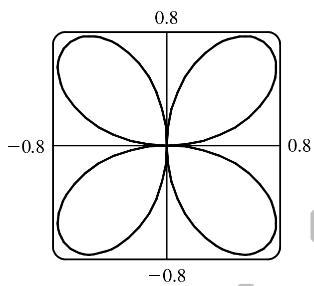
72. $r = 2 + \cos(9\theta/4)$. The parameter interval is $[0, 8\pi]$.



73. It appears that the graph of $r = 1 + \sin\left(\theta - \frac{\pi}{6}\right)$ is the same shape as the graph of $r = 1 + \sin\theta$, but rotated counterclockwise about the origin by $\frac{\pi}{6}$. Similarly, the graph of $r = 1 + \sin\left(\theta - \frac{\pi}{3}\right)$ is rotated by $\frac{\pi}{3}$. In general, the graph of $r = f(\theta - \alpha)$ is the same shape as that of $r = f(\theta)$, but rotated counterclockwise through α about the origin. That is, for any point (r_0, θ_0) on the curve $r = f(\theta)$, the point $(r_0, \theta_0 + \alpha)$ is on the curve $r = f(\theta - \alpha)$, since $r_0 = f(\theta_0) = f((\theta_0 + \alpha) - \alpha)$.



74.



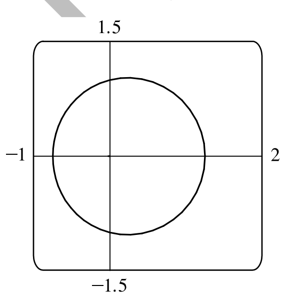
From the graph, the highest points seem to have $y \approx 0.77$. To find the exact value, we solve $dy/d\theta = 0$. $y = r\sin\theta = \sin\theta\,\sin 2\theta \Rightarrow$

$$\begin{aligned} dy/d\theta &= 2\sin\theta\,\cos 2\theta + \cos\theta\,\sin 2\theta \\ &= 2\sin\theta\,(2\cos^2\theta - 1) + \cos\theta\,(2\sin\theta\,\cos\theta) \\ &= 2\sin\theta\,(3\cos^2\theta - 1) \end{aligned}$$

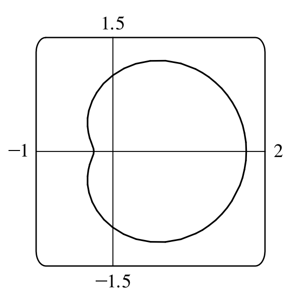
In the first quadrant, this is 0 when $\cos\theta = \frac{1}{\sqrt{3}} \Leftrightarrow \sin\theta = \sqrt{\frac{2}{3}} \Leftrightarrow$

$y = 2\sin^2\theta\cos\theta = 2 \cdot \frac{2}{3} \cdot \frac{1}{\sqrt{3}} = \frac{4}{9}\sqrt{3} \approx 0.77$.

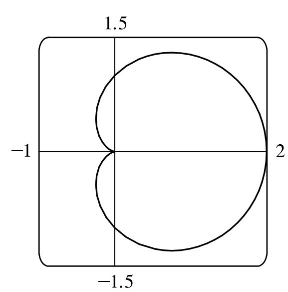
75. Consider curves with polar equation $r = 1 + c\cos\theta$, where c is a real number. If $c = 0$, we get a circle of radius 1 centered at the pole. For $0 < c \leq 0.5$, the curve gets slightly larger, moves right, and flattens out a bit on the left side. For $0.5 < c < 1$, the left side has a dimple shape. For $c = 1$, the dimple becomes a cusp. For $c > 1$, there is an internal loop. For $c \geq 0$, the rightmost point on the curve is $(1 + c, 0)$. For $c < 0$, the curves are reflections through the vertical axis of the curves with $c > 0$.



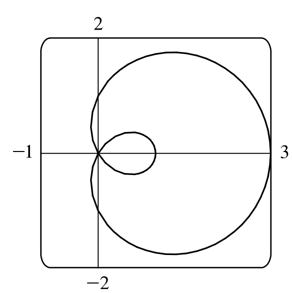
$c = 0.25$



$c = 0.75$

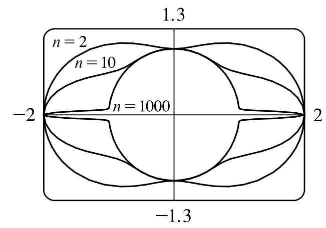


$c = 1$

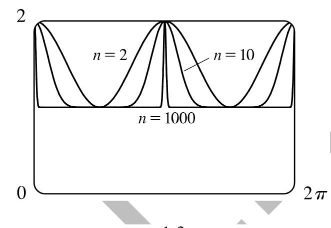


$c = 2$

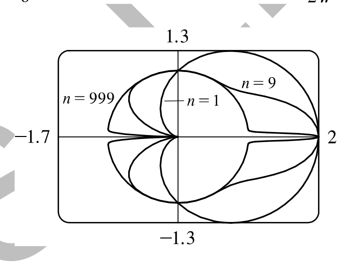
76. Consider the polar curves $r = 1 + \cos^n \theta$, where n is a positive integer. First, let $\boldsymbol{n}$ **be an even positive integer**. The first figure shows that the curve has a peanut shape for $n = 2$, but as n increases, the ends are squeezed. As n becomes large, the curves look more and more like the unit circle, but with spikes to the points $(2, 0)$ and $(2, \pi)$.



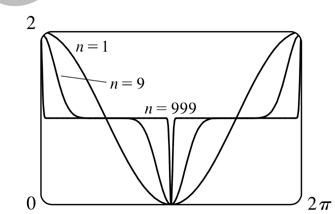
The second figure shows r as a function of θ in Cartesian coordinates for the same values of n. We can see that for large n, the graph is similar to the graph of $y = 1$, but with spikes to $y = 2$ for $x = 0$, π, and 2π. (Note that when $0 < \cos\theta < 1$, $\cos^{1000}\theta$ is very small.)



Next, let $\boldsymbol{n}$ **be an odd positive integer**. The third figure shows that the curve is a cardioid for $n = 1$, but as n increases, the heart shape becomes more pronounced. As n becomes large, the curves again look more like the unit circle, but with an outward spike to $(2, 0)$ and an inward spike to $(0, \pi)$.



The fourth figure shows r as a function of θ in Cartesian coordinates for the same values of n. We can see that for large n, the graph is similar to the graph of $y = 1$, but spikes to $y = 2$ for $x = 0$ and π, and to $y = 0$ for $x = \pi$.



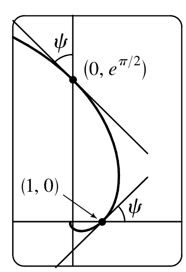
77. $\tan\psi = \tan(\phi - \theta) = \dfrac{\tan\phi - \tan\theta}{1 + \tan\phi\,\tan\theta} = \dfrac{\dfrac{dy}{dx} - \tan\theta}{1 + \dfrac{dy}{dx}\tan\theta} = \dfrac{\dfrac{dy/d\theta}{dx/d\theta} - \tan\theta}{1 + \dfrac{dy/d\theta}{dx/d\theta}\tan\theta}$

$$= \frac{\dfrac{dy}{d\theta} - \dfrac{dx}{d\theta}\tan\theta}{\dfrac{dx}{d\theta} + \dfrac{dy}{d\theta}\tan\theta} = \frac{\left(\dfrac{dr}{d\theta}\sin\theta + r\cos\theta\right) - \tan\theta\left(\dfrac{dr}{d\theta}\cos\theta - r\sin\theta\right)}{\left(\dfrac{dr}{d\theta}\cos\theta - r\sin\theta\right) + \tan\theta\left(\dfrac{dr}{d\theta}\sin\theta + r\cos\theta\right)} = \frac{r\cos\theta + r\cdot\dfrac{\sin^2\theta}{\cos\theta}}{\dfrac{dr}{d\theta}\cos\theta + \dfrac{dr}{d\theta}\cdot\dfrac{\sin^2\theta}{\cos\theta}}$$

$$= \frac{r\cos^2\theta + r\sin^2\theta}{\dfrac{dr}{d\theta}\cos^2\theta + \dfrac{dr}{d\theta}\sin^2\theta} = \frac{r}{dr/d\theta}$$

78. (a) $r = e^\theta \Rightarrow dr/d\theta = e^\theta$, so by Exercise 77, $\tan\psi = r/e^\theta = 1 \Rightarrow \psi = \arctan 1 = \frac{\pi}{4}$.

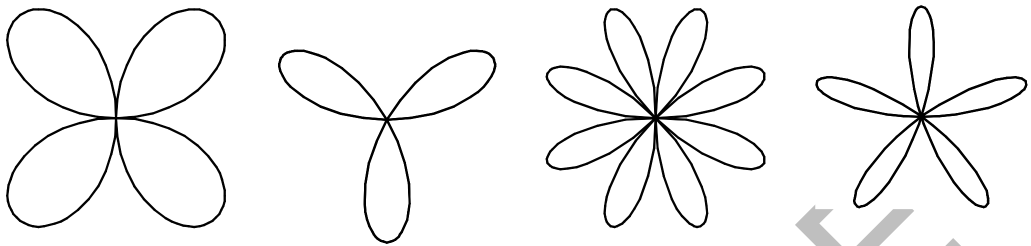
(b) The Cartesian equation of the tangent line at $(1, 0)$ is $y = x - 1$, and that of the tangent line at $(0, e^{\pi/2})$ is $y = e^{\pi/2} - x$.



(c) Let a be the tangent of the angle between the tangent and radial lines, that is, $a = \tan\psi$. Then, by Exercise 77, $a = \dfrac{r}{dr/d\theta} \Rightarrow \dfrac{dr}{d\theta} = \dfrac{1}{a}r \Rightarrow r = Ce^{\theta/a}$ (by Theorem 9.4.2).

LABORATORY PROJECT Families of Polar Curves

1. (a) $r = \sin n\theta$.

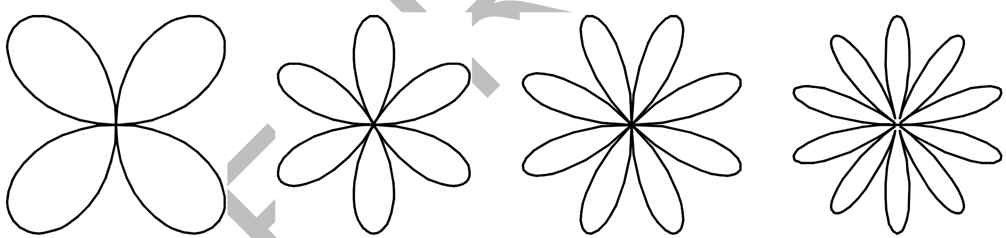


$n = 2$ $n = 3$ $n = 4$ $n = 5$

From the graphs, it seems that when n is even, the number of loops in the curve (called a rose) is $2n$, and when n is odd, the number of loops is simply n. This is because in the case of n odd, every point on the graph is traversed twice, due to the fact that

$$r(\theta + \pi) = \sin[n(\theta + \pi)] = \sin n\theta \, \cos n\pi + \cos n\theta \, \sin n\pi = \begin{cases} \sin n\theta & \text{if } n \text{ is even} \\ -\sin n\theta & \text{if } n \text{ is odd} \end{cases}$$

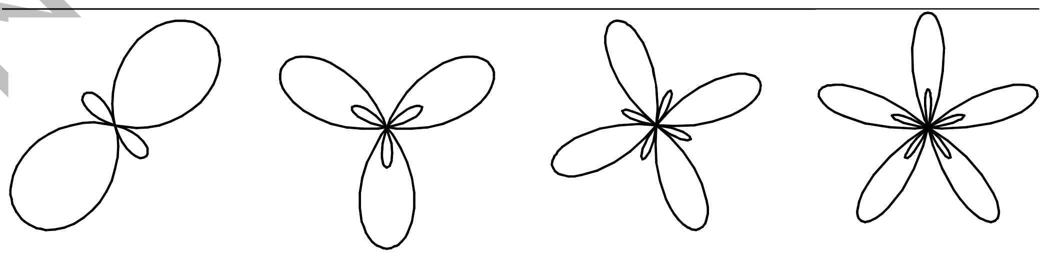
(b) The graph of $r = |\sin n\theta|$ has $2n$ loops whether n is odd or even, since $r(\theta + \pi) = r(\theta)$.



$n = 2$ $n = 3$ $n = 4$ $n = 5$

2. $r = 1 + c\sin n\theta$. We vary n while keeping c constant at 2. As n changes, the curves change in the same way as those in Exercise 1: the number of loops increases. Note that if n is even, the smaller loops are outside the larger ones; if n is odd, they are inside.

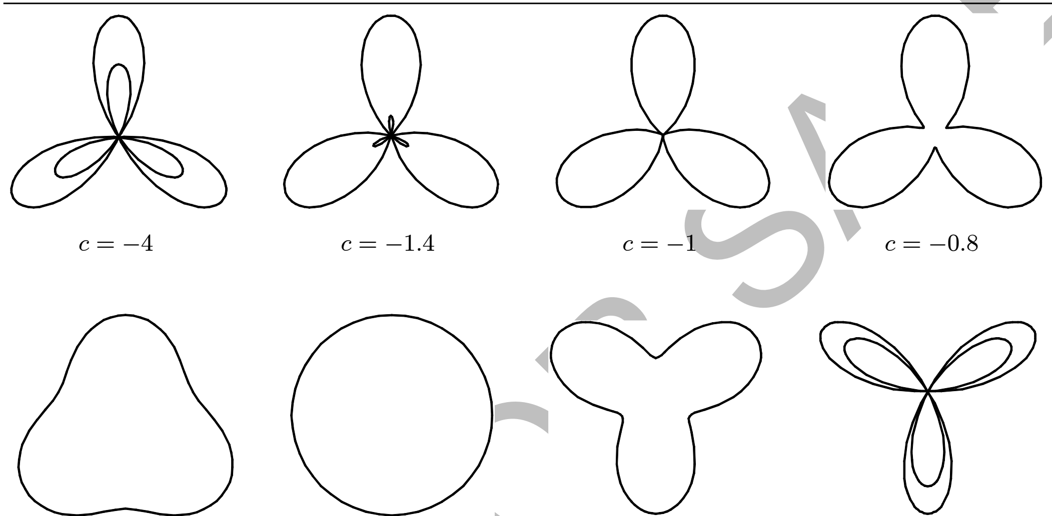
$c = 2$



$n = 2$ $n = 3$ $n = 4$ $n = 5$

Now we vary c while keeping $n = 3$. As c increases toward 0, the entire graph gets smaller (the graphs below are not to scale) and the smaller loops shrink in relation to the large ones. At $c = -1$, the small loops disappear entirely, and for $-1 < c < 1$, the graph is a simple, closed curve (at $c = 0$ it is a circle). As c continues to increase, the same changes are seen, but in reverse order, since $1 + (-c)\sin n\theta = 1 + c\sin n(\theta + \pi)$, so the graph for $c = c_0$ is the same as that for $c = -c_0$, with a rotation through π. As $c \to \infty$, the smaller loops get relatively closer in size to the large ones. Note that the distance between the outermost points of corresponding inner and outer loops is always 2. Maple's `animate` command (or Mathematica's `Animate`) is very useful for seeing the changes that occur as c varies.

$\boldsymbol{n = 3}$



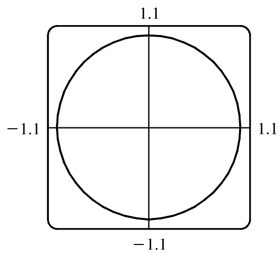
$c = -4$ $\quad c = -1.4$ $\quad c = -1$ $\quad c = -0.8$

$c = -0.2$ $\quad c = 0$ $\quad c = 0.5$ $\quad c = 8$

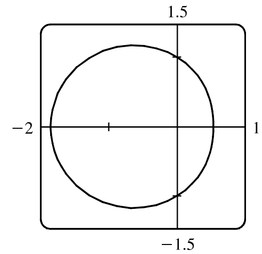
3. $r = \dfrac{1 - a\cos\theta}{1 + a\cos\theta}$. We start with $a = 0$, since in this case the curve is simply the circle $r = 1$.

As a increases, the graph moves to the left, and its right side becomes flattened. As a increases through about 0.4, the right side seems to grow a dimple, which upon closer investigation (with narrower θ-ranges) seems to appear at $a \approx 0.42$ [the actual value is $\sqrt{2} - 1$]. As $a \to 1$, this dimple becomes more pronounced, and the curve begins to stretch out horizontally, until at $a = 1$ the denominator vanishes at $\theta = \pi$, and the dimple becomes an actual cusp. For $a > 1$ we must choose our parameter interval carefully, since $r \to \infty$ as $1 + a\cos\theta \to 0 \quad \Leftrightarrow \quad \theta \to \pm\cos^{-1}(-1/a)$. As a increases from 1, the curve splits into two parts. The left part has a loop, which grows larger as a increases, and the right part grows broader vertically, and its left tip develops a dimple when $a \approx 2.42$ [actually, $\sqrt{2} + 1$]. As a increases, the dimple grows more and more pronounced. If $a < 0$, we get the same graph as we do for the corresponding positive a-value, but with a rotation through π about the pole, as happened when c was replaced with $-c$ in Exercise 2.

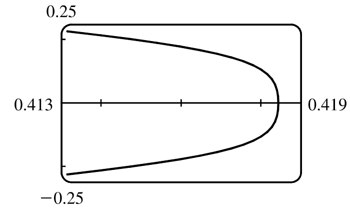
[continued]



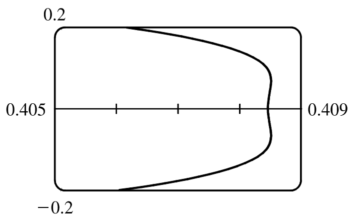
$a = 0$



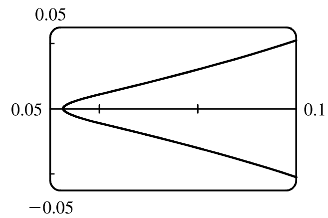
$a = 0.3$



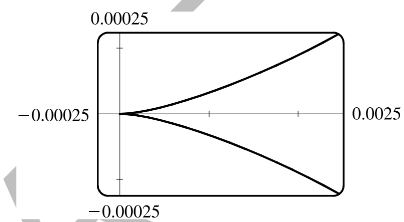
$a = 0.41, |\theta| \leq 0.5$



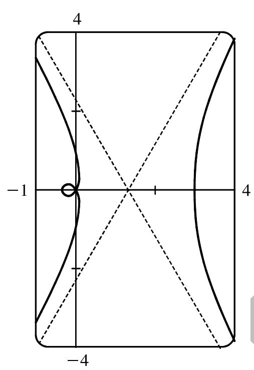
$a = 0.42, |\theta| \leq 0.5$



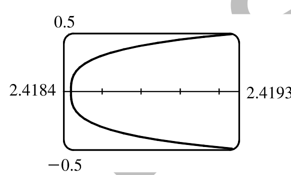
$a = 0.9, |\theta| \leq 0.5$



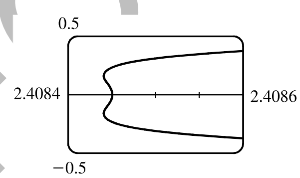
$a = 1, |\theta| \leq 0.1$



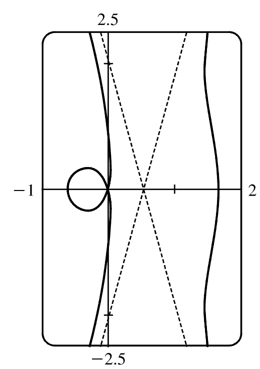
$a = 2$



$a = 2.41, |\theta - \pi| \leq 0.2$



$a = 2.42, |\theta - \pi| \leq 0.2$



$a = 4$

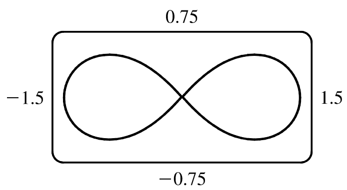
4. Most graphing devices cannot plot implicit polar equations, so we must first find an explicit expression (or expressions) for r in terms of θ, a, and c. We note that the given equation, $r^4 - 2c^2r^2\cos 2\theta + c^4 - a^4 = 0$, is a quadratic in r^2, so we use the quadratic formula and find that

$$r^2 = \frac{2c^2\cos 2\theta \pm \sqrt{4c^4\cos^2 2\theta - 4(c^4 - a^4)}}{2} = c^2\cos 2\theta \pm \sqrt{a^4 - c^4\sin^2 2\theta}$$

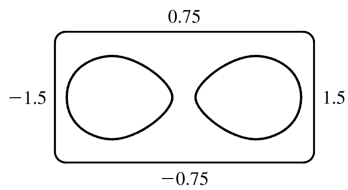
so $r = \pm\sqrt{c^2\cos 2\theta \pm \sqrt{a^4 - c^4\sin^2 2\theta}}$. So for each graph, we must plot four curves to be sure of plotting all the points which satisfy the given equation. Note that all four functions have period π.

We start with the case $a = c = 1$, and the resulting curve resembles the symbol for infinity. If we let a decrease, the curve splits into two symmetric parts, and as a decreases further, the parts become smaller, further apart, and rounder. If instead we let a increase from 1, the two lobes of the curve join together, and as a increases further they continue to merge, until at

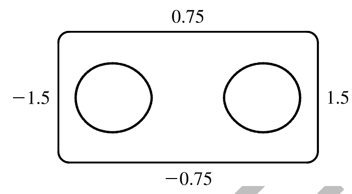
$a \approx 1.4$, the graph no longer has dimples, and has an oval shape. As $a \to \infty$, the oval becomes larger and rounder, since the c^2 and c^4 terms lose their significance. Note that the shape of the graph seems to depend only on the ratio c/a, while the size of the graph varies as c and a jointly increase.



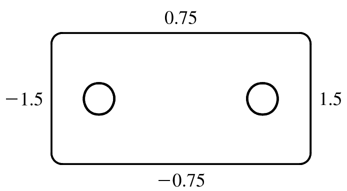
$(a, c) = (1, 1)$



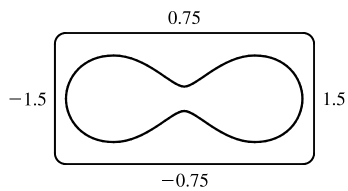
$(a, c) = (0.99, 1)$



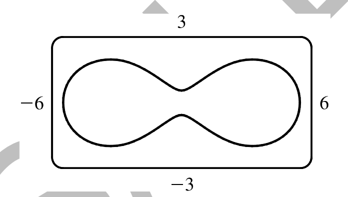
$(a, c) = (0.9, 1)$



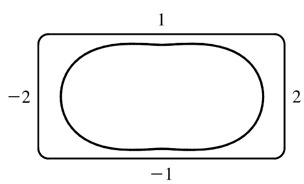
$(a, c) = (0.6, 1)$



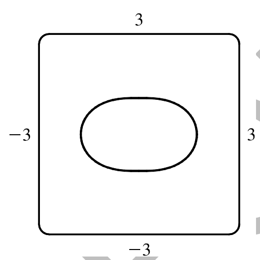
$(a, c) = (1.01, 1)$



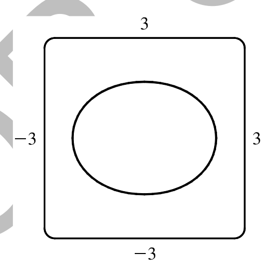
$(a, c) = (4.04, 4)$



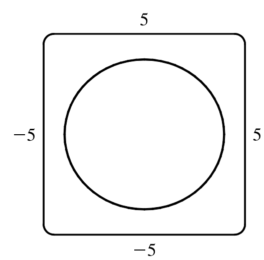
$(a, c) = (1.3, 1)$



$(a, c) = (1.5, 1)$



$(a, c) = (2, 1)$



$(a, c) = (4, 1)$

10.4 Areas and Lengths in Polar Coordinates

1. $r = e^{-\theta/4}$, $\pi/2 \le \theta \le \pi$.

$$A = \int_{\pi/2}^{\pi} \tfrac{1}{2} r^2\, d\theta = \int_{\pi/2}^{\pi} \tfrac{1}{2}(e^{-\theta/4})^2\, d\theta = \int_{\pi/2}^{\pi} \tfrac{1}{2} e^{-\theta/2}\, d\theta = \tfrac{1}{2}\Big[-2e^{-\theta/2}\Big]_{\pi/2}^{\pi} = -1(e^{-\pi/2} - e^{-\pi/4}) = e^{-\pi/4} - e^{-\pi/2}$$

2. $r = \cos\theta$, $0 \le \theta \le \pi/6$.

$$A = \int_0^{\pi/6} \tfrac{1}{2} r^2\, d\theta = \int_0^{\pi/6} \tfrac{1}{2}\cos^2\theta\, d\theta = \tfrac{1}{2}\int_0^{\pi/6} \tfrac{1}{2}(1 + \cos 2\theta)\, d\theta = \tfrac{1}{4}\big[\theta + \tfrac{1}{2}\sin 2\theta\big]_0^{\pi/6}$$
$$= \tfrac{1}{4}\big(\tfrac{\pi}{6} + \tfrac{1}{2}\cdot\tfrac{1}{2}\sqrt{3}\big) = \tfrac{\pi}{24} + \tfrac{1}{16}\sqrt{3}$$

3. $r = \sin\theta + \cos\theta$, $0 \le \theta \le \pi$.

$$A = \int_0^{\pi} \frac{1}{2} r^2\, d\theta = \int_0^{\pi} \frac{1}{2}(\sin\theta + \cos\theta)^2\, d\theta = \int_0^{\pi} \frac{1}{2}(\sin^2\theta + 2\sin\theta\,\cos\theta + \cos^2\theta)\, d\theta = \int_0^{\pi} \frac{1}{2}(1 + \sin 2\theta)\, d\theta$$
$$= \tfrac{1}{2}\Big[\theta - \tfrac{1}{2}\cos 2\theta\Big]_0^{\pi} = \tfrac{1}{2}\big[\big(\pi - \tfrac{1}{2}\big) - \big(0 - \tfrac{1}{2}\big)\big] = \tfrac{\pi}{2}$$

4. $r = 1/\theta,\ \pi/2 \le \theta \le 2\pi$.

$$A = \int_{\pi/2}^{2\pi} \frac{1}{2} r^2\, d\theta = \int_{\pi/2}^{2\pi} \frac{1}{2}\left(\frac{1}{\theta}\right)^2 d\theta = \int_{\pi/2}^{2\pi} \frac{1}{2}\theta^{-2}\, d\theta = \frac{1}{2}\left[-\frac{1}{\theta}\right]_{\pi/2}^{2\pi}$$
$$= \tfrac{1}{2}\left(-\tfrac{1}{2\pi} + \tfrac{2}{\pi}\right) = \tfrac{1}{2}\left(-\tfrac{1}{2\pi} + \tfrac{4}{2\pi}\right) = \tfrac{3}{4\pi}$$

5. $r^2 = \sin 2\theta,\ 0 \le \theta \le \pi/2$.

$$A = \int_0^{\pi/2} \tfrac{1}{2} r^2\, d\theta = \int_0^{\pi/2} \tfrac{1}{2}\sin 2\theta\, d\theta = \left[-\tfrac{1}{4}\cos 2\theta\right]_0^{\pi/2} = -\tfrac{1}{4}(\cos\pi - \cos 0) = -\tfrac{1}{4}(-1-1) = \tfrac{1}{2}$$

6. $r = 2 + \cos\theta,\ \pi/2 \le \theta \le \pi$.

$$A = \int_{\pi/2}^{\pi} \tfrac{1}{2} r^2\, d\theta = \int_{\pi/2}^{\pi} \tfrac{1}{2}(2+\cos\theta)^2\, d\theta = \int_{\pi/2}^{\pi} \tfrac{1}{2}(4 + 4\cos\theta + \cos^2\theta)\, d\theta = \int_{\pi/2}^{\pi} \tfrac{1}{2}[4 + 4\cos\theta + \tfrac{1}{2}(1+\cos 2\theta)]\, d\theta$$
$$= \int_{\pi/2}^{\pi} \left(\tfrac{9}{4} + 2\cos\theta + \tfrac{1}{4}\cos 2\theta\right) d\theta = \left[\tfrac{9}{4}\theta + 2\sin\theta + \tfrac{1}{8}\sin 2\theta\right]_{\pi/2}^{\pi} = \left(\tfrac{9\pi}{4} + 0 + 0\right) - \left(\tfrac{9\pi}{8} + 2 + 0\right) = \tfrac{9\pi}{8} - 2$$

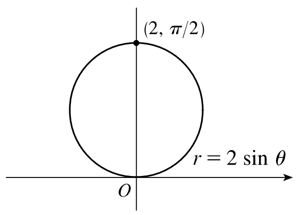
7. $r = 4 + 3\sin\theta,\ -\frac{\pi}{2} \le \theta \le \frac{\pi}{2}$.

$$A = \int_{-\pi/2}^{\pi/2} \tfrac{1}{2}((4+3\sin\theta)^2\, d\theta = \tfrac{1}{2}\int_{-\pi/2}^{\pi/2}(16 + 24\sin\theta + 9\sin^2\theta)\, d\theta$$
$$= \tfrac{1}{2}\int_{-\pi/2}^{\pi/2}(16 + 9\sin^2\theta)\, d\theta \qquad \text{[by Theorem 5.5.7(b)]}$$
$$= \tfrac{1}{2}\cdot 2\int_0^{\pi/2}\left[16 + 9\cdot\tfrac{1}{2}(1-\cos 2\theta)\right] d\theta \qquad \text{[by Theorem 5.5.7(a)]}$$
$$= \int_0^{\pi/2}\left(\tfrac{41}{2} - \tfrac{9}{2}\cos 2\theta\right) d\theta = \left[\tfrac{41}{2}\theta - \tfrac{9}{4}\sin 2\theta\right]_0^{\pi/2} = \left(\tfrac{41\pi}{4} - 0\right) - (0-0) = \tfrac{41\pi}{4}$$

8. $r = \sqrt{\ln\theta},\ 1 \le \theta \le 2\pi$.

$$A = \int_1^{2\pi} \tfrac{1}{2}\left(\sqrt{\ln\theta}\right)^2 d\theta = \int_1^{2\pi}\tfrac{1}{2}\ln\theta\, d\theta = \left[\tfrac{1}{2}\theta\ln\theta\right]_1^{2\pi} - \int_1^{2\pi}\tfrac{1}{2}\, d\theta \qquad \begin{bmatrix} u = \ln\theta, & dv = \frac{1}{2}\,d\theta \\ du = (1/\theta)\,d\theta, & v = \frac{1}{2}\theta \end{bmatrix}$$
$$= [\pi\ln(2\pi) - 0] - \left[\tfrac{1}{2}\theta\right]_1^{2\pi} = \pi\ln(2\pi) - \pi + \tfrac{1}{2}$$

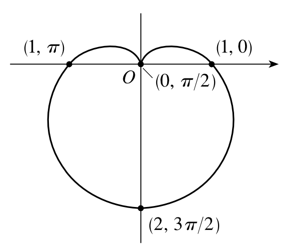
9. The area is bounded by $r = 2\sin\theta$ for $\theta = 0$ to $\theta = \pi$.



$$A = \int_0^{\pi}\tfrac{1}{2}r^2\, d\theta = \tfrac{1}{2}\int_0^{\pi}(2\sin\theta)^2\, d\theta = \tfrac{1}{2}\int_0^{\pi}4\sin^2\theta\, d\theta$$
$$= 2\int_0^{\pi}\tfrac{1}{2}(1-\cos 2\theta)d\theta = \left[\theta - \tfrac{1}{2}\sin 2\theta\right]_0^{\pi} = \pi$$

Also, note that this is a circle with radius 1, so its area is $\pi(1)^2 = \pi$.

10. $A = \int_0^{2\pi}\tfrac{1}{2}r^2\, d\theta = \int_0^{2\pi}\tfrac{1}{2}(1-\sin\theta)^2\, d\theta$



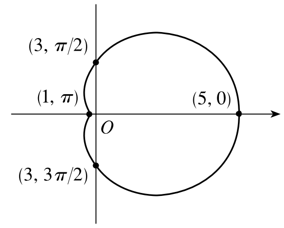
$$= \tfrac{1}{2}\int_0^{2\pi}(1 - 2\sin\theta + \sin^2\theta)\, d\theta = \tfrac{1}{2}\int_0^{2\pi}\left[1 - 2\sin\theta + \tfrac{1}{2}(1-\cos 2\theta)\right] d\theta$$
$$= \tfrac{1}{2}\int_0^{2\pi}\left(\tfrac{3}{2} - 2\sin\theta - \tfrac{1}{2}\cos 2\theta\right) d\theta = \tfrac{1}{2}\left[\tfrac{3}{2}\theta + 2\cos\theta - \tfrac{1}{4}\sin 2\theta\right]_0^{2\pi}$$
$$= \tfrac{1}{2}[(3\pi + 2) - (2)] = \tfrac{3\pi}{2}$$

11. $A = \int_0^{2\pi} \frac{1}{2} r^2 \, d\theta = \int_0^{2\pi} \frac{1}{2}(3 + 2\cos\theta)^2 \, d\theta = \frac{1}{2}\int_0^{2\pi} (9 + 12\cos\theta + 4\cos^2\theta) \, d\theta$

$= \frac{1}{2}\int_0^{2\pi} \left[9 + 12\cos\theta + 4 \cdot \frac{1}{2}(1 + \cos 2\theta)\right] d\theta$

$= \frac{1}{2}\int_0^{2\pi} (11 + 12\cos\theta + 2\cos 2\theta) \, d\theta = \frac{1}{2}\left[11\theta + 12\sin\theta + \sin 2\theta\right]_0^{2\pi}$

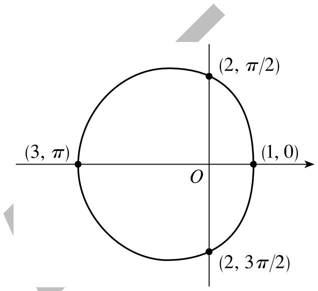
$= \frac{1}{2}(22\pi) = 11\pi$



12. $A = \int_0^{2\pi} \frac{1}{2} r^2 \, d\theta = \int_0^{2\pi} \frac{1}{2}(2 - \cos\theta)^2 \, d\theta = \int_0^{2\pi} \frac{1}{2}(4 - 4\cos\theta + \cos^2\theta) \, d\theta$

$= \int_0^{2\pi} \frac{1}{2}\left[4 - 4\cos\theta + \frac{1}{2}(1 + \cos 2\theta)\right] d\theta = \int_0^{2\pi} \left(\frac{9}{4} - 2\cos\theta + \frac{1}{4}\cos 2\theta\right) d\theta$

$= \left[\frac{9}{4}\theta - 2\sin\theta + \frac{1}{8}\sin 2\theta\right]_0^{2\pi} = \left(\frac{9\pi}{2} - 0 + 0\right) - (0 - 0 + 0) = \frac{9\pi}{2}$

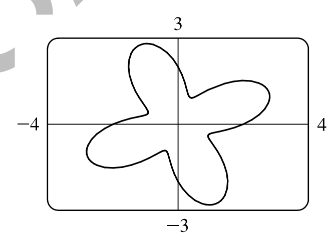


13. $A = \int_0^{2\pi} \frac{1}{2} r^2 \, d\theta = \int_0^{2\pi} \frac{1}{2}(2 + \sin 4\theta)^2 \, d\theta = \frac{1}{2}\int_0^{2\pi} (4 + 4\sin 4\theta + \sin^2 4\theta) \, d\theta$

$= \frac{1}{2}\int_0^{2\pi} \left[4 + 4\sin 4\theta + \frac{1}{2}(1 - \cos 8\theta)\right] d\theta$

$= \frac{1}{2}\int_0^{2\pi} \left(\frac{9}{2} + 4\sin 4\theta - \frac{1}{2}\cos 8\theta\right) d\theta = \frac{1}{2}\left[\frac{9}{2}\theta - \cos 4\theta - \frac{1}{16}\sin 8\theta\right]_0^{2\pi}$

$= \frac{1}{2}[(9\pi - 1) - (-1)] = \frac{9}{2}\pi$

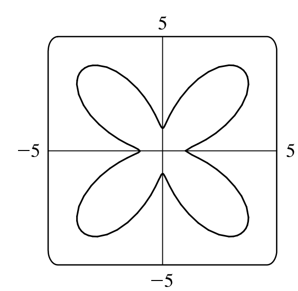


14. $A = \int_0^{2\pi} \frac{1}{2} r^2 \, d\theta = \int_0^{2\pi} \frac{1}{2}(3 - 2\cos 4\theta)^2 \, d\theta = \frac{1}{2}\int_0^{2\pi} (9 - 12\cos 4\theta + 4\cos^2 4\theta) \, d\theta$

$= \frac{1}{2}\int_0^{2\pi} \left[9 - 12\cos 4\theta + 4 \cdot \frac{1}{2}(1 + \cos 8\theta)\right] d\theta$

$= \frac{1}{2}\int_0^{2\pi} (11 - 12\cos 4\theta + 2\cos 8\theta) \, d\theta = \frac{1}{2}\left[11\theta - 3\sin 4\theta + \frac{1}{4}\sin 8\theta\right]_0^{2\pi}$

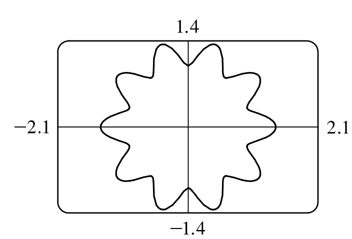
$= \frac{1}{2}(22\pi) = 11\pi$



15. $A = \int_0^{2\pi} \frac{1}{2} r^2 \, d\theta = \int_0^{2\pi} \frac{1}{2}\left(\sqrt{1 + \cos^2 5\theta}\right)^2 d\theta$

$= \frac{1}{2}\int_0^{2\pi} (1 + \cos^2 5\theta) \, d\theta = \frac{1}{2}\int_0^{2\pi} \left[1 + \frac{1}{2}(1 + \cos 10\theta)\right] d\theta$

$= \frac{1}{2}\left[\frac{3}{2}\theta + \frac{1}{20}\sin 10\theta\right]_0^{2\pi} = \frac{1}{2}(3\pi) = \frac{3}{2}\pi$



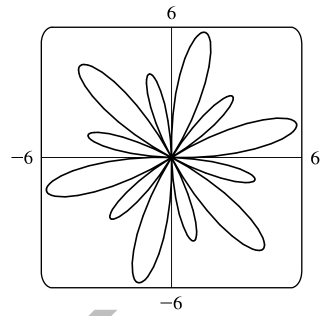
16. $A = \int_0^{2\pi} \frac{1}{2} r^2\, d\theta = \int_0^{2\pi} \frac{1}{2}(1 + 5\sin 6\theta)^2\, d\theta$

$= \frac{1}{2}\int_0^{2\pi} (1 + 10\sin 6\theta + 25\sin^2 6\theta)\, d\theta$

$= \frac{1}{2}\int_0^{2\pi} \left[1 + 10\sin 6\theta + 25 \cdot \frac{1}{2}(1 - \cos 12\theta)\right] d\theta$

$= \frac{1}{2}\int_0^{2\pi} \left[\frac{27}{2} + 10\sin 6\theta - \frac{25}{2}\cos 12\theta\right] d\theta = \frac{1}{2}\left[\frac{27}{2}\theta - \frac{5}{3}\cos 6\theta - \frac{25}{24}\sin 12\theta\right]_0^{2\pi}$

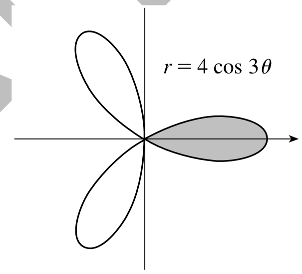
$= \frac{1}{2}\left[\left(27\pi - \frac{5}{3}\right) - \left(-\frac{5}{3}\right)\right] = \frac{27}{2}\pi$



17. The curve passes through the pole when $r = 0 \;\Rightarrow\; 4\cos 3\theta = 0 \;\Rightarrow\; \cos 3\theta = 0 \;\Rightarrow\; 3\theta = \frac{\pi}{2} + \pi n \;\Rightarrow$ $\theta = \frac{\pi}{6} + \frac{\pi}{3}n$. The part of the shaded loop above the polar axis is traced out for $\theta = 0$ to $\theta = \pi/6$, so we'll use $-\pi/6$ and $\pi/6$ as our limits of integration.

$A = \int_{-\pi/6}^{\pi/6} \frac{1}{2}(4\cos 3\theta)^2\, d\theta = 2\int_0^{\pi/6} \frac{1}{2}(16\cos^2 3\theta)\, d\theta$

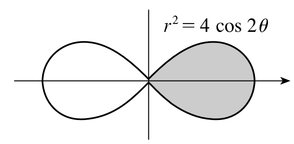
$= 16\int_0^{\pi/6} \frac{1}{2}(1 + \cos 6\theta)\, d\theta = 8\left[\theta + \frac{1}{6}\sin 6\theta\right]_0^{\pi/6} = 8\left(\frac{\pi}{6}\right) = \frac{4}{3}\pi$



18. The curve given by $r^2 = 4\cos 2\theta$ passes through the pole when $r = 0 \;\Rightarrow\; 4\cos 2\theta = 0 \;\Rightarrow\; \cos 2\theta = 0 \;\Rightarrow$ $2\theta = \frac{\pi}{2} + \pi n \;\Rightarrow\; \theta = \frac{\pi}{4} + \frac{\pi}{2}n$. The part of the shaded loop above the polar axis is traced out for $\theta = 0$ to $\theta = \pi/4$, so we'll use $-\pi/4$ to $\pi/4$ as our limits of integration.

$A = \int_{-\pi/4}^{\pi/4} \frac{1}{2}(4\cos 2\theta)\, d\theta = 2\int_0^{\pi/4} 2\cos 2\theta\, d\theta = 2\Big[\sin 2\theta\Big]_0^{\pi/4}$

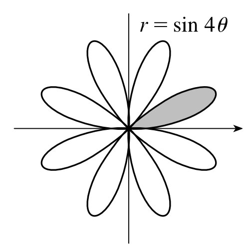
$= 2\sin\frac{\pi}{2} = 2(1) = 2$



19. $r = 0 \;\Rightarrow\; \sin 4\theta = 0 \;\Rightarrow\; 4\theta = \pi n \;\Rightarrow\; \theta = \frac{\pi}{4}n$.

$A = \int_0^{\pi/4} \frac{1}{2}(\sin 4\theta)^2\, d\theta = \frac{1}{2}\int_0^{\pi/4} \sin^2 4\theta\, d\theta = \frac{1}{2}\int_0^{\pi/4} \frac{1}{2}(1 - \cos 8\theta)\, d\theta$

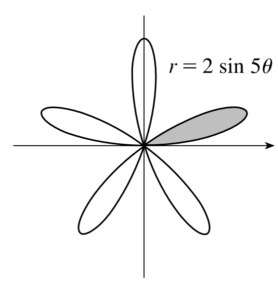
$= \frac{1}{4}\left[\theta - \frac{1}{8}\sin 8\theta\right]_0^{\pi/4} = \frac{1}{4}\left(\frac{\pi}{4}\right) = \frac{1}{16}\pi$



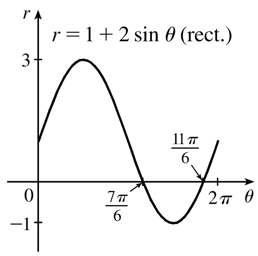
20. $r = 0 \;\Rightarrow\; 2\sin 5\theta = 0 \;\Rightarrow\; \sin 5\theta = 0 \;\Rightarrow\; 5\theta = \pi n \;\Rightarrow\; \theta = \frac{\pi}{5}n$.

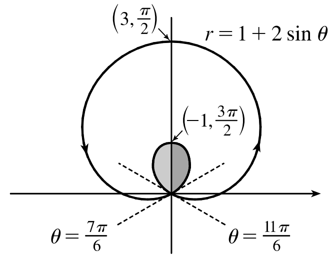
$A = \int_0^{\pi/5} \frac{1}{2}(2\sin 5\theta)^2\, d\theta = \frac{1}{2}\int_0^{\pi/5} 4\sin^2 5\theta\, d\theta$

$= 2\int_0^{\pi/5} \frac{1}{2}(1 - \cos 10\theta)\, d\theta = \left[\theta - \frac{1}{10}\sin 10\theta\right]_0^{\pi/5} = \frac{\pi}{5}$



21.





This is a limaçon, with inner loop traced out between $\theta = \frac{7\pi}{6}$ and $\frac{11\pi}{6}$ [found by solving $r = 0$].

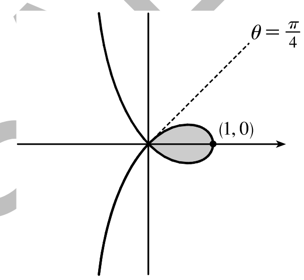
$$A = 2\int_{7\pi/6}^{3\pi/2} \tfrac{1}{2}(1 + 2\sin\theta)^2\,d\theta = \int_{7\pi/6}^{3\pi/2} \left(1 + 4\sin\theta + 4\sin^2\theta\right)d\theta = \int_{7\pi/6}^{3\pi/2} \left[1 + 4\sin\theta + 4\cdot\tfrac{1}{2}(1 - \cos 2\theta)\right]d\theta$$

$$= \Big[\theta - 4\cos\theta + 2\theta - \sin 2\theta\Big]_{7\pi/6}^{3\pi/2} = \left(\tfrac{9\pi}{2}\right) - \left(\tfrac{7\pi}{2} + 2\sqrt{3} - \tfrac{\sqrt{3}}{2}\right) = \pi - \tfrac{3\sqrt{3}}{2}$$

22. To determine when the strophoid $r = 2\cos\theta - \sec\theta$ passes through the pole, we solve

$r = 0 \;\Rightarrow\; 2\cos\theta - \dfrac{1}{\cos\theta} = 0 \;\Rightarrow\; 2\cos^2\theta - 1 = 0 \;\Rightarrow\; \cos^2\theta = \dfrac{1}{2} \;\Rightarrow$

$\cos\theta = \pm\dfrac{1}{\sqrt{2}} \;\Rightarrow\; \theta = \frac{\pi}{4}$ or $\theta = \frac{3\pi}{4}$ for $0 \le \theta \le \pi$ with $\theta \ne \frac{\pi}{2}$.



$$A = 2\int_0^{\pi/4} \tfrac{1}{2}(2\cos\theta - \sec\theta)^2\,d\theta = \int_0^{\pi/4} (4\cos^2\theta - 4 + \sec^2\theta)\,d\theta$$

$$= \int_0^{\pi/4} \left[4\cdot\tfrac{1}{2}(1 + \cos 2\theta) - 4 + \sec^2\theta\right]d\theta = \int_0^{\pi/4} (-2 + 2\cos 2\theta + \sec^2\theta)\,d\theta$$

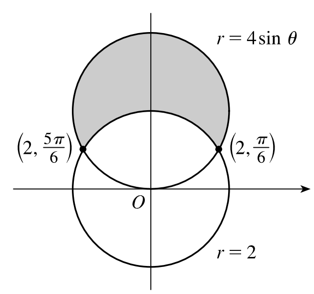
$$= \big[-2\theta + \sin 2\theta + \tan\theta\big]_0^{\pi/4} = \left(-\tfrac{\pi}{2} + 1 + 1\right) - 0 = 2 - \tfrac{\pi}{2}$$

23. $4\sin\theta = 2 \;\Rightarrow\; \sin\theta = \frac{1}{2} \;\Rightarrow\; \theta = \frac{\pi}{6}$ or $\frac{5\pi}{6} \;\Rightarrow$

$$A = \int_{\pi/6}^{5\pi/6} \tfrac{1}{2}[(4\sin\theta)^2 - 2^2]\,d\theta = 2\int_{\pi/6}^{\pi/2} \tfrac{1}{2}(16\sin^2\theta - 4)\,d\theta$$

$$= \int_{\pi/6}^{\pi/2} \left[16\cdot\tfrac{1}{2}(1 - \cos 2\theta) - 4\right]d\theta = \int_{\pi/6}^{\pi/2} (4 - 8\cos 2\theta)\,d\theta$$

$$= \Big[4\theta - 4\sin 2\theta\Big]_{\pi/6}^{\pi/2} = (2\pi - 0) - \left(\tfrac{2\pi}{3} - 2\sqrt{3}\right) = \tfrac{4\pi}{3} + 2\sqrt{3}$$

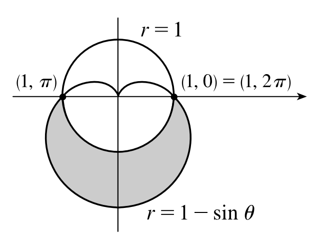


24. $1 - \sin\theta = 1 \;\Rightarrow\; \sin\theta = 0 \;\Rightarrow\; \theta = 0$ or $\pi \;\Rightarrow$

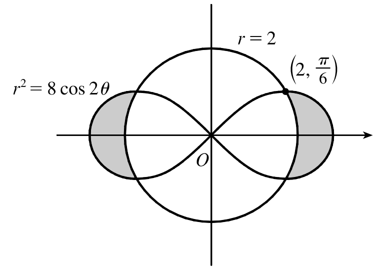
$$A = \int_\pi^{2\pi} \tfrac{1}{2}\left[(1 - \sin\theta)^2 - 1\right]d\theta = \tfrac{1}{2}\int_\pi^{2\pi} (\sin^2\theta - 2\sin\theta)\,d\theta$$

$$= \tfrac{1}{4}\int_\pi^{2\pi} (1 - \cos 2\theta - 4\sin\theta)\,d\theta = \tfrac{1}{4}\Big[\theta - \tfrac{1}{2}\sin 2\theta + 4\cos\theta\Big]_\pi^{2\pi}$$

$$= \tfrac{1}{4}\pi + 2$$

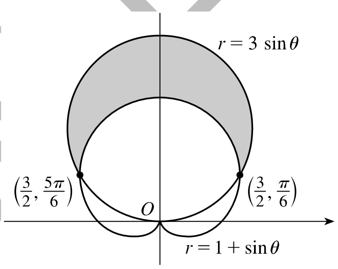


25. To find the area inside the leminiscate $r^2 = 8\cos 2\theta$ and outside the circle $r = 2$, we first note that the two curves intersect when $r^2 = 8\cos 2\theta$ and $r = 2$, that is, when $\cos 2\theta = \frac{1}{2}$. For $-\pi < \theta \le \pi$, $\cos 2\theta = \frac{1}{2} \Leftrightarrow 2\theta = \pm\pi/3$ or $\pm 5\pi/3 \Leftrightarrow \theta = \pm\pi/6$ or $\pm 5\pi/6$. The figure shows that the desired area is 4 times the area between the curves from 0 to $\pi/6$. Thus,



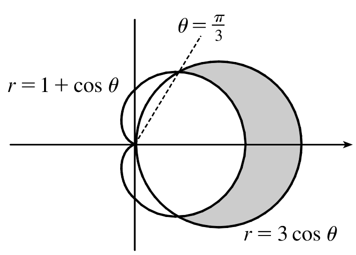
$$A = 4\int_0^{\pi/6}\left[\tfrac{1}{2}(8\cos 2\theta) - \tfrac{1}{2}(2)^2\right]d\theta = 8\int_0^{\pi/6}(2\cos 2\theta - 1)\,d\theta$$
$$= 8\left[\sin 2\theta - \theta\right]_0^{\pi/6} = 8\left(\sqrt{3}/2 - \pi/6\right) = 4\sqrt{3} - 4\pi/3$$

26. $3\sin\theta = 1 + \sin\theta \Rightarrow \sin\theta = \frac{1}{2} \Rightarrow \theta = \frac{\pi}{6}$ or $\frac{5\pi}{6} \Rightarrow$



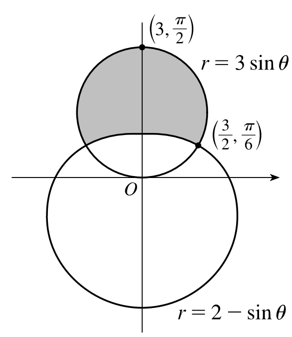
$$A = \int_{\pi/6}^{5\pi/6} \tfrac{1}{2}[(3\sin\theta)^2 - (1+\sin\theta)^2]\,d\theta$$
$$= 2\int_{\pi/6}^{\pi/2} \tfrac{1}{2}(9\sin^2\theta - 1 - 2\sin\theta - \sin^2\theta)\,d\theta$$
$$= \int_{\pi/6}^{\pi/2} (8\sin^2\theta - 1 - 2\sin\theta)\,d\theta$$
$$= \int_{\pi/6}^{\pi/2} \left[8\cdot\tfrac{1}{2}(1-\cos 2\theta) - 1 - 2\sin\theta\right]d\theta = \int_{\pi/6}^{\pi/2}(3 - 4\cos 2\theta - 2\sin\theta)\,d\theta$$
$$= \left[3\theta - 2\sin 2\theta + 2\cos\theta\right]_{\pi/6}^{\pi/2} = \left(\tfrac{3\pi}{2} - 0 + 0\right) - \left(\tfrac{\pi}{2} - \sqrt{3} + \sqrt{3}\right) = \pi$$

27. $3\cos\theta = 1 + \cos\theta \Leftrightarrow \cos\theta = \frac{1}{2} \Rightarrow \theta = \frac{\pi}{3}$ or $-\frac{\pi}{3}$.



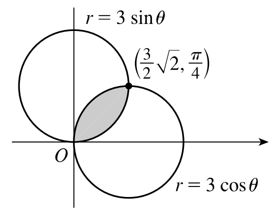
$$A = 2\int_0^{\pi/3}\tfrac{1}{2}[(3\cos\theta)^2 - (1+\cos\theta)^2]\,d\theta$$
$$= \int_0^{\pi/3}(8\cos^2\theta - 2\cos\theta - 1)\,d\theta = \int_0^{\pi/3}[4(1+\cos 2\theta) - 2\cos\theta - 1]\,d\theta$$
$$= \int_0^{\pi/3}(3 + 4\cos 2\theta - 2\cos\theta)\,d\theta = \left[3\theta + 2\sin 2\theta - 2\sin\theta\right]_0^{\pi/3}$$
$$= \pi + \sqrt{3} - \sqrt{3} = \pi$$

28. $3\sin\theta = 2 - \sin\theta \Rightarrow 4\sin\theta = 2 \Rightarrow \sin\theta = \frac{1}{2} \Rightarrow \theta = \frac{\pi}{6}$ or $\frac{5\pi}{6}$.



$$A = 2\int_{\pi/6}^{\pi/2}\tfrac{1}{2}[(3\sin\theta)^2 - (2-\sin\theta)^2]\,d\theta$$
$$= \int_{\pi/6}^{\pi/2}(9\sin^2\theta - 4 + 4\sin\theta - \sin^2\theta]\,d\theta$$
$$= \int_{\pi/6}^{\pi/2}(8\sin^2\theta + 4\sin\theta - 4)\,d\theta$$
$$= 4\int_{\pi/6}^{\pi/2}\left[2\cdot\tfrac{1}{2}(1-\cos 2\theta) + \sin\theta - 1\right]d\theta$$
$$= 4\int_{\pi/6}^{\pi/2}(\sin\theta - \cos 2\theta)\,d\theta = 4\left[-\cos\theta - \tfrac{1}{2}\sin 2\theta\right]_{\pi/6}^{\pi/2}$$
$$= 4\left[(0-0) - \left(-\tfrac{\sqrt{3}}{2} - \tfrac{\sqrt{3}}{4}\right)\right] = 4\left(\tfrac{3\sqrt{3}}{4}\right) = 3\sqrt{3}$$

29. $3\sin\theta = 3\cos\theta \;\Rightarrow\; \dfrac{3\sin\theta}{3\cos\theta} = 1 \;\Rightarrow\; \tan\theta = 1 \;\Rightarrow\; \theta = \frac{\pi}{4} \;\Rightarrow$



$$A = 2\int_0^{\pi/4} \tfrac{1}{2}(3\sin\theta)^2\,d\theta = \int_0^{\pi/4} 9\sin^2\theta\,d\theta = \int_0^{\pi/4} 9\cdot\tfrac{1}{2}(1-\cos 2\theta)\,d\theta$$

$$= \int_0^{\pi/4}\left(\tfrac{9}{2} - \tfrac{9}{2}\cos 2\theta\right)d\theta = \left[\tfrac{9}{2}\theta - \tfrac{9}{4}\sin 2\theta\right]_0^{\pi/4} = \left(\tfrac{9\pi}{8} - \tfrac{9}{4}\right) - (0-0)$$

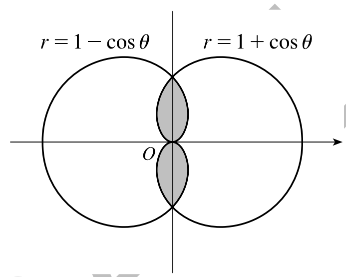
$$= \tfrac{9\pi}{8} - \tfrac{9}{4}$$

30. $A = 4\int_0^{\pi/2}\frac{1}{2}(1-\cos\theta)^2\,d\theta = 2\int_0^{\pi/2}(1 - 2\cos\theta + \cos^2\theta)\,d\theta$

$$= 2\int_0^{\pi/2}\left[1 - 2\cos\theta + \tfrac{1}{2}(1+\cos 2\theta)\right]d\theta$$

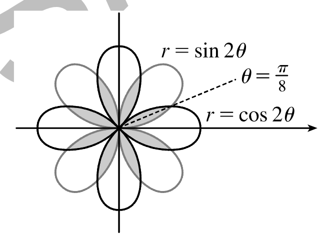
$$= 2\int_0^{\pi/2}\left(\tfrac{3}{2} - 2\cos\theta + \tfrac{1}{2}\cos 2\theta\right)d\theta = \int_0^{\pi/2}(3 - 4\cos\theta + \cos 2\theta)\,d\theta$$

$$= \left[3\theta - 4\sin\theta + \tfrac{1}{2}\sin 2\theta\right]_0^{\pi/2} = \tfrac{3\pi}{2} - 4$$



31. $\sin 2\theta = \cos 2\theta \;\Rightarrow\; \dfrac{\sin 2\theta}{\cos 2\theta} = 1 \;\Rightarrow\; \tan 2\theta = 1 \;\Rightarrow\; 2\theta = \frac{\pi}{4} \;\Rightarrow$

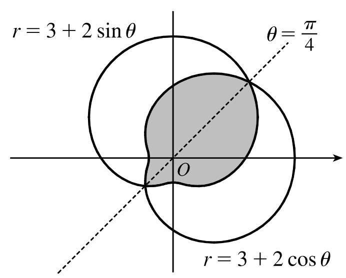
$\theta = \frac{\pi}{8} \;\Rightarrow$



$$A = 8\cdot 2\int_0^{\pi/8}\tfrac{1}{2}\sin^2 2\theta\,d\theta = 8\int_0^{\pi/8}\tfrac{1}{2}(1-\cos 4\theta)\,d\theta$$

$$= 4\left[\theta - \tfrac{1}{4}\sin 4\theta\right]_0^{\pi/8} = 4\left(\tfrac{\pi}{8} - \tfrac{1}{4}\cdot 1\right) = \tfrac{\pi}{2} - 1$$

32. $3 + 2\cos\theta = 3 + 2\sin\theta \;\Rightarrow\; \cos\theta = \sin\theta \;\Rightarrow\; \theta = \frac{\pi}{4}$ or $\frac{5\pi}{4}$.



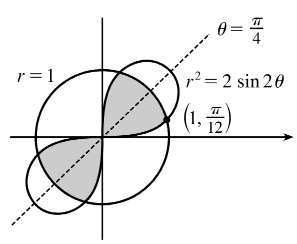
$$A = 2\int_{\pi/4}^{5\pi/4}\tfrac{1}{2}(3+2\cos\theta)^2\,d\theta = \int_{\pi/4}^{5\pi/4}(9 + 12\cos\theta + 4\cos^2\theta)\,d\theta$$

$$= \int_{\pi/4}^{5\pi/4}\left[9 + 12\cos\theta + 4\cdot\tfrac{1}{2}(1+\cos 2\theta)\right]d\theta$$

$$= \int_{\pi/4}^{5\pi/4}(11 + 12\cos\theta + 2\cos 2\theta)\,d\theta = \left[11\theta + 12\sin\theta + \sin 2\theta\right]_{\pi/4}^{5\pi/4}$$

$$= \left(\tfrac{55\pi}{4} - 6\sqrt{2} + 1\right) - \left(\tfrac{11\pi}{4} + 6\sqrt{2} + 1\right) = 11\pi - 12\sqrt{2}$$

33. From the figure, we see that the shaded region is 4 times the shaded region from $\theta = 0$ to $\theta = \pi/4$. $r^2 = 2\sin 2\theta$ and $r = 1 \;\Rightarrow$ $2\sin 2\theta = 1^2 \;\Rightarrow\; \sin 2\theta = \frac{1}{2} \;\Rightarrow\; 2\theta = \frac{\pi}{6} \;\Rightarrow\; \theta = \frac{\pi}{12}$.

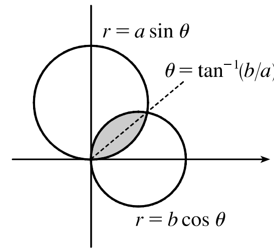


$$A = 4\int_0^{\pi/12}\tfrac{1}{2}(2\sin 2\theta)\,d\theta + 4\int_{\pi/12}^{\pi/4}\tfrac{1}{2}(1)^2\,d\theta$$

$$= \int_0^{\pi/12} 4\sin 2\theta\,d\theta + \int_{\pi/12}^{\pi/4} 2\,d\theta = \Big[-2\cos 2\theta\Big]_0^{\pi/12} + \Big[2\theta\Big]_{\pi/12}^{\pi/4}$$

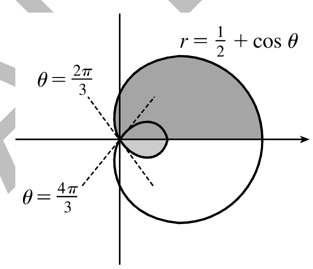
$$= \left(-\sqrt{3} + 2\right) + \left(\tfrac{\pi}{2} - \tfrac{\pi}{6}\right) = -\sqrt{3} + 2 + \tfrac{\pi}{3}$$

34. Let $\alpha = \tan^{-1}(b/a)$. Then



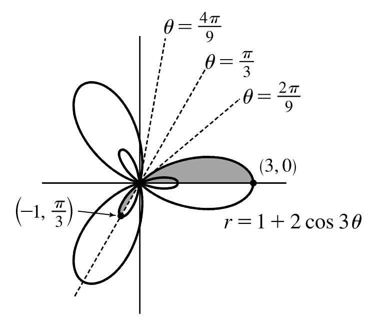
$$\begin{aligned} A &= \int_0^\alpha \tfrac{1}{2}(a\sin\theta)^2\,d\theta + \int_\alpha^{\pi/2} \tfrac{1}{2}(b\cos\theta)^2\,d\theta \\ &= \tfrac{1}{4}a^2\left[\theta - \tfrac{1}{2}\sin 2\theta\right]_0^\alpha + \tfrac{1}{4}b^2\left[\theta + \tfrac{1}{2}\sin 2\theta\right]_\alpha^{\pi/2} \\ &= \tfrac{1}{4}\alpha(a^2-b^2) + \tfrac{1}{8}\pi b^2 - \tfrac{1}{4}(a^2+b^2)(\sin\alpha\,\cos\alpha) \\ &= \tfrac{1}{4}(a^2-b^2)\,\tan^{-1}(b/a) + \tfrac{1}{8}\pi b^2 - \tfrac{1}{4}ab \end{aligned}$$

35. The darker shaded region (from $\theta = 0$ to $\theta = 2\pi/3$) represents $\frac{1}{2}$ of the desired area plus $\frac{1}{2}$ of the area of the inner loop. From this area, we'll subtract $\frac{1}{2}$ of the area of the inner loop (the lighter shaded region from $\theta = 2\pi/3$ to $\theta = \pi$), and then double that difference to obtain the desired area.



$$\begin{aligned} A &= 2\left[\int_0^{2\pi/3} \tfrac{1}{2}\left(\tfrac{1}{2}+\cos\theta\right)^2\,d\theta - \int_{2\pi/3}^{\pi} \tfrac{1}{2}\left(\tfrac{1}{2}+\cos\theta\right)^2\,d\theta\right] \\ &= \int_0^{2\pi/3}\left(\tfrac{1}{4}+\cos\theta+\cos^2\theta\right)d\theta - \int_{2\pi/3}^{\pi}\left(\tfrac{1}{4}+\cos\theta+\cos^2\theta\right)d\theta \\ &= \int_0^{2\pi/3}\left[\tfrac{1}{4}+\cos\theta+\tfrac{1}{2}(1+\cos 2\theta)\right]d\theta \\ &\qquad - \int_{2\pi/3}^{\pi}\left[\tfrac{1}{4}+\cos\theta+\tfrac{1}{2}(1+\cos 2\theta)\right]d\theta \\ &= \left[\frac{\theta}{4}+\sin\theta+\frac{\theta}{2}+\frac{\sin 2\theta}{4}\right]_0^{2\pi/3} - \left[\frac{\theta}{4}+\sin\theta+\frac{\theta}{2}+\frac{\sin 2\theta}{4}\right]_{2\pi/3}^{\pi} \\ &= \left(\tfrac{\pi}{6}+\tfrac{\sqrt{3}}{2}+\tfrac{\pi}{3}-\tfrac{\sqrt{3}}{8}\right) - \left(\tfrac{\pi}{4}+\tfrac{\pi}{2}\right) + \left(\tfrac{\pi}{6}+\tfrac{\sqrt{3}}{2}+\tfrac{\pi}{3}-\tfrac{\sqrt{3}}{8}\right) \\ &= \tfrac{\pi}{4}+\tfrac{3}{4}\sqrt{3} = \tfrac{1}{4}\left(\pi+3\sqrt{3}\right) \end{aligned}$$

36. $r = 0 \;\Rightarrow\; 1+2\cos 3\theta = 0 \;\Rightarrow\; \cos 3\theta = -\frac{1}{2} \;\Rightarrow\; 3\theta = \frac{2\pi}{3}, \frac{4\pi}{3}$ [for $0 \le 3\theta \le 2\pi$] $\;\Rightarrow\; \theta = \frac{2\pi}{9}, \frac{4\pi}{9}$. The darker shaded region (from $\theta = 0$ to $\theta = 2\pi/9$) represents $\frac{1}{2}$ of the desired area plus $\frac{1}{2}$ of the area of the inner loop. From this area, we'll subtract $\frac{1}{2}$ of the area of the inner loop (the lighter shaded region from $\theta = 2\pi/9$ to $\theta = \pi/3$), and then double that difference to obtain the desired area.



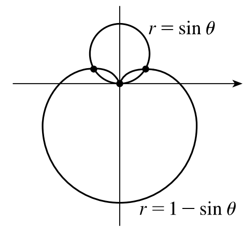
$$A = 2\left[\int_0^{2\pi/9} \tfrac{1}{2}(1+2\cos 3\theta)^2\,d\theta - \int_{2\pi/9}^{\pi/3} \tfrac{1}{2}(1+2\cos 3\theta)^2\,d\theta\right]$$

Now
$$\begin{aligned} r^2 &= (1+2\cos 3\theta)^2 = 1+4\cos 3\theta+4\cos^2 3\theta = 1+4\cos 3\theta + 4\cdot\tfrac{1}{2}(1+\cos 6\theta) \\ &= 1+4\cos 3\theta+2+2\cos 6\theta = 3+4\cos 3\theta+2\cos 6\theta \end{aligned}$$

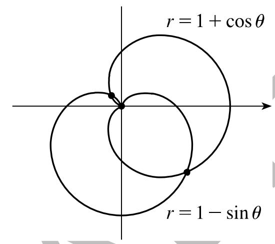
and $\int r^2 d\theta = 3\theta + \frac{4}{3}\sin 3\theta + \frac{1}{3}\sin 6\theta + C$, so

$$\begin{aligned} A &= \left[3\theta+\tfrac{4}{3}\sin 3\theta+\tfrac{1}{3}\sin 6\theta\right]_0^{2\pi/9} - \left[3\theta+\tfrac{4}{3}\sin 3\theta+\tfrac{1}{3}\sin 6\theta\right]_{2\pi/9}^{\pi/3} \\ &= \left[\left(\tfrac{2\pi}{3}+\tfrac{4}{3}\cdot\tfrac{\sqrt{3}}{2}+\tfrac{1}{3}\cdot\tfrac{-\sqrt{3}}{2}\right)-0\right] - \left[(\pi+0+0)-\left(\tfrac{2\pi}{3}+\tfrac{4}{3}\cdot\tfrac{\sqrt{3}}{2}+\tfrac{1}{3}\cdot\tfrac{-\sqrt{3}}{2}\right)\right] \\ &= \tfrac{4\pi}{3}+\tfrac{4}{3}\sqrt{3}-\tfrac{1}{3}\sqrt{3}-\pi = \tfrac{\pi}{3}+\sqrt{3} \end{aligned}$$

37. The pole is a point of intersection. $\sin\theta = 1 - \sin\theta \;\Rightarrow\; 2\sin\theta = 1 \;\Rightarrow$ $\sin\theta = \frac{1}{2} \;\Rightarrow\; \theta = \frac{\pi}{6}$ or $\frac{5\pi}{6}$. So the other points of intersection are $\left(\frac{1}{2}, \frac{\pi}{6}\right)$ and $\left(\frac{1}{2}, \frac{5\pi}{6}\right)$.



38. The pole is a point of intersection. $1 + \cos\theta = 1 - \sin\theta \;\Rightarrow$ $\cos\theta = -\sin\theta \;\Rightarrow\; \dfrac{\cos\theta}{\sin\theta} = -1 \;\Rightarrow\; \cot\theta = -1 \;\Rightarrow\; \theta = \frac{3\pi}{4}$ or $\frac{7\pi}{4}$. So the other points of intersection are $\left(1 - \frac{1}{2}\sqrt{2}, \frac{3\pi}{4}\right)$ and $\left(1 + \frac{1}{2}\sqrt{2}, \frac{7\pi}{4}\right)$.



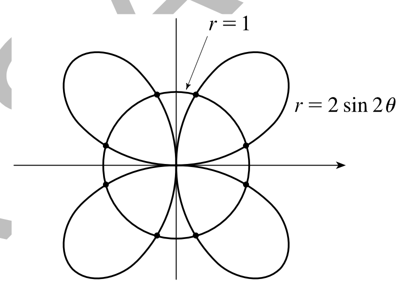
39. $2\sin 2\theta = 1 \;\Rightarrow\; \sin 2\theta = \frac{1}{2} \;\Rightarrow\; 2\theta = \frac{\pi}{6}, \frac{5\pi}{6}, \frac{13\pi}{6}$, or $\frac{17\pi}{6}$.

By symmetry, the eight points of intersection are given by

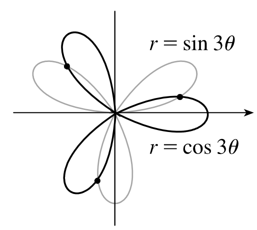
$(1, \theta)$, where $\theta = \frac{\pi}{12}, \frac{5\pi}{12}, \frac{13\pi}{12}$, and $\frac{17\pi}{12}$, and

$(-1, \theta)$, where $\theta = \frac{7\pi}{12}, \frac{11\pi}{12}, \frac{19\pi}{12}$, and $\frac{23\pi}{12}$.

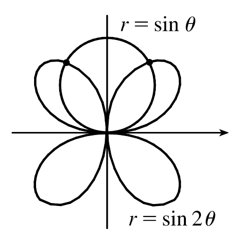
[There are many ways to describe these points.]



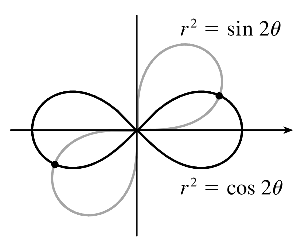
40. Clearly the pole lies on both curves. $\sin 3\theta = \cos 3\theta \;\Rightarrow\; \tan 3\theta = 1 \;\Rightarrow$ $3\theta = \frac{\pi}{4} + n\pi$ [n any integer] $\Rightarrow\; \theta = \frac{\pi}{12} + \frac{\pi}{3}n \;\Rightarrow$ $\theta = \frac{\pi}{12}, \frac{5\pi}{12}$, or $\frac{3\pi}{4}$, so the three remaining intersection points are $\left(\frac{1}{\sqrt{2}}, \frac{\pi}{12}\right)$, $\left(-\frac{1}{\sqrt{2}}, \frac{5\pi}{12}\right)$, and $\left(\frac{1}{\sqrt{2}}, \frac{3\pi}{4}\right)$.



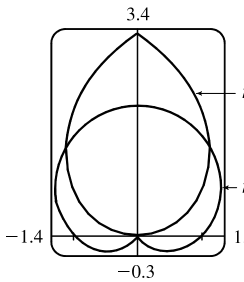
41. The pole is a point of intersection. $\sin\theta = \sin 2\theta = 2\sin\theta\,\cos\theta \;\Leftrightarrow$ $\sin\theta\,(1 - 2\cos\theta) = 0 \;\Leftrightarrow\; \sin\theta = 0$ or $\cos\theta = \frac{1}{2} \;\Rightarrow$ $\theta = 0, \pi, \frac{\pi}{3}$, or $-\frac{\pi}{3} \;\Rightarrow$ the other intersection points are $\left(\frac{\sqrt{3}}{2}, \frac{\pi}{3}\right)$ and $\left(\frac{\sqrt{3}}{2}, \frac{2\pi}{3}\right)$ [by symmetry].

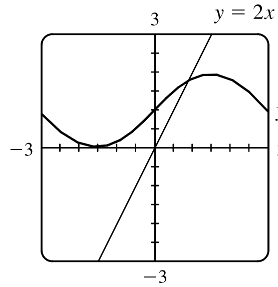


42. Clearly the pole is a point of intersection. $\sin 2\theta = \cos 2\theta \;\Rightarrow$ $\tan 2\theta = 1 \;\Rightarrow\; 2\theta = \frac{\pi}{4} + 2n\pi$ [since $\sin 2\theta$ and $\cos 2\theta$ must be positive in the equations] $\Rightarrow\; \theta = \frac{\pi}{8} + n\pi \;\Rightarrow\; \theta = \frac{\pi}{8}$ or $\frac{9\pi}{8}$. So the curves also intersect at $\left(\frac{1}{\sqrt[4]{2}}, \frac{\pi}{8}\right)$ and $\left(\frac{1}{\sqrt[4]{2}}, \frac{9\pi}{8}\right)$.



43.



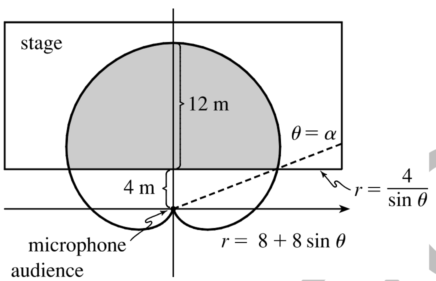


From the first graph, we see that the pole is one point of intersection. By zooming in or using the cursor, we find the θ-values of the intersection points to be $\alpha \approx 0.88786 \approx 0.89$ and $\pi - \alpha \approx 2.25$. (The first of these values may be more easily estimated by plotting $y = 1 + \sin x$ and $y = 2x$ in rectangular coordinates; see the second graph.) By symmetry, the total area contained is twice the area contained in the first quadrant, that is,

$$A = 2\int_0^{\alpha} \tfrac{1}{2}(2\theta)^2\ d\theta + 2\int_{\alpha}^{\pi/2} \tfrac{1}{2}(1+\sin\theta)^2\ d\theta = \int_0^{\alpha} 4\theta^2\ d\theta + \int_{\alpha}^{\pi/2} \left[1 + 2\sin\theta + \tfrac{1}{2}(1-\cos 2\theta)\right] d\theta$$

$$= \left[\tfrac{4}{3}\theta^3\right]_0^{\alpha} + \left[\theta - 2\cos\theta + \left(\tfrac{1}{2}\theta - \tfrac{1}{4}\sin 2\theta\right)\right]_{\alpha}^{\pi/2} = \tfrac{4}{3}\alpha^3 + \left[\left(\tfrac{\pi}{2} + \tfrac{\pi}{4}\right) - \left(\alpha - 2\cos\alpha + \tfrac{1}{2}\alpha - \tfrac{1}{4}\sin 2\alpha\right)\right] \approx 3.4645$$

44.



We need to find the shaded area A in the figure. The horizontal line representing the front of the stage has equation $y = 4 \;\Leftrightarrow\; r\sin\theta = 4 \;\Rightarrow\; r = 4/\sin\theta$. This line intersects the curve $r = 8 + 8\sin\theta$ when $8 + 8\sin\theta = \dfrac{4}{\sin\theta} \;\Rightarrow$ $8\sin\theta + 8\sin^2\theta = 4 \;\Rightarrow\; 2\sin^2\theta + 2\sin\theta - 1 = 0 \;\Rightarrow$

$$\sin\theta = \frac{-2 \pm \sqrt{4+8}}{4} = \frac{-2 \pm 2\sqrt{3}}{4} = \frac{-1+\sqrt{3}}{2} \quad \text{[the other value is less than } -1] \;\Rightarrow\; \theta = \sin^{-1}\left(\frac{\sqrt{3}-1}{2}\right).$$

This angle is about 21.5° and is denoted by α in the figure.

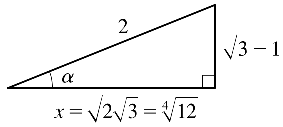
$$A = 2\int_{\alpha}^{\pi/2} \tfrac{1}{2}(8+8\sin\theta)^2\,d\theta - 2\int_{\alpha}^{\pi/2} \tfrac{1}{2}(4\csc\theta)^2\,d\theta = 64\int_{\alpha}^{\pi/2}(1 + 2\sin\theta + \sin^2\theta)\,d\theta - 16\int_{\alpha}^{\pi/2}\csc^2\theta\,d\theta$$

$$= 64\int_{\alpha}^{\pi/2}\left(1 + 2\sin\theta + \tfrac{1}{2} - \tfrac{1}{2}\cos 2\theta\right)\ d\theta + 16\int_{\alpha}^{\pi/2}(-\csc^2\theta)\,d\theta = 64\left[\tfrac{3}{2}\theta - 2\cos\theta - \tfrac{1}{4}\sin 2\theta\right]_{\alpha}^{\pi/2} + 16\left[\cot\theta\right]_{\alpha}^{\pi/2}$$

$$= 16\left[6\theta - 8\cos\theta - \sin 2\theta + \cot\theta\right]_{\alpha}^{\pi/a} = 16[(3\pi - 0 - 0 + 0) - (6\alpha - 8\cos\alpha - \sin 2\alpha + \cot\alpha)]$$

$$= 48\pi - 96\alpha + 128\cos\alpha + 16\sin 2\alpha - 16\cot\alpha$$

From the figure, $x^2 + \left(\sqrt{3}-1\right)^2 = 2^2 \;\Rightarrow\; x^2 = 4 - \left(3 - 2\sqrt{3} + 1\right) \;\Rightarrow$ $x^2 = 2\sqrt{3} = \sqrt{12}$, so $x = \sqrt{2\sqrt{3}} = \sqrt[4]{12}$. Using the trigonometric relationships for a right triangle and the identity $\sin 2\alpha = 2\sin\alpha\,\cos\alpha$, we continue:



$$A = 48\pi - 96\alpha + 128\cdot\frac{\sqrt[4]{12}}{2} + 16\cdot 2\cdot\frac{\sqrt{3}-1}{2}\cdot\frac{\sqrt[4]{12}}{2} - 16\cdot\frac{\sqrt[4]{12}}{\sqrt{3}-1}\cdot\frac{\sqrt{3}+1}{\sqrt{3}+1}$$

$$= 48\pi - 96\alpha + 64\sqrt[4]{12} + 8\sqrt[4]{12}\left(\sqrt{3}-1\right) - 8\sqrt[4]{12}\left(\sqrt{3}+1\right) = 48\pi + 48\sqrt[4]{12} - 96\sin^{-1}\left(\frac{\sqrt{3}-1}{2}\right)$$

$$\approx 204.16\ \text{m}^2$$

45. $L = \int_a^b \sqrt{r^2 + (dr/d\theta)^2}\,d\theta = \int_0^\pi \sqrt{(2\cos\theta)^2 + (-2\sin\theta)^2}\,d\theta$

$= \int_0^\pi \sqrt{4(\cos^2\theta + \sin^2\theta)}\,d\theta = \int_0^\pi \sqrt{4}\,d\theta = \big[2\theta\big]_0^\pi = 2\pi$

As a check, note that the curve is a circle of radius 1, so its circumference is $2\pi(1) = 2\pi$.

46. $L = \int_a^b \sqrt{r^2 + (dr/d\theta)^2}\,d\theta = \int_0^{2\pi} \sqrt{(5^\theta)^2 + (5^\theta \ln 5)^2}\,d\theta = \int_0^{2\pi} \sqrt{5^{2\theta}[1 + (\ln 5)^2]}\,d\theta$

$= \sqrt{1 + (\ln 5)^2}\int_0^{2\pi} \sqrt{5^{2\theta}}\,d\theta = \sqrt{1 + (\ln 5)^2}\int_0^{2\pi} 5^\theta\,d\theta = \sqrt{1 + (\ln 5)^2}\left[\dfrac{5^\theta}{\ln 5}\right]_0^{2\pi}$

$= \sqrt{1 + (\ln 5)^2}\left(\dfrac{5^{2\pi}}{\ln 5} - \dfrac{1}{\ln 5}\right) = \dfrac{\sqrt{1 + (\ln 5)^2}}{\ln 5}(5^{2\pi} - 1)$

47. $L = \int_a^b \sqrt{r^2 + (dr/d\theta)^2}\,d\theta = \int_0^{2\pi} \sqrt{(\theta^2)^2 + (2\theta)^2}\,d\theta = \int_0^{2\pi} \sqrt{\theta^4 + 4\theta^2}\,d\theta$

$= \int_0^{2\pi} \sqrt{\theta^2(\theta^2 + 4)}\,d\theta = \int_0^{2\pi} \theta\sqrt{\theta^2 + 4}\,d\theta$

Now let $u = \theta^2 + 4$, so that $du = 2\theta\,d\theta$ $\left[\theta\,d\theta = \frac{1}{2}\,du\right]$ and

$$\int_0^{2\pi} \theta\sqrt{\theta^2 + 4}\,d\theta = \int_4^{4\pi^2+4} \tfrac{1}{2}\sqrt{u}\,du = \tfrac{1}{2}\cdot\tfrac{2}{3}\left[u^{3/2}\right]_4^{4(\pi^2+1)} = \tfrac{1}{3}[4^{3/2}(\pi^2 + 1)^{3/2} - 4^{3/2}] = \tfrac{8}{3}[(\pi^2 + 1)^{3/2} - 1]$$

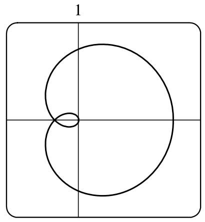
48. $L = \int_a^b \sqrt{r^2 + (dr/d\theta)^2}\,d\theta = \int_0^{2\pi} \sqrt{[2(1 + \cos\theta)]^2 + (-2\sin\theta)^2}\,d\theta = \int_0^{2\pi} \sqrt{4 + 8\cos\theta + 4\cos^2\theta + 4\sin^2\theta}\,d\theta$

$= \int_0^{2\pi} \sqrt{8 + 8\cos\theta}\,d\theta = \sqrt{8}\int_0^{2\pi} \sqrt{1 + \cos\theta}\,d\theta = \sqrt{8}\int_0^{2\pi} \sqrt{2\cdot\frac{1}{2}(1 + \cos\theta)}\,d\theta$

$= \sqrt{8}\int_0^{2\pi} \sqrt{2\cos^2\dfrac{\theta}{2}}\,d\theta = \sqrt{8}\,\sqrt{2}\int_0^{2\pi} \left|\cos\dfrac{\theta}{2}\right| d\theta = 4\cdot 2\int_0^\pi \cos\dfrac{\theta}{2}\,d\theta$ [by symmetry]

$= 8\left[2\sin\dfrac{\theta}{2}\right]_0^\pi = 8(2) = 16$

49. The curve $r = \cos^4(\theta/4)$ is completely traced with $0 \le \theta \le 4\pi$.



$r^2 + (dr/d\theta)^2 = [\cos^4(\theta/4)]^2 + \left[4\cos^3(\theta/4)\cdot(-\sin(\theta/4))\cdot\frac{1}{4}\right]^2$

$= \cos^8(\theta/4) + \cos^6(\theta/4)\sin^2(\theta/4)$

$= \cos^6(\theta/4)[\cos^2(\theta/4) + \sin^2(\theta/4)] = \cos^6(\theta/4)$

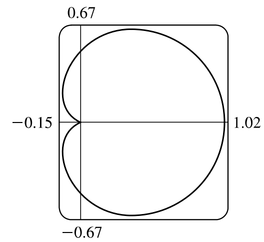
$L = \int_0^{4\pi} \sqrt{\cos^6(\theta/4)}\,d\theta = \int_0^{4\pi} \left|\cos^3(\theta/4)\right|\,d\theta$

$= 2\int_0^{2\pi} \cos^3(\theta/4)\,d\theta$ [since $\cos^3(\theta/4) \ge 0$ for $0 \le \theta \le 2\pi$] $= 8\int_0^{\pi/2} \cos^3 u\,du$ $\left[u = \frac{1}{4}\theta\right]$

$= 8\int_0^{\pi/2} (1 - \sin^2 u)\cos u\,du = 8\int_0^1 (1 - x^2)\,dx$ $\begin{bmatrix} x = \sin u, \\ dx = \cos u\,du \end{bmatrix}$

$= 8\left[x - \frac{1}{3}x^3\right]_0^1 = 8\left(1 - \frac{1}{3}\right) = \frac{16}{3}$

50. The curve $r = \cos^2(\theta/2)$ is completely traced with $0 \le \theta \le 2\pi$.



$$\begin{aligned} r^2 + (dr/d\theta)^2 &= [\cos^2(\theta/2)]^2 + \left[2\cos(\theta/2)\cdot(-\sin(\theta/2))\cdot\tfrac{1}{2}\right]^2 \\ &= \cos^4(\theta/2) + \cos^2(\theta/2)\sin^2(\theta/2) \\ &= \cos^2(\theta/2)[\cos^2(\theta/2)+\sin^2(\theta/2)] \\ &= \cos^2(\theta/2) \end{aligned}$$

$L = \int_0^{2\pi}\sqrt{\cos^2(\theta/2)}\,d\theta = \int_0^{2\pi}|\cos(\theta/2)|\,d\theta = 2\int_0^{\pi}\cos(\theta/2)\,d\theta$ [since $\cos(\theta/2) \ge 0$ for $0 \le \theta \le \pi$]

$= 4\int_0^{\pi/2}\cos u\,du \quad \left[u = \tfrac{1}{2}\theta\right] \quad = 4\big[\sin u\big]_0^{\pi/2} = 4(1-0) = 4$

51. One loop of the curve $r = \cos 2\theta$ is traced with $-\pi/4 \le \theta \le \pi/4$.

$r^2 + \left(\dfrac{dr}{d\theta}\right)^2 = \cos^2 2\theta + (-2\sin 2\theta)^2 = \cos^2 2\theta + 4\sin^2 2\theta = 1 + 3\sin^2 2\theta \quad \Rightarrow$

$L = \displaystyle\int_{-\pi/4}^{\pi/4}\sqrt{1+3\sin^2 2\theta}\,d\theta \approx 2.4221.$

52. $r^2 + \left(\dfrac{dr}{d\theta}\right)^2 = \tan^2\theta + (\sec^2\theta)^2 \quad \Rightarrow \quad L = \displaystyle\int_{\pi/6}^{\pi/3}\sqrt{\tan^2\theta + \sec^4\theta}\,d\theta \approx 1.2789$

53. The curve $r = \sin(6\sin\theta)$ is completely traced with $0 \le \theta \le \pi$. $r = \sin(6\sin\theta) \quad \Rightarrow$

$\dfrac{dr}{d\theta} = \cos(6\sin\theta)\cdot 6\cos\theta$, so $r^2 + \left(\dfrac{dr}{d\theta}\right)^2 = \sin^2(6\sin\theta) + 36\cos^2\theta\cos^2(6\sin\theta) \quad \Rightarrow$

$L = \displaystyle\int_0^{\pi}\sqrt{\sin^2(6\sin\theta) + 36\cos^2\theta\,\cos^2(6\sin\theta)}\,d\theta \approx 8.0091.$

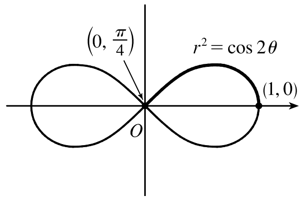
54. The curve $r = \sin(\theta/4)$ is completely traced with $0 \le \theta \le 8\pi$. $r = \sin(\theta/4) \quad \Rightarrow \quad \dfrac{dr}{d\theta} = \frac{1}{4}\cos(\theta/4)$, so

$r^2 + \left(\dfrac{dr}{d\theta}\right)^2 = \sin^2(\theta/4) + \frac{1}{16}\cos^2(\theta/4) \quad \Rightarrow \quad L = \displaystyle\int_0^{8\pi}\sqrt{\sin^2(\theta/4) + \tfrac{1}{16}\cos^2(\theta/4)}\,d\theta \approx 17.1568.$

55. (a) From (10.2.6),

$$\begin{aligned} S &= \textstyle\int_a^b 2\pi y\sqrt{(dx/d\theta)^2 + (dy/d\theta)^2}\,d\theta \\ &= \textstyle\int_a^b 2\pi y\sqrt{r^2 + (dr/d\theta)^2}\,d\theta \qquad \text{[from the derivation of Equation 10.4.5]} \\ &= \textstyle\int_a^b 2\pi r\sin\theta\sqrt{r^2 + (dr/d\theta)^2}\,d\theta \end{aligned}$$

(b) The curve $r^2 = \cos 2\theta$ goes through the pole when $\cos 2\theta = 0 \quad \Rightarrow$ $2\theta = \frac{\pi}{2} \quad \Rightarrow \quad \theta = \frac{\pi}{4}$. We'll rotate the curve from $\theta = 0$ to $\theta = \frac{\pi}{4}$ and double this value to obtain the total surface area generated.



$r^2 = \cos 2\theta \quad \Rightarrow \quad 2r\,\dfrac{dr}{d\theta} = -2\sin 2\theta \quad \Rightarrow \quad \left(\dfrac{dr}{d\theta}\right)^2 = \dfrac{\sin^2 2\theta}{r^2} = \dfrac{\sin^2 2\theta}{\cos 2\theta}.$

$S = 2\displaystyle\int_0^{\pi/4} 2\pi\sqrt{\cos 2\theta}\sin\theta\sqrt{\cos 2\theta + (\sin^2 2\theta)/\cos 2\theta}\,d\theta = 4\pi\int_0^{\pi/4}\sqrt{\cos 2\theta}\sin\theta\sqrt{\frac{\cos^2 2\theta + \sin^2 2\theta}{\cos 2\theta}}\,d\theta$

$= 4\pi\displaystyle\int_0^{\pi/4}\sqrt{\cos 2\theta}\sin\theta\,\frac{1}{\sqrt{\cos 2\theta}}\,d\theta = 4\pi\int_0^{\pi/4}\sin\theta\,d\theta = 4\pi\big[-\cos\theta\big]_0^{\pi/4} = -4\pi\left(\tfrac{\sqrt{2}}{2} - 1\right) = 2\pi\left(2 - \sqrt{2}\right)$

56. (a) Rotation around $\theta = \frac{\pi}{2}$ is the same as rotation around the y-axis, that is, $S = \int_a^b 2\pi x\, ds$ where $ds = \sqrt{(dx/dt)^2 + (dy/dt)^2}\, dt$ for a parametric equation, and for the special case of a polar equation, $x = r\cos\theta$ and $ds = \sqrt{(dx/d\theta)^2 + (dy/d\theta)^2}\, d\theta = \sqrt{r^2 + (dr/d\theta)^2}\, d\theta$ [see the derivation of Equation 10.4.5]. Therefore, for a polar equation rotated around $\theta = \frac{\pi}{2}$, $S = \int_a^b 2\pi r\cos\theta \sqrt{r^2 + (dr/d\theta)^2}\, d\theta$.

(b) As in the solution for Exercise 55(b), we can double the surface area generated by rotating the curve from $\theta = 0$ to $\theta = \frac{\pi}{4}$ to obtain the total surface area.

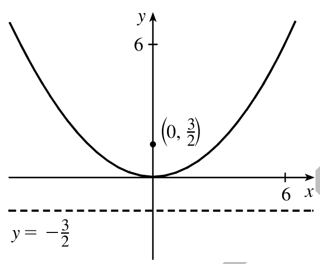
$$S = 2\int_0^{\pi/4} 2\pi \sqrt{\cos 2\theta}\cos\theta \sqrt{\cos 2\theta + (\sin^2 2\theta)/\cos 2\theta}\, d\theta = 4\pi \int_0^{\pi/4} \sqrt{\cos 2\theta}\cos\theta \sqrt{\frac{\cos^2 2\theta + \sin^2 2\theta}{\cos 2\theta}}\, d\theta$$

$$= 4\pi \int_0^{\pi/4} \sqrt{\cos 2\theta}\cos\theta \frac{1}{\sqrt{\cos 2\theta}}\, d\theta = 4\pi \int_0^{\pi/4} \cos\theta\, d\theta = 4\pi \big[\sin\theta\big]_0^{\pi/4} = 4\pi\left(\frac{\sqrt{2}}{2} - 0\right) = 2\sqrt{2}\,\pi$$

10.5 Conic Sections

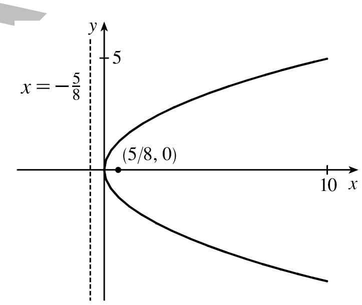
1. $x^2 = 6y$ and $x^2 = 4py \Rightarrow 4p = 6 \Rightarrow p = \frac{3}{2}$.

The vertex is $(0, 0)$, the focus is $\left(0, \frac{3}{2}\right)$, and the directrix is $y = -\frac{3}{2}$.



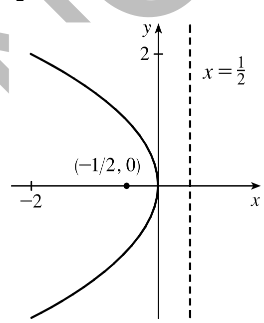
2. $2y^2 = 5x \Rightarrow y^2 = \frac{5}{2}x$. $4p = \frac{5}{2} \Rightarrow p = \frac{5}{8}$.

The vertex is $(0, 0)$, the focus is $\left(\frac{5}{8}, 0\right)$, and the directrix is $x = -\frac{5}{8}$.



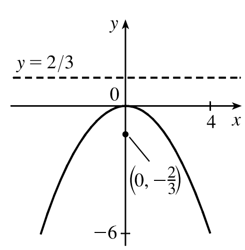
3. $2x = -y^2 \Rightarrow y^2 = -2x$. $4p = -2 \Rightarrow p = -\frac{1}{2}$.

The vertex is $(0, 0)$, the focus is $\left(-\frac{1}{2}, 0\right)$, and the directrix is $x = \frac{1}{2}$.

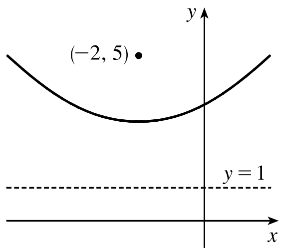


4. $3x^2 + 8y = 0 \Rightarrow 3x^2 = -8y \Rightarrow x^2 = -\frac{8}{3}y$.

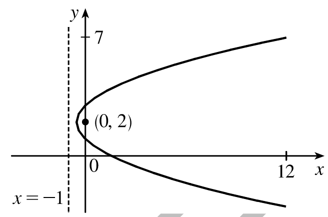
$4p = -\frac{8}{3} \Rightarrow p = -\frac{2}{3}$. The vertex is $(0, 0)$, the focus is $\left(0, -\frac{2}{3}\right)$, and the directrix is $y = \frac{2}{3}$.



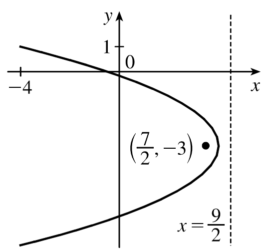
5. $(x+2)^2 = 8(y-3)$. $4p = 8$, so $p = 2$. The vertex is $(-2,3)$, the focus is $(-2,5)$, and the directrix is $y = 1$.



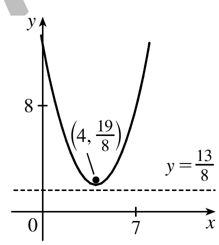
6. $(y-2)^2 = 2x+1 = 2\left(x+\frac{1}{2}\right)$. $4p = 2$, so $p = \frac{1}{2}$. The vertex is $\left(-\frac{1}{2}, 2\right)$, the focus is $(0,2)$, and the directrix is $x = -1$.



7. $y^2 + 6y + 2x + 1 = 0 \quad \Leftrightarrow \quad y^2 + 6y = -2x - 1$
$\Leftrightarrow \quad y^2 + 6y + 9 = -2x + 8 \quad \Leftrightarrow$
$(y+3)^2 = -2(x-4)$. $4p = -2$, so $p = -\frac{1}{2}$.
The vertex is $(4,-3)$, the focus is $\left(\frac{7}{2}, -3\right)$, and the directrix is $x = \frac{9}{2}$.



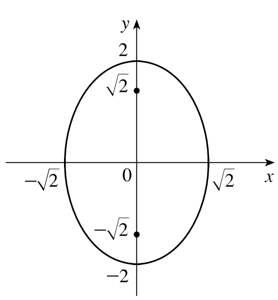
8. $2x^2 - 16x - 3y + 38 = 0 \quad \Leftrightarrow \quad 2x^2 - 16x = 3y - 38$
$\Leftrightarrow \quad 2(x^2 - 8x + 16) = 3y - 38 + 32 \quad \Leftrightarrow$
$2(x-4)^2 = 3y - 6 \quad \Leftrightarrow \quad (x-4)^2 = \frac{3}{2}(y-2)$.
$4p = \frac{3}{2}$, so $p = \frac{3}{8}$. The vertex is $(4,2)$, the focus is $\left(4, \frac{19}{8}\right)$, and the directrix is $y = \frac{13}{8}$.



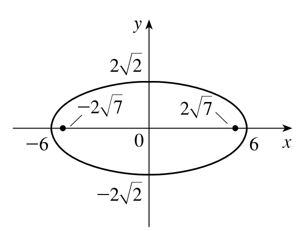
9. The equation has the form $y^2 = 4px$, where $p < 0$. Since the parabola passes through $(-1,1)$, we have $1^2 = 4p(-1)$, so $4p = -1$ and an equation is $y^2 = -x$ or $x = -y^2$. $4p = -1$, so $p = -\frac{1}{4}$ and the focus is $\left(-\frac{1}{4}, 0\right)$ while the directrix is $x = \frac{1}{4}$.

10. The vertex is $(2,-2)$, so the equation is of the form $(x-2)^2 = 4p(y+2)$, where $p > 0$. The point $(0,0)$ is on the parabola, so $4 = 4p(2)$ and $4p = 2$. Thus, an equation is $(x-2)^2 = 2(y+2)$. $4p = 2$, so $p = \frac{1}{2}$ and the focus is $\left(2, -\frac{3}{2}\right)$ while the directrix is $y = -\frac{5}{2}$.

11. $\dfrac{x^2}{2} + \dfrac{y^2}{4} = 1 \quad \Rightarrow \quad a = \sqrt{4} = 2$, $b = \sqrt{2}$, $c = \sqrt{a^2 - b^2} = \sqrt{4-2} = \sqrt{2}$. The ellipse is centered at $(0,0)$, with vertices at $(0,\pm 2)$. The foci are $\left(0, \pm\sqrt{2}\right)$.



12. $\dfrac{x^2}{36} + \dfrac{y^2}{8} = 1 \quad \Rightarrow \quad a = \sqrt{36} = 6$, $b = \sqrt{8}$, $c = \sqrt{a^2 - b^2} = \sqrt{36-8} = \sqrt{28} = 2\sqrt{7}$. The ellipse is centered at $(0,0)$, with vertices at $(\pm 6, 0)$. The foci are $(\pm 2\sqrt{7}, 0)$.

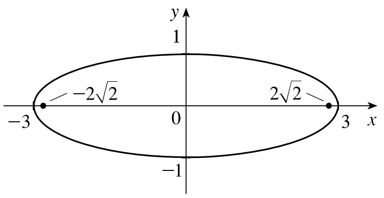


13. $x^2 + 9y^2 = 9 \quad \Leftrightarrow \quad \dfrac{x^2}{9} + \dfrac{y^2}{1} = 1 \quad \Rightarrow \quad a = \sqrt{9} = 3,$

$b = \sqrt{1} = 1$, $c = \sqrt{a^2 - b^2} = \sqrt{9-1} = \sqrt{8} = 2\sqrt{2}$.

The ellipse is centered at $(0,0)$, with vertices $(\pm 3, 0)$.

The foci are $(\pm 2\sqrt{2}, 0)$.

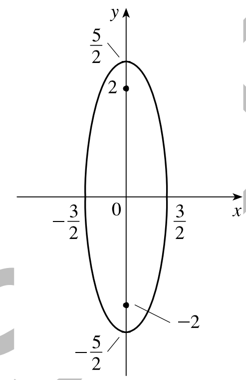


14. $100x^2 + 36y^2 = 225 \quad \Leftrightarrow \quad \dfrac{x^2}{\frac{225}{100}} + \dfrac{y^2}{\frac{225}{36}} = 1 \quad \Leftrightarrow$

$\dfrac{x^2}{\frac{9}{4}} + \dfrac{y^2}{\frac{25}{4}} = 1 \quad \Rightarrow \quad a = \sqrt{\frac{25}{4}} = \frac{5}{2}$, $b = \sqrt{\frac{9}{4}} = \frac{3}{2}$,

$c = \sqrt{a^2 - b^2} = \sqrt{\frac{25}{4} - \frac{9}{4}} = 2$. The ellipse is centered

at $(0,0)$, with vertices $\left(0, \pm\frac{5}{2}\right)$. The foci are $(0, \pm 2)$.



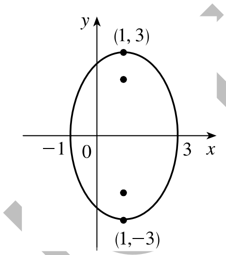
15. $9x^2 - 18x + 4y^2 = 27 \quad \Leftrightarrow$

$9(x^2 - 2x + 1) + 4y^2 = 27 + 9 \quad \Leftrightarrow$

$9(x-1)^2 + 4y^2 = 36 \quad \Leftrightarrow \quad \dfrac{(x-1)^2}{4} + \dfrac{y^2}{9} = 1 \quad \Rightarrow$

$a = 3$, $b = 2$, $c = \sqrt{5} \quad \Rightarrow \quad$ center $(1, 0)$,

vertices $(1, \pm 3)$, foci $\left(1, \pm\sqrt{5}\right)$



16. $x^2 + 3y^2 + 2x - 12y + 10 = 0 \quad \Leftrightarrow$

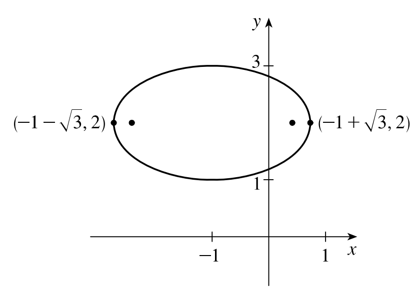
$x^2 + 2x + 1 + 3(y^2 - 4y + 4) = -10 + 1 + 12 \quad \Leftrightarrow$

$(x+1)^2 + 3(y-2)^2 = 3 \quad \Leftrightarrow$

$\dfrac{(x+1)^2}{3} + \dfrac{(y-2)^2}{1} = 1 \quad \Rightarrow \quad a = \sqrt{3}$, $b = 1$,

$c = \sqrt{2} \quad \Rightarrow \quad$ center $(-1, 2)$, vertices $\left(-1 \pm \sqrt{3}, 2\right)$,

foci $\left(-1 \pm \sqrt{2}, 2\right)$



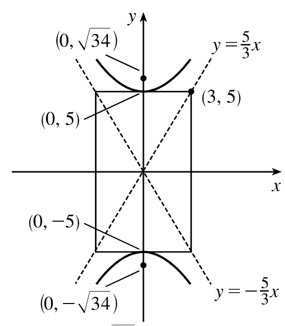
17. The center is $(0,0)$, $a = 3$, and $b = 2$, so an equation is $\dfrac{x^2}{4} + \dfrac{y^2}{9} = 1$. $c = \sqrt{a^2 - b^2} = \sqrt{5}$, so the foci are $\left(0, \pm\sqrt{5}\right)$.

18. The ellipse is centered at $(2, 1)$, with $a = 3$ and $b = 2$. An equation is $\dfrac{(x-2)^2}{9} + \dfrac{(y-1)^2}{4} = 1$. $c = \sqrt{a^2 - b^2} = \sqrt{5}$, so the foci are $\left(2 \pm \sqrt{5}, 1\right)$.

19. $\dfrac{y^2}{25} - \dfrac{x^2}{9} = 1 \quad \Rightarrow \quad a = 5, b = 3, c = \sqrt{25+9} = \sqrt{34} \quad \Rightarrow$

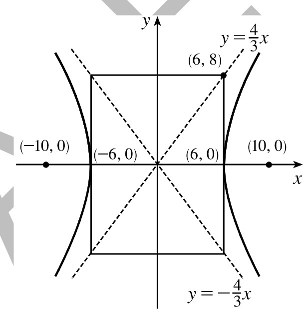
center $(0,0)$, vertices $(0,\pm 5)$, foci $\left(0, \pm\sqrt{34}\right)$, asymptotes $y = \pm\frac{5}{3}x$.

Note: It is helpful to draw a $2a$-by-$2b$ rectangle whose center is the center of the hyperbola. The asymptotes are the extended diagonals of the rectangle.



20. $\dfrac{x^2}{36} - \dfrac{y^2}{64} = 1 \quad \Rightarrow \quad a = 6, b = 8, c = \sqrt{36+64} = 10 \quad \Rightarrow$

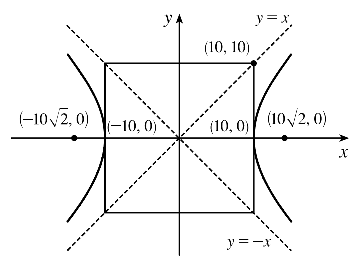
center $(0,0)$, vertices $(\pm 6, 0)$, foci $(\pm 10, 0)$, asymptotes $y = \pm\frac{8}{6}x = \pm\frac{4}{3}x$



21. $x^2 - y^2 = 100 \quad \Leftrightarrow \quad \dfrac{x^2}{100} - \dfrac{y^2}{100} = 1 \quad \Rightarrow \quad a = b = 10,$

$c = \sqrt{100+100} = 10\sqrt{2} \quad \Rightarrow \quad$ center $(0,0)$, vertices $(\pm 10, 0)$,

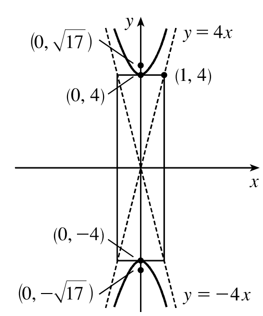
foci $\left(\pm 10\sqrt{2}, 0\right)$, asymptotes $y = \pm\frac{10}{10}x = \pm x$



22. $y^2 - 16x^2 = 16 \quad \Leftrightarrow \quad \dfrac{y^2}{16} - \dfrac{x^2}{1} = 1 \quad \Rightarrow \quad a = 4, b = 1,$

$c = \sqrt{16+1} = \sqrt{17} \quad \Rightarrow \quad$ center $(0,0)$, vertices $(0, \pm 4)$,

foci $\left(0, \pm\sqrt{17}\right)$, asymptotes $y = \pm\frac{4}{1}x = \pm 4x$

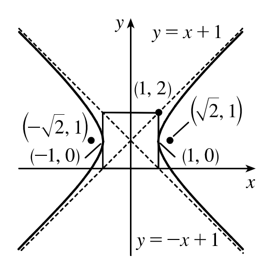


23. $x^2 - y^2 + 2y = 2 \quad \Leftrightarrow \quad x^2 - (y^2 - 2y + 1) = 2 - 1 \quad \Leftrightarrow$

$\dfrac{x^2}{1} - \dfrac{(y-1)^2}{1} = 1 \quad \Rightarrow \quad a = b = 1, c = \sqrt{1+1} = \sqrt{2} \quad \Rightarrow$

center $(0,1)$, vertices $(\pm 1, 1)$, foci $\left(\pm\sqrt{2}, 1\right)$,

asymptotes $y - 1 = \pm\frac{1}{1}x = \pm x$.

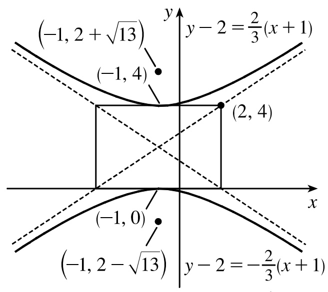


24. $9y^2 - 4x^2 - 36y - 8x = 4 \quad \Leftrightarrow$

$9(y^2 - 4y + 4) - 4(x^2 + 2x + 1) = 4 + 36 - 4 \quad \Leftrightarrow$

$9(y-2)^2 - 4(x+1)^2 = 36 \quad \Leftrightarrow \quad \dfrac{(y-2)^2}{4} - \dfrac{(x+1)^2}{9} = 1 \quad \Rightarrow$

$a = 2$, $b = 3$, $c = \sqrt{4+9} = \sqrt{13} \quad \Rightarrow$ center $(-1, 2)$, vertices $(-1, 2 \pm 2)$, foci $\left(-1, 2 \pm \sqrt{13}\right)$, asymptotes $y - 2 = \pm\frac{2}{3}(x+1)$.



25. $4x^2 = y^2 + 4 \quad \Leftrightarrow \quad 4x^2 - y^2 = 4 \quad \Leftrightarrow \quad \dfrac{x^2}{1} - \dfrac{y^2}{4} = 1$. This is an equation of a *hyperbola* with vertices $(\pm 1, 0)$. The foci are at $\left(\pm\sqrt{1+4}, 0\right) = \left(\pm\sqrt{5}, 0\right)$.

26. $4x^2 = y + 4 \quad \Leftrightarrow \quad x^2 = \frac{1}{4}(y+4)$. This is an equation of a *parabola* with $4p = \frac{1}{4}$, so $p = \frac{1}{16}$. The vertex is $(0, -4)$ and the focus is $\left(0, -4 + \frac{1}{16}\right) = \left(0, -\frac{63}{16}\right)$.

27. $x^2 = 4y - 2y^2 \quad \Leftrightarrow \quad x^2 + 2y^2 - 4y = 0 \quad \Leftrightarrow \quad x^2 + 2(y^2 - 2y + 1) = 2 \quad \Leftrightarrow \quad x^2 + 2(y-1)^2 = 2 \quad \Leftrightarrow$

$\dfrac{x^2}{2} + \dfrac{(y-1)^2}{1} = 1$. This is an equation of an *ellipse* with vertices at $\left(\pm\sqrt{2}, 1\right)$. The foci are at $\left(\pm\sqrt{2-1}, 1\right) = (\pm 1, 1)$.

28. $y^2 - 2 = x^2 - 2x \quad \Leftrightarrow \quad y^2 - x^2 + 2x = 2 \quad \Leftrightarrow \quad y^2 - (x^2 - 2x + 1) = 2 - 1 \quad \Leftrightarrow \quad \dfrac{y^2}{1} - \dfrac{(x-1)^2}{1} = 1$. This is an equation of a *hyperbola* with vertices $(1, \pm 1)$. The foci are at $\left(1, \pm\sqrt{1+1}\right) = \left(1, \pm\sqrt{2}\right)$.

29. $3x^2 - 6x - 2y = 1 \quad \Leftrightarrow \quad 3x^2 - 6x = 2y + 1 \quad \Leftrightarrow \quad 3(x^2 - 2x + 1) = 2y + 1 + 3 \quad \Leftrightarrow \quad 3(x-1)^2 = 2y + 4 \quad \Leftrightarrow$

$(x-1)^2 = \frac{2}{3}(y+2)$. This is an equation of a *parabola* with $4p = \frac{2}{3}$, so $p = \frac{1}{6}$. The vertex is $(1, -2)$ and the focus is $\left(1, -2 + \frac{1}{6}\right) = \left(1, -\frac{11}{6}\right)$.

30. $x^2 - 2x + 2y^2 - 8y + 7 = 0 \quad \Leftrightarrow \quad (x^2 - 2x + 1) + 2(y^2 - 4y + 4) = -7 + 1 + 8 \quad \Leftrightarrow \quad (x-1)^2 + 2(y-2)^2 = 2 \quad \Leftrightarrow$

$\dfrac{(x-1)^2}{2} + \dfrac{(y-2)^2}{1} = 1$. This is an equation of an *ellipse* with vertices at $\left(1 \pm \sqrt{2}, 2\right)$. The foci are at $\left(1 \pm \sqrt{2-1}, 2\right) = (1 \pm 1, 2)$.

31. The parabola with vertex $(0, 0)$ and focus $(1, 0)$ opens to the right and has $p = 1$, so its equation is $y^2 = 4px$, or $y^2 = 4x$.

32. The parabola with focus $(0, 0)$ and directrix $y = 6$ has vertex $(0, 3)$ and opens downward, so $p = -3$ and its equation is $(x-0)^2 = 4p(y-3)$, or $x^2 = -12(y-3)$.

33. The distance from the focus $(-4, 0)$ to the directrix $x = 2$ is $2 - (-4) = 6$, so the distance from the focus to the vertex is $\frac{1}{2}(6) = 3$ and the vertex is $(-1, 0)$. Since the focus is to the left of the vertex, $p = -3$. An equation is $y^2 = 4p(x+1) \quad \Rightarrow$ $y^2 = -12(x+1)$.

34. The parabola with vertex $(2, 3)$ and focus $(2, -1)$ opens downward and has $p = -1 - 3 = -4$, so its equation is $(x-2)^2 = 4p(y-3)$, or $(x-2)^2 = -16(y-3)$.

35. The parabola with vertex $(3, -1)$ having a horizontal axis has equation $[y - (-1)]^2 = 4p(x - 3)$. Since it passes through $(-15, 2)$, $(2 + 1)^2 = 4p(-15 - 3) \Rightarrow 9 = 4p(-18) \Rightarrow 4p = -\frac{1}{2}$. An equation is $(y + 1)^2 = -\frac{1}{2}(x - 3)$.

36. The parabola with vertical axis and passing through $(0, 4)$ has equation $y = ax^2 + bx + 4$. It also passes through $(1, 3)$ and $(-2, -6)$, so

$$\begin{cases} 3 = a + b + 4 \\ -6 = 4a - 2b + 4 \end{cases} \Rightarrow \begin{cases} -1 = a + b \\ -10 = 4a - 2b \end{cases} \Rightarrow \begin{cases} -1 = a + b \\ -5 = 2a - b \end{cases}$$

Adding the last two equations gives us $3a = -6$, or $a = -2$. Since $a + b = -1$, we have $b = 1$, and an equation is $y = -2x^2 + x + 4$.

37. The ellipse with foci $(\pm 2, 0)$ and vertices $(\pm 5, 0)$ has center $(0, 0)$ and a horizontal major axis, with $a = 5$ and $c = 2$, so $b^2 = a^2 - c^2 = 25 - 4 = 21$. An equation is $\dfrac{x^2}{25} + \dfrac{y^2}{21} = 1$.

38. The ellipse with foci $(0, \pm\sqrt{2})$ and vertices $(0, \pm 2)$ has center $(0, 0)$ and a vertical major axis, with $a = 2$ and $c = \sqrt{2}$, so $b^2 = a^2 - c^2 = 4 - 2 = 2$. An equation is $\dfrac{x^2}{2} + \dfrac{y^2}{4} = 1$.

39. Since the vertices are $(0, 0)$ and $(0, 8)$, the ellipse has center $(0, 4)$ with a vertical axis and $a = 4$. The foci at $(0, 2)$ and $(0, 6)$ are 2 units from the center, so $c = 2$ and $b = \sqrt{a^2 - c^2} = \sqrt{4^2 - 2^2} = \sqrt{12}$. An equation is $\dfrac{(x-0)^2}{b^2} + \dfrac{(y-4)^2}{a^2} = 1 \Rightarrow \dfrac{x^2}{12} + \dfrac{(y-4)^2}{16} = 1$.

40. Since the foci are $(0, -1)$ and $(8, -1)$, the ellipse has center $(4, -1)$ with a horizontal axis and $c = 4$. The vertex $(9, -1)$ is 5 units from the center, so $a = 5$ and $b = \sqrt{a^2 - c^2} = \sqrt{5^2 - 4^2} = \sqrt{9}$. An equation is $\dfrac{(x-4)^2}{a^2} + \dfrac{(y+1)^2}{b^2} = 1 \Rightarrow \dfrac{(x-4)^2}{25} + \dfrac{(y+1)^2}{9} = 1$.

41. An equation of an ellipse with center $(-1, 4)$ and vertex $(-1, 0)$ is $\dfrac{(x+1)^2}{b^2} + \dfrac{(y-4)^2}{4^2} = 1$. The focus $(-1, 6)$ is 2 units from the center, so $c = 2$. Thus, $b^2 + 2^2 = 4^2 \Rightarrow b^2 = 12$, and the equation is $\dfrac{(x+1)^2}{12} + \dfrac{(y-4)^2}{16} = 1$.

42. Foci $F_1(-4, 0)$ and $F_2(4, 0) \Rightarrow c = 4$ and an equation is $\dfrac{x^2}{a^2} + \dfrac{y^2}{b^2} = 1$. The ellipse passes through $P(-4, 1.8)$, so $2a = |PF_1| + |PF_2| \Rightarrow 2a = 1.8 + \sqrt{8^2 + (1.8)^2} \Rightarrow 2a = 1.8 + 8.2 \Rightarrow a = 5$.
$b^2 = a^2 - c^2 = 25 - 16 = 9$ and the equation is $\dfrac{x^2}{25} + \dfrac{y^2}{9} = 1$.

43. An equation of a hyperbola with vertices $(\pm 3, 0)$ is $\dfrac{x^2}{3^2} - \dfrac{y^2}{b^2} = 1$. Foci $(\pm 5, 0) \Rightarrow c = 5$ and $3^2 + b^2 = 5^2 \Rightarrow b^2 = 25 - 9 = 16$, so the equation is $\dfrac{x^2}{9} - \dfrac{y^2}{16} = 1$.

44. An equation of a hyperbola with vertices $(0, \pm 2)$ is $\dfrac{y^2}{2^2} - \dfrac{x^2}{b^2} = 1$. Foci $(0, \pm 5)$ $\Rightarrow$ $c = 5$ and $2^2 + b^2 = 5^2$ $\Rightarrow$ $b^2 = 25 - 4 = 21$, so the equation is $\dfrac{y^2}{4} - \dfrac{x^2}{21} = 1$.

45. The center of a hyperbola with vertices $(-3, -4)$ and $(-3, 6)$ is $(-3, 1)$, so $a = 5$ and an equation is $\dfrac{(y-1)^2}{5^2} - \dfrac{(x+3)^2}{b^2} = 1$. Foci $(-3, -7)$ and $(-3, 9)$ $\Rightarrow$ $c = 8$, so $5^2 + b^2 = 8^2$ $\Rightarrow$ $b^2 = 64 - 25 = 39$ and the equation is $\dfrac{(y-1)^2}{25} - \dfrac{(x+3)^2}{39} = 1$.

46. The center of a hyperbola with vertices $(-1, 2)$ and $(7, 2)$ is $(3, 2)$, so $a = 4$ and an equation is $\dfrac{(x-3)^2}{4^2} - \dfrac{(y-2)^2}{b^2} = 1$. Foci $(-2, 2)$ and $(8, 2)$ $\Rightarrow$ $c = 5$, so $4^2 + b^2 = 5^2$ $\Rightarrow$ $b^2 = 25 - 16 = 9$ and the equation is $\dfrac{(x-3)^2}{16} - \dfrac{(y-2)^2}{9} = 1$.

47. The center of a hyperbola with vertices $(\pm 3, 0)$ is $(0, 0)$, so $a = 3$ and an equation is $\dfrac{x^2}{3^2} - \dfrac{y^2}{b^2} = 1$. Asymptotes $y = \pm 2x$ $\Rightarrow$ $\dfrac{b}{a} = 2$ $\Rightarrow$ $b = 2(3) = 6$ and the equation is $\dfrac{x^2}{9} - \dfrac{y^2}{36} = 1$.

48. The center of a hyperbola with foci $(2, 0)$ and $(2, 8)$ is $(2, 4)$, so $c = 4$ and an equation is $\dfrac{(y-4)^2}{a^2} - \dfrac{(x-2)^2}{b^2} = 1$. The asymptote $y = 3 + \frac{1}{2}x$ has slope $\frac{1}{2}$, so $\dfrac{a}{b} = \dfrac{1}{2}$ $\Rightarrow$ $b = 2a$ and $a^2 + b^2 = c^2$ $\Rightarrow$ $a^2 + (2a)^2 = 4^2$ $\Rightarrow$ $5a^2 = 16$ $\Rightarrow$ $a^2 = \frac{16}{5}$ and so $b^2 = 16 - \frac{16}{5} = \frac{64}{5}$. Thus, an equation is $\dfrac{(y-4)^2}{16/5} - \dfrac{(x-2)^2}{64/5} = 1$.

49. In Figure 8, we see that the point on the ellipse closest to a focus is the closer vertex (which is a distance $a - c$ from it) while the farthest point is the other vertex (at a distance of $a + c$). So for this lunar orbit, $(a - c) + (a + c) = 2a = (1728 + 110) + (1728 + 314)$, or $a = 1940$; and $(a + c) - (a - c) = 2c = 314 - 110$, or $c = 102$. Thus, $b^2 = a^2 - c^2 = 3{,}753{,}196$, and the equation is $\dfrac{x^2}{3{,}763{,}600} + \dfrac{y^2}{3{,}753{,}196} = 1$.

50. (a) Choose V to be the origin, with x-axis through V and F. Then F is $(p, 0)$, A is $(p, 5)$, so substituting A into the equation $y^2 = 4px$ gives $25 = 4p^2$ so $p = \frac{5}{2}$ and $y^2 = 10x$.

(b) $x = 11$ $\Rightarrow$ $y = \sqrt{110}$ $\Rightarrow$ $|CD| = 2\sqrt{110}$

51. (a) Set up the coordinate system so that A is $(-200, 0)$ and B is $(200, 0)$.

$|PA| - |PB| = (1200)(980) = 1{,}176{,}000 \text{ ft} = \frac{2450}{11} \text{ mi} = 2a$ $\Rightarrow$ $a = \frac{1225}{11}$, and $c = 200$ so

$b^2 = c^2 - a^2 = \dfrac{3{,}339{,}375}{121}$ $\Rightarrow$ $\dfrac{121x^2}{1{,}500{,}625} - \dfrac{121y^2}{3{,}339{,}375} = 1$.

(b) Due north of B $\Rightarrow$ $x = 200$ $\Rightarrow$ $\dfrac{(121)(200)^2}{1{,}500{,}625} - \dfrac{121y^2}{3{,}339{,}375} = 1$ $\Rightarrow$ $y = \dfrac{133{,}575}{539} \approx 248$ mi

52. $|PF_1| - |PF_2| = \pm 2a \;\Leftrightarrow\; \sqrt{(x+c)^2 + y^2} - \sqrt{(x-c)^2 + y^2} = \pm 2a \;\Leftrightarrow$

$\sqrt{(x+c)^2 + y^2} = \sqrt{(x-c)^2 + y^2} \pm 2a \;\Leftrightarrow\; (x+c)^2 + y^2 = (x-c)^2 + y^2 + 4a^2 \pm 4a\sqrt{(x-c)^2 + y^2} \;\Leftrightarrow$

$4cx - 4a^2 = \pm 4a\sqrt{(x-c)^2 + y^2} \;\Leftrightarrow\; c^2x^2 - 2a^2cx + a^4 = a^2(x^2 - 2cx + c^2 + y^2) \;\Leftrightarrow$

$(c^2 - a^2)x^2 - a^2y^2 = a^2(c^2 - a^2) \;\Leftrightarrow\; b^2x^2 - a^2y^2 = a^2b^2$ [where $b^2 = c^2 - a^2$] $\Leftrightarrow\; \dfrac{x^2}{a^2} - \dfrac{y^2}{b^2} = 1$

53. The function whose graph is the upper branch of this hyperbola is concave upward. The function is

$y = f(x) = a\sqrt{1 + \dfrac{x^2}{b^2}} = \dfrac{a}{b}\sqrt{b^2 + x^2}$, so $y' = \dfrac{a}{b}x(b^2 + x^2)^{-1/2}$ and

$y'' = \dfrac{a}{b}\left[(b^2 + x^2)^{-1/2} - x^2(b^2 + x^2)^{-3/2}\right] = ab(b^2 + x^2)^{-3/2} > 0$ for all x, and so f is concave upward.

54. We can follow exactly the same sequence of steps as in the derivation of Formula 4, except we use the points $(1,1)$ and $(-1,-1)$ in the distance formula (first equation of that derivation) so $\sqrt{(x-1)^2 + (y-1)^2} + \sqrt{(x+1)^2 + (y+1)^2} = 4$ will lead (after moving the second term to the right, squaring, and simplifying) to $2\sqrt{(x+1)^2 + (y+1)^2} = x + y + 4$, which, after squaring and simplifying again, leads to $3x^2 - 2xy + 3y^2 = 8$.

55. (a) If $k > 16$, then $k - 16 > 0$, and $\dfrac{x^2}{k} + \dfrac{y^2}{k-16} = 1$ is an *ellipse* since it is the sum of two squares on the left side.

(b) If $0 < k < 16$, then $k - 16 < 0$, and $\dfrac{x^2}{k} + \dfrac{y^2}{k-16} = 1$ is a *hyperbola* since it is the difference of two squares on the left side.

(c) If $k < 0$, then $k - 16 < 0$, and there is *no curve* since the left side is the sum of two negative terms, which cannot equal 1.

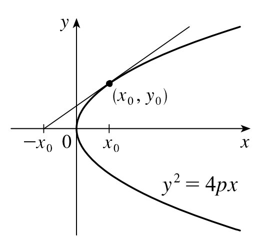
(d) In case (a), $a^2 = k$, $b^2 = k - 16$, and $c^2 = a^2 - b^2 = 16$, so the foci are at $(\pm 4, 0)$. In case (b), $k - 16 < 0$, so $a^2 = k$, $b^2 = 16 - k$, and $c^2 = a^2 + b^2 = 16$, and so again the foci are at $(\pm 4, 0)$.

56. (a) $y^2 = 4px \;\Rightarrow\; 2yy' = 4p \;\Rightarrow\; y' = \dfrac{2p}{y}$, so the tangent line is

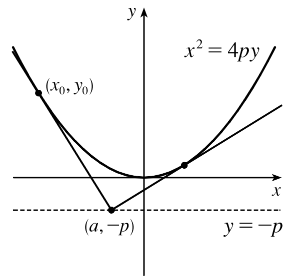
$y - y_0 = \dfrac{2p}{y_0}(x - x_0) \;\Rightarrow\; yy_0 - y_0^2 = 2p(x - x_0) \;\Leftrightarrow$

$yy_0 - 4px_0 = 2px - 2px_0 \;\Rightarrow\; yy_0 = 2p(x + x_0)$.

(b) The x-intercept is $-x_0$.



57. $x^2 = 4py \;\Rightarrow\; 2x = 4py' \;\Rightarrow\; y' = \dfrac{x}{2p}$, so the tangent line at (x_0, y_0) is $y - \dfrac{x_0^2}{4p} = \dfrac{x_0}{2p}(x - x_0)$. This line passes through the point $(a, -p)$ on the directrix, so $-p - \dfrac{x_0^2}{4p} = \dfrac{x_0}{2p}(a - x_0) \;\Rightarrow\; -4p^2 - x_0^2 = 2ax_0 - 2x_0^2 \;\Leftrightarrow$



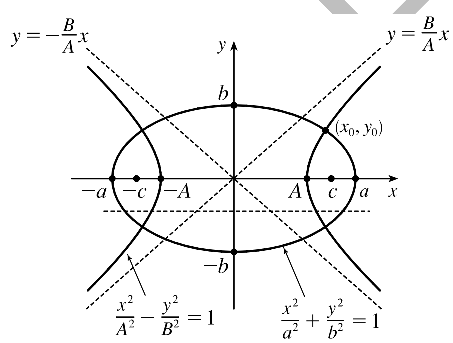
$x_0^2 - 2ax_0 - 4p^2 = 0 \quad \Leftrightarrow \quad x_0^2 - 2ax_0 + a^2 = a^2 + 4p^2 \quad \Leftrightarrow$

$(x_0 - a)^2 = a^2 + 4p^2 \quad \Leftrightarrow \quad x_0 = a \pm \sqrt{a^2 + 4p^2}$. The slopes of the tangent lines at $x = a \pm \sqrt{a^2 + 4p^2}$ are $\dfrac{a \pm \sqrt{a^2 + 4p^2}}{2p}$, so the product of the two slopes is

$$\frac{a + \sqrt{a^2 + 4p^2}}{2p} \cdot \frac{a - \sqrt{a^2 + 4p^2}}{2p} = \frac{a^2 - (a^2 + 4p^2)}{4p^2} = \frac{-4p^2}{4p^2} = -1,$$

showing that the tangent lines are perpendicular.

58. Without a loss of generality, let the ellipse, hyperbola, and foci be as shown in the figure.



The curves intersect (eliminate y^2) $\Rightarrow$

$B^2\left(\dfrac{x^2}{A^2} - \dfrac{y^2}{B^2}\right) + b^2\left(\dfrac{x^2}{a^2} + \dfrac{y^2}{b^2}\right) = B^2 + b^2 \quad \Rightarrow$

$\dfrac{B^2x^2}{A^2} + \dfrac{b^2x^2}{a^2} = B^2 + b^2 \quad \Rightarrow \quad x^2\left(\dfrac{B^2}{A^2} + \dfrac{b^2}{a^2}\right) = B^2 + b^2 \quad \Rightarrow$

$x^2 = \dfrac{B^2 + b^2}{\dfrac{a^2B^2 + b^2A^2}{A^2a^2}} = \dfrac{A^2a^2(B^2 + b^2)}{a^2B^2 + b^2A^2}.$

Similarly, $y^2 = \dfrac{B^2b^2(a^2 - A^2)}{b^2A^2 + a^2B^2}.$

Next we find the slopes of the tangent lines of the curves: $\dfrac{x^2}{a^2} + \dfrac{y^2}{b^2} = 1 \quad \Rightarrow \quad \dfrac{2x}{a^2} + \dfrac{2yy'}{b^2} = 0 \quad \Rightarrow \quad \dfrac{yy'}{b^2} = -\dfrac{x}{a^2} \quad \Rightarrow$ $y'_E = -\dfrac{b^2}{a^2}\dfrac{x}{y}$ and $\dfrac{x^2}{A^2} - \dfrac{y^2}{B^2} = 1 \quad \Rightarrow \quad \dfrac{2x}{A^2} - \dfrac{2yy'}{B^2} = 0 \quad \Rightarrow \quad \dfrac{yy'}{B^2} = \dfrac{x}{A^2} \quad \Rightarrow \quad y'_H = \dfrac{B^2}{A^2}\dfrac{x}{y}$. The product of the slopes at (x_0, y_0) is $y'_E\, y'_H = -\dfrac{b^2B^2x_0^2}{a^2A^2y_0^2} = -\dfrac{b^2B^2\left[\dfrac{A^2a^2(B^2 + b^2)}{a^2B^2 + b^2A^2}\right]}{a^2A^2\left[\dfrac{B^2b^2(a^2 - A^2)}{b^2A^2 + a^2B^2}\right]} = -\dfrac{B^2 + b^2}{a^2 - A^2}$. Since $a^2 - b^2 = c^2$ and $A^2 + B^2 = c^2$, we have $a^2 - b^2 = A^2 + B^2 \quad \Rightarrow \quad a^2 - A^2 = b^2 + B^2$, so the product of the slopes is -1, and hence, the tangent lines at each point of intersection are perpendicular.

59. $9x^2 + 4y^2 = 36 \quad \Leftrightarrow \quad \dfrac{x^2}{4} + \dfrac{y^2}{9} = 1$. We use the parametrization $x = 2\cos t$, $y = 3\sin t$, $0 \le t \le 2\pi$. The circumference is given by

$$\begin{aligned} L &= \int_0^{2\pi} \sqrt{(dx/dt)^2 + (dy/dt)^2}\, dt = \int_0^{2\pi} \sqrt{(-2\sin t)^2 + (3\cos t)^2}\, dt \\ &= \int_0^{2\pi} \sqrt{4\sin^2 t + 9\cos^2 t}\, dt = \int_0^{2\pi} \sqrt{4 + 5\cos^2 t}\, dt \end{aligned}$$

Now use Simpson's Rule with $n = 8$, $\Delta t = \dfrac{2\pi - 0}{8} = \dfrac{\pi}{4}$, and $f(t) = \sqrt{4 + 5\cos^2 t}$ to get

$L \approx S_8 = \frac{\pi/4}{3}\left[f(0) + 4f\left(\frac{\pi}{4}\right) + 2f\left(\frac{\pi}{2}\right) + 4f\left(\frac{3\pi}{4}\right) + 2f(\pi) + 4f\left(\frac{5\pi}{4}\right) + 2f\left(\frac{3\pi}{2}\right) + 4f\left(\frac{7\pi}{4}\right) + f(2\pi)\right] \approx 15.9.$

60. The length of the major axis is $2a$, so $a = \frac{1}{2}(1.18 \times 10^{10}) = 5.9 \times 10^9$. The length of the minor axis is $2b$, so $b = \frac{1}{2}(1.14 \times 10^{10}) = 5.7 \times 10^9$. An equation of the ellipse is $\dfrac{x^2}{a^2} + \dfrac{y^2}{b^2} = 1$, or converting into parametric equations,

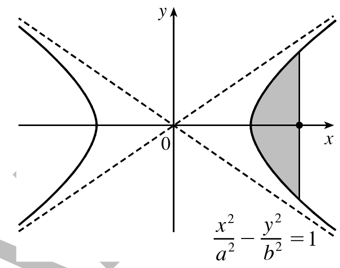
$x = a\cos\theta$ and $y = b\sin\theta$. So

$$L = 4\int_0^{\pi/2} \sqrt{(dx/d\theta)^2 + (dy/d\theta)^2}\,d\theta = 4\int_0^{\pi/2} \sqrt{a^2\sin^2\theta + b^2\cos^2\theta}\,d\theta$$

Using Simpson's Rule with $n = 10$, $\Delta\theta = \frac{\pi/2 - 0}{10} = \frac{\pi}{20}$, and $f(\theta) = \sqrt{a^2\sin^2\theta + b^2\cos^2\theta}$, we get

$$L \approx 4 \cdot S_{10} = 4 \cdot \tfrac{\pi}{20 \cdot 3}\left[f(0) + 4f\left(\tfrac{\pi}{20}\right) + 2f\left(\tfrac{2\pi}{20}\right) + \cdots + 2f\left(\tfrac{8\pi}{20}\right) + 4f\left(\tfrac{9\pi}{20}\right) + f\left(\tfrac{\pi}{2}\right)\right] \approx 3.64 \times 10^{10}\text{ km}$$

61. $\dfrac{x^2}{a^2} - \dfrac{y^2}{b^2} = 1 \;\Rightarrow\; \dfrac{y^2}{b^2} = \dfrac{x^2 - a^2}{a^2} \;\Rightarrow\; y = \pm\dfrac{b}{a}\sqrt{x^2 - a^2}$.



$$A = 2\int_a^c \frac{b}{a}\sqrt{x^2 - a^2}\,dx \overset{39}{=} \frac{2b}{a}\left[\frac{x}{2}\sqrt{x^2 - a^2} - \frac{a^2}{2}\ln\left|x + \sqrt{x^2 - a^2}\right|\right]_a^c$$

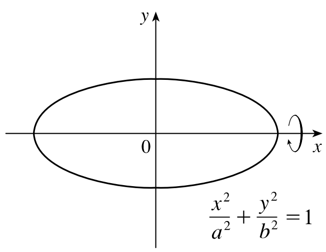
$$= \frac{b}{a}\left[c\sqrt{c^2 - a^2} - a^2\ln\left|c + \sqrt{c^2 - a^2}\right| + a^2\ln|a|\right]$$

Since $a^2 + b^2 = c^2$, $c^2 - a^2 = b^2$, and $\sqrt{c^2 - a^2} = b$.

$$= \frac{b}{a}\left[cb - a^2\ln(c + b) + a^2\ln a\right] = \frac{b}{a}\left[cb + a^2(\ln a - \ln(b + c))\right]$$

$$= b^2c/a + ab\ln[a/(b + c)], \text{ where } c^2 = a^2 + b^2.$$

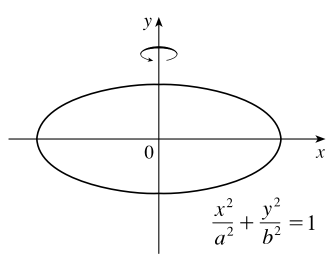
62. (a) $\dfrac{x^2}{a^2} + \dfrac{y^2}{b^2} = 1 \;\Rightarrow\; \dfrac{y^2}{b^2} = \dfrac{a^2 - x^2}{a^2} \;\Rightarrow\; y = \pm\dfrac{b}{a}\sqrt{a^2 - x^2}$.



$$V = \int_{-a}^{a} \pi\left(\frac{b}{a}\sqrt{a^2 - x^2}\right)^2 dx = 2\pi\,\frac{b^2}{a^2}\int_0^a (a^2 - x^2)\,dx$$

$$= \frac{2\pi b^2}{a^2}\left[a^2x - \tfrac{1}{3}x^3\right]_0^a = \frac{2\pi b^2}{a^2}\left(\frac{2a^3}{3}\right) = \frac{4}{3}\pi b^2 a$$

(b) $\dfrac{x^2}{a^2} + \dfrac{y^2}{b^2} = 1 \;\Rightarrow\; \dfrac{x^2}{a^2} = \dfrac{b^2 - y^2}{b^2} \;\Rightarrow\; x = \pm\dfrac{a}{b}\sqrt{b^2 - y^2}$.



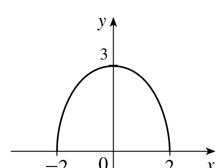
$$V = \int_{-b}^{b} \pi\left(\frac{a}{b}\sqrt{b^2 - y^2}\right)^2 dy = 2\pi\,\frac{a^2}{b^2}\int_0^b (b^2 - y^2)\,dy$$

$$= \frac{2\pi a^2}{b^2}\left[b^2y - \tfrac{1}{3}y^3\right]_0^b = \frac{2\pi a^2}{b^2}\left(\frac{2b^3}{3}\right) = \frac{4}{3}\pi a^2 b$$

63. $9x^2 + 4y^2 = 36 \;\Leftrightarrow\; \dfrac{x^2}{4} + \dfrac{y^2}{9} = 1 \;\Rightarrow\; a = 3, b = 2$. By symmetry, $\overline{x} = 0$. By Example 2 in Section 7.3, the area of the top half of the ellipse is $\frac{1}{2}(\pi ab) = 3\pi$. Solve $9x^2 + 4y^2 = 36$ for y to get an equation for the top half of the ellipse: $9x^2 + 4y^2 = 36 \;\Leftrightarrow\; 4y^2 = 36 - 9x^2 \;\Leftrightarrow\; y^2 = \frac{9}{4}(4 - x^2) \;\Rightarrow\; y = \frac{3}{2}\sqrt{4 - x^2}$. Now

$$\overline{y} = \frac{1}{A}\int_a^b \frac{1}{2}[f(x)]^2\,dx = \frac{1}{3\pi}\int_{-2}^{2} \frac{1}{2}\left(\frac{3}{2}\sqrt{4 - x^2}\right)^2 dx = \frac{3}{8\pi}\int_{-2}^{2}(4 - x^2)\,dx$$

$$= \frac{3}{8\pi} \cdot 2\int_0^2 (4 - x^2)\,dx = \frac{3}{4\pi}\left[4x - \frac{1}{3}x^3\right]_0^2 = \frac{3}{4\pi}\left(\frac{16}{3}\right) = \frac{4}{\pi}$$



so the centroid is $(0, 4/\pi)$.

64. (a) Consider the ellipse $\dfrac{x^2}{a^2}+\dfrac{y^2}{b^2}=1$ with $a>b$, so that the major axis is the x-axis. Let the ellipse be parametrized by $x=a\cos t$, $y=b\sin t$, $0\le t\le 2\pi$. Then

$$\left(\frac{dx}{dt}\right)^2+\left(\frac{dy}{dt}\right)^2=a^2\sin^2 t+b^2\cos^2 t=a^2(1-\cos^2 t)+b^2\cos^2 t=a^2+(b^2-a^2)\cos^2 t=a^2-c^2\cos^2 t,$$

where $c^2=a^2-b^2$. Using symmetry and rotating the ellipse about the major axis gives us surface area

$$S=\int 2\pi y\,ds=2\int_0^{\pi/2}2\pi(b\sin t)\sqrt{a^2-c^2\cos^2 t}\,dt=4\pi b\int_c^0\sqrt{a^2-u^2}\left(-\frac{1}{c}\,du\right)\qquad\begin{bmatrix}u=c\cos t\\ du=-c\sin t\,dt\end{bmatrix}$$

$$=\frac{4\pi b}{c}\int_0^c\sqrt{a^2-u^2}\,du\overset{30}{=}\frac{4\pi b}{c}\left[\frac{u}{2}\sqrt{a^2-u^2}+\frac{a^2}{2}\sin^{-1}\left(\frac{u}{a}\right)\right]_0^c=\frac{2\pi b}{c}\left[c\sqrt{a^2-c^2}+a^2\sin^{-1}\left(\frac{c}{a}\right)\right]$$

$$=\frac{2\pi b}{c}\left[bc+a^2\sin^{-1}\left(\frac{c}{a}\right)\right]$$

(b) As in part (a),

$$\left(\frac{dx}{dt}\right)^2+\left(\frac{dy}{dt}\right)^2=a^2\sin^2 t+b^2\cos^2 t=a^2\sin^2 t+b^2(1-\sin^2 t)=b^2+(a^2-b^2)\sin^2 t=b^2+c^2\sin^2 t.$$

Rotating about the minor axis gives us

$$S=\int 2\pi x\,ds=2\int_0^{\pi/2}2\pi(a\cos t)\sqrt{b^2+c^2\sin^2 t}\,dt=4\pi a\int_0^c\sqrt{b^2+u^2}\left(\frac{1}{c}\,du\right)\qquad\begin{bmatrix}u=c\sin t\\ du=c\cos t\,dt\end{bmatrix}$$

$$\overset{21}{=}\frac{4\pi a}{c}\left[\frac{u}{2}\sqrt{b^2+u^2}+\frac{b^2}{2}\ln\big(u+\sqrt{b^2+u^2}\big)\right]_0^c=\frac{2\pi a}{c}\left[c\sqrt{b^2+c^2}+b^2\ln\big(c+\sqrt{b^2+c^2}\big)-b^2\ln b\right]$$

$$=\frac{2\pi a}{c}\left[ac+b^2\ln\left(\frac{a+c}{b}\right)\right]$$

65. Differentiating implicitly, $\dfrac{x^2}{a^2}+\dfrac{y^2}{b^2}=1 \;\Rightarrow\; \dfrac{2x}{a^2}+\dfrac{2yy'}{b^2}=0 \;\Rightarrow\; y'=-\dfrac{b^2x}{a^2y}$ $[y\neq 0]$. Thus, the slope of the tangent line at P is $-\dfrac{b^2x_1}{a^2y_1}$. The slope of F_1P is $\dfrac{y_1}{x_1+c}$ and of F_2P is $\dfrac{y_1}{x_1-c}$. By the formula in Problem 21 on text page 273, we have

$$\tan\alpha=\frac{\dfrac{y_1}{x_1+c}+\dfrac{b^2x_1}{a^2y_1}}{1-\dfrac{b^2x_1y_1}{a^2y_1(x_1+c)}}=\frac{a^2y_1^2+b^2x_1(x_1+c)}{a^2y_1(x_1+c)-b^2x_1y_1}=\frac{a^2b^2+b^2cx_1}{c^2x_1y_1+a^2cy_1}\qquad\begin{bmatrix}\text{using } b^2x_1^2+a^2y_1^2=a^2b^2,\\ \text{and } a^2-b^2=c^2\end{bmatrix}$$

$$=\frac{b^2(cx_1+a^2)}{cy_1(cx_1+a^2)}=\frac{b^2}{cy_1}$$

and

$$\tan\beta=\frac{-\dfrac{b^2x_1}{a^2y_1}-\dfrac{y_1}{x_1-c}}{1-\dfrac{b^2x_1y_1}{a^2y_1(x_1-c)}}=\frac{-a^2y_1^2-b^2x_1(x_1-c)}{a^2y_1\,(x_1-c)-b^2x_1y_1}=\frac{-a^2b^2+b^2cx_1}{c^2x_1y_1-a^2cy_1}=\frac{b^2(cx_1-a^2)}{cy_1(cx_1-a^2)}=\frac{b^2}{cy_1}$$

Thus, $\alpha=\beta$.

66. The slopes of the line segments F_1P and F_2P are $\dfrac{y_1}{x_1+c}$ and $\dfrac{y_1}{x_1-c}$, where P is (x_1,y_1). Differentiating implicitly, $\dfrac{2x}{a^2}-\dfrac{2yy'}{b^2}=0 \;\Rightarrow\; y'=\dfrac{b^2x}{a^2y} \;\Rightarrow\;$ the slope of the tangent at P is $\dfrac{b^2x_1}{a^2y_1}$, so by the formula in Problem 21 on text page 273,

$$\tan\alpha = \frac{\dfrac{b^2x_1}{a^2y_1} - \dfrac{y_1}{x_1+c}}{1 + \dfrac{b^2x_1y_1}{a^2y_1(x_1+c)}} = \frac{b^2x_1(x_1+c) - a^2y_1^2}{a^2y_1(x_1+c) + b^2x_1y_1} = \frac{b^2(cx_1+a^2)}{cy_1(cx_1+a^2)} \quad \left[\begin{array}{c}\text{using } x_1^2/a^2 - y_1^2/b^2 = 1, \\ \text{and } a^2+b^2=c^2\end{array}\right] = \frac{b^2}{cy_1}$$

and

$$\tan\beta = \frac{-\dfrac{b^2x_1}{a^2y_1} + \dfrac{y_1}{x_1-c}}{1 + \dfrac{b^2x_1y_1}{a^2y_1(x_1-c)}} = \frac{-b^2x_1(x_1-c) + a^2y_1^2}{a^2y_1(x_1-c) + b^2x_1y_1} = \frac{b^2(cx_1-a^2)}{cy_1(cx_1-a^2)} = \frac{b^2}{cy_1}$$

So $\alpha = \beta$.

10.6 Conic Sections in Polar Coordinates

1. The directrix $x = 4$ is to the right of the focus at the origin, so we use the form with "$+\ e\cos\theta$" in the denominator. (See Theorem 6 and Figure 2.) An equation of the ellipse is $r = \dfrac{ed}{1+e\cos\theta} = \dfrac{\frac{1}{2}\cdot 4}{1+\frac{1}{2}\cos\theta} = \dfrac{4}{2+\cos\theta}$.

2. The directrix $x = -3$ is to the left of the focus at the origin, so we use the form with "$-\ e\cos\theta$" in the denominator. $e = 1$ for a parabola, so an equation is $r = \dfrac{ed}{1-e\cos\theta} = \dfrac{1\cdot 3}{1-1\cos\theta} = \dfrac{3}{1-\cos\theta}$.

3. The directrix $y = 2$ is above the focus at the origin, so we use the form with "$+\ e\sin\theta$" in the denominator. An equation of the hyperbola is $r = \dfrac{ed}{1+e\sin\theta} = \dfrac{1.5(2)}{1+1.5\sin\theta} = \dfrac{6}{2+3\sin\theta}$.

4. The directrix $x = 3$ is to the right of the focus at the origin, so we use the form with "$+\ e\cos\theta$" in the denominator. An equation of the hyperbola is $r = \dfrac{ed}{1+e\cos\theta} = \dfrac{3\cdot 3}{1+3\cos\theta} = \dfrac{9}{1+3\cos\theta}$.

5. The vertex $(2,\pi)$ is to the left of the focus at the origin, so we use the form with "$-e\cos\theta$" in the denominator. An equation of the ellipse is $r = \dfrac{ed}{1-e\cos\theta}$. Using eccentricity $e = \dfrac{2}{3}$ with $\theta = \pi$ and $r = 2$, we get $2 = \dfrac{\frac{2}{3}d}{1-\frac{2}{3}(-1)} \quad\Rightarrow$

$2 = \dfrac{2d}{5} \quad\Rightarrow\quad d = 5$, so we have $r = \dfrac{\frac{2}{3}(5)}{1-\frac{2}{3}\cos\theta} = \dfrac{10}{3-2\cos\theta}$.

6. The directrix $r = 4\csc\theta$ (equivalent to $r\sin\theta = 4$ or $y = 4$) is above the focus at the origin, so we will use the form with "$+e\sin\theta$" in the denominator. The distance from the focus to the directrix is $d = 4$, so an equation of the ellipse is

$r = \dfrac{ed}{1+e\sin\theta} = \dfrac{(0.6)(4)}{1+0.6\sin\theta}\cdot\dfrac{5}{5} = \dfrac{12}{5+3\sin\theta}$.

7. The vertex $\left(3,\frac{\pi}{2}\right)$ is 3 units above the focus at the origin, so the directrix is 6 units above the focus ($d = 6$), and we use the form "$+e\sin\theta$" in the denominator. $e = 1$ for a parabola, so an equation is $r = \dfrac{ed}{1+e\sin\theta} = \dfrac{1(6)}{1+1\sin\theta} = \dfrac{6}{1+\sin\theta}$.

8. The directrix $r = -2\sec\theta$ (equivalent to $r\cos\theta = -2$ or $x = -2$) is left of the focus at the origin, so we will use the form with "$-e\cos\theta$" in the denominator. The distance from the focus to the directrix is $d = 2$, so an equation of the hyperbola is $r = \dfrac{ed}{1 - e\cos\theta} = \dfrac{2(2)}{1 - 2\cos\theta} = \dfrac{4}{1 - 2\cos\theta}$.

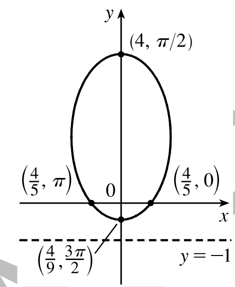
9. $r = \dfrac{4}{5 - 4\sin\theta} \cdot \dfrac{1/5}{1/5} = \dfrac{4/5}{1 - \frac{4}{5}\sin\theta}$, where $e = \frac{4}{5}$ and $ed = \frac{4}{5} \quad\Rightarrow\quad d = 1$.

(a) Eccentricity $= e = \frac{4}{5}$

(b) Since $e = \frac{4}{5} < 1$, the conic is an ellipse.

(c) Since "$-\ e\sin\theta$" appears in the denominator, the directrix is below the focus at the origin, $d = |Fl| = 1$, so an equation of the directrix is $y = -1$.

(d) The vertices are $\left(4, \frac{\pi}{2}\right)$ and $\left(\frac{4}{9}, \frac{3\pi}{2}\right)$.



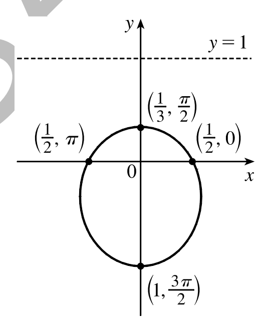
10. $r = \dfrac{1}{2 + \sin\theta} \cdot \dfrac{1/2}{1/2} = \dfrac{1/2}{1 + \frac{1}{2}\sin\theta}$, where $e = \dfrac{1}{2}$ and $ed = \dfrac{1}{2} \quad\Rightarrow\quad d = 1$.

(a) Eccentricity $= e = \dfrac{1}{2}$

(b) Since $e = \dfrac{1}{2} < 1$, the conic is an ellipse.

(c) Since "$+e\sin\theta$" appears in the denominator, the directrix is above the focus at the origin, $d = |Fl| = 1$, so an equation of the directrix is $y = 1$.

(d) The vertices are $\left(\frac{1}{3}, \frac{\pi}{2}\right)$ and $\left(1, \frac{3\pi}{2}\right)$.



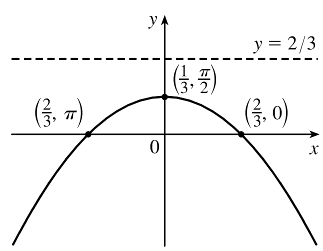
11. $r = \dfrac{2}{3 + 3\sin\theta} \cdot \dfrac{1/3}{1/3} = \dfrac{2/3}{1 + 1\sin\theta}$, where $e = 1$ and $ed = \frac{2}{3} \quad\Rightarrow\quad d = \frac{2}{3}$.

(a) Eccentricity $= e = 1$

(b) Since $e = 1$, the conic is a parabola.

(c) Since "$+\ e\sin\theta$" appears in the denominator, the directrix is above the focus at the origin. $d = |Fl| = \frac{2}{3}$, so an equation of the directrix is $y = \frac{2}{3}$.

(d) The vertex is at $\left(\frac{1}{3}, \frac{\pi}{2}\right)$, midway between the focus and directrix.



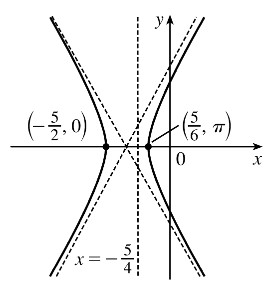
12. $r = \dfrac{5}{2 - 4\cos\theta} \cdot \dfrac{1/2}{1/2} = \dfrac{5/2}{1 - 2\cos\theta}$, where $e = 2$ and $ed = \dfrac{5}{2} \quad\Rightarrow\quad d = \dfrac{5}{4}$.

(a) Eccentricity $= e = 2$

(b) Since $e = 2 > 1$, the conic is a hyperbola.

(c) Since "$-e\cos\theta$" appears in the denominator, the directrix is to the left the focus at the origin. $d = |Fl| = \frac{5}{4}$, so an equation of the directrix is $x = -\frac{5}{4}$.

(d) The vertices are $\left(-\frac{5}{2}, 0\right)$ and $\left(\frac{5}{6}, \pi\right)$, so the center is midway between them, that is, $\left(\frac{5}{3}, \pi\right)$.



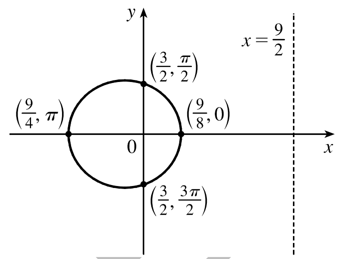
13. $r = \dfrac{9}{6 + 2\cos\theta} \cdot \dfrac{1/6}{1/6} = \dfrac{3/2}{1 + \frac{1}{3}\cos\theta}$, where $e = \frac{1}{3}$ and $ed = \frac{3}{2} \;\Rightarrow\; d = \frac{9}{2}$.

(a) Eccentricity $= e = \frac{1}{3}$

(b) Since $e = \frac{1}{3} < 1$, the conic is an ellipse.

(c) Since "$+e\cos\theta$" appears in the denominator, the directrix is to the right of the focus at the origin. $d = |Fl| = \frac{9}{2}$, so an equation of the directrix is $x = \frac{9}{2}$.

(d) The vertices are $\left(\frac{9}{8}, 0\right)$ and $\left(\frac{9}{4}, \pi\right)$, so the center is midway between them, that is, $\left(\frac{9}{16}, \pi\right)$.



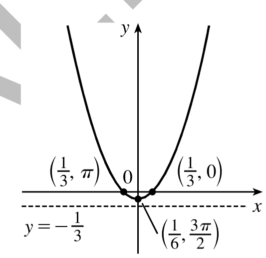
14. $r = \dfrac{1}{3 - 3\sin\theta} \cdot \dfrac{1/3}{1/3} = \dfrac{1/3}{1 - 1\sin\theta}$, where $e = 1$ and $ed = \dfrac{1}{3} \;\Rightarrow\; d = \dfrac{1}{3}$

(a) Eccentricity $= e = 1$

(b) Since $e = 1$, the conic is a parabola.

(c) Since "$-e\sin\theta$" appears in the denominator, the directrix is below the focus at the origin, $d = |Fl| = \frac{1}{3}$, so an equation of the directrix is $y = -\frac{1}{3}$.

(d) The vertex is at $\left(\frac{1}{6}, \frac{3\pi}{2}\right)$, midway between the focus and the directrix.



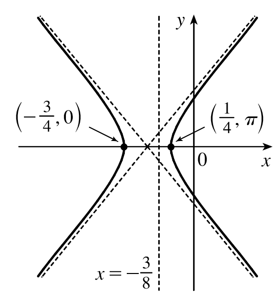
15. $r = \dfrac{3}{4 - 8\cos\theta} \cdot \dfrac{1/4}{1/4} = \dfrac{3/4}{1 - 2\cos\theta}$, where $e = 2$ and $ed = \frac{3}{4} \;\Rightarrow\; d = \frac{3}{8}$.

(a) Eccentricity $= e = 2$

(b) Since $e = 2 > 1$, the conic is a hyperbola.

(c) Since "$-e\cos\theta$" appears in the denominator, the directrix is to the left of the focus at the origin. $d = |Fl| = \frac{3}{8}$, so an equation of the directrix is $x = -\frac{3}{8}$.

(d) The vertices are $\left(-\frac{3}{4}, 0\right)$ and $\left(\frac{1}{4}, \pi\right)$, so the center is midway between them, that is, $\left(\frac{1}{2}, \pi\right)$.



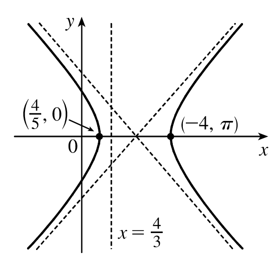
16. $r = \dfrac{4}{2 + 3\cos\theta} \cdot \dfrac{1/2}{1/2} = \dfrac{2}{1 + \frac{3}{2}\cos\theta}$, where $e = \dfrac{3}{2}$ and $ed = 2 \;\Rightarrow\; d = \dfrac{4}{3}$.

(a) Eccentricity $= e = \dfrac{3}{2}$

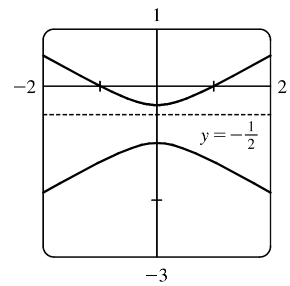
(b) Since $e = \dfrac{3}{2} > 1$, the conic is a hyperbola.

(c) Since "$+e\cos\theta$" appears in the denominator, the directrix is to the right of the focus at the origin. $d = |Fl| = \frac{4}{3}$, so an equation of the directrix is $x = \frac{4}{3}$.

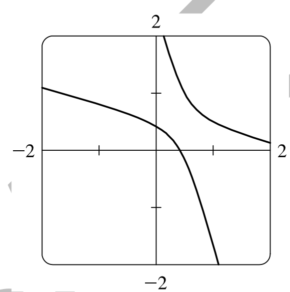
(d) The vertices are $\left(\frac{4}{5}, 0\right)$ and $(-4, \pi)$, so the center is midway between them, that is, $\left(\frac{8}{5}, 0\right)$.



17. (a) $r = \dfrac{1}{1 - 2\sin\theta}$, where $e = 2$ and $ed = 1 \quad \Rightarrow \quad d = \frac{1}{2}$. The eccentricity $e = 2 > 1$, so the conic is a hyperbola. Since "$-e\sin\theta$" appears in the denominator, the directrix is below the focus at the origin. $d = |Fl| = \frac{1}{2}$, so an equation of the directrix is $y = -\frac{1}{2}$. The vertices are $\left(-1, \frac{\pi}{2}\right)$ and $\left(\frac{1}{3}, \frac{3\pi}{2}\right)$, so the center is midway between them, that is, $\left(\frac{2}{3}, \frac{3\pi}{2}\right)$.



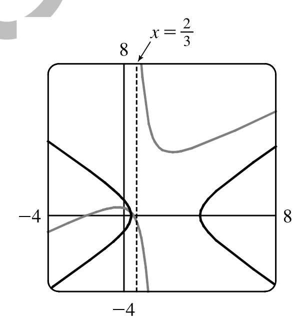
(b) By the discussion that precedes Example 4, the equation is $r = \dfrac{1}{1 - 2\sin\left(\theta - \frac{3\pi}{4}\right)}$.



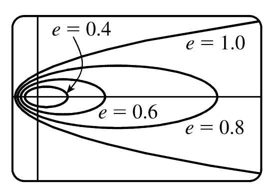
18. $r = \dfrac{4}{5 + 6\cos\theta} = \dfrac{4/5}{1 + \frac{6}{5}\cos\theta}$, so $e = \frac{6}{5}$ and $ed = \frac{4}{5} \quad \Rightarrow \quad d = \frac{2}{3}$.

An equation of the directrix is $x = \frac{2}{3} \quad \Rightarrow \quad r\cos\theta = \frac{2}{3} \quad \Rightarrow \quad r = \dfrac{2}{3\cos\theta}$.

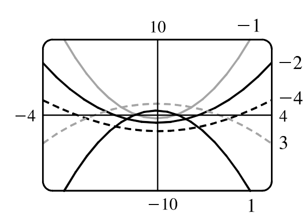
If the hyperbola is rotated about its focus (the origin) through an angle $\pi/3$, its equation is the same as that of the original, with θ replaced by $\theta - \frac{\pi}{3}$ (see Example 4), so $r = \dfrac{4}{5 + 6\cos\left(\theta - \frac{\pi}{3}\right)}$.



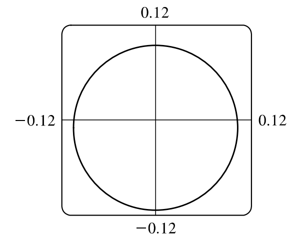
19. For $e < 1$ the curve is an ellipse. It is nearly circular when e is close to 0. As e increases, the graph is stretched out to the right, and grows larger (that is, its right-hand focus moves to the right while its left-hand focus remains at the origin.) At $e = 1$, the curve becomes a parabola with focus at the origin.



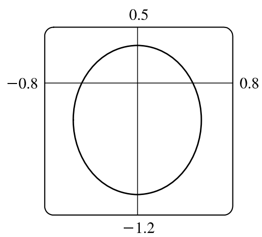
20. (a) The value of d does not seem to affect the shape of the conic (a parabola) at all, just its size, position, and orientation (for $d < 0$ it opens upward, for $d > 0$ it opens downward).



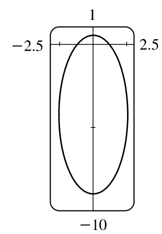
(b) We consider only positive values of e. When $0 < e < 1$, the conic is an ellipse. As $e \to 0^+$, the graph approaches perfect roundness and zero size. As e increases, the ellipse becomes more elongated, until at $e = 1$ it turns into a parabola. For $e > 1$, the conic is a hyperbola, which moves downward and gets broader as e continues to increase.



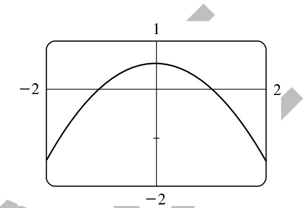
$e = 0.1$



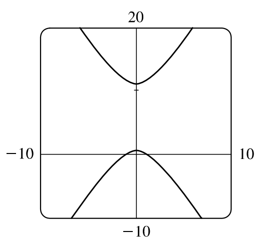
$e = 0.5$



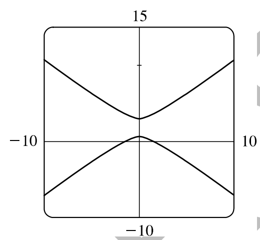
$e = 0.9$



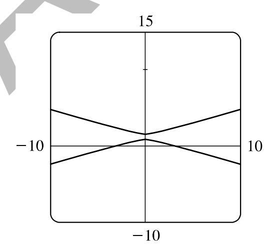
$e = 1$



$e = 1.1$



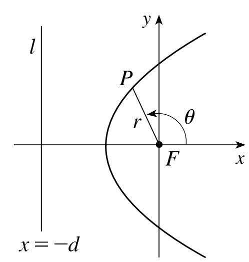
$e = 1.5$



$e = 10$

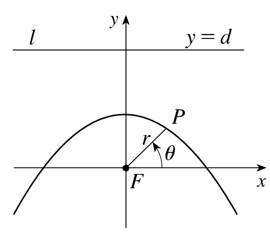
21. $|PF| = e\,|Pl| \;\Rightarrow\; r = e[d - r\cos(\pi - \theta)] = e(d + r\cos\theta) \;\Rightarrow$

$r(1 - e\cos\theta) = ed \;\Rightarrow\; r = \dfrac{ed}{1 - e\cos\theta}$



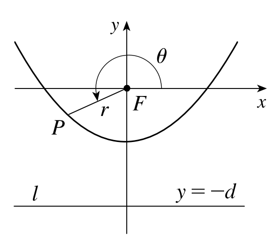
22. $|PF| = e\,|Pl| \;\Rightarrow\; r = e[d - r\sin\theta] \;\Rightarrow\; r(1 + e\sin\theta) = ed \;\Rightarrow$

$r = \dfrac{ed}{1 + e\sin\theta}$



23. $|PF| = e\,|Pl| \;\Rightarrow\; r = e[d - r\sin(\theta - \pi)] = e(d + r\sin\theta) \;\Rightarrow$

$r(1 - e\sin\theta) = ed \;\Rightarrow\; r = \dfrac{ed}{1 - e\sin\theta}$



24. The parabolas intersect at the two points where $\dfrac{c}{1+\cos\theta} = \dfrac{d}{1-\cos\theta} \quad\Rightarrow\quad \cos\theta = \dfrac{c-d}{c+d} \quad\Rightarrow\quad r = \dfrac{c+d}{2}$.

For the first parabola, $\dfrac{dr}{d\theta} = \dfrac{c\sin\theta}{(1+\cos\theta)^2}$, so

$$\frac{dy}{dx} = \frac{(dr/d\theta)\sin\theta + r\cos\theta}{(dr/d\theta)\cos\theta - r\sin\theta} = \frac{c\sin^2\theta + c\cos\theta(1+\cos\theta)}{c\sin\theta\cos\theta - c\sin\theta(1+\cos\theta)} = \frac{1+\cos\theta}{-\sin\theta}$$

and similarly for the second, $\dfrac{dy}{dx} = \dfrac{1-\cos\theta}{\sin\theta} = \dfrac{\sin\theta}{1+\cos\theta}$. Since the product of these slopes is -1, the parabolas intersect at right angles.

25. We are given $e = 0.093$ and $a = 2.28\times 10^8$. By (7), we have

$$r = \frac{a(1-e^2)}{1+e\cos\theta} = \frac{2.28\times 10^8[1-(0.093)^2]}{1+0.093\cos\theta} \approx \frac{2.26\times 10^8}{1+0.093\cos\theta}$$

26. We are given $e = 0.048$ and $2a = 1.56\times 10^9 \quad\Rightarrow\quad a = 7.8\times 10^8$. By (7), we have

$$r = \frac{a(1-e^2)}{1+e\cos\theta} = \frac{7.8\times 10^8[1-(0.048)^2]}{1+0.048\cos\theta} \approx \frac{7.78\times 10^8}{1+0.048\cos\theta}$$

27. Here $2a =$ length of major axis $= 36.18$ AU $\quad\Rightarrow\quad a = 18.09$ AU and $e = 0.97$. By (7), the equation of the orbit is $r = \dfrac{18.09[1-(0.97)^2]}{1+0.97\cos\theta} \approx \dfrac{1.07}{1+0.97\cos\theta}$. By (8), the maximum distance from the comet to the sun is $18.09(1+0.97) \approx 35.64$ AU or about 3.314 billion miles.

28. Here $2a =$ length of major axis $= 356.5$ AU $\quad\Rightarrow\quad a = 178.25$ AU and $e = 0.9951$. By (7), the equation of the orbit is $r = \dfrac{178.25[1-(0.9951)^2]}{1+0.9951\cos\theta} \approx \dfrac{1.7426}{1+0.9951\cos\theta}$. By (8), the minimum distance from the comet to the sun is $178.25(1-0.9951) \approx 0.8734$ AU or about 81 million miles.

29. The minimum distance is at perihelion, where $4.6\times 10^7 = r = a(1-e) = a(1-0.206) = a(0.794) \quad\Rightarrow$
$a = 4.6\times 10^7/0.794$. So the maximum distance, which is at aphelion, is
$r = a(1+e) = \left(4.6\times 10^7/0.794\right)(1.206) \approx 7.0\times 10^7$ km.

30. At perihelion, $r = a(1-e) = 4.43\times 10^9$, and at aphelion, $r = a(1+e) = 7.37\times 10^9$. Adding, we get $2a = 11.80\times 10^9$, so $a = 5.90\times 10^9$ km. Therefore $1+e = a(1+e)/a = \frac{7.37}{5.90} \approx 1.249$ and $e \approx 0.249$.

31. From Exercise 29, we have $e = 0.206$ and $a(1-e) = 4.6\times 10^7$ km. Thus, $a = 4.6\times 10^7/0.794$. From (7), we can write the equation of Mercury's orbit as $r = a\dfrac{1-e^2}{1+e\cos\theta}$. So since

$$\frac{dr}{d\theta} = \frac{a(1-e^2)e\sin\theta}{(1+e\cos\theta)^2} \quad\Rightarrow$$

$$r^2 + \left(\frac{dr}{d\theta}\right)^2 = \frac{a^2(1-e^2)^2}{(1+e\cos\theta)^2} + \frac{a^2(1-e^2)^2\,e^2\sin^2\theta}{(1+e\cos\theta)^4} = \frac{a^2(1-e^2)^2}{(1+e\cos\theta)^4}\,(1+2e\cos\theta+e^2)$$

the length of the orbit is

$$L = \int_0^{2\pi} \sqrt{r^2 + (dr/d\theta)^2}\, d\theta = a(1 - e^2) \int_0^{2\pi} \frac{\sqrt{1 + e^2 + 2e\cos\theta}}{(1 + e\cos\theta)^2}\, d\theta \approx 3.6 \times 10^8 \text{ km}$$

This seems reasonable, since Mercury's orbit is nearly circular, and the circumference of a circle of radius a is $2\pi a \approx 3.6 \times 10^8$ km.

TRUE-FALSE QUIZ

1. False. Consider the curve defined by $x = f(t) = (t-1)^3$ and $y = g(t) = (t-1)^2$. Then $g'(t) = 2(t-1)$, so $g'(1) = 0$, but its graph has a *vertical* tangent when $t = 1$. *Note:* The statement is true if $f'(1) \neq 0$ when $g'(1) = 0$.

2. False. If $x = f(t)$ and $y = g(t)$ are twice differentiable, then $\dfrac{d^2y}{dx^2} = \dfrac{d}{dx}\left(\dfrac{dy}{dx}\right) = \dfrac{\dfrac{d}{dt}\left(\dfrac{dy}{dx}\right)}{\dfrac{dx}{dt}}$.

3. False. For example, if $f(t) = \cos t$ and $g(t) = \sin t$ for $0 \le t \le 4\pi$, then the curve is a circle of radius 1, hence its length is 2π, but $\int_0^{4\pi} \sqrt{[f'(t)]^2 + [g'(t)]^2}\, dt = \int_0^{4\pi} \sqrt{(-\sin t)^2 + (\cos t)^2}\, dt = \int_0^{4\pi} 1\, dt = 4\pi$, since as t increases from 0 to 4π, the circle is traversed twice.

4. False. If $(r, \theta) = (1, \pi)$, then $(x, y) = (-1, 0)$, so $\tan^{-1}(y/x) = \tan^{-1} 0 = 0 \neq \theta$. The statement is true for points in quadrants I and IV.

5. True. The curve $r = 1 - \sin 2\theta$ is unchanged if we rotate it through 180° about O because $1 - \sin 2(\theta + \pi) = 1 - \sin(2\theta + 2\pi) = 1 - \sin 2\theta$. So it's unchanged if we replace r by $-r$. (See the discussion after Example 8 in Section 10.3.) In other words, it's the same curve as $r = -(1 - \sin 2\theta) = \sin 2\theta - 1$.

6. True. The polar equation $r = 2$, the Cartesian equation $x^2 + y^2 = 4$, and the parametric equations $x = 2\sin 3t$, $y = 2\cos 3t$ $[0 \le t \le 2\pi]$ all describe the circle of radius 2 centered at the origin.

7. False. The first pair of equations gives the portion of the parabola $y = x^2$ with $x \ge 0$, whereas the second pair of equations traces out the whole parabola $y = x^2$.

8. True. $y^2 = 2y + 3x \quad \Leftrightarrow \quad (y-1)^2 = 3x + 1 = 3\left(x + \frac{1}{3}\right) = 4\left(\frac{3}{4}\right)\left(x + \frac{1}{3}\right)$, which is the equation of a parabola with vertex $\left(-\frac{1}{3}, 1\right)$ and focus $\left(-\frac{1}{3} + \frac{3}{4}, 1\right)$, opening to the right.

9. True. By rotating and translating the parabola, we can assume it has an equation of the form $y = cx^2$, where $c > 0$. The tangent at the point $\left(a, ca^2\right)$ is the line $y - ca^2 = 2ca(x - a)$; i.e., $y = 2cax - ca^2$. This tangent meets the parabola at the points $\left(x, cx^2\right)$ where $cx^2 = 2cax - ca^2$. This equation is equivalent to $x^2 = 2ax - a^2$ [since $c > 0$]. But $x^2 = 2ax - a^2 \quad \Leftrightarrow \quad x^2 - 2ax + a^2 = 0 \quad \Leftrightarrow \quad (x-a)^2 = 0 \quad \Leftrightarrow \quad x = a \quad \Leftrightarrow$ $\left(x, cx^2\right) = \left(a, ca^2\right)$. This shows that each tangent meets the parabola at exactly one point.

10. True. Consider a hyperbola with focus at the origin, oriented so that its polar equation is $r = \dfrac{ed}{1 + e\cos\theta}$, where $e > 1$.

The directrix is $x = d$, but along the hyperbola we have $x = r\cos\theta = \dfrac{ed\cos\theta}{1 + e\cos\theta} = d\left(\dfrac{e\cos\theta}{1 + e\cos\theta}\right) \neq d$.

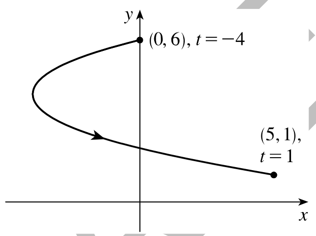
10 Review

EXERCISES

1. $x = t^2 + 4t$, $y = 2 - t$, $-4 \le t \le 1$. $t = 2 - y$, so

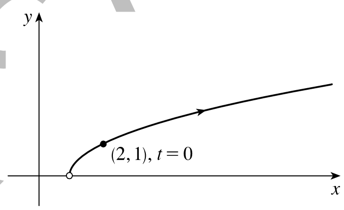
$x = (2 - y)^2 + 4(2 - y) = 4 - 4y + y^2 + 8 - 4y = y^2 - 8y + 12 \quad \Leftrightarrow$

$x + 4 = y^2 - 8y + 16 = (y - 4)^2$. This is part of a parabola with vertex $(-4, 4)$, opening to the right.



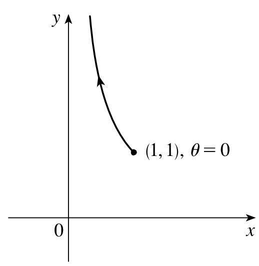
2. $x = 1 + e^{2t}$, $y = e^t$.

$x = 1 + e^{2t} = 1 + (e^t)^2 = 1 + y^2$, $y > 0$.



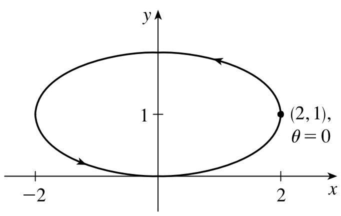
3. $y = \sec\theta = \dfrac{1}{\cos\theta} = \dfrac{1}{x}$. Since $0 \le \theta \le \pi/2$, $0 < x \le 1$ and $y \ge 1$.

This is part of the hyperbola $y = 1/x$.



4. $x = 2\cos\theta$, $y = 1 + \sin\theta$, $\cos^2\theta + \sin^2\theta = 1 \quad \Rightarrow$

$\left(\dfrac{x}{2}\right)^2 + (y - 1)^2 = 1 \quad \Rightarrow \quad \dfrac{x^2}{4} + (y - 1)^2 = 1$. This is an ellipse, centered at $(0, 1)$, with semimajor axis of length 2 and semiminor axis of length 1.



5. Three different sets of parametric equations for the curve $y = \sqrt{x}$ are

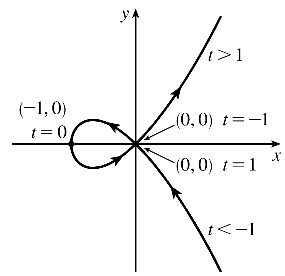
(i) $x = t, \quad y = \sqrt{t}$

(ii) $x = t^4, \quad y = t^2$

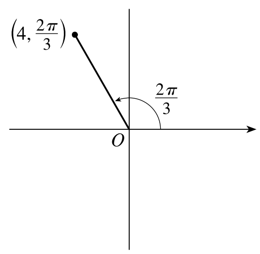
(iii) $x = \tan^2 t, \quad y = \tan t, \quad 0 \le t < \pi/2$

There are many other sets of equations that also give this curve.

6. For $t < -1$, $x > 0$ and $y < 0$ with x decreasing and y increasing. When $t = -1$, $(x, y) = (0, 0)$. When $-1 < t < 0$, we have $-1 < x < 0$ and $0 < y < 1/2$. When $t = 0$, $(x, y) = (-1, 0)$. When $0 < t < 1$, $-1 < x < 0$ and $-\frac{1}{2} < y < 0$. When $t = 1$, $(x, y) = (0, 0)$ again. When $t > 1$, both x and y are positive and increasing.



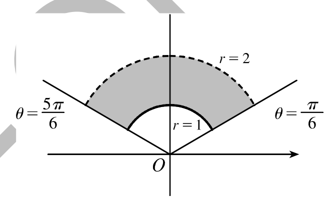
7. (a)



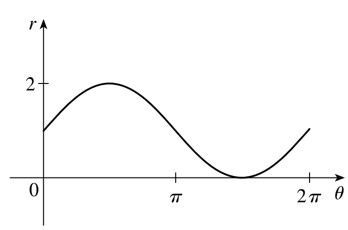
The Cartesian coordinates are $x = 4\cos\frac{2\pi}{3} = 4\left(-\frac{1}{2}\right) = -2$ and $y = 4\sin\frac{2\pi}{3} = 4\left(\frac{\sqrt{3}}{2}\right) = 2\sqrt{3}$, that is, the point $\left(-2, 2\sqrt{3}\right)$.

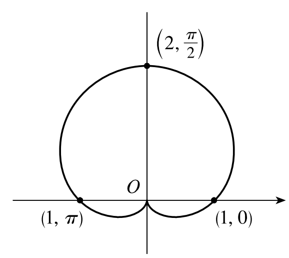
(b) Given $x = -3$ and $y = 3$, we have $r = \sqrt{(-3)^2 + 3^2} = \sqrt{18} = 3\sqrt{2}$. Also, $\tan\theta = \dfrac{y}{x} \;\Rightarrow\; \tan\theta = \dfrac{3}{-3}$, and since $(-3, 3)$ is in the second quadrant, $\theta = \frac{3\pi}{4}$. Thus, one set of polar coordinates for $(-3, 3)$ is $\left(3\sqrt{2}, \frac{3\pi}{4}\right)$, and two others are $\left(3\sqrt{2}, \frac{11\pi}{4}\right)$ and $\left(-3\sqrt{2}, \frac{7\pi}{4}\right)$.

8. $1 \le r < 2,\ \frac{\pi}{6} \le \theta \le \frac{5\pi}{6}$

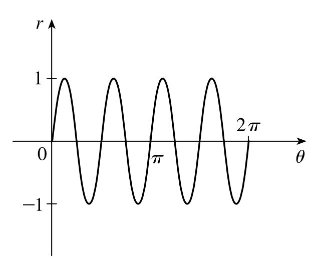


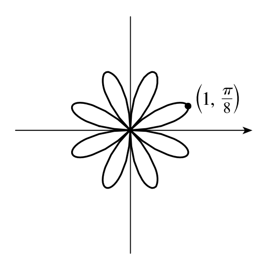
9. $r = 1 + \sin\theta$. This cardioid is symmetric about the $\theta = \pi/2$ axis.



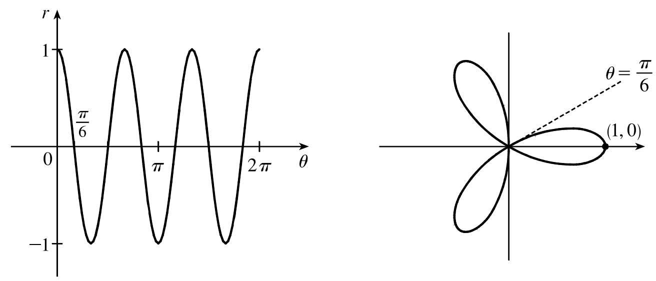


10. $r = \sin 4\theta$. This is an eight-leaved rose.

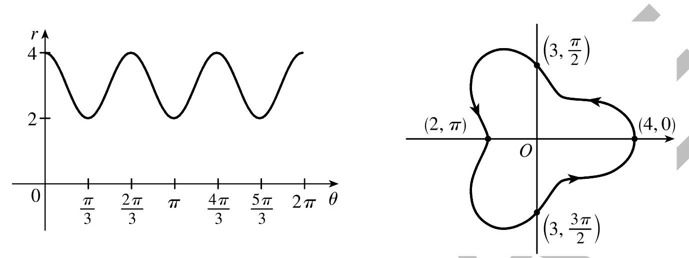




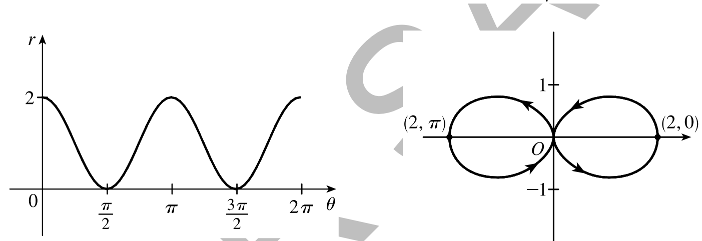
11. $r = \cos 3\theta$. This is a three-leaved rose. The curve is traced twice.



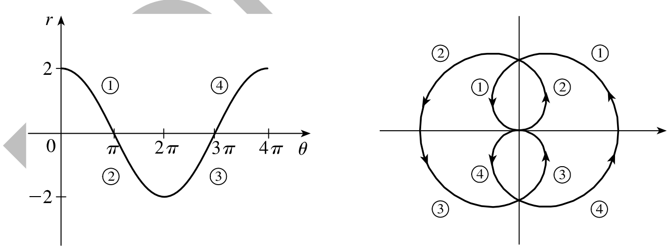
12. $r = 3 + \cos 3\theta$. The curve is symmetric about the horizontal axis.



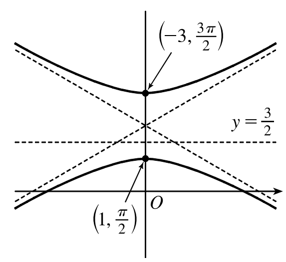
13. $r = 1 + \cos 2\theta$. The curve is symmetric about the pole and both the horizontal and vertical axes.



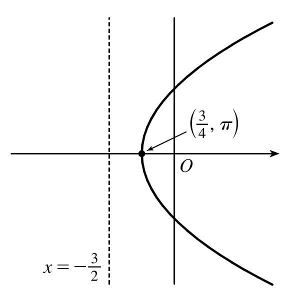
14. $r = 2\cos(\theta/2)$. The curve is symmetric about the pole and both the horizontal and vertical axes.



15. $r = \dfrac{3}{1 + 2\sin\theta} \quad \Rightarrow \quad e = 2 > 1$, so the conic is a hyperbola. $de = 3 \quad \Rightarrow$ $d = \frac{3}{2}$ and the form "$+2\sin\theta$" imply that the directrix is above the focus at the origin and has equation $y = \frac{3}{2}$. The vertices are $\left(1, \frac{\pi}{2}\right)$ and $\left(-3, \frac{3\pi}{2}\right)$.



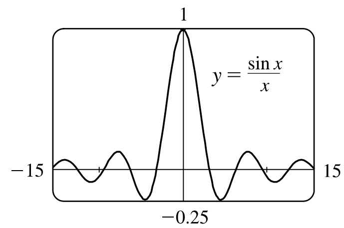
16. $r = \dfrac{3}{2 - 2\cos\theta} \cdot \dfrac{1/2}{1/2} = \dfrac{3/2}{1 - 1\cos\theta} \quad \Rightarrow \quad e = 1$, so the conic is a parabola. $de = \frac{3}{2} \quad \Rightarrow \quad d = \frac{3}{2}$ and the form "$-2\cos\theta$" imply that the directrix is to the left of the focus at the origin and has equation $x = -\frac{3}{2}$. The vertex is $\left(\frac{3}{4}, \pi\right)$.

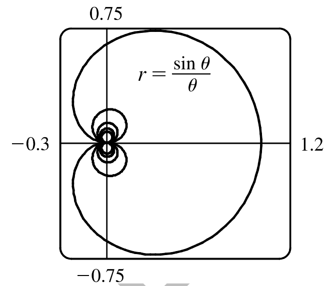


17. $x + y = 2 \quad \Leftrightarrow \quad r\cos\theta + r\sin\theta = 2 \quad \Leftrightarrow \quad r(\cos\theta + \sin\theta) = 2 \quad \Leftrightarrow \quad r = \dfrac{2}{\cos\theta + \sin\theta}$

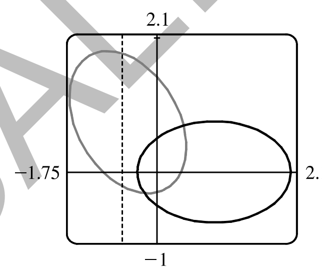
18. $x^2 + y^2 = 2 \quad \Rightarrow \quad r^2 = 2 \quad \Rightarrow \quad r = \sqrt{2}$. $[r = -\sqrt{2}$ gives the same curve.]

19. $r = (\sin\theta)/\theta$. As $\theta \to \pm\infty$, $r \to 0$. As $\theta \to 0$, $r \to 1$. In the first figure, there are an infinite number of x-intercepts at $x = \pi n$, n a nonzero integer. These correspond to pole points in the second figure.





20. $r = \dfrac{2}{4 - 3\cos\theta} = \dfrac{1/2}{1 - \frac{3}{4}\cos\theta} \quad \Rightarrow \quad e = \frac{3}{4}$ and $d = \frac{2}{3}$. The equation of the directrix is $x = -\frac{2}{3} \quad \Rightarrow \quad r = -2/(3\cos\theta)$. To obtain the equation of the rotated ellipse, we replace θ in the original equation with $\theta - \frac{2\pi}{3}$, and get $r = \dfrac{2}{4 - 3\cos\left(\theta - \frac{2\pi}{3}\right)}$.



21. $x = \ln t$, $y = 1 + t^2$; $t = 1$. $\dfrac{dy}{dt} = 2t$ and $\dfrac{dx}{dt} = \dfrac{1}{t}$, so $\dfrac{dy}{dx} = \dfrac{dy/dt}{dx/dt} = \dfrac{2t}{1/t} = 2t^2$.

When $t = 1$, $(x, y) = (0, 2)$ and $dy/dx = 2$.

22. $x = t^3 + 6t + 1,\ y = 2t - t^2;\quad t = -1$. $\dfrac{dy}{dx} = \dfrac{dy/dt}{dx/dt} = \dfrac{2 - 2t}{3t^2 + 6}$. When $t = -1$, $(x, y) = (-6, -3)$ and $\dfrac{dy}{dx} = \dfrac{4}{9}$.

23. $r = e^{-\theta} \quad \Rightarrow \quad y = r\sin\theta = e^{-\theta}\sin\theta$ and $x = r\cos\theta = e^{-\theta}\cos\theta \quad \Rightarrow$

$$\frac{dy}{dx} = \frac{dy/d\theta}{dx/d\theta} = \frac{\frac{dr}{d\theta}\sin\theta + r\cos\theta}{\frac{dr}{d\theta}\cos\theta - r\sin\theta} = \frac{-e^{-\theta}\sin\theta + e^{-\theta}\cos\theta}{-e^{-\theta}\cos\theta - e^{-\theta}\sin\theta} \cdot \frac{-e^{\theta}}{-e^{\theta}} = \frac{\sin\theta - \cos\theta}{\cos\theta + \sin\theta}.$$

When $\theta = \pi$, $\dfrac{dy}{dx} = \dfrac{0 - (-1)}{-1 + 0} = \dfrac{1}{-1} = -1$.

24. $r = 3 + \cos 3\theta \quad \Rightarrow \quad \dfrac{dy}{dx} = \dfrac{dy/d\theta}{dx/d\theta} = \dfrac{\frac{dr}{d\theta}\sin\theta + r\cos\theta}{\frac{dr}{d\theta}\cos\theta - r\sin\theta} = \dfrac{-3\sin 3\theta\sin\theta + (3 + \cos 3\theta)\cos\theta}{-3\sin 3\theta\cos\theta - (3 + \cos 3\theta)\sin\theta}$.

When $\theta = \pi/2$, $\dfrac{dy}{dx} = \dfrac{(-3)(-1)(1) + (3 + 0)\cdot 0}{(-3)(-1)(0) - (3 + 0)\cdot 1} = \dfrac{3}{-3} = -1$.

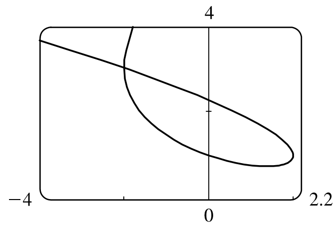
25. $x = t + \sin t,\ y = t - \cos t \quad \Rightarrow \quad \dfrac{dy}{dx} = \dfrac{dy/dt}{dx/dt} = \dfrac{1 + \sin t}{1 + \cos t} \quad \Rightarrow$

$$\frac{d^2y}{dx^2} = \frac{\frac{d}{dt}\left(\frac{dy}{dx}\right)}{dx/dt} = \frac{\dfrac{(1 + \cos t)\,\cos t - (1 + \sin t)(-\sin t)}{(1 + \cos t)^2}}{1 + \cos t} = \frac{\cos t + \cos^2 t + \sin t + \sin^2 t}{(1 + \cos t)^3} = \frac{1 + \cos t + \sin t}{(1 + \cos t)^3}$$

26. $x = 1 + t^2$, $y = t - t^3$. $\dfrac{dy}{dt} = 1 - 3t^2$ and $\dfrac{dx}{dt} = 2t$, so $\dfrac{dy}{dx} = \dfrac{dy/dt}{dx/dt} = \dfrac{1 - 3t^2}{2t} = \frac{1}{2}t^{-1} - \frac{3}{2}t$.

$$\frac{d^2y}{dx^2} = \frac{d(dy/dx)/dt}{dx/dt} = \frac{-\frac{1}{2}t^{-2} - \frac{3}{2}}{2t} = -\tfrac{1}{4}t^{-3} - \tfrac{3}{4}t^{-1} = -\frac{1}{4t^3}\left(1 + 3t^2\right) = -\frac{3t^2 + 1}{4t^3}.$$

27. We graph the curve $x = t^3 - 3t$, $y = t^2 + t + 1$ for $-2.2 \le t \le 1.2$. By zooming in or using a cursor, we find that the lowest point is about $(1.4, 0.75)$. To find the exact values, we find the t-value at which $dy/dt = 2t + 1 = 0 \quad \Leftrightarrow \quad t = -\frac{1}{2} \quad \Leftrightarrow \quad (x, y) = \left(\frac{11}{8}, \frac{3}{4}\right)$.



28. We estimate the coordinates of the point of intersection to be $(-2, 3)$. In fact this is exact, since both $t = -2$ and $t = 1$ give the point $(-2, 3)$. So the area enclosed by the loop is

$$\int_{t=-2}^{t=1} y\,dx = \int_{-2}^{1} (t^2 + t + 1)(3t^2 - 3)\,dt = \int_{-2}^{1} (3t^4 + 3t^3 - 3t - 3)\,dt$$

$$= \left[\tfrac{3}{5}t^5 + \tfrac{3}{4}t^4 - \tfrac{3}{2}t^2 - 3t\right]_{-2}^{1} = \left(\tfrac{3}{5} + \tfrac{3}{4} - \tfrac{3}{2} - 3\right) - \left[-\tfrac{96}{5} + 12 - 6 - (-6)\right] = \tfrac{81}{20}$$

29. $x = 2a\cos t - a\cos 2t \quad \Rightarrow \quad \dfrac{dx}{dt} = -2a\sin t + 2a\sin 2t = 2a\sin t(2\cos t - 1) = 0 \quad \Leftrightarrow$

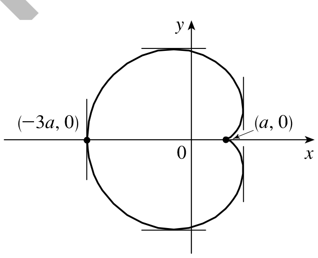
$\sin t = 0$ or $\cos t = \frac{1}{2} \quad \Rightarrow \quad t = 0, \frac{\pi}{3}, \pi$, or $\frac{5\pi}{3}$.

$y = 2a\sin t - a\sin 2t \quad \Rightarrow \quad \dfrac{dy}{dt} = 2a\cos t - 2a\cos 2t = 2a\left(1 + \cos t - 2\cos^2 t\right) = 2a(1 - \cos t)(1 + 2\cos t) = 0 \quad \Rightarrow$

$t = 0, \frac{2\pi}{3}$, or $\frac{4\pi}{3}$.

Thus the graph has vertical tangents where $t = \frac{\pi}{3}, \pi$ and $\frac{5\pi}{3}$, and horizontal tangents where $t = \frac{2\pi}{3}$ and $\frac{4\pi}{3}$. To determine what the slope is where $t = 0$, we use l'Hospital's Rule to evaluate $\lim\limits_{t \to 0} \dfrac{dy/dt}{dx/dt} = 0$, so there is a horizontal tangent there.

t	x	y
0	a	0
$\frac{\pi}{3}$	$\frac{3}{2}a$	$\frac{\sqrt{3}}{2}a$
$\frac{2\pi}{3}$	$-\frac{1}{2}a$	$\frac{3\sqrt{3}}{2}a$
π	$-3a$	0
$\frac{4\pi}{3}$	$-\frac{1}{2}a$	$-\frac{3\sqrt{3}}{2}a$
$\frac{5\pi}{3}$	$\frac{3}{2}a$	$-\frac{\sqrt{3}}{2}a$



30. From Exercise 29, $x = 2a\cos t - a\cos 2t$, $y = 2a\sin t - a\sin 2t \quad \Rightarrow$

$$A = 2\int_{\pi}^{0} (2a\sin t - a\sin 2t)(-2a\sin t + 2a\sin 2t)\,dt = 4a^2 \int_0^{\pi} (2\sin^2 t + \sin^2 2t - 3\sin t\sin 2t)\,dt$$

$$= 4a^2 \int_0^{\pi} \left[(1 - \cos 2t) + \tfrac{1}{2}(1 - \cos 4t) - 6\sin^2 t\,\cos t\right] dt = 4a^2\left[t - \tfrac{1}{2}\sin 2t + \tfrac{1}{2}t - \tfrac{1}{8}\sin 4t - 2\sin^3 t\right]_0^{\pi}$$

$$= 4a^2\left(\tfrac{3}{2}\right)\pi = 6\pi a^2$$

31. The curve $r^2 = 9\cos 5\theta$ has 10 "petals." For instance, for $-\frac{\pi}{10} \le \theta \le \frac{\pi}{10}$, there are two petals, one with $r > 0$ and one with $r < 0$.

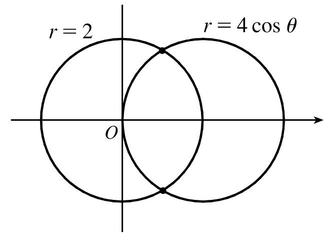
$$A = 10\int_{-\pi/10}^{\pi/10} \tfrac{1}{2}r^2\,d\theta = 5\int_{-\pi/10}^{\pi/10} 9\cos 5\theta\,d\theta = 5 \cdot 9 \cdot 2\int_0^{\pi/10} \cos 5\theta\,d\theta = 18\big[\sin 5\theta\big]_0^{\pi/10} = 18$$

32. $r = 1 - 3\sin\theta$. The inner loop is traced out as θ goes from $\alpha = \sin^{-1}\left(\frac{1}{3}\right)$ to $\pi - \alpha$, so

$$A = \int_{\alpha}^{\pi - \alpha} \tfrac{1}{2}r^2\,d\theta = \int_{\alpha}^{\pi/2} (1 - 3\sin\theta)^2\,d\theta = \int_{\alpha}^{\pi/2} \left[1 - 6\sin\theta + \tfrac{9}{2}(1 - \cos 2\theta)\right] d\theta$$

$$= \left[\tfrac{11}{2}\theta + 6\cos\theta - \tfrac{9}{4}\sin 2\theta\right]_{\alpha}^{\pi/2} = \tfrac{11}{4}\pi - \tfrac{11}{2}\sin^{-1}\left(\tfrac{1}{3}\right) - 3\sqrt{2}$$

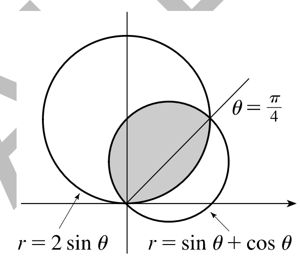
33. The curves intersect when $4\cos\theta = 2 \;\Rightarrow\; \cos\theta = \frac{1}{2} \;\Rightarrow\; \theta = \pm\frac{\pi}{3}$ for $-\pi \le \theta \le \pi$. The points of intersection are $\left(2, \frac{\pi}{3}\right)$ and $\left(2, -\frac{\pi}{3}\right)$.



34. The two curves clearly both contain the pole. For other points of intersection, $\cot\theta = 2\cos(\theta + 2n\pi)$ or $-2\cos(\theta + \pi + 2n\pi)$, both of which reduce to $\cot\theta = 2\cos\theta \;\Leftrightarrow\; \cos\theta = 2\sin\theta\cos\theta \;\Leftrightarrow\; \cos\theta(1 - 2\sin\theta) = 0 \;\Rightarrow$ $\cos\theta = 0$ or $\sin\theta = \frac{1}{2} \;\Rightarrow\; \theta = \frac{\pi}{6}, \frac{\pi}{2}, \frac{5\pi}{6}$ or $\frac{3\pi}{2} \;\Rightarrow$ intersection points are $\left(0, \frac{\pi}{2}\right)$, $\left(\sqrt{3}, \frac{\pi}{6}\right)$, and $\left(\sqrt{3}, \frac{11\pi}{6}\right)$.

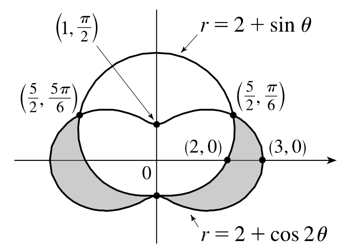
35. The curves intersect where $2\sin\theta = \sin\theta + \cos\theta \;\Rightarrow$ $\sin\theta = \cos\theta \;\Rightarrow \theta = \frac{\pi}{4}$, and also at the origin (at which $\theta = \frac{3\pi}{4}$ on the second curve).

$$A = \int_0^{\pi/4} \tfrac{1}{2}(2\sin\theta)^2\,d\theta + \int_{\pi/4}^{3\pi/4} \tfrac{1}{2}(\sin\theta + \cos\theta)^2\,d\theta$$
$$= \int_0^{\pi/4} (1 - \cos 2\theta)\,d\theta + \tfrac{1}{2}\int_{\pi/4}^{3\pi/4} (1 + \sin 2\theta)\,d\theta$$
$$= \left[\theta - \tfrac{1}{2}\sin 2\theta\right]_0^{\pi/4} + \left[\tfrac{1}{2}\theta - \tfrac{1}{4}\cos 2\theta\right]_{\pi/4}^{3\pi/4} = \tfrac{1}{2}(\pi - 1)$$



36. $A = 2\int_{-\pi/2}^{\pi/6} \frac{1}{2}\left[(2 + \cos 2\theta)^2 - (2 + \sin\theta)^2\right] d\theta$

$$= \int_{-\pi/2}^{\pi/6} \left[4\cos 2\theta + \cos^2 2\theta - 4\sin\theta - \sin^2\theta\right] d\theta$$
$$= \left[2\sin 2\theta + \tfrac{1}{2}\theta + \tfrac{1}{8}\sin 4\theta + 4\cos\theta - \tfrac{1}{2}\theta + \tfrac{1}{4}\sin 2\theta\right]_{-\pi/2}^{\pi/6}$$
$$= \tfrac{51}{16}\sqrt{3}$$



37. $x = 3t^2,\; y = 2t^3$.

$$L = \int_0^2 \sqrt{(dx/dt)^2 + (dy/dt)^2}\,dt = \int_0^2 \sqrt{(6t)^2 + (6t^2)^2}\,dt = \int_0^2 \sqrt{36t^2 + 36t^4}\,dt = \int_0^2 \sqrt{36t^2}\sqrt{1 + t^2}\,dt$$
$$= \int_0^2 6\,|t|\sqrt{1 + t^2}\,dt = 6\int_0^2 t\sqrt{1 + t^2}\,dt = 6\int_1^5 u^{1/2}\left(\tfrac{1}{2}du\right) \qquad \left[u = 1 + t^2,\, du = 2t\,dt\right]$$
$$= 6 \cdot \tfrac{1}{2} \cdot \tfrac{2}{3}\left[u^{3/2}\right]_1^5 = 2(5^{3/2} - 1) = 2\left(5\sqrt{5} - 1\right)$$

38. $x = 2 + 3t, \quad y = \cosh 3t \;\Rightarrow\; (dx/dt)^2 + (dy/dt)^2 = 3^2 + (3\sinh 3t)^2 = 9(1 + \sinh^2 3t) = 9\cosh^2 3t$, so $L = \int_0^1 \sqrt{9\cosh^2 3t}\,dt = \int_0^1 |3\cosh 3t|\,dt = \int_0^1 3\cosh 3t\,dt = \left[\sinh 3t\right]_0^1 = \sinh 3 - \sinh 0 = \sinh 3$.

39. $L = \int_\pi^{2\pi} \sqrt{r^2 + (dr/d\theta)^2}\,d\theta = \int_\pi^{2\pi} \sqrt{(1/\theta)^2 + (-1/\theta^2)^2}\,d\theta = \displaystyle\int_\pi^{2\pi} \frac{\sqrt{\theta^2 + 1}}{\theta^2}\,d\theta$

$$\overset{24}{=} \left[-\frac{\sqrt{\theta^2 + 1}}{\theta} + \ln\left(\theta + \sqrt{\theta^2 + 1}\right)\right]_\pi^{2\pi} = \frac{\sqrt{\pi^2 + 1}}{\pi} - \frac{\sqrt{4\pi^2 + 1}}{2\pi} + \ln\left(\frac{2\pi + \sqrt{4\pi^2 + 1}}{\pi + \sqrt{\pi^2 + 1}}\right)$$
$$= \frac{2\sqrt{\pi^2 + 1} - \sqrt{4\pi^2 + 1}}{2\pi} + \ln\left(\frac{2\pi + \sqrt{4\pi^2 + 1}}{\pi + \sqrt{\pi^2 + 1}}\right)$$

40. $L = \int_0^\pi \sqrt{r^2 + (dr/d\theta)^2}\, d\theta = \int_0^\pi \sqrt{\sin^6\left(\frac{1}{3}\theta\right) + \sin^4\left(\frac{1}{3}\theta\right)\cos^2\left(\frac{1}{3}\theta\right)}\, d\theta$

$= \int_0^\pi \sin^2\left(\frac{1}{3}\theta\right) d\theta = \left[\frac{1}{2}\left(\theta - \frac{3}{2}\sin\left(\frac{2}{3}\theta\right)\right)\right]_0^\pi = \frac{1}{2}\pi - \frac{3}{8}\sqrt{3}$

41. $x = 4\sqrt{t},\ y = \dfrac{t^3}{3} + \dfrac{1}{2t^2},\ 1 \le t \le 4 \quad \Rightarrow$

$S = \int_1^4 2\pi y \sqrt{(dx/dt)^2 + (dy/dt)^2}\, dt = \int_1^4 2\pi\left(\frac{1}{3}t^3 + \frac{1}{2}t^{-2}\right)\sqrt{\left(2/\sqrt{t}\right)^2 + (t^2 - t^{-3})^2}\, dt$

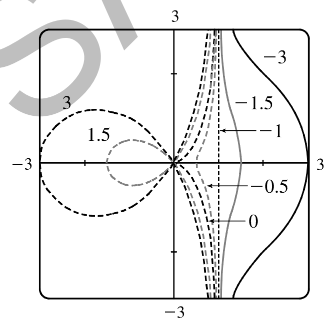
$= 2\pi \int_1^4 \left(\frac{1}{3}t^3 + \frac{1}{2}t^{-2}\right)\sqrt{(t^2 + t^{-3})^2}\, dt = 2\pi \int_1^4 \left(\frac{1}{3}t^5 + \frac{5}{6} + \frac{1}{2}t^{-5}\right) dt = 2\pi\left[\frac{1}{18}t^6 + \frac{5}{6}t - \frac{1}{8}t^{-4}\right]_1^4 = \frac{471{,}295}{1024}\pi$

42. $x = 2 + 3t, \quad y = \cosh 3t \quad \Rightarrow \quad (dx/dt)^2 + (dy/dt)^2 = 3^2 + (3\sinh 3t)^2 = 9(1 + \sinh^2 3t) = 9\cosh^2 3t$, so

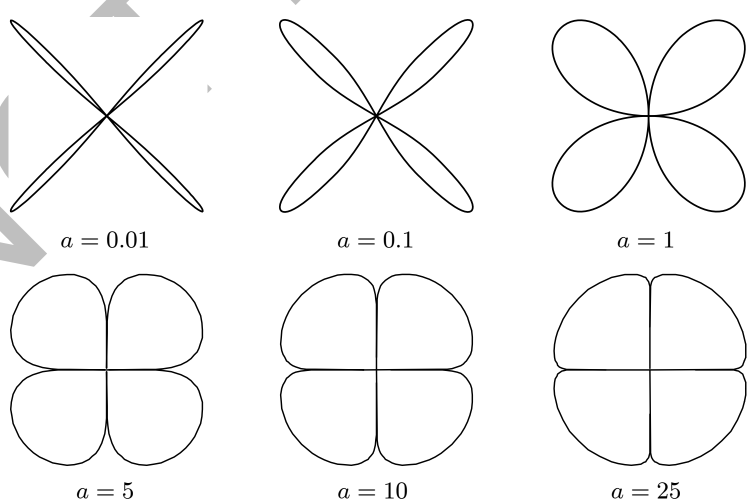
$S = \int_0^1 2\pi y\, ds = \int_0^1 2\pi \cosh 3t \sqrt{9\cosh^2 3t}\, dt = \int_0^1 2\pi \cosh 3t\, |3\cosh 3t|\, dt = \int_0^1 2\pi \cosh 3t \cdot 3\cosh 3t\, dt$

$= 6\pi \int_0^1 \cosh^2 3t\, dt = 6\pi \int_0^1 \frac{1}{2}(1 + \cosh 6t)\, dt = 3\pi\left[t + \frac{1}{6}\sinh 6t\right]_0^1 = 3\pi\left(1 + \frac{1}{6}\sinh 6\right) = 3\pi + \frac{\pi}{2}\sinh 6$

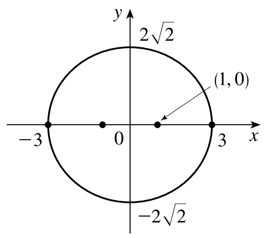
43. For all c except -1, the curve is asymptotic to the line $x = 1$. For $c < -1$, the curve bulges to the right near $y = 0$. As c increases, the bulge becomes smaller, until at $c = -1$ the curve is the straight line $x = 1$. As c continues to increase, the curve bulges to the left, until at $c = 0$ there is a cusp at the origin. For $c > 0$, there is a loop to the left of the origin, whose size and roundness increase as c increases. Note that the x-intercept of the curve is always $-c$.



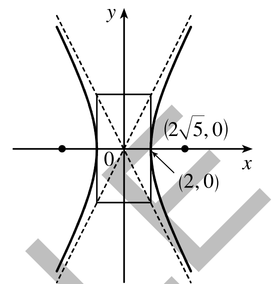
44. For a close to 0, the graph of $r^a = |\sin 2\theta|$ consists of four thin petals. As a increases, the petals get wider, until as $a \to \infty$, each petal occupies almost its entire quarter-circle.



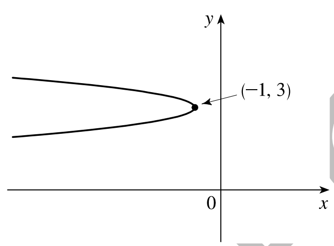
45. $\dfrac{x^2}{9} + \dfrac{y^2}{8} = 1$ is an ellipse with center $(0, 0)$.
$a = 3$, $b = 2\sqrt{2}$, $c = 1 \quad \Rightarrow$
foci $(\pm 1, 0)$, vertices $(\pm 3, 0)$.



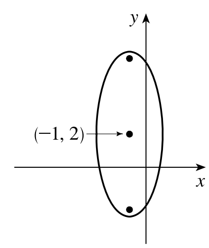
46. $4x^2 - y^2 = 16 \quad \Leftrightarrow \quad \dfrac{x^2}{4} - \dfrac{y^2}{16} = 1$ is a hyperbola with center $(0, 0)$, vertices $(\pm 2, 0)$, $a = 2$, $b = 4$, $c = \sqrt{16 + 4} = 2\sqrt{5}$, foci $\left(\pm 2\sqrt{5}, 0\right)$ and asymptotes $y = \pm 2x$.



47. $6y^2 + x - 36y + 55 = 0 \quad \Leftrightarrow$
$6(y^2 - 6y + 9) = -(x + 1) \quad \Leftrightarrow$
$(y - 3)^2 = -\frac{1}{6}(x + 1)$, a parabola with vertex $(-1, 3)$, opening to the left, $p = -\frac{1}{24} \quad \Rightarrow \quad$ focus $\left(-\frac{25}{24}, 3\right)$ and directrix $x = -\frac{23}{24}$.



48. $25x^2 + 4y^2 + 50x - 16y = 59 \quad \Leftrightarrow$
$25(x + 1)^2 + 4(y - 2)^2 = 100 \quad \Leftrightarrow$
$\frac{1}{4}(x + 1)^2 + \frac{1}{25}(y - 2)^2 = 1$ is an ellipse centered at $(-1, 2)$ with foci on the line $x = -1$, vertices $(-1, 7)$ and $(-1, -3)$; $a = 5$, $b = 2 \quad \Rightarrow \quad c = \sqrt{21} \quad \Rightarrow$
foci $\left(-1, 2 \pm \sqrt{21}\right)$.



49. The ellipse with foci $(\pm 4, 0)$ and vertices $(\pm 5, 0)$ has center $(0, 0)$ and a horizontal major axis, with $a = 5$ and $c = 4$, so $b^2 = a^2 - c^2 = 5^2 - 4^2 = 9$. An equation is $\dfrac{x^2}{25} + \dfrac{y^2}{9} = 1$.

50. The distance from the focus $(2, 1)$ to the directrix $x = -4$ is $2 - (-4) = 6$, so the distance from the focus to the vertex is $\frac{1}{2}(6) = 3$ and the vertex is $(-1, 1)$. Since the focus is to the right of the vertex, $p = 3$. An equation is $(y - 1)^2 = 4 \cdot 3[x - (-1)]$, or $(y - 1)^2 = 12(x + 1)$.

51. The center of a hyperbola with foci $(0, \pm 4)$ is $(0, 0)$, so $c = 4$ and an equation is $\dfrac{y^2}{a^2} - \dfrac{x^2}{b^2} = 1$.
The asymptote $y = 3x$ has slope 3, so $\dfrac{a}{b} = \dfrac{3}{1} \quad \Rightarrow \quad a = 3b$ and $a^2 + b^2 = c^2 \quad \Rightarrow \quad (3b)^2 + b^2 = 4^2 \quad \Rightarrow$
$10b^2 = 16 \quad \Rightarrow \quad b^2 = \frac{8}{5}$ and so $a^2 = 16 - \frac{8}{5} = \frac{72}{5}$. Thus, an equation is $\dfrac{y^2}{72/5} - \dfrac{x^2}{8/5} = 1$, or $\dfrac{5y^2}{72} - \dfrac{5x^2}{8} = 1$.

52. Center is $(3, 0)$, and $a = \frac{8}{2} = 4$, $c = 2 \quad \Leftrightarrow \quad b = \sqrt{4^2 - 2^2} = \sqrt{12} \quad \Rightarrow$
an equation of the ellipse is $\dfrac{(x - 3)^2}{12} + \dfrac{y^2}{16} = 1$.

53. $x^2 + y = 100 \quad \Leftrightarrow \quad x^2 = -(y - 100)$ has its vertex at $(0, 100)$, so one of the vertices of the ellipse is $(0, 100)$. Another form of the equation of a parabola is $x^2 = 4p(y - 100)$ so $4p(y - 100) = -(y - 100) \quad \Rightarrow \quad 4p = -1 \quad \Rightarrow \quad p = -\frac{1}{4}$. Therefore the shared focus is found at $\left(0, \frac{399}{4}\right)$ so $2c = \frac{399}{4} - 0 \quad \Rightarrow \quad c = \frac{399}{8}$ and the center of the ellipse is $\left(0, \frac{399}{8}\right)$. So $a = 100 - \frac{399}{8} = \frac{401}{8}$ and $b^2 = a^2 - c^2 = \dfrac{401^2 - 399^2}{8^2} = 25$. So the equation of the ellipse is $\dfrac{x^2}{b^2} + \dfrac{\left(y - \frac{399}{8}\right)^2}{a^2} = 1 \quad \Rightarrow$

$\dfrac{x^2}{25} + \dfrac{\left(y - \frac{399}{8}\right)^2}{\left(\frac{401}{8}\right)^2} = 1$, or $\dfrac{x^2}{25} + \dfrac{(8y - 399)^2}{160{,}801} = 1$.

54. $\dfrac{x^2}{a^2} + \dfrac{y^2}{b^2} = 1 \quad \Rightarrow \quad \dfrac{2x}{a^2} + \dfrac{2y}{b^2}\dfrac{dy}{dx} = 0 \quad \Rightarrow \quad \dfrac{dy}{dx} = -\dfrac{b^2}{a^2}\dfrac{x}{y}$. Therefore $\dfrac{dy}{dx} = m \quad \Leftrightarrow \quad y = -\dfrac{b^2}{a^2}\dfrac{x}{m}$. Combining this condition with $\dfrac{x^2}{a^2} + \dfrac{y^2}{b^2} = 1$, we find that $x = \pm\dfrac{a^2 m}{\sqrt{a^2m^2 + b^2}}$. In other words, the two points on the ellipse where the tangent has slope m are $\left(\pm\dfrac{a^2 m}{\sqrt{a^2m^2 + b^2}}, \mp\dfrac{b^2}{\sqrt{a^2m^2 + b^2}}\right)$. The tangent lines at these points have the equations

$y \pm \dfrac{b^2}{\sqrt{a^2m^2 + b^2}} = m\left(x \mp \dfrac{a^2 m}{\sqrt{a^2m^2 + b^2}}\right)$ or $y = mx \mp \dfrac{a^2m^2}{\sqrt{a^2m^2 + b^2}} \mp \dfrac{b^2}{\sqrt{a^2m^2 + b^2}} = mx \mp \sqrt{a^2m^2 + b^2}$.

55. Directrix $x = 4 \quad \Rightarrow \quad d = 4$, so $e = \frac{1}{3} \quad \Rightarrow \quad r = \dfrac{ed}{1 + e\cos\theta} = \dfrac{4}{3 + \cos\theta}$.

56. See the end of the proof of Theorem 10.6.1. If $e > 1$, then $1 - e^2 < 0$ and Equations 10.6.4 become $a^2 = \dfrac{e^2d^2}{(e^2 - 1)^2}$ and $b^2 = \dfrac{e^2d^2}{e^2 - 1}$, so $\dfrac{b^2}{a^2} = e^2 - 1$. The asymptotes $y = \pm\dfrac{b}{a}x$ have slopes $\pm\dfrac{b}{a} = \pm\sqrt{e^2 - 1}$, so the angles they make with the polar axis are $\pm\tan^{-1}\left[\sqrt{e^2 - 1}\right] = \cos^{-1}(\pm 1/e)$.

57. In polar coordinates, an equation for the circle is $r = 2a\sin\theta$. Thus, the coordinates of Q are $x = r\cos\theta = 2a\sin\theta\,\cos\theta$ and $y = r\sin\theta = 2a\sin^2\theta$. The coordinates of R are $x = 2a\cot\theta$ and $y = 2a$. Since P is the midpoint of QR, we use the midpoint formula to get $x = a(\sin\theta\,\cos\theta + \cot\theta)$ and $y = a(1 + \sin^2\theta)$.

58. (a) If (a, b) lies on the curve, then there is some parameter value t_1 such that $\dfrac{3t_1}{1 + t_1^3} = a$ and $\dfrac{3t_1^2}{1 + t_1^3} = b$. If $t_1 = 0$, the point is $(0, 0)$, which lies on the line $y = x$. If $t_1 \neq 0$, then the point corresponding to $t = \dfrac{1}{t_1}$ is given by

$x = \dfrac{3(1/t_1)}{1 + (1/t_1)^3} = \dfrac{3t_1^2}{t_1^3 + 1} = b$, $y = \dfrac{3(1/t_1)^2}{1 + (1/t_1)^3} = \dfrac{3t_1}{t_1^3 + 1} = a$. So (b, a) also lies on the curve. [Another way to see this is to do part (e) first; the result is immediate.] The curve intersects the line $y = x$ when $\dfrac{3t}{1 + t^3} = \dfrac{3t^2}{1 + t^3} \quad \Rightarrow$

$t = t^2 \quad \Rightarrow \quad t = 0$ or 1, so the points are $(0, 0)$ and $\left(\frac{3}{2}, \frac{3}{2}\right)$.

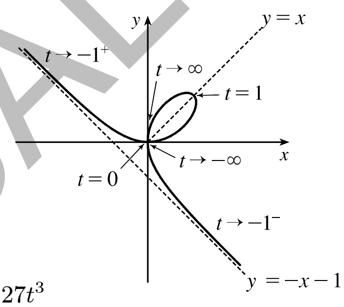
(b) $\dfrac{dy}{dt} = \dfrac{(1+t^3)(6t) - 3t^2(3t^2)}{(1+t^3)^2} = \dfrac{6t - 3t^4}{(1+t^3)^2} = 0$ when $6t - 3t^4 = 3t(2 - t^3) = 0 \quad \Rightarrow \quad t = 0$ or $t = \sqrt[3]{2}$, so there are horizontal tangents at $(0,0)$ and $\left(\sqrt[3]{2}, \sqrt[3]{4}\right)$. Using the symmetry from part (a), we see that there are vertical tangents at $(0,0)$ and $\left(\sqrt[3]{4}, \sqrt[3]{2}\right)$.

(c) Notice that as $t \to -1^+$, we have $x \to -\infty$ and $y \to \infty$. As $t \to -1^-$, we have $x \to \infty$ and $y \to -\infty$. Also $y - (-x - 1) = y + x + 1 = \dfrac{3t + 3t^2 + (1+t^3)}{1+t^3} = \dfrac{(t+1)^3}{1+t^3} = \dfrac{(t+1)^2}{t^2 - t + 1} \to 0$ as $t \to -1$. So $y = -x - 1$ is a slant asymptote.

(d) $\dfrac{dx}{dt} = \dfrac{(1+t^3)(3) - 3t(3t^2)}{(1+t^3)^2} = \dfrac{3 - 6t^3}{(1+t^3)^2}$ and from part (b) we have $\dfrac{dy}{dt} = \dfrac{6t - 3t^4}{(1+t^3)^2}$. So $\dfrac{dy}{dx} = \dfrac{dy/dt}{dx/dt} = \dfrac{t(2-t^3)}{1 - 2t^3}$.

Also $\dfrac{d^2y}{dx^2} = \dfrac{\frac{d}{dt}\left(\frac{dy}{dx}\right)}{dx/dt} = \dfrac{2(1+t^3)^4}{3(1-2t^3)^3} > 0 \quad \Leftrightarrow \quad t < \dfrac{1}{\sqrt[3]{2}}$.

So the curve is concave upward there and has a minimum point at $(0,0)$ and a maximum point at $\left(\sqrt[3]{2}, \sqrt[3]{4}\right)$. Using this together with the information from parts (a), (b), and (c), we sketch the curve.



(e) $x^3 + y^3 = \left(\dfrac{3t}{1+t^3}\right)^3 + \left(\dfrac{3t^2}{1+t^3}\right)^3 = \dfrac{27t^3 + 27t^6}{(1+t^3)^3} = \dfrac{27t^3(1+t^3)}{(1+t^3)^3} = \dfrac{27t^3}{(1+t^3)^2}$

and $3xy = 3\left(\dfrac{3t}{1+t^3}\right)\left(\dfrac{3t^2}{1+t^3}\right) = \dfrac{27t^3}{(1+t^3)^2}$, so $x^3 + y^3 = 3xy$.

(f) We start with the equation from part (e) and substitute $x = r\cos\theta$, $y = r\sin\theta$. Then $x^3 + y^3 = 3xy \quad \Rightarrow$ $r^3\cos^3\theta + r^3\sin^3\theta = 3r^2\cos\theta\,\sin\theta$. For $r \neq 0$, this gives $r = \dfrac{3\cos\theta\,\sin\theta}{\cos^3\theta + \sin^3\theta}$. Dividing numerator and denominator by $\cos^3\theta$, we obtain $r = \dfrac{3\left(\frac{1}{\cos\theta}\right)\frac{\sin\theta}{\cos\theta}}{1 + \frac{\sin^3\theta}{\cos^3\theta}} = \dfrac{3\sec\theta\,\tan\theta}{1 + \tan^3\theta}$.

(g) The loop corresponds to $\theta \in \left(0, \frac{\pi}{2}\right)$, so its area is

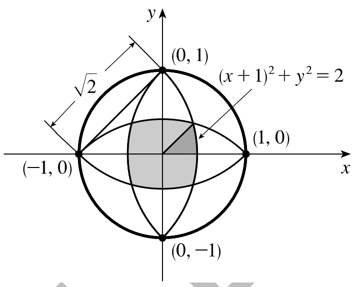
$$A = \int_0^{\pi/2} \frac{r^2}{2}\,d\theta = \frac{1}{2}\int_0^{\pi/2}\left(\frac{3\sec\theta\,\tan\theta}{1+\tan^3\theta}\right)^2 d\theta = \frac{9}{2}\int_0^{\pi/2}\frac{\sec^2\theta\,\tan^2\theta}{(1+\tan^3\theta)^2}\,d\theta = \frac{9}{2}\int_0^{\infty}\frac{u^2\,du}{(1+u^3)^2} \quad [\text{let } u = \tan\theta]$$

$$= \lim_{b\to\infty} \tfrac{9}{2}\left[-\tfrac{1}{3}(1+u^3)^{-1}\right]_0^b = \tfrac{3}{2}$$

(h) By symmetry, the area between the folium and the line $y = -x - 1$ is equal to the enclosed area in the third quadrant, plus twice the enclosed area in the fourth quadrant. The area in the third quadrant is $\frac{1}{2}$, and since $y = -x - 1 \quad \Rightarrow$ $r\sin\theta = -r\cos\theta - 1 \quad \Rightarrow \quad r = -\dfrac{1}{\sin\theta + \cos\theta}$, the area in the fourth quadrant is

$$\frac{1}{2}\int_{-\pi/2}^{-\pi/4}\left[\left(-\frac{1}{\sin\theta+\cos\theta}\right)^2 - \left(\frac{3\sec\theta\,\tan\theta}{1+\tan^3\theta}\right)^2\right]d\theta \overset{\text{CAS}}{=} \frac{1}{2}.$$ Therefore, the total area is $\frac{1}{2} + 2\left(\frac{1}{2}\right) = \frac{3}{2}$.

PROBLEMS PLUS



1. See the figure. The circle with center $(-1, 0)$ and radius $\sqrt{2}$ has equation $(x+1)^2+y^2=2$ and describes the circular arc from $(0,-1)$ to $(0,1)$. Converting the equation to polar coordinates gives us

$(r\cos\theta+1)^2+(r\sin\theta)^2=2 \quad\Rightarrow$

$r^2\cos^2\theta+2r\cos\theta+1+r^2\sin^2\theta=2 \quad\Rightarrow$

$r^2(\cos^2\theta+\sin^2\theta)+2r\cos\theta=1 \quad\Rightarrow\quad r^2+2r\cos\theta=1$. Using the quadratic formula to solve for r gives us

$$r=\frac{-2\cos\theta\pm\sqrt{4\cos^2\theta+4}}{2}=-\cos\theta+\sqrt{\cos^2\theta+1} \text{ for } r>0.$$

The darkest shaded region is $\frac{1}{8}$ of the entire shaded region A, so $\frac{1}{8}A=\int_0^{\pi/4}\frac{1}{2}r^2\,d\theta=\frac{1}{2}\int_0^{\pi/4}(1-2r\cos\theta)\,d\theta \quad\Rightarrow$

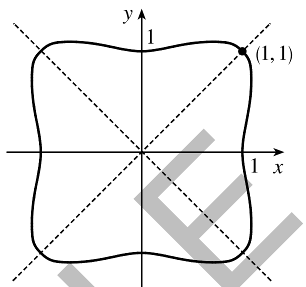
$$\begin{aligned}
\tfrac{1}{4}A &= \int_0^{\pi/4}\left[1-2\cos\theta\left(-\cos\theta+\sqrt{\cos^2\theta+1}\right)\right]d\theta=\int_0^{\pi/4}\left(1+2\cos^2\theta-2\cos\theta\sqrt{\cos^2\theta+1}\right)d\theta\\
&=\int_0^{\pi/4}\left[1+2\cdot\tfrac{1}{2}(1+\cos 2\theta)-2\cos\theta\sqrt{(1-\sin^2\theta)+1}\right]d\theta\\
&=\int_0^{\pi/4}(2+\cos 2\theta)\,d\theta-2\int_0^{\pi/4}\cos\theta\sqrt{2-\sin^2\theta}\,d\theta\\
&=\left[2\theta+\tfrac{1}{2}\sin 2\theta\right]_0^{\pi/4}-2\int_0^{1/\sqrt{2}}\sqrt{2-u^2}\,du \qquad \begin{bmatrix}u=\sin\theta,\\ du=\cos\theta\,d\theta\end{bmatrix}\\
&=\left(\frac{\pi}{2}+\frac{1}{2}\right)-(0+0)-2\left[\frac{u}{2}\sqrt{2-u^2}+\sin^{-1}\frac{u}{\sqrt{2}}\right]_0^{1/\sqrt{2}} \qquad \begin{bmatrix}\text{Formula 30,}\\ a=\sqrt{2}\end{bmatrix}\\
&=\frac{\pi}{2}+\frac{1}{2}-2\left(\frac{1}{2\sqrt{2}}\cdot\frac{\sqrt{3}}{\sqrt{2}}+\frac{\pi}{6}\right)=\frac{\pi}{2}+\frac{1}{2}-\frac{1}{2}\sqrt{3}-\frac{\pi}{3}=\frac{\pi}{6}+\frac{1}{2}-\frac{1}{2}\sqrt{3}.
\end{aligned}$$

Thus, $A=4\left(\frac{\pi}{6}+\frac{1}{2}-\frac{1}{2}\sqrt{3}\right)=\frac{2\pi}{3}+2-2\sqrt{3}$.

2. (a) The curve $x^4+y^4=x^2+y^2$ is symmetric about both axes and about the line $y=x$ (since interchanging x and y does not change the equation) so we need only consider $y\ge x\ge 0$ to begin with. Implicit differentiation gives $4x^3+4y^3y'=2x+2yy' \quad\Rightarrow\quad y'=\dfrac{x(1-2x^2)}{y(2y^2-1)} \quad\Rightarrow\quad y'=0$ when $x=0$ and when $x=\pm\frac{1}{\sqrt{2}}$. If $x=0$, then $y^4=y^2 \quad\Rightarrow\quad y^2(y^2-1)=0 \quad\Rightarrow\quad y=0$ or ± 1. The point $(0,0)$ can't be a highest or lowest point because it is isolated. [If $-1<x<1$ and $-1<y<1$, then $x^4<x^2$ and $y^4<y^2 \quad\Rightarrow\quad x^4+y^4<x^2+y^2$, except for $(0,0)$.] If $x=\frac{1}{\sqrt{2}}$, then $x^2=\frac{1}{2}$, $x^4=\frac{1}{4}$, so $\frac{1}{4}+y^4=\frac{1}{2}+y^2 \quad\Rightarrow\quad 4y^4-4y^2-1=0 \quad\Rightarrow\quad y^2=\frac{4\pm\sqrt{16+16}}{8}=\frac{1\pm\sqrt{2}}{2}$. But $y^2>0$, so $y^2=\frac{1+\sqrt{2}}{2} \quad\Rightarrow\quad y=\pm\sqrt{\frac{1}{2}\left(1+\sqrt{2}\right)}$. Near the point $(0,1)$, the denominator of y' is positive and the numerator changes from negative to positive as x increases through 0, so $(0,1)$ is a local minimum point. At

$\left(\frac{1}{\sqrt{2}}, \sqrt{\frac{1+\sqrt{2}}{2}}\right)$, y' changes from positive to negative, so that point gives a maximum. By symmetry, the highest points on the curve are $\left(\pm\frac{1}{\sqrt{2}}, \sqrt{\frac{1+\sqrt{2}}{2}}\right)$ and the lowest points are $\left(\pm\frac{1}{\sqrt{2}}, -\sqrt{\frac{1+\sqrt{2}}{2}}\right)$.

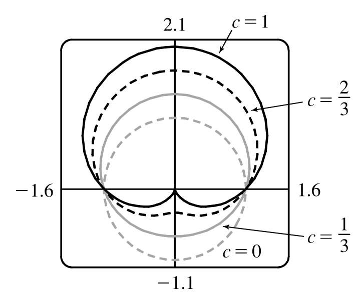
(b) We use the information from part (a), together with symmetry with respect to the axes and the lines $y = \pm x$, to sketch the curve.



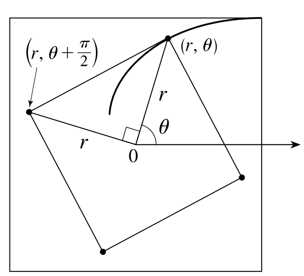
(c) In polar coordinates, $x^4 + y^4 = x^2 + y^2$ becomes $r^4\cos^4\theta + r^4\sin^4\theta = r^2$ or $r^2 = \dfrac{1}{\cos^4\theta + \sin^4\theta}$. By the symmetry shown in part (b), the area enclosed by the curve is $A = 8\displaystyle\int_0^{\pi/4} \frac{1}{2} r^2\, d\theta = 4\int_0^{\pi/4} \frac{d\theta}{\cos^4\theta + \sin^4\theta} \overset{\text{CAS}}{=} \sqrt{2}\,\pi$.

3. In terms of x and y, we have $x = r\cos\theta = (1 + c\sin\theta)\cos\theta = \cos\theta + c\sin\theta\cos\theta = \cos\theta + \frac{1}{2}c\sin 2\theta$ and $y = r\sin\theta = (1 + c\sin\theta)\sin\theta = \sin\theta + c\sin^2\theta$. Now $-1 \le \sin\theta \le 1 \;\Rightarrow\; -1 \le \sin\theta + c\sin^2\theta \le 1 + c \le 2$, so $-1 \le y \le 2$. Furthermore, $y = 2$ when $c = 1$ and $\theta = \frac{\pi}{2}$, while $y = -1$ for $c = 0$ and $\theta = \frac{3\pi}{2}$. Therefore, we need a viewing rectangle with $-1 \le y \le 2$.

To find the x-values, look at the equation $x = \cos\theta + \frac{1}{2}c\sin 2\theta$ and use the fact that $\sin 2\theta \ge 0$ for $0 \le \theta \le \frac{\pi}{2}$ and $\sin 2\theta \le 0$ for $-\frac{\pi}{2} \le \theta \le 0$. [Because $r = 1 + c\sin\theta$ is symmetric about the y-axis, we only need to consider $-\frac{\pi}{2} \le \theta \le \frac{\pi}{2}$.] So for $-\frac{\pi}{2} \le \theta \le 0$, x has a maximum value when $c = 0$ and then $x = \cos\theta$ has a maximum value of 1 at $\theta = 0$. Thus, the maximum value of x must occur on $\left[0, \frac{\pi}{2}\right]$ with $c = 1$. Then $x = \cos\theta + \frac{1}{2}\sin 2\theta \;\Rightarrow\; \frac{dx}{d\theta} = -\sin\theta + \cos 2\theta = -\sin\theta + 1 - 2\sin^2\theta \;\Rightarrow\; \frac{dx}{d\theta} = -(2\sin\theta - 1)(\sin\theta + 1) = 0$ when $\sin\theta = -1$ or $\frac{1}{2}$ [but $\sin\theta \ne -1$ for $0 \le \theta \le \frac{\pi}{2}$]. If $\sin\theta = \frac{1}{2}$, then $\theta = \frac{\pi}{6}$ and $x = \cos\frac{\pi}{6} + \frac{1}{2}\sin\frac{\pi}{3} = \frac{3}{4}\sqrt{3}$. Thus, the maximum value of x is $\frac{3}{4}\sqrt{3}$, and, by symmetry, the minimum value is $-\frac{3}{4}\sqrt{3}$. Therefore, the smallest viewing rectangle that contains every member of the family of polar curves $r = 1 + c\sin\theta$, where $0 \le c \le 1$, is $\left[-\frac{3}{4}\sqrt{3}, \frac{3}{4}\sqrt{3}\right] \times [-1, 2]$.



4. (a) Let us find the polar equation of the path of the bug that starts in the upper right corner of the square. If the polar coordinates of this bug, at a particular moment, are (r, θ), then the polar coordinates of the bug that it is crawling toward must be $\left(r, \theta + \frac{\pi}{2}\right)$. (The next bug must be the same distance from the origin and the angle between the lines joining the bugs to the pole must be $\frac{\pi}{2}$.) The Cartesian coordinates of the first bug are $(r\cos\theta, r\sin\theta)$ and for the second bug we have $x = r\cos\left(\theta + \frac{\pi}{2}\right) = -r\sin\theta$, $y = r\sin\left(\theta + \frac{\pi}{2}\right) = r\cos\theta$. So the slope of the line joining the bugs is



$\dfrac{r\cos\theta - r\sin\theta}{-r\sin\theta - r\cos\theta} = \dfrac{\sin\theta - \cos\theta}{\sin\theta + \cos\theta}$. This must be equal to the slope of the tangent line at (r, θ), so by Equation 10.3.3 we have $\dfrac{(dr/d\theta)\sin\theta + r\cos\theta}{(dr/d\theta)\cos\theta - r\sin\theta} = \dfrac{\sin\theta - \cos\theta}{\sin\theta + \cos\theta}$. Solving for $\dfrac{dr}{d\theta}$, we get

$\dfrac{dr}{d\theta}\sin^2\theta + \dfrac{dr}{d\theta}\sin\theta\cos\theta + r\sin\theta\cos\theta + r\cos^2\theta = \dfrac{dr}{d\theta}\sin\theta\cos\theta - \dfrac{dr}{d\theta}\cos^2\theta - r\sin^2\theta + r\sin\theta\cos\theta \Rightarrow$

$\dfrac{dr}{d\theta}\left(\sin^2\theta + \cos^2\theta\right) + r\left(\cos^2\theta + \sin^2\theta\right) = 0 \quad\Rightarrow\quad \dfrac{dr}{d\theta} = -r$. Solving this differential equation as a separable equation (as in Section 9.3), or using Theorem 9.4.2 with $k = -1$, we get $r = Ce^{-\theta}$. To determine C we use the fact that, at its starting position, $\theta = \frac{\pi}{4}$ and $r = \frac{1}{\sqrt{2}}a$, so $\frac{1}{\sqrt{2}}a = Ce^{-\pi/4} \quad\Rightarrow\quad C = \frac{1}{\sqrt{2}}ae^{\pi/4}$. Therefore, a polar equation of the bug's path is $r = \frac{1}{\sqrt{2}}ae^{\pi/4}e^{-\theta}$ or $r = \frac{1}{\sqrt{2}}ae^{(\pi/4)-\theta}$.

(b) The distance traveled by this bug is $L = \int_{\pi/4}^{\infty}\sqrt{r^2 + (dr/d\theta)^2}\,d\theta$, where $\dfrac{dr}{d\theta} = \dfrac{a}{\sqrt{2}}e^{\pi/4}(-e^{-\theta})$ and so $r^2 + (dr/d\theta)^2 = \frac{1}{2}a^2e^{\pi/2}e^{-2\theta} + \frac{1}{2}a^2e^{\pi/2}e^{-2\theta} = a^2e^{\pi/2}e^{-2\theta}$. Thus

$$\begin{aligned} L &= \int_{\pi/4}^{\infty} ae^{\pi/4}e^{-\theta}\,d\theta = ae^{\pi/4}\lim_{t\to\infty}\int_{\pi/4}^{t} e^{-\theta}\,d\theta = ae^{\pi/4}\lim_{t\to\infty}\left[-e^{-\theta}\right]_{\pi/4}^{t} \\ &= ae^{\pi/4}\lim_{t\to\infty}\left[e^{-\pi/4} - e^{-t}\right] = ae^{\pi/4}e^{-\pi/4} = a \end{aligned}$$

5. Without loss of generality, assume the hyperbola has equation $\dfrac{x^2}{a^2} - \dfrac{y^2}{b^2} = 1$. Use implicit differentiation to get

$\dfrac{2x}{a^2} - \dfrac{2y\,y'}{b^2} = 0$, so $y' = \dfrac{b^2x}{a^2y}$. The tangent line at the point (c, d) on the hyperbola has equation $y - d = \dfrac{b^2c}{a^2d}(x - c)$.

The tangent line intersects the asymptote $y = \dfrac{b}{a}x$ when $\dfrac{b}{a}x - d = \dfrac{b^2c}{a^2d}(x - c) \quad\Rightarrow\quad abdx - a^2d^2 = b^2cx - b^2c^2 \quad\Rightarrow$

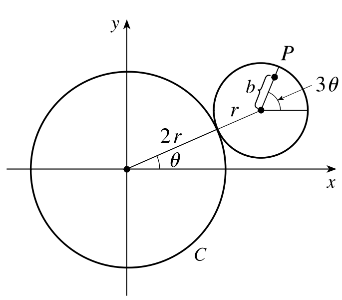
$abdx - b^2cx = a^2d^2 - b^2c^2 \quad\Rightarrow\quad x = \dfrac{a^2d^2 - b^2c^2}{b(ad - bc)} = \dfrac{ad + bc}{b}$ and the y-value is $\dfrac{b}{a}\dfrac{ad + bc}{b} = \dfrac{ad + bc}{a}$.

Similarly, the tangent line intersects $y = -\dfrac{b}{a}x$ at $\left(\dfrac{bc - ad}{b}, \dfrac{ad - bc}{a}\right)$. The midpoint of these intersection points is

$\left(\dfrac{1}{2}\left(\dfrac{ad + bc}{b} + \dfrac{bc - ad}{b}\right), \dfrac{1}{2}\left(\dfrac{ad + bc}{a} + \dfrac{ad - bc}{a}\right)\right) = \left(\dfrac{1}{2}\dfrac{2bc}{b}, \dfrac{1}{2}\dfrac{2ad}{a}\right) = (c, d)$, the point of tangency.

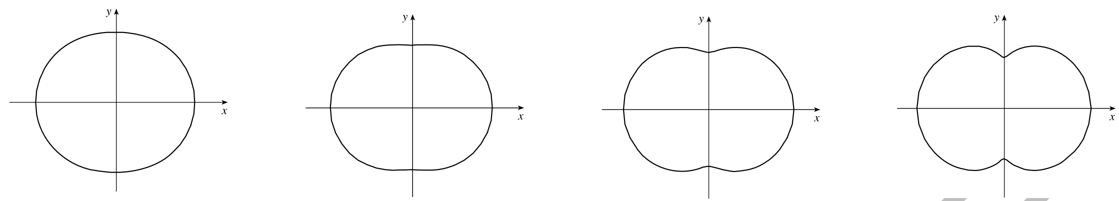
Note: If $y = 0$, then at $(\pm a, 0)$, the tangent line is $x = \pm a$, and the points of intersection are clearly equidistant from the point of tangency.

6. (a) Since the smaller circle rolls without slipping around C, the amount of arc traversed on C ($2r\theta$ in the figure) must equal the amount of arc of the smaller circle that has been in contact with C. Since the smaller circle has radius r, it must have turned through an angle of $2r\theta/r = 2\theta$. In addition to turning through an angle 2θ, the little circle has rolled through an angle θ against C. Thus, P has turned through an angle of 3θ as shown in the figure. (If the little circle had turned through an angle of 2θ with its center pinned to the x-axis,

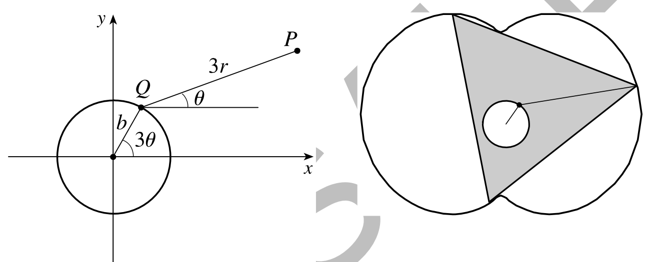


then P would have turned only 2θ instead of 3θ. The movement of the little circle around C adds θ to the angle.) From the figure, we see that the center of the small circle has coordinates $(3r\cos\theta, 3r\sin\theta)$. Thus, P has coordinates (x, y), where $x = b\cos 3\theta + 3r\cos\theta$ and $y = b\sin 3\theta + 3r\sin\theta$.

(b)



(c) The diagram gives an alternate description of point P on the epitrochoid. Q moves around a circle of radius b, and P rotates one-third as fast with respect to Q at a distance of $3r$. Place an equilateral triangle with sides of length $3\sqrt{3}r$ so that its centroid is at Q and one vertex is at P. (The distance from the centroid to a vertex is $\frac{1}{\sqrt{3}}$ times the length of a side of the equilateral triangle.)



As θ increases by $\frac{2\pi}{3}$, the point Q travels once around the circle of radius b, returning to its original position. At the same time, P (and the rest of the triangle) rotate through an angle of $\frac{2\pi}{3}$ about Q, so P's position is occupied by another vertex. In this way, we see that the epitrochoid traced out by P is simultaneously traced out by the other two vertices as well. The whole equilateral triangle sits inside the epitrochoid (touching it only with its vertices) and each vertex traces out the curve once while the centroid moves around the circle three times.

(d) We view the epitrochoid as being traced out in the same way as in part (c), by a rotor for which the distance from its center to each vertex is $3r$, so it has radius $6r$. To show that the rotor fits inside the epitrochoid, it suffices to show that for any position of the tracing point P, there are no points on the opposite side of the rotor which are outside the epitrochoid. But the most likely case of intersection is when P is on the y-axis, so as long as the diameter of the rotor $\left(\text{which is } 3\sqrt{3}\,r\right)$ is less than the distance between the y-intercepts, the rotor will fit. The y-intercepts occur when $\theta = \frac{\pi}{2}$ or $\theta = \frac{3\pi}{2}$ $\Rightarrow$ $y = -b + 3r$ or $y = b - 3r$, so the distance between the intercepts is $(-b + 3r) - (b - 3r) = 6r - 2b$, and the rotor will fit if $3\sqrt{3}\,r \le 6r - 2b \iff 2b \le 6r - 3\sqrt{3}\,r \iff b \le \frac{3}{2}\left(2 - \sqrt{3}\right)r$.

11 □ INFINITE SEQUENCES AND SERIES

11.1 Sequences

1. (a) A sequence is an ordered list of numbers. It can also be defined as a function whose domain is the set of positive integers.

(b) The terms a_n approach 8 as n becomes large. In fact, we can make a_n as close to 8 as we like by taking n sufficiently large.

(c) The terms a_n become large as n becomes large. In fact, we can make a_n as large as we like by taking n sufficiently large.

2. (a) From Definition 1, a convergent sequence is a sequence for which $\lim_{n\to\infty} a_n$ exists. Examples: $\{1/n\}$, $\{1/2^n\}$

(b) A divergent sequence is a sequence for which $\lim_{n\to\infty} a_n$ *does not* exist. Examples: $\{n\}$, $\{\sin n\}$

3. $a_n = \dfrac{2^n}{2n+1}$, so the sequence is $\left\{\dfrac{2^1}{2(1)+1}, \dfrac{2^2}{2(2)+1}, \dfrac{2^3}{2(3)+1}, \dfrac{2^4}{2(4)+1}, \dfrac{2^5}{2(5)+1}, \dots\right\} = \left\{\dfrac{2}{3}, \dfrac{4}{5}, \dfrac{8}{7}, \dfrac{16}{9}, \dfrac{32}{11}, \dots\right\}$.

4. $a_n = \dfrac{n^2-1}{n^2+1}$, so the sequence is $\left\{\dfrac{1-1}{1+1}, \dfrac{4-1}{4+1}, \dfrac{9-1}{9+1}, \dfrac{16-1}{16+1}, \dfrac{25-1}{25+1}, \dots\right\} = \left\{0, \dfrac{3}{5}, \dfrac{8}{10}, \dfrac{15}{17}, \dfrac{24}{26}, \dots\right\}$.

5. $a_n = \dfrac{(-1)^{n-1}}{5^n}$, so the sequence is $\left\{\dfrac{1}{5^1}, \dfrac{-1}{5^2}, \dfrac{1}{5^3}, \dfrac{-1}{5^4}, \dfrac{1}{5^5}, \dots\right\} = \left\{\dfrac{1}{5}, -\dfrac{1}{25}, \dfrac{1}{125}, -\dfrac{1}{625}, \dfrac{1}{3125}, \dots\right\}$.

6. $a_n = \cos\dfrac{n\pi}{2}$, so the sequence is $\left\{\cos\dfrac{\pi}{2}, \cos\pi, \cos\dfrac{3\pi}{2}, \cos 2\pi, \cos\dfrac{5\pi}{2}, \dots\right\} = \{0, -1, 0, 1, 0, \dots\}$.

7. $a_n = \dfrac{1}{(n+1)!}$, so the sequence is $\left\{\dfrac{1}{2!}, \dfrac{1}{3!}, \dfrac{1}{4!}, \dfrac{1}{5!}, \dfrac{1}{6!}, \dots\right\} = \left\{\dfrac{1}{2}, \dfrac{1}{6}, \dfrac{1}{24}, \dfrac{1}{120}, \dfrac{1}{720}, \dots\right\}$.

8. $a_n = \dfrac{(-1)^n n}{n!+1}$, so $a_1 = \dfrac{(-1)^1 1}{1!+1} = \dfrac{-1}{2}$, and the sequence is

$$\left\{\frac{-1}{2}, \frac{2}{2+1}, \frac{-3}{6+1}, \frac{4}{24+1}, \frac{-5}{120+1}, \dots\right\} = \left\{-\frac{1}{2}, \frac{2}{3}, -\frac{3}{7}, \frac{4}{25}, -\frac{5}{121}, \dots\right\}.$$

9. $a_1 = 1$, $a_{n+1} = 5a_n - 3$. Each term is defined in terms of the preceding term. $a_2 = 5a_1 - 3 = 5(1) - 3 = 2$.
$a_3 = 5a_2 - 3 = 5(2) - 3 = 7$. $a_4 = 5a_3 - 3 = 5(7) - 3 = 32$. $a_5 = 5a_4 - 3 = 5(32) - 3 = 157$.
The sequence is $\{1, 2, 7, 32, 157, \dots\}$.

10. $a_1 = 6$, $a_{n+1} = \dfrac{a_n}{n}$. $a_2 = \dfrac{a_1}{1} = \dfrac{6}{1} = 6$. $a_3 = \dfrac{a_2}{2} = \dfrac{6}{2} = 3$. $a_4 = \dfrac{a_3}{3} = \dfrac{3}{3} = 1$. $a_5 = \dfrac{a_4}{4} = \dfrac{1}{4}$.
The sequence is $\{6, 6, 3, 1, \frac{1}{4}, \dots\}$.

11. $a_1 = 2$, $a_{n+1} = \dfrac{a_n}{1+a_n}$. $a_2 = \dfrac{a_1}{1+a_1} = \dfrac{2}{1+2} = \dfrac{2}{3}$. $a_3 = \dfrac{a_2}{1+a_2} = \dfrac{2/3}{1+2/3} = \dfrac{2}{5}$. $a_4 = \dfrac{a_3}{1+a_3} = \dfrac{2/5}{1+2/5} = \dfrac{2}{7}$.
$a_5 = \dfrac{a_4}{1+a_4} = \dfrac{2/7}{1+2/7} = \dfrac{2}{9}$. The sequence is $\{2, \frac{2}{3}, \frac{2}{5}, \frac{2}{7}, \frac{2}{9}, \dots\}$.

12. $a_1 = 2, a_2 = 1, a_{n+1} = a_n - a_{n-1}$. Each term is defined in term of the two preceding terms.

$a_3 = a_2 - a_1 = 1 - 2 = -1$. $a_4 = a_3 - a_2 = -1 - 1 = -2$. $a_5 = a_4 - a_3 = -2 - (-1) = -1$.

$a_6 = a_5 - a_4 = -1 - (-2) = 1$. The sequence is $\{2, 1, -1, -2, -1, 1, \ldots\}$.

13. $\left\{\frac{1}{2}, \frac{1}{4}, \frac{1}{6}, \frac{1}{8}, \frac{1}{10}, \ldots\right\}$. The denominator is two times the number of the term, n, so $a_n = \dfrac{1}{2n}$.

14. $\left\{4, -1, \frac{1}{4}, -\frac{1}{16}, \frac{1}{64}, \ldots\right\}$. The first term is 4 and each term is $-\frac{1}{4}$ times the preceding one, so $a_n = 4\left(-\frac{1}{4}\right)^{n-1}$.

15. $\left\{-3, 2, -\frac{4}{3}, \frac{8}{9}, -\frac{16}{27}, \ldots\right\}$. The first term is -3 and each term is $-\frac{2}{3}$ times the preceding one, so $a_n = -3\left(-\frac{2}{3}\right)^{n-1}$.

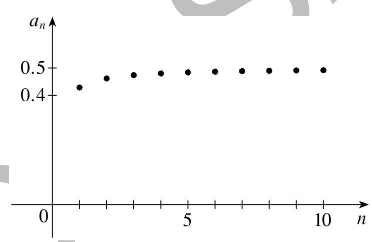
16. $\{5, 8, 11, 14, 17, \ldots\}$. Each term is larger than the preceding term by 3, so $a_n = a_1 + d(n-1) = 5 + 3(n-1) = 3n + 2$.

17. $\left\{\frac{1}{2}, -\frac{4}{3}, \frac{9}{4}, -\frac{16}{5}, \frac{25}{6}, \ldots\right\}$. The numerator of the nth term is n^2 and its denominator is $n+1$. Including the alternating signs, we get $a_n = (-1)^{n+1}\dfrac{n^2}{n+1}$.

18. $\{1, 0, -1, 0, 1, 0, -1, 0, \ldots\}$. Two possibilities are $a_n = \sin\dfrac{n\pi}{2}$ and $a_n = \cos\dfrac{(n-1)\pi}{2}$.

19.

n	$a_n = \dfrac{3n}{1+6n}$
1	0.4286
2	0.4615
3	0.4737
4	0.4800
5	0.4839
6	0.4865
7	0.4884
8	0.4898
9	0.4909
10	0.4918

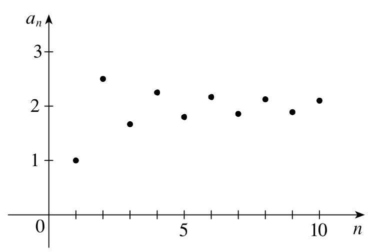


It appears that $\lim\limits_{n\to\infty} a_n = 0.5$.

$$\lim_{n\to\infty} \frac{3n}{1+6n} = \lim_{n\to\infty} \frac{(3n)/n}{(1+6n)/n} = \lim_{n\to\infty} \frac{3}{1/n + 6} = \frac{3}{6} = \frac{1}{2}$$

20.

n	$a_n = 2 + \dfrac{(-1)^n}{n}$
1	1.0000
2	2.5000
3	1.6667
4	2.2500
5	1.8000
6	2.1667
7	1.8571
8	2.1250
9	1.8889
10	2.1000



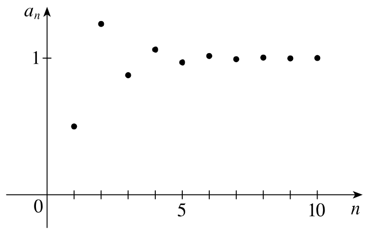
It appears that $\lim\limits_{n\to\infty} a_n = 2$.

$$\lim_{n\to\infty}\left(2 + \frac{(-1)^n}{n}\right) = \lim_{n\to\infty} 2 + \lim_{n\to\infty} \frac{(-1)^n}{n} = 2 + 0 = 2 \text{ since } \lim_{n\to\infty} \frac{1}{n} = 0$$

and by Theorem 6, $\lim\limits_{n\to\infty} \dfrac{(-1)^n}{n} = 0$.

21.

n	$a_n = 1 + \left(-\frac{1}{2}\right)^n$
1	0.5000
2	1.2500
3	0.8750
4	1.0625
5	0.9688
6	1.0156
7	0.9922
8	1.0039
9	0.9980
10	1.0010

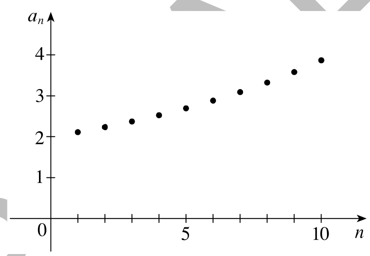


It appears that $\lim_{n\to\infty} a_n = 1$.

$\lim_{n\to\infty} \left(1 + \left(-\frac{1}{2}\right)^n\right) = \lim_{n\to\infty} 1 + \lim_{n\to\infty} \left(-\frac{1}{2}\right)^n = 1 + 0 = 1$ since $\lim_{n\to\infty} \left(-\frac{1}{2}\right)^n = 0$ by (9).

22.

n	$a_n = 1 + \dfrac{10^n}{9^n}$
1	2.1111
2	2.2346
3	2.3717
4	2.5242
5	2.6935
6	2.8817
7	3.0908
8	3.3231
9	3.5812
10	3.8680



It appears that the sequence does not have a limit.

$\lim_{n\to\infty} \dfrac{10^n}{9^n} = \lim_{n\to\infty} \left(\dfrac{10}{9}\right)^n$, which diverges by (9) since $\frac{10}{9} > 1$.

23. $a_n = \dfrac{3 + 5n^2}{n + n^2} = \dfrac{(3 + 5n^2)/n^2}{(n + n^2)/n^2} = \dfrac{5 + 3/n^2}{1 + 1/n}$, so $a_n \to \dfrac{5 + 0}{1 + 0} = 5$ as $n \to \infty$. Converges

24. $a_n = \dfrac{3 + 5n^2}{1 + n} = \dfrac{(3 + 5n^2)/n}{(1 + n)/n} = \dfrac{3/n + 5n}{1/n + 1}$, so $a_n \to \infty$ as $n \to \infty$ since $\lim_{n\to\infty} \left(\dfrac{3}{n} + 5n\right) = \infty$ and $\lim_{n\to\infty} \left(\dfrac{1}{n} + 1\right) = 0 + 1 = 1$. Diverges

25. $a_n = \dfrac{n^4}{n^3 - 2n} = \dfrac{n^4/n^3}{(n^3 - 2n)/n^3} = \dfrac{n}{1 - 2/n^2}$, so $a_n \to \infty$ as $n \to \infty$ since $\lim_{n\to\infty} n = \infty$ and $\lim_{n\to\infty} \left(1 - \dfrac{2}{n^2}\right) = 1 - 0 = 1$. Diverges

26. $a_n = 2 + (0.86)^n \to 2 + 0 = 2$ as $n \to \infty$ since $\lim_{n\to\infty} (0.86)^n = 0$ by (9) with $r = 0.86$. Converges

27. $a_n = 3^n 7^{-n} = \dfrac{3^n}{7^n} = \left(\dfrac{3}{7}\right)^n$, so $\lim_{n\to\infty} a_n = 0$ by (9) with $r = \dfrac{3}{7}$. Converges

28. $a_n = \dfrac{3\sqrt{n}}{\sqrt{n}+2} = \dfrac{3\sqrt{n}/\sqrt{n}}{(\sqrt{n}+2)/\sqrt{n}} = \dfrac{3}{1+2/\sqrt{n}} \to \dfrac{3}{1+0} = 3$ as $n \to \infty$. Converges

29. Because the natural exponential function is continuous at 0, Theorem 7 enables us to write

$\lim\limits_{n\to\infty} a_n = \lim\limits_{n\to\infty} e^{-1/\sqrt{n}} = e^{\lim_{n\to\infty}(-1/\sqrt{n})} = e^0 = 1.$ Converges

30. $a_n = \dfrac{4^n}{1+9^n} = \dfrac{4^n/9^n}{(1+9^n)/9^n} = \dfrac{(4/9)^n}{(1/9)^n+1} \to \dfrac{0}{0+1} = 0$ as $n \to \infty$ since $\lim\limits_{n\to\infty}\left(\dfrac{4}{9}\right)^n = 0$ and

$\lim\limits_{n\to\infty}\left(\dfrac{1}{9}\right)^n = 0$ by (9). Converges

31. $a_n = \sqrt{\dfrac{1+4n^2}{1+n^2}} = \sqrt{\dfrac{(1+4n^2)/n^2}{(1+n^2)/n^2}} = \sqrt{\dfrac{(1/n^2)+4}{(1/n^2)+1}} \to \sqrt{4} = 2$ as $n \to \infty$ since $\lim\limits_{n\to\infty}(1/n^2) = 0$. Converges

32. $a_n = \cos\left(\dfrac{n\pi}{n+1}\right) = \cos\left(\dfrac{n\pi/n}{(n+1)/n}\right) = \cos\left(\dfrac{\pi}{1+1/n}\right)$, so $a_n \to \cos\pi = -1$ as $n \to \infty$ since $\lim\limits_{n\to\infty} 1/n = 0$.

Converges

33. $a_n = \dfrac{n^2}{\sqrt{n^3+4n}} = \dfrac{n^2/\sqrt{n^3}}{\sqrt{n^3+4n}/\sqrt{n^3}} = \dfrac{\sqrt{n}}{\sqrt{1+4/n^2}}$, so $a_n \to \infty$ as $n \to \infty$ since $\lim\limits_{n\to\infty}\sqrt{n} = \infty$ and

$\lim\limits_{n\to\infty}\sqrt{1+4/n^2} = 1.$ Diverges

34. If $b_n = \dfrac{2n}{n+2}$, then $\lim\limits_{n\to\infty} b_n = \lim\limits_{n\to\infty}\dfrac{(2n)/n}{(n+2)/n} = \lim\limits_{n\to\infty}\dfrac{2}{1+2/n} = \dfrac{2}{1} = 2$. Since the natural exponential function is continuous at 2, by Theorem 7, $\lim\limits_{n\to\infty} e^{2n/(n+2)} = e^{\lim_{n\to\infty} b_n} = e^2$. Converges

35. $\lim\limits_{n\to\infty}|a_n| = \lim\limits_{n\to\infty}\left|\dfrac{(-1)^n}{2\sqrt{n}}\right| = \dfrac{1}{2}\lim\limits_{n\to\infty}\dfrac{1}{n^{1/2}} = \dfrac{1}{2}(0) = 0$, so $\lim\limits_{n\to\infty} a_n = 0$ by (6). Converges

36. $\lim\limits_{n\to\infty}\dfrac{n}{n+\sqrt{n}} = \lim\limits_{n\to\infty}\dfrac{n/n}{(n+\sqrt{n})/n} = \lim\limits_{n\to\infty}\dfrac{1}{1+1/\sqrt{n}} = \dfrac{1}{1+0} = 1.$ Thus, $a_n = \dfrac{(-1)^{n+1}n}{n+\sqrt{n}}$ has odd-numbered terms that approach 1 and even-numbered terms that approach -1 as $n \to \infty$, and hence, the sequence $\{a_n\}$ is divergent.

37. $a_n = \dfrac{(2n-1)!}{(2n+1)!} = \dfrac{(2n-1)!}{(2n+1)(2n)(2n-1)!} = \dfrac{1}{(2n+1)(2n)} \to 0$ as $n \to \infty$. Converges

38. $a_n = \dfrac{\ln n}{\ln 2n} = \dfrac{\ln n}{\ln 2 + \ln n} = \dfrac{1}{\frac{\ln 2}{\ln n}+1} \to \dfrac{1}{0+1} = 1$ as $n \to \infty$. Converges

39. $a_n = \sin n$. This sequence diverges since the terms don't approach any particular real number as $n \to \infty$. The terms take on values between -1 and 1. Diverges

40. $a_n = \dfrac{\tan^{-1} n}{n}$. $\lim\limits_{n\to\infty}\tan^{-1} n = \lim\limits_{x\to\infty}\tan^{-1} x = \dfrac{\pi}{2}$ by (3), so $\lim\limits_{n\to\infty} a_n = 0$. Converges

41. $a_n = n^2e^{-n} = \dfrac{n^2}{e^n}$. Since $\lim\limits_{x\to\infty}\dfrac{x^2}{e^x} \overset{\text{H}}{=} \lim\limits_{x\to\infty}\dfrac{2x}{e^x} \overset{\text{H}}{=} \lim\limits_{x\to\infty}\dfrac{2}{e^x} = 0$, it follows from Theorem 3 that $\lim\limits_{n\to\infty} a_n = 0$. Converges

42. $a_n = \ln(n+1) - \ln n = \ln\left(\frac{n+1}{n}\right) = \ln\left(1+\frac{1}{n}\right) \to \ln(1) = 0$ as $n \to \infty$ because ln is continuous. Converges

43. $0 \le \frac{\cos^2 n}{2^n} \le \frac{1}{2^n}$ [since $0 \le \cos^2 n \le 1$], so since $\lim\limits_{n\to\infty} \frac{1}{2^n} = 0$, $\left\{\frac{\cos^2 n}{2^n}\right\}$ converges to 0 by the Squeeze Theorem.

44. $a_n = \sqrt[n]{2^{1+3n}} = (2^{1+3n})^{1/n} = (2^1 2^{3n})^{1/n} = 2^{1/n}2^3 = 8 \cdot 2^{1/n}$, so

$\lim\limits_{n\to\infty} a_n = 8 \lim\limits_{n\to\infty} 2^{1/n} = 8 \cdot 2^{\lim_{n\to\infty}(1/n)} = 8 \cdot 2^0 = 8$ by Theorem 7, since the function $f(x) = 2^x$ is continuous at 0.

Converges

45. $a_n = n\sin(1/n) = \frac{\sin(1/n)}{1/n}$. Since $\lim\limits_{x\to\infty} \frac{\sin(1/x)}{1/x} = \lim\limits_{t\to 0^+} \frac{\sin t}{t}$ [where $t = 1/x$] $= 1$, it follows from Theorem 3

that $\{a_n\}$ converges to 1.

46. $a_n = 2^{-n}\cos n\pi$. $0 \le \left|\frac{\cos n\pi}{2^n}\right| \le \frac{1}{2^n} = \left(\frac{1}{2}\right)^n$, so $\lim\limits_{n\to\infty} |a_n| = 0$ by (9), and $\lim\limits_{n\to\infty} a_n = 0$ by (6). Converges

47. $y = \left(1+\frac{2}{x}\right)^x \Rightarrow \ln y = x\ln\left(1+\frac{2}{x}\right)$, so

$$\lim_{x\to\infty} \ln y = \lim_{x\to\infty} \frac{\ln(1+2/x)}{1/x} \overset{\text{H}}{=} \lim_{x\to\infty} \frac{\left(\frac{1}{1+2/x}\right)\left(-\frac{2}{x^2}\right)}{-1/x^2} = \lim_{x\to\infty} \frac{2}{1+2/x} = 2 \Rightarrow$$

$\lim\limits_{x\to\infty} \left(1+\frac{2}{x}\right)^x = \lim\limits_{x\to\infty} e^{\ln y} = e^2$, so by Theorem 3, $\lim\limits_{n\to\infty} \left(1+\frac{2}{n}\right)^n = e^2$. Converges

48. $y = x^{1/x} \Rightarrow \ln y = \frac{1}{x}\ln x$, so $\lim\limits_{x\to\infty} \ln y = \lim\limits_{x\to\infty} \frac{\ln x}{x} \overset{\text{H}}{=} \lim\limits_{x\to\infty} \frac{1/x}{1} = \lim\limits_{x\to\infty} \frac{1}{x} = 0 \Rightarrow$

$\lim\limits_{x\to\infty} x^{1/x} = \lim\limits_{x\to\infty} e^{\ln y} = e^0 = 1$, so by Theorem 3, $\lim\limits_{n\to\infty} \sqrt[n]{n} = 1$. Converges

49. $a_n = \ln(2n^2+1) - \ln(n^2+1) = \ln\left(\frac{2n^2+1}{n^2+1}\right) = \ln\left(\frac{2+1/n^2}{1+1/n^2}\right) \to \ln 2$ as $n \to \infty$. Converges

50. $\lim\limits_{x\to\infty} \frac{(\ln x)^2}{x} \overset{\text{H}}{=} \lim\limits_{x\to\infty} \frac{2(\ln x)(1/x)}{1} = 2\lim\limits_{x\to\infty} \frac{\ln x}{x} \overset{\text{H}}{=} 2\lim\limits_{x\to\infty} \frac{1/x}{1} = 0$, so by Theorem 3, $\lim\limits_{n\to\infty} \frac{(\ln n)^2}{n} = 0$. Converges

51. $a_n = \arctan(\ln n)$. Let $f(x) = \arctan(\ln x)$. Then $\lim\limits_{x\to\infty} f(x) = \frac{\pi}{2}$ since $\ln x \to \infty$ as $x \to \infty$ and arctan is continuous.

Thus, $\lim\limits_{n\to\infty} a_n = \lim\limits_{n\to\infty} f(n) = \frac{\pi}{2}$. Converges

52. $a_n = n - \sqrt{n+1}\sqrt{n+3} = n - \sqrt{n^2+4n+3} = \frac{n - \sqrt{n^2+4n+3}}{1} \cdot \frac{n+\sqrt{n^2+4n+3}}{n+\sqrt{n^2+4n+3}}$

$$= \frac{n^2-(n^2+4n+3)}{n+\sqrt{n^2+4n+3}} = \frac{-4n-3}{n+\sqrt{n^2+4n+3}} = \frac{(-4n-3)/n}{\left(n+\sqrt{n^2+4n+3}\right)/n} = \frac{-4-3/n}{1+\sqrt{1+4/n+3/n^2}},$$

so $\lim\limits_{n\to\infty} a_n = \frac{-4-0}{1+\sqrt{1+0+0}} = \frac{-4}{2} = -2$. Converges

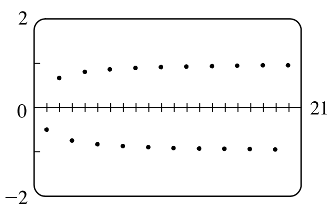
53. $\{0, 1, 0, 0, 1, 0, 0, 0, 1, \ldots\}$ diverges since the sequence takes on only two values, 0 and 1, and never stays arbitrarily close to either one (or any other value) for n sufficiently large.

54. $\left\{\frac{1}{1}, \frac{1}{3}, \frac{1}{2}, \frac{1}{4}, \frac{1}{3}, \frac{1}{5}, \frac{1}{4}, \frac{1}{6}, \ldots\right\}$. $a_{2n-1} = \dfrac{1}{n}$ and $a_{2n} = \dfrac{1}{n+2}$ for all positive integers n. $\lim\limits_{n\to\infty} a_n = 0$ since $\lim\limits_{n\to\infty} a_{2n-1} = \lim\limits_{n\to\infty} \dfrac{1}{n} = 0$ and $\lim\limits_{n\to\infty} a_{2n} = \lim\limits_{n\to\infty} \dfrac{1}{n+2} = 0$. For n sufficiently large, a_n can be made as close to 0 as we like. Converges

55. $a_n = \dfrac{n!}{2^n} = \dfrac{1}{2} \cdot \dfrac{2}{2} \cdot \dfrac{3}{2} \cdot \cdots \cdot \dfrac{(n-1)}{2} \cdot \dfrac{n}{2} \geq \dfrac{1}{2} \cdot \dfrac{n}{2}$ [for $n > 1$] $= \dfrac{n}{4} \to \infty$ as $n \to \infty$, so $\{a_n\}$ diverges.

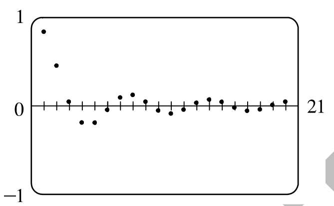
56. $0 < |a_n| = \dfrac{3^n}{n!} = \dfrac{3}{1} \cdot \dfrac{3}{2} \cdot \dfrac{3}{3} \cdot \cdots \cdot \dfrac{3}{(n-1)} \cdot \dfrac{3}{n} \leq \dfrac{3}{1} \cdot \dfrac{3}{2} \cdot \dfrac{3}{n}$ [for $n > 2$] $= \dfrac{27}{2n} \to 0$ as $n \to \infty$, so by the Squeeze Theorem and Theorem 6, $\{(-3)^n/n!\}$ converges to 0.

57.



From the graph, it appears that the sequence $\{a_n\} = \left\{(-1)^n \dfrac{n}{n+1}\right\}$ is divergent, since it oscillates between 1 and -1 (approximately). To prove this, suppose that $\{a_n\}$ converges to L. If $b_n = \dfrac{n}{n+1}$, then $\{b_n\}$ converges to 1, and $\lim\limits_{n\to\infty} \dfrac{a_n}{b_n} = \dfrac{L}{1} = L$. But $\dfrac{a_n}{b_n} = (-1)^n$, so $\lim\limits_{n\to\infty} \dfrac{a_n}{b_n}$ does not exist. This contradiction shows that $\{a_n\}$ diverges.

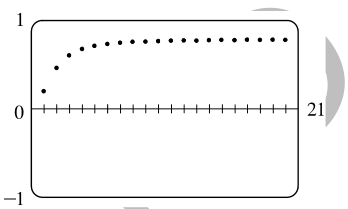
58.



From the graph, it appears that the sequence converges to 0.

$|a_n| = \left|\dfrac{\sin n}{n}\right| = \dfrac{|\sin n|}{|n|} \leq \dfrac{1}{n}$, so $\lim\limits_{n\to\infty} |a_n| = 0$. By (6), it follows that $\lim\limits_{n\to\infty} a_n = 0$.

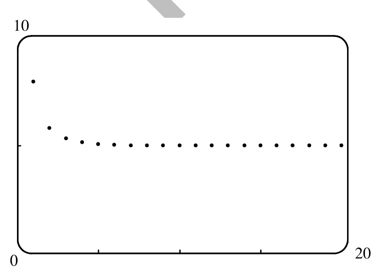
59.



From the graph, it appears that the sequence converges to a number between 0.7 and 0.8.

$a_n = \arctan\left(\dfrac{n^2}{n^2+4}\right) = \arctan\left(\dfrac{n^2/n^2}{(n^2+4)/n^2}\right) = \arctan\left(\dfrac{1}{1+4/n^2}\right) \to$ $\arctan 1 = \dfrac{\pi}{4}$ [≈ 0.785] as $n \to \infty$.

60.



From the graph, it appears that the sequence converges to 5.

$$5 = \sqrt[n]{5^n} \leq \sqrt[n]{3^n + 5^n} \leq \sqrt[n]{5^n + 5^n} = \sqrt[n]{2}\,\sqrt[n]{5^n}$$
$$= \sqrt[n]{2} \cdot 5 \to 5 \text{ as } n \to \infty \quad \left[\lim_{n\to\infty} 2^{1/n} = 2^0 = 1\right]$$

Hence, $a_n \to 5$ by the Squeeze Theorem.

[continued]

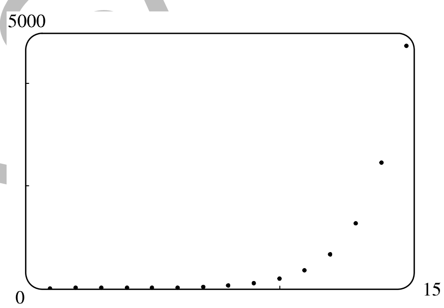
Alternate solution: Let $y = (3^x + 5^x)^{1/x}$. Then

$$\lim_{x\to\infty} \ln y = \lim_{x\to\infty} \frac{\ln(3^x + 5^x)}{x} \overset{\text{H}}{=} \lim_{x\to\infty} \frac{3^x \ln 3 + 5^x \ln 5}{3^x + 5^x} = \lim_{x\to\infty} \frac{\left(\frac{3}{5}\right)^x \ln 3 + \ln 5}{\left(\frac{3}{5}\right)^x + 1} = \ln 5,$$

so $\lim\limits_{x\to\infty} y = e^{\ln 5} = 5$, and so $\left\{ \sqrt[n]{3^n + 5^n} \right\}$ converges to 5.

61. 
From the graph, it appears that the sequence $\{a_n\} = \left\{ \dfrac{n^2 \cos n}{1 + n^2} \right\}$ is divergent, since it oscillates between 1 and -1 (approximately). To prove this, suppose that $\{a_n\}$ converges to L. If $b_n = \dfrac{n^2}{1 + n^2}$, then $\{b_n\}$ converges to 1, and $\lim\limits_{n\to\infty} \dfrac{a_n}{b_n} = \dfrac{L}{1} = L$. But $\dfrac{a_n}{b_n} = \cos n$, so $\lim\limits_{n\to\infty} \dfrac{a_n}{b_n}$ does not exist. This contradiction shows that $\{a_n\}$ diverges.

62. 



From the graphs, it seems that the sequence diverges. $a_n = \dfrac{1 \cdot 3 \cdot 5 \cdot \cdots \cdot (2n-1)}{n!}$. We first prove by induction that $a_n \geq \left(\dfrac{3}{2}\right)^{n-1}$ for all n. This is clearly true for $n = 1$, so let $P(n)$ be the statement that the above is true for n. We must show it is then true for $n + 1$. $a_{n+1} = a_n \cdot \dfrac{2n+1}{n+1} \geq \left(\dfrac{3}{2}\right)^{n-1} \cdot \dfrac{2n+1}{n+1}$ (induction hypothesis). But $\dfrac{2n+1}{n+1} \geq \dfrac{3}{2}$ [since $2(2n+1) \geq 3(n+1) \iff 4n + 2 \geq 3n + 3 \iff n \geq 1$], and so we get that $a_{n+1} \geq \left(\frac{3}{2}\right)^{n-1} \cdot \frac{3}{2} = \left(\frac{3}{2}\right)^n$ which is $P(n+1)$. Thus, we have proved our first assertion, so since $\left\{ \left(\frac{3}{2}\right)^{n-1} \right\}$ diverges [by (9)], so does the given sequence $\{a_n\}$.

63. 
From the graph, it appears that the sequence approaches 0.

$$0 < a_n = \frac{1 \cdot 3 \cdot 5 \cdot \cdots \cdot (2n-1)}{(2n)^n} = \frac{1}{2n} \cdot \frac{3}{2n} \cdot \frac{5}{2n} \cdot \cdots \cdot \frac{2n-1}{2n}$$

$$\leq \frac{1}{2n} \cdot (1) \cdot (1) \cdot \cdots \cdot (1) = \frac{1}{2n} \to 0 \text{ as } n \to \infty$$

So by the Squeeze Theorem, $\left\{ \dfrac{1 \cdot 3 \cdot 5 \cdot \cdots \cdot (2n-1)}{(2n)^n} \right\}$ converges to 0.

64. (a) $a_1 = 1$, $a_{n+1} = 4 - a_n$ for $n \geq 1$. $a_1 = 1$, $a_2 = 4 - a_1 = 4 - 1 = 3$, $a_3 = 4 - a_2 = 4 - 3 = 1$, $a_4 = 4 - a_3 = 4 - 1 = 3$, $a_5 = 4 - a_4 = 4 - 3 = 1$. Since the terms of the sequence alternate between 1 and 3, the sequence is divergent.

(b) $a_1 = 2$, $a_2 = 4 - a_1 = 4 - 2 = 2$, $a_3 = 4 - a_2 = 4 - 2 = 2$. Since all of the terms are 2, $\lim_{n\to\infty} a_n = 2$ and hence, the sequence is convergent.

65. (a) $a_n = 1000(1.06)^n \quad \Rightarrow \quad a_1 = 1060$, $a_2 = 1123.60$, $a_3 = 1191.02$, $a_4 = 1262.48$, and $a_5 = 1338.23$.

(b) $\lim_{n\to\infty} a_n = 1000 \lim_{n\to\infty} (1.06)^n$, so the sequence diverges by (9) with $r = 1.06 > 1$.

66. (a) Substitute 1 to 6 for n in $I_n = 100\left(\dfrac{1.0025^n - 1}{0.0025} - n\right)$ to get $I_1 = \$0$, $I_2 = \$0.25$, $I_3 = \$0.75$, $I_4 = \$1.50$, $I_5 = \$2.51$, and $I_6 = \$3.76$.

(b) For two years, use $2 \cdot 12 = 24$ for n to get \$70.28.

67. (a) We are given that the initial population is 5000, so $P_0 = 5000$. The number of catfish increases by 8% per month and is decreased by 300 per month, so $P_1 = P_0 + 8\%P_0 - 300 = 1.08P_0 - 300$, $P_2 = 1.08P_1 - 300$, and so on. Thus, $P_n = 1.08P_{n-1} - 300$.

(b) Using the recursive formula with $P_0 = 5000$, we get $P_1 = 5100$, $P_2 = 5208$, $P_3 = 5325$ (rounding any portion of a catfish), $P_4 = 5451$, $P_5 = 5587$, and $P_6 = 5734$, which is the number of catfish in the pond after six months.

68. $a_{n+1} = \begin{cases} \frac{1}{2}a_n & \text{if } a_n \text{ is an even number} \\ 3a_n + 1 & \text{if } a_n \text{ is an odd number} \end{cases}$ When $a_1 = 11$, the first 40 terms are 11, 34, 17, 52, 26, 13, 40, 20, 10, 5, 16, 8, 4, 2, 1, 4, 2, 1, 4, 2, 1, 4, 2, 1, 4, 2, 1, 4, 2, 1, 4, 2, 1, 4, 2, 1, 4, 2, 1, 4. When $a_1 = 25$, the first 40 terms are 25, 76, 38, 19, 58, 29, 88, 44, 22, 11, 34, 17, 52, 26, 13, 40, 20, 10, 5, 16, 8, 4, 2, 1, 4, 2, 1, 4, 2, 1, 4, 2, 1, 4, 2, 1, 4, 2, 1, 4.
The famous Collatz conjecture is that this sequence always reaches 1, regardless of the starting point a_1.

69. If $|r| \geq 1$, then $\{r^n\}$ diverges by (9), so $\{nr^n\}$ diverges also, since $|nr^n| = n\,|r^n| \geq |r^n|$. If $|r| < 1$ then $\lim_{x\to\infty} xr^x = \lim_{x\to\infty} \dfrac{x}{r^{-x}} \overset{\text{H}}{=} \lim_{x\to\infty} \dfrac{1}{(-\ln r)\,r^{-x}} = \lim_{x\to\infty} \dfrac{r^x}{-\ln r} = 0$, so $\lim_{n\to\infty} nr^n = 0$, and hence $\{nr^n\}$ converges whenever $|r| < 1$.

70. (a) Let $\lim_{n\to\infty} a_n = L$. By Definition 2, this means that for every $\varepsilon > 0$ there is an integer N such that $|a_n - L| < \varepsilon$ whenever $n > N$. Thus, $|a_{n+1} - L| < \varepsilon$ whenever $n + 1 > N \quad \Leftrightarrow \quad n > N - 1$. It follows that $\lim_{n\to\infty} a_{n+1} = L$ and so $\lim_{n\to\infty} a_n = \lim_{n\to\infty} a_{n+1}$.

(b) If $L = \lim_{n\to\infty} a_n$ then $\lim_{n\to\infty} a_{n+1} = L$ also, so L must satisfy $L = 1/(1 + L) \quad \Rightarrow \quad L^2 + L - 1 = 0 \quad \Rightarrow \quad L = \frac{-1+\sqrt{5}}{2}$ (since L has to be nonnegative if it exists).

71. Since $\{a_n\}$ is a decreasing sequence, $a_n > a_{n+1}$ for all $n \ge 1$. Because all of its terms lie between 5 and 8, $\{a_n\}$ is a bounded sequence. By the Monotonic Sequence Theorem, $\{a_n\}$ is convergent; that is, $\{a_n\}$ has a limit L. L must be less than 8 since $\{a_n\}$ is decreasing, so $5 \le L < 8$.

72. Since $\{a_n\} = \{\cos n\} \approx \{0.54, -0.42, -0.99, -0.65, 0.28, \ldots\}$, the sequence is not monotonic. The sequence is bounded since $-1 \le \cos n \le 1$ for all n.

73. $a_n = \dfrac{1}{2n+3}$ is decreasing since $a_{n+1} = \dfrac{1}{2(n+1)+3} = \dfrac{1}{2n+5} < \dfrac{1}{2n+3} = a_n$ for each $n \ge 1$. The sequence is bounded since $0 < a_n \le \frac{1}{5}$ for all $n \ge 1$. Note that $a_1 = \frac{1}{5}$.

74. $a_n > a_{n+1} \quad\Leftrightarrow\quad \dfrac{1-n}{2+n} > \dfrac{1-(n+1)}{2+(n+1)} \quad\Leftrightarrow\quad \dfrac{1-n}{2+n} > \dfrac{-n}{n+3} \quad\Leftrightarrow\quad -n^2 - 2n + 3 > -n^2 - 2n \quad\Leftrightarrow\quad 3 > 0$, which is true for all $n \ge 1$, so $\{a_n\}$ is decreasing. Since $a_1 = 0$ and $\lim\limits_{n\to\infty} \dfrac{1-n}{2+n} = \lim\limits_{n\to\infty} \dfrac{1/n - 1}{2/n + 1} = -1$, the sequence is bounded $(-1 < a_n \le 0)$.

75. The terms of $a_n = n(-1)^n$ alternate in sign, so the sequence is not monotonic. The first five terms are -1, 2, -3, 4, and -5. Since $\lim\limits_{n\to\infty} |a_n| = \lim\limits_{n\to\infty} n = \infty$, the sequence is not bounded.

76. Since $\{a_n\} = \left\{2 + \dfrac{(-1)^n}{n}\right\} = \left\{1, 2\frac{1}{2}, 1\frac{2}{3}, \ldots\right\}$, the sequence is not monotonic. The sequence is bounded since $1 \le a_n \le \frac{5}{2}$ for all n.

77. $a_n = 3 - 2ne^{-n}$. Let $f(x) = 3 - 2xe^{-x}$. Then $f'(x) = 0 - 2[x(-e^{-x}) + e^{-x}] = 2e^{-x}(x-1)$, which is positive for $x > 1$, so f is increasing on $(1, \infty)$. It follows that the sequence $\{a_n\} = \{f(n)\}$ is increasing. The sequence is bounded below by $a_1 = 3 - 2e^{-1} \approx 2.26$ and above by 3, so the sequence is bounded.

78. $a_n = n^3 - 3n + 3$. Let $f(x) = x^3 - 3x + 3$. Then $f'(x) = 3x^2 - 3 = 3(x^2 - 1)$, which is positive for $x > 1$, so f is increasing on $(1, \infty)$. It follows that the sequence $\{a_n\} = \{f(n)\}$ is increasing. The sequence is bounded below by $a_1 = 1$, but is not bounded above, so it is not bounded.

79. For $\left\{\sqrt{2}, \sqrt{2\sqrt{2}}, \sqrt{2\sqrt{2\sqrt{2}}}, \ldots\right\}$, $a_1 = 2^{1/2}$, $a_2 = 2^{3/4}$, $a_3 = 2^{7/8}$, …, so $a_n = 2^{(2^n - 1)/2^n} = 2^{1-(1/2^n)}$.

$\lim\limits_{n\to\infty} a_n = \lim\limits_{n\to\infty} 2^{1-(1/2^n)} = 2^1 = 2$.

Alternate solution: Let $L = \lim\limits_{n\to\infty} a_n$. (We could show the limit exists by showing that $\{a_n\}$ is bounded and increasing.) Then L must satisfy $L = \sqrt{2 \cdot L} \quad\Rightarrow\quad L^2 = 2L \quad\Rightarrow\quad L(L-2) = 0$. $L \ne 0$ since the sequence increases, so $L = 2$.

80. (a) Let P_n be the statement that $a_{n+1} \ge a_n$ and $a_n \le 3$. P_1 is obviously true. We will assume that P_n is true and then show that as a consequence P_{n+1} must also be true. $a_{n+2} \ge a_{n+1} \quad\Leftrightarrow\quad \sqrt{2 + a_{n+1}} \ge \sqrt{2 + a_n} \quad\Leftrightarrow\quad 2 + a_{n+1} \ge 2 + a_n \quad\Leftrightarrow\quad a_{n+1} \ge a_n$, which is the induction hypothesis. $a_{n+1} \le 3 \quad\Leftrightarrow\quad \sqrt{2 + a_n} \le 3 \quad\Leftrightarrow$

$2 + a_n \le 9 \;\Leftrightarrow\; a_n \le 7$, which is certainly true because we are assuming that $a_n \le 3$. So P_n is true for all n, and so $a_1 \le a_n \le 3$ (showing that the sequence is bounded), and hence by the Monotonic Sequence Theorem, $\lim_{n\to\infty} a_n$ exists.

(b) If $L = \lim_{n\to\infty} a_n$, then $\lim_{n\to\infty} a_{n+1} = L$ also, so $L = \sqrt{2+L} \;\Rightarrow\; L^2 = 2 + L \;\Leftrightarrow\; L^2 - L - 2 = 0 \;\Leftrightarrow\; (L+1)(L-2) = 0 \;\Leftrightarrow\; L = 2$ [since L can't be negative].

81. $a_1 = 1$, $a_{n+1} = 3 - \dfrac{1}{a_n}$. We show by induction that $\{a_n\}$ is increasing and bounded above by 3. Let P_n be the proposition that $a_{n+1} > a_n$ and $0 < a_n < 3$. Clearly P_1 is true. Assume that P_n is true. Then $a_{n+1} > a_n \;\Rightarrow\; \dfrac{1}{a_{n+1}} < \dfrac{1}{a_n} \;\Rightarrow\; -\dfrac{1}{a_{n+1}} > -\dfrac{1}{a_n}$. Now $a_{n+2} = 3 - \dfrac{1}{a_{n+1}} > 3 - \dfrac{1}{a_n} = a_{n+1} \;\Leftrightarrow\; P_{n+1}$. This proves that $\{a_n\}$ is increasing and bounded above by 3, so $1 = a_1 < a_n < 3$, that is, $\{a_n\}$ is bounded, and hence convergent by the Monotonic Sequence Theorem. If $L = \lim_{n\to\infty} a_n$, then $\lim_{n\to\infty} a_{n+1} = L$ also, so L must satisfy $L = 3 - 1/L \;\Rightarrow\; L^2 - 3L + 1 = 0 \;\Rightarrow\; L = \frac{3 \pm \sqrt{5}}{2}$. But $L > 1$, so $L = \frac{3+\sqrt{5}}{2}$.

82. $a_1 = 2$, $a_{n+1} = \dfrac{1}{3 - a_n}$. We use induction. Let P_n be the statement that $0 < a_{n+1} \le a_n \le 2$. Clearly P_1 is true, since $a_2 = 1/(3-2) = 1$. Now assume that P_n is true. Then $a_{n+1} \le a_n \;\Rightarrow\; -a_{n+1} \ge -a_n \;\Rightarrow\; 3 - a_{n+1} \ge 3 - a_n \;\Rightarrow\; a_{n+2} = \dfrac{1}{3 - a_{n+1}} \le \dfrac{1}{3 - a_n} = a_{n+1}$. Also $a_{n+2} > 0$ [since $3 - a_{n+1}$ is positive] and $a_{n+1} \le 2$ by the induction hypothesis, so P_{n+1} is true. To find the limit, we use the fact that $\lim_{n\to\infty} a_n = \lim_{n\to\infty} a_{n+1} \;\Rightarrow\; L = \frac{1}{3-L} \;\Rightarrow\; L^2 - 3L + 1 = 0 \;\Rightarrow\; L = \frac{3\pm\sqrt{5}}{2}$. But $L \le 2$, so we must have $L = \frac{3-\sqrt{5}}{2}$.

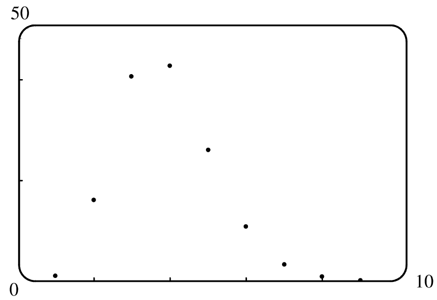
83. (a) Let a_n be the number of rabbit pairs in the nth month. Clearly $a_1 = 1 = a_2$. In the nth month, each pair that is 2 or more months old (that is, a_{n-2} pairs) will produce a new pair to add to the a_{n-1} pairs already present. Thus, $a_n = a_{n-1} + a_{n-2}$, so that $\{a_n\} = \{f_n\}$, the Fibonacci sequence.

(b) $a_n = \dfrac{f_{n+1}}{f_n} \;\Rightarrow\; a_{n-1} = \dfrac{f_n}{f_{n-1}} = \dfrac{f_{n-1} + f_{n-2}}{f_{n-1}} = 1 + \dfrac{f_{n-2}}{f_{n-1}} = 1 + \dfrac{1}{f_{n-1}/f_{n-2}} = 1 + \dfrac{1}{a_{n-2}}$. If $L = \lim_{n\to\infty} a_n$, then $L = \lim_{n\to\infty} a_{n-1}$ and $L = \lim_{n\to\infty} a_{n-2}$, so L must satisfy $L = 1 + \dfrac{1}{L} \;\Rightarrow\; L^2 - L - 1 = 0 \;\Rightarrow\; L = \frac{1+\sqrt{5}}{2}$ [since L must be positive].

84. (a) If f is continuous, then $f(L) = f\left(\lim_{n\to\infty} a_n\right) = \lim_{n\to\infty} f(a_n) = \lim_{n\to\infty} a_{n+1} = \lim_{n\to\infty} a_n = L$ by Exercise 70(a).

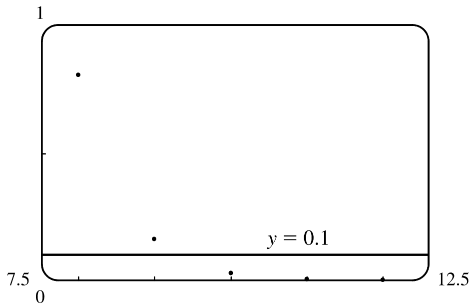
(b) By repeatedly pressing the cosine key on the calculator (that is, taking cosine of the previous answer) until the displayed value stabilizes, we see that $L \approx 0.73909$.

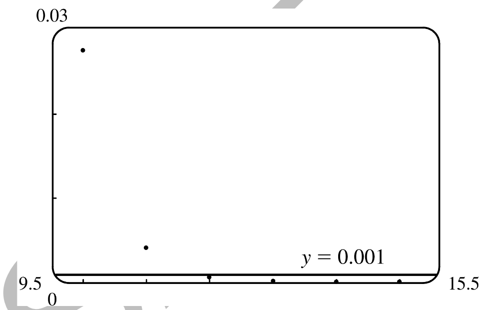
85. (a)



From the graph, it appears that the sequence $\left\{\dfrac{n^5}{n!}\right\}$ converges to 0, that is, $\lim\limits_{n\to\infty} \dfrac{n^5}{n!} = 0$.

(b)





From the first graph, it seems that the smallest possible value of N corresponding to $\varepsilon = 0.1$ is 9, since $n^5/n! < 0.1$ whenever $n \geq 10$, but $9^5/9! > 0.1$. From the second graph, it seems that for $\varepsilon = 0.001$, the smallest possible value for N is 11 since $n^5/n! < 0.001$ whenever $n \geq 12$.

86. Let $\varepsilon > 0$ and let N be any positive integer larger than $\ln(\varepsilon)/\ln|r|$. If $n > N$, then $n > \ln(\varepsilon)/\ln|r| \;\Rightarrow\; n\ln|r| < \ln\varepsilon$ [since $|r| < 1 \Rightarrow \ln|r| < 0$] $\;\Rightarrow\; \ln(|r|^n) < \ln\varepsilon \;\Rightarrow\; |r|^n < \varepsilon \;\Rightarrow\; |r^n - 0| < \varepsilon$, and so by Definition 2, $\lim\limits_{n\to\infty} r^n = 0$.

87. Theorem 6: If $\lim\limits_{n\to\infty} |a_n| = 0$ then $\lim\limits_{n\to\infty} -|a_n| = 0$, and since $-|a_n| \leq a_n \leq |a_n|$, we have that $\lim\limits_{n\to\infty} a_n = 0$ by the Squeeze Theorem.

88. Theorem 7: If $\lim\limits_{n\to\infty} a_n = L$ and the function f is continuous at L, then $\lim\limits_{n\to\infty} f(a_n) = f(L)$.

Proof: We must show that, given a number $\varepsilon > 0$, there is an integer N such that $|f(a_n) - f(L)| < \varepsilon$ whenever $n > N$. Suppose $\varepsilon > 0$. Since f is continuous at L, there is a number $\delta > 0$ such that $|f(x) - f(L)| < \varepsilon$ if $|x - L| < \delta$. Since $\lim\limits_{n\to\infty} a_n = L$, there is an integer N such that $|a_n - L| < \delta$ if $n > N$. Suppose $n > N$. Then $0 < |a_n - L| < \delta$, so $|f(a_n) - f(L)| < \varepsilon$.

89. To Prove: If $\lim\limits_{n\to\infty} a_n = 0$ and $\{b_n\}$ is bounded, then $\lim\limits_{n\to\infty} (a_n b_n) = 0$.

Proof: Since $\{b_n\}$ is bounded, there is a positive number M such that $|b_n| \leq M$ and hence, $|a_n|\,|b_n| \leq |a_n|\,M$ for all $n \geq 1$. Let $\varepsilon > 0$ be given. Since $\lim\limits_{n\to\infty} a_n = 0$, there is an integer N such that $|a_n - 0| < \dfrac{\varepsilon}{M}$ if $n > N$. Then $|a_n b_n - 0| = |a_n b_n| = |a_n|\,|b_n| \leq |a_n|\,M = |a_n - 0|\,M < \dfrac{\varepsilon}{M} \cdot M = \varepsilon$ for all $n > N$. Since ε was arbitrary, $\lim\limits_{n\to\infty} (a_n b_n) = 0$.

90. (a) $\dfrac{b^{n+1}-a^{n+1}}{b-a} = b^n + b^{n-1}a + b^{n-2}a^2 + b^{n-3}a^3 + \cdots + ba^{n-1} + a^n$

$< b^n + b^{n-1}b + b^{n-2}b^2 + b^{n-3}b^3 + \cdots + bb^{n-1} + b^n = (n+1)b^n$

(b) Since $b - a > 0$, we have $b^{n+1} - a^{n+1} < (n+1)b^n(b-a) \Rightarrow b^{n+1} - (n+1)b^n(b-a) < a^{n+1} \Rightarrow$ $b^n[(n+1)a - nb] < a^{n+1}$.

(c) With this substitution, $(n+1)a - nb = 1$, and so $b^n = \left(1+\dfrac{1}{n}\right)^n < a^{n+1} = \left(1+\dfrac{1}{n+1}\right)^{n+1}$.

(d) With this substitution, we get $\left(1+\dfrac{1}{2n}\right)^n\left(\dfrac{1}{2}\right) < 1 \Rightarrow \left(1+\dfrac{1}{2n}\right)^n < 2 \Rightarrow \left(1+\dfrac{1}{2n}\right)^{2n} < 4$.

(e) $a_n < a_{2n}$ since $\{a_n\}$ is increasing, so $a_n < a_{2n} < 4$.

(f) Since $\{a_n\}$ is increasing and bounded above by 4, $a_1 \le a_n \le 4$, and so $\{a_n\}$ is bounded and monotonic, and hence has a limit by the Monotonic Sequence Theorem.

91. (a) First we show that $a > a_1 > b_1 > b$.

$a_1 - b_1 = \frac{a+b}{2} - \sqrt{ab} = \frac{1}{2}\left(a - 2\sqrt{ab} + b\right) = \frac{1}{2}\left(\sqrt{a} - \sqrt{b}\right)^2 > 0$ [since $a > b$] $\Rightarrow a_1 > b_1$. Also $a - a_1 = a - \frac{1}{2}(a+b) = \frac{1}{2}(a-b) > 0$ and $b - b_1 = b - \sqrt{ab} = \sqrt{b}\left(\sqrt{b} - \sqrt{a}\right) < 0$, so $a > a_1 > b_1 > b$. In the same way we can show that $a_1 > a_2 > b_2 > b_1$ and so the given assertion is true for $n = 1$. Suppose it is true for $n = k$, that is, $a_k > a_{k+1} > b_{k+1} > b_k$. Then

$a_{k+2} - b_{k+2} = \frac{1}{2}(a_{k+1} + b_{k+1}) - \sqrt{a_{k+1}b_{k+1}} = \frac{1}{2}\left(a_{k+1} - 2\sqrt{a_{k+1}b_{k+1}} + b_{k+1}\right) = \frac{1}{2}\left(\sqrt{a_{k+1}} - \sqrt{b_{k+1}}\right)^2 > 0,$

$a_{k+1} - a_{k+2} = a_{k+1} - \frac{1}{2}(a_{k+1} + b_{k+1}) = \frac{1}{2}(a_{k+1} - b_{k+1}) > 0$, and

$b_{k+1} - b_{k+2} = b_{k+1} - \sqrt{a_{k+1}b_{k+1}} = \sqrt{b_{k+1}}\left(\sqrt{b_{k+1}} - \sqrt{a_{k+1}}\right) < 0 \Rightarrow a_{k+1} > a_{k+2} > b_{k+2} > b_{k+1},$

so the assertion is true for $n = k + 1$. Thus, it is true for all n by mathematical induction.

(b) From part (a) we have $a > a_n > a_{n+1} > b_{n+1} > b_n > b$, which shows that both sequences, $\{a_n\}$ and $\{b_n\}$, are monotonic and bounded. So they are both convergent by the Monotonic Sequence Theorem.

(c) Let $\lim\limits_{n\to\infty} a_n = \alpha$ and $\lim\limits_{n\to\infty} b_n = \beta$. Then $\lim\limits_{n\to\infty} a_{n+1} = \lim\limits_{n\to\infty} \dfrac{a_n + b_n}{2} \Rightarrow \alpha = \dfrac{\alpha+\beta}{2} \Rightarrow$ $2\alpha = \alpha + \beta \Rightarrow \alpha = \beta$.

92. (a) Let $\varepsilon > 0$. Since $\lim\limits_{n\to\infty} a_{2n} = L$, there exists N_1 such that $|a_{2n} - L| < \varepsilon$ for $n > N_1$. Since $\lim\limits_{n\to\infty} a_{2n+1} = L$, there exists N_2 such that $|a_{2n+1} - L| < \varepsilon$ for $n > N_2$. Let $N = \max\{2N_1, 2N_2 + 1\}$ and let $n > N$. If n is even, then $n = 2m$ where $m > N_1$, so $|a_n - L| = |a_{2m} - L| < \varepsilon$. If n is odd, then $n = 2m + 1$, where $m > N_2$, so $|a_n - L| = |a_{2m+1} - L| < \varepsilon$. Therefore $\lim\limits_{n\to\infty} a_n = L$.

(b) $a_1 = 1$, $a_2 = 1 + \frac{1}{1+1} = \frac{3}{2} = 1.5$, $a_3 = 1 + \frac{1}{5/2} = \frac{7}{5} = 1.4$, $a_4 = 1 + \frac{1}{12/5} = \frac{17}{12} = 1.41\overline{6}$,

$a_5 = 1 + \frac{1}{29/12} = \frac{41}{29} \approx 1.413793$, $a_6 = 1 + \frac{1}{70/29} = \frac{99}{70} \approx 1.414286$, $a_7 = 1 + \frac{1}{169/70} = \frac{239}{169} \approx 1.414201$,

$a_8 = 1 + \frac{1}{408/169} = \frac{577}{408} \approx 1.414216$. Notice that $a_1 < a_3 < a_5 < a_7$ and $a_2 > a_4 > a_6 > a_8$. It appears that the odd terms are increasing and the even terms are decreasing. Let's prove that $a_{2n-2} > a_{2n}$ and $a_{2n-1} < a_{2n+1}$ by mathematical induction. Suppose that $a_{2k-2} > a_{2k}$. Then $1 + a_{2k-2} > 1 + a_{2k} \Rightarrow \dfrac{1}{1+a_{2k-2}} < \dfrac{1}{1+a_{2k}} \Rightarrow$

$1 + \dfrac{1}{1+a_{2k-2}} < 1 + \dfrac{1}{1+a_{2k}} \Rightarrow a_{2k-1} < a_{2k+1} \Rightarrow 1 + a_{2k-1} < 1 + a_{2k+1} \Rightarrow$

$\dfrac{1}{1+a_{2k-1}} > \dfrac{1}{1+a_{2k+1}} \Rightarrow 1 + \dfrac{1}{1+a_{2k-1}} > 1 + \dfrac{1}{1+a_{2k+1}} \Rightarrow a_{2k} > a_{2k+2}$. We have thus shown, by induction, that the odd terms are increasing and the even terms are decreasing. Also all terms lie between 1 and 2, so both $\{a_n\}$ and $\{b_n\}$ are bounded monotonic sequences and are therefore convergent by the Monotonic Sequence Theorem. Let $\lim_{n\to\infty} a_{2n} = L$. Then $\lim_{n\to\infty} a_{2n+2} = L$ also. We have

$$a_{n+2} = 1 + \frac{1}{1 + 1 + 1/(1+a_n)} = 1 + \frac{1}{(3+2a_n)/(1+a_n)} = \frac{4+3a_n}{3+2a_n}$$

so $a_{2n+2} = \dfrac{4+3a_{2n}}{3+2a_{2n}}$. Taking limits of both sides, we get $L = \dfrac{4+3L}{3+2L} \Rightarrow 3L + 2L^2 = 4 + 3L \Rightarrow L^2 = 2 \Rightarrow$ $L = \sqrt{2}$ [since $L > 0$]. Thus, $\lim_{n\to\infty} a_{2n} = \sqrt{2}$. Similarly we find that $\lim_{n\to\infty} a_{2n+1} = \sqrt{2}$. So, by part (a), $\lim_{n\to\infty} a_n = \sqrt{2}$.

93. (a) Suppose $\{p_n\}$ converges to p. Then $p_{n+1} = \dfrac{bp_n}{a+p_n} \Rightarrow \lim_{n\to\infty} p_{n+1} = \dfrac{b \lim_{n\to\infty} p_n}{a + \lim_{n\to\infty} p_n} \Rightarrow p = \dfrac{bp}{a+p} \Rightarrow$ $p^2 + ap = bp \Rightarrow p(p + a - b) = 0 \Rightarrow p = 0$ or $p = b - a$.

(b) $p_{n+1} = \dfrac{bp_n}{a+p_n} = \dfrac{\left(\frac{b}{a}\right)p_n}{1 + \frac{p_n}{a}} < \left(\dfrac{b}{a}\right)p_n$ since $1 + \dfrac{p_n}{a} > 1$.

(c) By part (b), $p_1 < \left(\dfrac{b}{a}\right)p_0$, $p_2 < \left(\dfrac{b}{a}\right)p_1 < \left(\dfrac{b}{a}\right)^2 p_0$, $p_3 < \left(\dfrac{b}{a}\right)p_2 < \left(\dfrac{b}{a}\right)^3 p_0$, etc. In general, $p_n < \left(\dfrac{b}{a}\right)^n p_0$, so $\lim_{n\to\infty} p_n \le \lim_{n\to\infty} \left(\dfrac{b}{a}\right)^n \cdot p_0 = 0$ since $b < a$. $\left[\text{By (7), } \lim_{n\to\infty} r^n = 0 \text{ if } -1 < r < 1. \text{ Here } r = \dfrac{b}{a} \in (0,1).\right]$

(d) Let $a < b$. We first show, by induction, that if $p_0 < b - a$, then $p_n < b - a$ and $p_{n+1} > p_n$.

For $n = 0$, we have $p_1 - p_0 = \dfrac{bp_0}{a+p_0} - p_0 = \dfrac{p_0(b-a-p_0)}{a+p_0} > 0$ since $p_0 < b - a$. So $p_1 > p_0$.

Now we suppose the assertion is true for $n = k$, that is, $p_k < b - a$ and $p_{k+1} > p_k$. Then

$b - a - p_{k+1} = b - a - \dfrac{bp_k}{a+p_k} = \dfrac{a(b-a) + bp_k - ap_k - bp_k}{a+p_k} = \dfrac{a(b-a-p_k)}{a+p_k} > 0$ because $p_k < b - a$. So $p_{k+1} < b - a$. And $p_{k+2} - p_{k+1} = \dfrac{bp_{k+1}}{a+p_{k+1}} - p_{k+1} = \dfrac{p_{k+1}(b-a-p_{k+1})}{a+p_{k+1}} > 0$ since $p_{k+1} < b - a$. Therefore, $p_{k+2} > p_{k+1}$. Thus, the assertion is true for $n = k + 1$. It is therefore true for all n by mathematical induction.

A similar proof by induction shows that if $p_0 > b - a$, then $p_n > b - a$ and $\{p_n\}$ is decreasing.

In either case the sequence $\{p_n\}$ is bounded and monotonic, so it is convergent by the Monotonic Sequence Theorem. It then follows from part (a) that $\lim_{n\to\infty} p_n = b - a$.

LABORATORY PROJECT Logistic Sequences

1. To write such a program in Maple it is best to calculate all the points first and then graph them. One possible sequence of commands [taking $p_0 = \frac{1}{2}$ and $k = 1.5$ for the difference equation] is

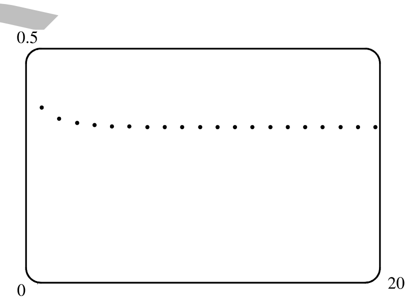
```
t:='t';p(0):=1/2;k:=1.5;
for j from 1 to 20  do p(j):=k*p(j-1)*(1-p(j-1)) od;
plot([seq([t,p(t)] t=0..20)],t=0..20,p=0..0.5,style=point);
```

In Mathematica, we can use the following program:

```
p[0]=1/2
k=1.5
p[j_]:=k*p[j-1]*(1-p[j-1])
P=Table[p[t],{t,20}]
ListPlot[P]
```

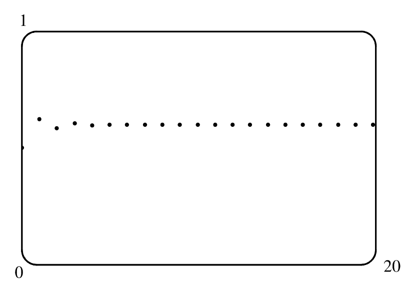
With $p_0 = \frac{1}{2}$ and $k = 1.5$:

n	p_n	n	p_n	n	p_n
0	0.5	7	0.3338465076	14	0.3333373303
1	0.375	8	0.3335895255	15	0.3333353318
2	0.3515625	9	0.3334613309	16	0.3333343326
3	0.3419494629	10	0.3333973076	17	0.3333338329
4	0.3375300416	11	0.3333653143	18	0.3333335831
5	0.3354052689	12	0.3333493223	19	0.3333334582
6	0.3343628617	13	0.3333413274	20	0.3333333958



With $p_0 = \frac{1}{2}$ and $k = 2.5$:

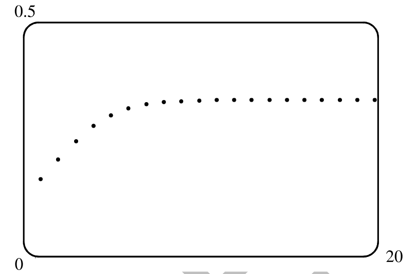
n	p_n	n	p_n	n	p_n
0	0.5	7	0.6004164790	14	0.5999967417
1	0.625	8	0.5997913269	15	0.6000016291
2	0.5859375	9	0.6001042277	16	0.5999991854
3	0.6065368651	10	0.5999478590	17	0.6000004073
4	0.5966247409	11	0.6000260637	18	0.5999997964
5	0.6016591486	12	0.5999869664	19	0.6000001018
6	0.5991635437	13	0.6000065164	20	0.5999999491



Both of these sequences seem to converge $\left(\text{the first to about } \frac{1}{3}, \text{ the second to about } 0.60\right)$.

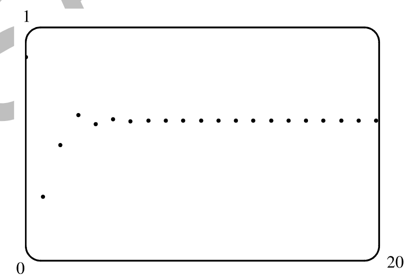
With $p_0 = \frac{7}{8}$ and $k = 1.5$:

n	p_n	n	p_n	n	p_n
0	0.875	7	0.3239166554	14	0.3332554829
1	0.1640625	8	0.3284919837	15	0.3332943990
2	0.2057189941	9	0.3308775005	16	0.3333138639
3	0.2450980344	10	0.3320963702	17	0.3333235980
4	0.2775374819	11	0.3327125567	18	0.3333284655
5	0.3007656421	12	0.3330223670	19	0.3333308994
6	0.3154585059	13	0.3331777051	20	0.3333321164



With $p_0 = \frac{7}{8}$ and $k = 2.5$:

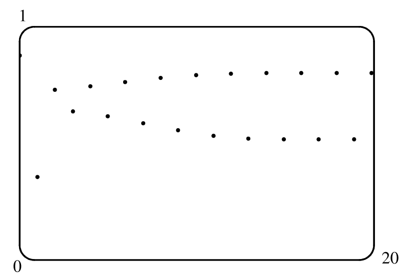
n	p_n	n	p_n	n	p_n
0	0.875	7	0.6016572368	14	0.5999869815
1	0.2734375	8	0.5991645155	15	0.6000065088
2	0.4966735840	9	0.6004159972	16	0.5999967455
3	0.6249723374	10	0.5997915688	17	0.6000016272
4	0.5859547872	11	0.6001041070	18	0.5999991864
5	0.6065294364	12	0.5999479194	19	0.6000004068
6	0.5966286980	13	0.6000260335	20	0.5999997966



The limit of the sequence seems to depend on k, but not on p_0.

2. With $p_0 = \frac{7}{8}$ and $k = 3.2$:

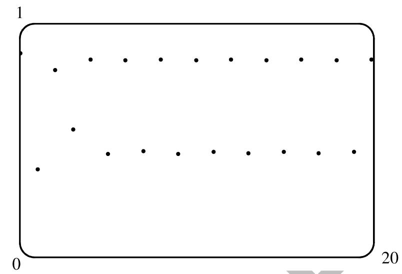
n	p_n	n	p_n	n	p_n
0	0.875	7	0.5830728495	14	0.7990633827
1	0.35	8	0.7779164854	15	0.5137954979
2	0.728	9	0.5528397669	16	0.7993909896
3	0.6336512	10	0.7910654689	17	0.5131681132
4	0.7428395416	11	0.5288988570	18	0.7994451225
5	0.6112926626	12	0.7973275394	19	0.5130643795
6	0.7603646184	13	0.5171082698	20	0.7994538304



It seems that eventually the terms fluctuate between two values (about 0.5 and 0.8 in this case).

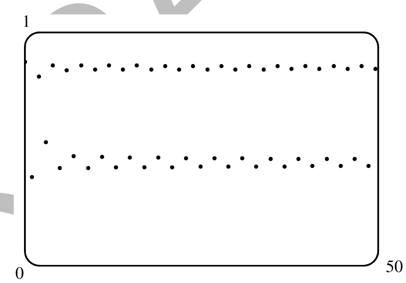
3. With $p_0 = \frac{7}{8}$ and $k = 3.42$:

n	p_n	n	p_n	n	p_n
0	0.875	7	0.4523028596	14	0.8442074951
1	0.3740625	8	0.8472194412	15	0.4498025048
2	0.8007579316	9	0.4426802161	16	0.8463823232
3	0.5456427596	10	0.8437633929	17	0.4446659586
4	0.8478752457	11	0.4508474156	18	0.8445284520
5	0.4411212220	12	0.8467373602	19	0.4490464985
6	0.8431438501	13	0.4438243545	20	0.8461207931

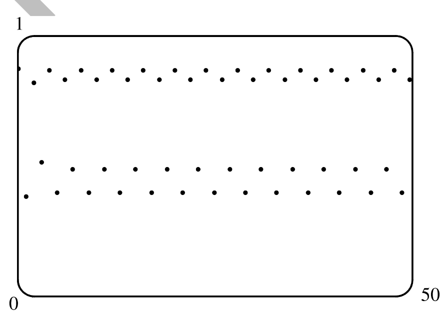


With $p_0 = \frac{7}{8}$ and $k = 3.45$:

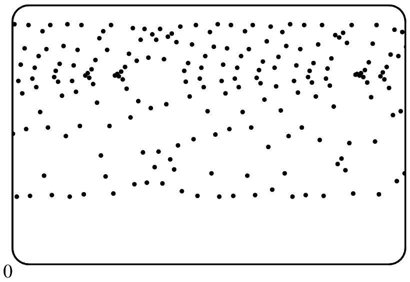
n	p_n	n	p_n	n	p_n
0	0.875	7	0.4670259170	14	0.8403376122
1	0.37734375	8	0.8587488490	15	0.4628875685
2	0.8105962830	9	0.4184824586	16	0.8577482026
3	0.5296783241	10	0.8395743720	17	0.4209559716
4	0.8594612299	11	0.4646778983	18	0.8409445432
5	0.4167173034	12	0.8581956045	19	0.4614610237
6	0.8385707740	13	0.4198508858	20	0.8573758782



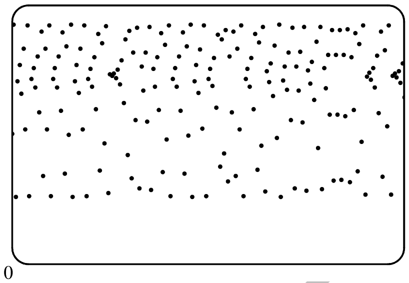
From the graphs above, it seems that for k between 3.4 and 3.5, the terms eventually fluctuate between four values. In the graph below, the pattern followed by the terms is $0.395, 0.832, 0.487, 0.869, 0.395, \ldots$. Note that even for $k = 3.42$ (as in the first graph), there are four distinct "branches"; even after 1000 terms, the first and third terms in the pattern differ by about 2×10^{-9}, while the first and fifth terms differ by only 2×10^{-10}. With $p_0 = \frac{7}{8}$ and $k = 3.48$:



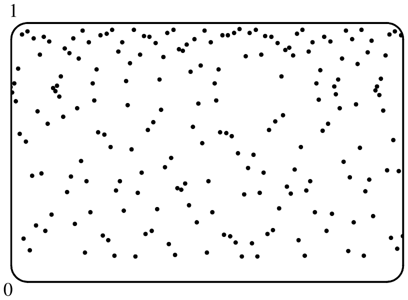
4.



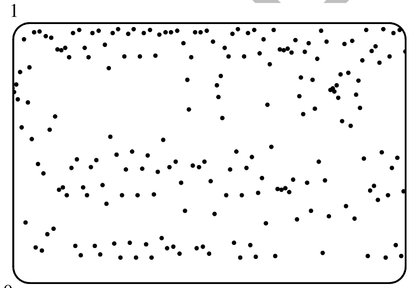
$p_0 = 0.5$, $k = 3.7$



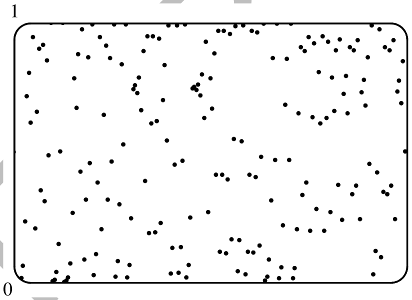
$p_0 = 0.501$, $k = 3.7$



$p_0 = 0.75$, $k = 3.9$



$p_0 = 0.749$, $k = 3.9$



$p_0 = 0.5$, $k = 3.999$

From the graphs, it seems that if p_0 is changed by 0.001, the whole graph changes completely. (Note, however, that this might be partially due to accumulated round-off error in the CAS. These graphs were generated by Maple with 100-digit accuracy, and different degrees of accuracy give different graphs.) There seem to be some some fleeting patterns in these graphs, but on the whole they are certainly very chaotic. As k increases, the graph spreads out vertically, with more extreme values close to 0 or 1.

11.2 Series

1. (a) A sequence is an ordered list of numbers whereas a series is the *sum* of a list of numbers.

(b) A series is convergent if the sequence of partial sums is a convergent sequence. A series is divergent if it is not convergent.

2. $\sum_{n=1}^{\infty} a_n = 5$ means that by adding sufficiently many terms of the series we can get as close as we like to the number 5.

In other words, it means that $\lim_{n\to\infty} s_n = 5$, where s_n is the nth partial sum, that is, $\sum_{i=1}^{n} a_i$.

3. $\sum_{n=1}^{\infty} a_n = \lim_{n\to\infty} s_n = \lim_{n\to\infty} [2 - 3(0.8)^n] = \lim_{n\to\infty} 2 - 3 \lim_{n\to\infty} (0.8)^n = 2 - 3(0) = 2$

4. $\sum_{n=1}^{\infty} a_n = \lim_{n\to\infty} s_n = \lim_{n\to\infty} \frac{n^2-1}{4n^2+1} = \lim_{n\to\infty} \frac{(n^2-1)/n^2}{(4n^2+1)/n^2} = \lim_{n\to\infty} \frac{1-1/n^2}{4+1/n^2} = \frac{1-0}{4+0} = \frac{1}{4}$

5. For $\sum_{n=1}^{\infty} \frac{1}{n^4+n^2}$, $a_n = \frac{1}{n^4+n^2}$. $s_1 = a_1 = \frac{1}{1^4+1^2} = \frac{1}{2} = 0.5$, $s_2 = s_1 + a_2 = \frac{1}{2} + \frac{1}{16+4} = 0.55$,

$s_3 = s_2 + a_3 \approx 0.5611$, $s_4 = s_3 + a_4 \approx 0.5648$, $s_5 = s_4 + a_5 \approx 0.5663$, $s_6 = s_5 + a_6 \approx 0.5671$,

$s_7 = s_6 + a_7 \approx 0.5675$, and $s_8 = s_7 + a_8 \approx 0.5677$. It appears that the series is convergent.

6. For $\sum_{n=1}^{\infty} \frac{1}{\sqrt[3]{n}}$, $a_n = \frac{1}{\sqrt[3]{n}}$. $s_1 = a_1 = \frac{1}{\sqrt[3]{1}} = 1$, $s_2 = s_1 + a_2 = 1 + \frac{1}{\sqrt[3]{2}} \approx 1.7937$,

$s_3 = s_2 + a_3 \approx 2.4871$, $s_4 = s_3 + a_4 \approx 3.1170$, $s_5 = s_4 + a_5 \approx 3.7018$, $s_6 = s_5 + a_6 \approx 4.2521$,

$s_7 = s_6 + a_7 \approx 4.7749$, and $s_8 = s_7 + a_8 \approx 5.2749$. It appears that the series is divergent.

7. For $\sum_{n=1}^{\infty} \sin n$, $a_n = \sin n$. $s_1 = a_1 = \sin 1 \approx 0.8415$, $s_2 = s_1 + a_2 \approx 1.7508$,

$s_3 = s_2 + a_3 \approx 1.8919$, $s_4 = s_3 + a_4 \approx 1.1351$, $s_5 = s_4 + a_5 \approx 0.1762$, $s_6 = s_5 + a_6 \approx -0.1033$,

$s_7 = s_6 + a_7 \approx 0.5537$, and $s_8 = s_7 + a_8 \approx 1.5431$. It appears that the series is divergent.

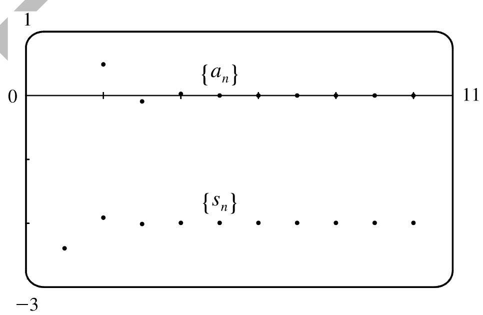
8. For $\sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{n!}$, $a_n = (-1)^{n-1}\frac{1}{n!}$. $s_1 = a_1 = \frac{1}{1!} = 1$, $s_2 = s_1 + a_2 = 1 - \frac{1}{2!} = 0.5$,

$s_3 = s_2 + a_3 = 0.5 + \frac{1}{3!} \approx 0.6667$, $s_4 = s_3 + a_4 = 0.625$, $s_5 = s_4 + a_5 \approx 0.6333$, $s_6 = s_5 + a_6 \approx 0.6319$,

$s_7 = s_6 + a_7 \approx 0.6321$, and $s_8 = s_7 + a_8 \approx 0.6321$. It appears that the series is convergent.

9.

n	s_n
1	−2.40000
2	−1.92000
3	−2.01600
4	−1.99680
5	−2.00064
6	−1.99987
7	−2.00003
8	−1.99999
9	−2.00000
10	−2.00000



From the graph and the table, it seems that the series converges to -2. In fact, it is a geometric series with $a = -2.4$ and $r = -\frac{1}{5}$, so its sum is $\sum_{n=1}^{\infty} \frac{12}{(-5)^n} = \frac{-2.4}{1-\left(-\frac{1}{5}\right)} = \frac{-2.4}{1.2} = -2$.

Note that the dot corresponding to $n = 1$ is part of both $\{a_n\}$ and $\{s_n\}$.

TI-86 Note: To graph $\{a_n\}$ and $\{s_n\}$, set your calculator to Param mode and DrawDot mode. (DrawDot is under GRAPH, MORE, FORMT (F3).) Now under `E(t)=` make the assignments: `xt1=t, yt1=12/(-5)^t, xt2=t, yt2=sum seq(yt1,t,1,t,1)`. (sum and seq are under LIST, OPS (F5), MORE.) Under WIND use `1,10,1,0,10,1,-3,1,1` to obtain a graph similar to the one above. Then use TRACE (F4) to see the values.

10.

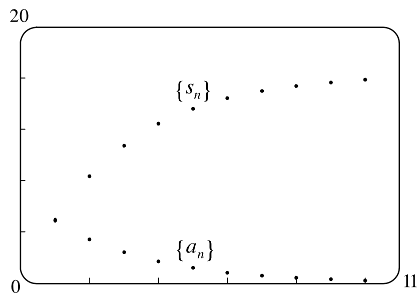
8	15.39175
9	15.67422
10	15.87196



From the graph and the table, we see that the terms are getting smaller and may approach 0, and that the series approaches a value near 16. The series is geometric with $a_1 = 4.9$ and $r = 0.7$, so its sum is $\sum_{n=1}^{\infty} \dfrac{7^{n+1}}{10^n} = \dfrac{4.9}{1-0.7} = \dfrac{4.9}{0.3} = 16.\overline{3}$.

13.

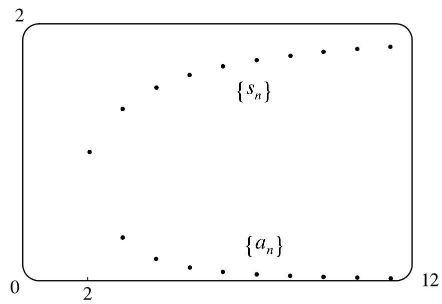
8	1.75000
9	1.77778
10	1.80000
11	1.81818



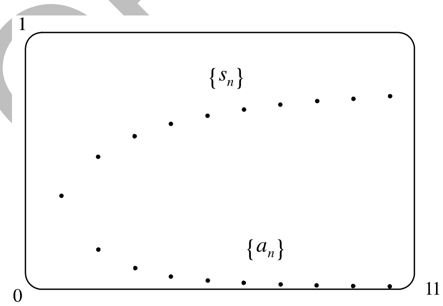
From the graph and the table, we see that the terms are getting smaller and may approach 0, and that the series may approach a number near 2. Using partial fractions, we have

$$\sum_{n=2}^{k} \frac{2}{n^2-n} = \sum_{n=2}^{k}\left(\frac{2}{n-1}-\frac{2}{n}\right)$$
$$= \left(\frac{2}{1}-\frac{2}{2}\right)+\left(\frac{2}{2}-\frac{2}{3}\right)+\left(\frac{2}{3}-\frac{2}{4}\right)$$
$$+\cdots+\left(\frac{2}{k-2}-\frac{2}{k-1}\right)+\left(\frac{2}{k-1}-\frac{2}{k}\right)$$
$$= 2-\frac{2}{k}$$

As $k\to\infty$, $2-\frac{2}{k}\to 2$, so $\sum_{n=2}^{\infty}\frac{2}{n^2-n}=2$.

14.

n	s_n
1	0.36205
2	0.51428
3	0.59407
4	0.64280
5	0.67557
6	0.69910
7	0.71680
8	0.73059
9	0.74164
10	0.75069



From the graph and the table, we see that the terms are getting smaller and may approach 0, and that the series may approach a number near 1.

$$\sum_{n=1}^{k}\left(\sin\frac{1}{n}-\sin\frac{1}{n+1}\right) = \left(\sin 1-\sin\frac{1}{2}\right)+\left(\sin\frac{1}{2}-\sin\frac{1}{3}\right)$$
$$+\cdots+\left(\sin\frac{1}{k-1}+\sin\frac{1}{k}\right)$$
$$+\left(\sin\frac{1}{k}-\sin\frac{1}{k+1}\right)$$
$$= \sin 1-\sin\frac{1}{k+1}$$

As $k\to\infty$, $\sin 1-\sin\frac{1}{k+1}\to\sin 1-\sin 0=\sin 1$, so

$\sum_{n=1}^{\infty}\left(\sin\frac{1}{n}-\sin\frac{1}{n+1}\right)=\sin 1\approx 0.84147.$

15. (a) $\lim_{n\to\infty} a_n = \lim_{n\to\infty} \dfrac{2n}{3n+1} = \dfrac{2}{3}$, so the *sequence* $\{a_n\}$ is convergent by (11.1.1).

(b) Since $\lim_{n\to\infty} a_n = \frac{2}{3} \neq 0$, the *series* $\sum_{n=1}^{\infty} a_n$ is divergent by the Test for Divergence.

16. (a) Both $\sum_{i=1}^{n} a_i$ and $\sum_{j=1}^{n} a_j$ represent the sum of the first n terms of the sequence $\{a_n\}$, that is, the nth partial sum.

(b) $\sum_{i=1}^{n} a_j = \underbrace{a_j + a_j + \cdots + a_j}_{n \text{ terms}} = na_j$, which, in general, is not the same as $\sum_{i=1}^{n} a_i = a_1 + a_2 + \cdots + a_n$.

17. $3 - 4 + \frac{16}{3} - \frac{64}{9} + \cdots$ is a geometric series with ratio $r = -\frac{4}{3}$. Since $|r| = \frac{4}{3} > 1$, the series diverges.

18. $4 + 3 + \frac{9}{4} + \frac{27}{16} + \cdots$ is a geometric series with ratio $\frac{3}{4}$. Since $|r| = \frac{3}{4} < 1$, the series converges to $\dfrac{a}{1-r} = \dfrac{4}{1-3/4} = 16$.

19. $10 - 2 + 0.4 - 0.08 + \cdots$ is a geometric series with ratio $-\frac{2}{10} = -\frac{1}{5}$. Since $|r| = \frac{1}{5} < 1$, the series converges to

$\dfrac{a}{1-r} = \dfrac{10}{1-(-1/5)} = \dfrac{10}{6/5} = \dfrac{50}{6} = \dfrac{25}{3}$.

20. $2 + 0.5 + 0.125 + 0.03125 + \cdots$ is a geometric series with ratio $r = \frac{0.5}{2} = \frac{1}{4}$. Since $|r| = \frac{1}{4} < 1$, the series converges

to $\dfrac{a}{1-r} = \dfrac{2}{1-1/4} = \dfrac{2}{3/4} = \dfrac{8}{3}$.

21. $\sum_{n=1}^{\infty} 12\,(0.73)^{n-1}$ is a geometric series with first term $a = 12$ and ratio $r = 0.73$. Since $|r| = 0.73 < 1$, the series converges

to $\dfrac{a}{1-r} = \dfrac{12}{1-0.73} = \dfrac{12}{0.27} = \dfrac{12(100)}{27} = \dfrac{400}{9}$.

22. $\sum_{n=1}^{\infty} \dfrac{5}{\pi^n} = 5\sum_{n=1}^{\infty} \left(\dfrac{1}{\pi}\right)^n$. The latter series is geometric with $a = \dfrac{1}{\pi}$ and ratio $r = \dfrac{1}{\pi}$. Since $|r| = \dfrac{1}{\pi} < 1$, it converges to

$\dfrac{1/\pi}{1-1/\pi} = \dfrac{1}{\pi - 1}$. Thus, the given series converges to $5\left(\dfrac{1}{\pi-1}\right) = \dfrac{5}{\pi-1}$.

23. $\sum_{n=1}^{\infty} \dfrac{(-3)^{n-1}}{4^n} = \dfrac{1}{4}\sum_{n=1}^{\infty}\left(-\dfrac{3}{4}\right)^{n-1}$. The latter series is geometric with $a = 1$ and ratio $r = -\frac{3}{4}$. Since $|r| = \frac{3}{4} < 1$, it

converges to $\dfrac{1}{1-(-3/4)} = \frac{4}{7}$. Thus, the given series converges to $\left(\frac{1}{4}\right)\left(\frac{4}{7}\right) = \frac{1}{7}$.

24. $\sum_{n=0}^{\infty} \dfrac{3^{n+1}}{(-2)^n} = 3\sum_{n=0}^{\infty}\left(-\frac{3}{2}\right)^n$ is a geometric series with ratio $r = -\frac{3}{2}$. Since $|r| = \frac{3}{2} > 1$, the series diverges.

25. $\sum_{n=1}^{\infty} \dfrac{e^{2n}}{6^{n-1}} = \sum_{n=1}^{\infty} \dfrac{(e^2)^n}{6^n 6^{-1}} = 6\sum_{n=1}^{\infty}\left(\dfrac{e^2}{6}\right)^n$ is a geometric series with ratio $r = \dfrac{e^2}{6}$. Since $|r| = \dfrac{e^2}{6}[\approx 1.23] > 1$, the series

diverges.

26. $\displaystyle\sum_{n=1}^{\infty}\frac{6\cdot 2^{2n-1}}{3^n}=\sum_{n=1}^{\infty}\frac{6(2^2)^n\cdot 2^{-1}}{3^n}=3\sum_{n=1}^{\infty}\left(\frac{4}{3}\right)^n$ is a geometric series with ratio $r=\frac{4}{3}$. Since $|r|=\frac{4}{3}>1$, the series diverges.

27. $\frac{1}{3}+\frac{1}{6}+\frac{1}{9}+\frac{1}{12}+\frac{1}{15}+\cdots=\sum_{n=1}^{\infty}\frac{1}{3n}=\frac{1}{3}\sum_{n=1}^{\infty}\frac{1}{n}$. This is a constant multiple of the divergent harmonic series, so it diverges.

28. $\frac{1}{3}+\frac{2}{9}+\frac{1}{27}+\frac{2}{81}+\frac{1}{243}+\frac{2}{729}+\cdots=\left(\frac{1}{3}+\frac{1}{27}+\frac{1}{243}+\cdots\right)+\left(\frac{2}{9}+\frac{2}{81}+\frac{2}{729}+\cdots\right)$, which are both convergent geometric series with sums $\dfrac{1/3}{1-1/9}=\dfrac{3}{8}$ and $\dfrac{2/9}{1-1/9}=\dfrac{1}{4}$, so the original series converges and its sum is $\frac{3}{8}+\frac{1}{4}=\frac{5}{8}$.

29. $\displaystyle\sum_{n=1}^{\infty}\frac{2+n}{1-2n}$ diverges by the Test for Divergence since $\displaystyle\lim_{n\to\infty}a_n=\lim_{n\to\infty}\frac{2+n}{1-2n}=\lim_{n\to\infty}\frac{2/n+1}{1/n-2}=-\frac{1}{2}\neq 0$.

30. $\displaystyle\sum_{k=1}^{\infty}\frac{k^2}{k^2-2k+5}$ diverges by the Test for Divergence since $\displaystyle\lim_{k\to\infty}\frac{k^2}{k^2-2k+5}=\lim_{k\to\infty}\frac{1}{1-2/k+5/k^2}=1\neq 0$.

31. $\displaystyle\sum_{n=1}^{\infty}3^{n+1}4^{-n}=\sum_{n=1}^{\infty}\frac{3^n\cdot 3^1}{4^n}=3\sum_{n=1}^{\infty}\left(\frac{3}{4}\right)^n$. The latter series is geometric with $a=\frac{3}{4}$ and ratio $r=\frac{3}{4}$. Since $|r|=\frac{3}{4}<1$, it converges to $\dfrac{3/4}{1-3/4}=3$. Thus, the given series converges to $3(3)=9$.

32.
$$\begin{aligned}\sum_{n=1}^{\infty}\left[(-0.2)^n+(0.6)^{n-1}\right]&=\sum_{n=1}^{\infty}(-0.2)^n+\sum_{n=1}^{\infty}(0.6)^{n-1}\qquad\text{[sum of two geometric series]}\\&=\frac{-0.2}{1-(-0.2)}+\frac{1}{1-0.6}=-\frac{1}{6}+\frac{5}{2}=\frac{7}{3}\end{aligned}$$

33. $\displaystyle\sum_{n=1}^{\infty}\frac{1}{4+e^{-n}}$ diverges by the Test for Divergence since $\displaystyle\lim_{n\to\infty}\frac{1}{4+e^{-n}}=\frac{1}{4+0}=\frac{1}{4}\neq 0$.

34. $\displaystyle\sum_{n=1}^{\infty}\frac{2^n+4^n}{e^n}$ diverges by the Test for Divergence since $\displaystyle\lim_{n\to\infty}\frac{2^n+4^n}{e^n}=\lim_{n\to\infty}\left(\frac{2^n}{e^n}+\frac{4^n}{e^n}\right)\geq\lim_{n\to\infty}\left(\frac{4}{e}\right)^n=\infty$ since $\frac{4}{e}>1$.

35. $\displaystyle\sum_{k=1}^{\infty}(\sin 100)^k$ is a geometric series with first term $a=\sin 100$ [≈ -0.506] and ratio $r=\sin 100$. Since $|r|<1$, the series converges to $\dfrac{\sin 100}{1-\sin 100}\approx -0.336$.

36. $\displaystyle\sum_{n=1}^{\infty}\frac{1}{1+\left(\frac{2}{3}\right)^n}$ diverges by the Test for Divergence since $\displaystyle\lim_{n\to\infty}\frac{1}{1+\left(\frac{2}{3}\right)^n}=\frac{1}{1+0}=1\neq 0$.

37. $\sum_{n=1}^{\infty} \ln\left(\dfrac{n^2+1}{2n^2+1}\right)$ diverges by the Test for Divergence since

$$\lim_{n\to\infty} a_n = \lim_{n\to\infty} \ln\left(\frac{n^2+1}{2n^2+1}\right) = \ln\left(\lim_{n\to\infty} \frac{n^2+1}{2n^2+1}\right) = \ln \tfrac{1}{2} \neq 0.$$

38. $\sum_{k=0}^{\infty} (\sqrt{2})^{-k} = \sum_{k=0}^{\infty} \left(\dfrac{1}{\sqrt{2}}\right)^k$ is a geometric series with first term $a = \left(\dfrac{1}{\sqrt{2}}\right)^0 = 1$ and ratio $r = \dfrac{1}{\sqrt{2}}$. Since $|r| < 1$, the series converges to $\dfrac{1}{1 - 1/\sqrt{2}} = \dfrac{\sqrt{2}}{\sqrt{2}-1} \approx 3.414$.

39. $\sum_{n=1}^{\infty} \arctan n$ diverges by the Test for Divergence since $\lim_{n\to\infty} a_n = \lim_{n\to\infty} \arctan n = \frac{\pi}{2} \neq 0$.

40. $\sum_{n=1}^{\infty} \left(\dfrac{3}{5^n} + \dfrac{2}{n}\right)$ diverges because $\sum_{n=1}^{\infty} \dfrac{2}{n} = 2\sum_{n=1}^{\infty} \dfrac{1}{n}$ diverges. (If it converged, then $\dfrac{1}{2} \cdot 2\sum_{n=1}^{\infty} \dfrac{1}{n}$ would also converge by Theorem 8(i), but we know from Example 9 that the harmonic series $\sum_{n=1}^{\infty} \dfrac{1}{n}$ diverges.) If the given series converges, then the difference $\sum_{n=1}^{\infty} \left(\dfrac{3}{5^n} + \dfrac{2}{n}\right) - \sum_{n=1}^{\infty} \dfrac{3}{5^n}$ must converge (since $\sum_{n=1}^{\infty} \dfrac{3}{5^n}$ is a convergent geometric series) and equal $\sum_{n=1}^{\infty} \dfrac{2}{n}$, but we have just seen that $\sum_{n=1}^{\infty} \dfrac{2}{n}$ diverges, so the given series must also diverge.

41. $\sum_{n=1}^{\infty} \dfrac{1}{e^n} = \sum_{n=1}^{\infty} \left(\dfrac{1}{e}\right)^n$ is a geometric series with first term $a = \dfrac{1}{e}$ and ratio $r = \dfrac{1}{e}$. Since $|r| = \dfrac{1}{e} < 1$, the series converges to $\dfrac{1/e}{1-1/e} = \dfrac{1/e}{1-1/e} \cdot \dfrac{e}{e} = \dfrac{1}{e-1}$. By Example 8, $\sum_{n=1}^{\infty} \dfrac{1}{n(n+1)} = 1$. Thus, by Theorem 8(ii),

$$\sum_{n=1}^{\infty} \left(\frac{1}{e^n} + \frac{1}{n(n+1)}\right) = \sum_{n=1}^{\infty} \frac{1}{e^n} + \sum_{n=1}^{\infty} \frac{1}{n(n+1)} = \frac{1}{e-1} + 1 = \frac{1}{e-1} + \frac{e-1}{e-1} = \frac{e}{e-1}.$$

42. $\sum_{n=1}^{\infty} \dfrac{e^n}{n^2}$ diverges by the Test for Divergence since $\lim_{n\to\infty} a_n = \lim_{n\to\infty} \dfrac{e^n}{n^2} = \lim_{x\to\infty} \dfrac{e^x}{x^2} \overset{\text{H}}{=} \lim_{x\to\infty} \dfrac{e^x}{2x} \overset{\text{H}}{=} \lim_{x\to\infty} \dfrac{e^x}{2} = \infty \neq 0$.

43. Using partial fractions, the partial sums of the series $\sum_{n=2}^{\infty} \dfrac{2}{n^2-1}$ are

$$\begin{aligned} s_n &= \sum_{i=2}^{n} \frac{2}{(i-1)(i+1)} = \sum_{i=2}^{n} \left(\frac{1}{i-1} - \frac{1}{i+1}\right) \\ &= \left(1 - \frac{1}{3}\right) + \left(\frac{1}{2} - \frac{1}{4}\right) + \left(\frac{1}{3} - \frac{1}{5}\right) + \cdots + \left(\frac{1}{n-3} - \frac{1}{n-1}\right) + \left(\frac{1}{n-2} - \frac{1}{n}\right) \end{aligned}$$

This sum is a telescoping series and $s_n = 1 + \dfrac{1}{2} - \dfrac{1}{n-1} - \dfrac{1}{n}$.

Thus, $\sum_{n=2}^{\infty} \dfrac{2}{n^2-1} = \lim_{n\to\infty} s_n = \lim_{n\to\infty} \left(1 + \dfrac{1}{2} - \dfrac{1}{n-1} - \dfrac{1}{n}\right) = \dfrac{3}{2}$.

44. For the series $\sum_{n=1}^{\infty} \ln \dfrac{n}{n+1}$,

$$s_n = (\ln 1 - \ln 2) + (\ln 2 - \ln 3) + (\ln 3 - \ln 4) + \cdots + [\ln n - \ln(n+1)] = \ln 1 - \ln(n+1) = -\ln(n+1)$$

[telescoping series]

Thus, $\lim_{n\to\infty} s_n = -\infty$, so the series is divergent.

45. For the series $\sum_{n=1}^{\infty} \dfrac{3}{n(n+3)}$, $s_n = \sum_{i=1}^{n} \dfrac{3}{i(i+3)} = \sum_{i=1}^{n}\left(\dfrac{1}{i} - \dfrac{1}{i+3}\right)$ [using partial fractions]. The latter sum is

$$\left(1 - \tfrac{1}{4}\right) + \left(\tfrac{1}{2} - \tfrac{1}{5}\right) + \left(\tfrac{1}{3} - \tfrac{1}{6}\right) + \left(\tfrac{1}{4} - \tfrac{1}{7}\right) + \cdots + \left(\tfrac{1}{n-3} - \tfrac{1}{n}\right) + \left(\tfrac{1}{n-2} - \tfrac{1}{n+1}\right) + \left(\tfrac{1}{n-1} - \tfrac{1}{n+2}\right) + \left(\tfrac{1}{n} - \tfrac{1}{n+3}\right)$$

$$= 1 + \tfrac{1}{2} + \tfrac{1}{3} - \tfrac{1}{n+1} - \tfrac{1}{n+2} - \tfrac{1}{n+3} \quad \text{[telescoping series]}$$

Thus, $\sum_{n=1}^{\infty} \dfrac{3}{n(n+3)} = \lim_{n\to\infty} s_n = \lim_{n\to\infty}\left(1 + \tfrac{1}{2} + \tfrac{1}{3} - \tfrac{1}{n+1} - \tfrac{1}{n+2} - \tfrac{1}{n+3}\right) = 1 + \tfrac{1}{2} + \tfrac{1}{3} = \tfrac{11}{6}$. Converges

46. For the series $\sum_{n=4}^{\infty}\left(\dfrac{1}{\sqrt{n}} - \dfrac{1}{\sqrt{n+1}}\right)$

$$s_n = \sum_{i=4}^{n}\left(\frac{1}{\sqrt{i}} - \frac{1}{\sqrt{i+1}}\right) = \left(\frac{1}{\sqrt{4}} - \frac{1}{\sqrt{5}}\right) + \left(\frac{1}{\sqrt{5}} - \frac{1}{\sqrt{6}}\right) + \cdots + \left(\frac{1}{\sqrt{n}} - \frac{1}{\sqrt{n+1}}\right) = \frac{1}{\sqrt{4}} - \frac{1}{\sqrt{n+1}}$$

[telescoping series]

Thus, $\sum_{n=4}^{\infty}\left(\dfrac{1}{\sqrt{n}} - \dfrac{1}{\sqrt{n+1}}\right) = \lim_{n\to\infty} s_n = \lim_{n\to\infty}\left(\dfrac{1}{\sqrt{4}} - \dfrac{1}{\sqrt{n+1}}\right) = \dfrac{1}{\sqrt{4}} - 0 = \dfrac{1}{2}$. Converges

47. For the series $\sum_{n=1}^{\infty}\left(e^{1/n} - e^{1/(n+1)}\right)$,

$$s_n = \sum_{i=1}^{n}\left(e^{1/i} - e^{1/(i+1)}\right) = (e^1 - e^{1/2}) + (e^{1/2} - e^{1/3}) + \cdots + \left(e^{1/n} - e^{1/(n+1)}\right) = e - e^{1/(n+1)}$$

[telescoping series]

Thus, $\sum_{n=1}^{\infty}\left(e^{1/n} - e^{1/(n+1)}\right) = \lim_{n\to\infty} s_n = \lim_{n\to\infty}\left(e - e^{1/(n+1)}\right) = e - e^0 = e - 1$. Converges

48. Using partial fractions, the partial sums of the series $\sum_{n=2}^{\infty} \dfrac{1}{n^3 - n}$ are

$$s_n = \sum_{i=2}^{n} \frac{1}{i(i-1)(i+1)} = \sum_{i=2}^{n}\left(-\frac{1}{i} + \frac{1/2}{i-1} + \frac{1/2}{i+1}\right) = \frac{1}{2}\sum_{i=2}^{n}\left(\frac{1}{i-1} - \frac{2}{i} + \frac{1}{i+1}\right)$$

$$= \frac{1}{2}\left[\left(\frac{1}{1} - \frac{2}{2} + \frac{1}{3}\right) + \left(\frac{1}{2} - \frac{2}{3} + \frac{1}{4}\right) + \left(\frac{1}{3} - \frac{2}{4} + \frac{1}{5}\right) + \left(\frac{1}{4} - \frac{2}{5} + \frac{1}{6}\right) + \cdots + \left(\frac{1}{n-3} - \frac{2}{n-2} + \frac{1}{n-1}\right) + \left(\frac{1}{n-2} - \frac{2}{n-1} + \frac{1}{n}\right) + \left(\frac{1}{n-1} - \frac{2}{n} + \frac{1}{n+1}\right)\right]$$

Note: In three consecutive expressions in parentheses, the 3rd term in the first expression plus the 2nd term in the second expression plus the 1st term in the third expression sum to 0.

$$= \frac{1}{2}\left(\frac{1}{1} - \frac{2}{2} + \frac{1}{2} + \frac{1}{n} - \frac{2}{n} + \frac{1}{n+1}\right) = \frac{1}{4} - \frac{1}{2n} + \frac{1}{2n+2}$$

Thus, $\sum_{n=2}^{\infty} \dfrac{1}{n^3 - n} = \lim_{n\to\infty} s_n = \lim_{n\to\infty}\left(\dfrac{1}{4} - \dfrac{1}{2n} + \dfrac{1}{2n+2}\right) = \dfrac{1}{4}$.

49. (a) Many people would guess that $x < 1$, but note that x consists of an infinite number of 9s.

(b) $x = 0.99999\ldots = \dfrac{9}{10} + \dfrac{9}{100} + \dfrac{9}{1000} + \dfrac{9}{10{,}000} + \cdots = \sum\limits_{n=1}^{\infty} \dfrac{9}{10^n}$, which is a geometric series with $a_1 = 0.9$ and $r = 0.1$. Its sum is $\dfrac{0.9}{1 - 0.1} = \dfrac{0.9}{0.9} = 1$, that is, $x = 1$.

(c) The number 1 has two decimal representations, $1.00000\ldots$ and $0.99999\ldots$.

(d) Except for 0, all rational numbers that have a terminating decimal representation can be written in more than one way. For example, 0.5 can be written as $0.49999\ldots$ as well as $0.50000\ldots$.

50. $a_1 = 1,\ a_n = (5 - n)a_{n-1} \quad \Rightarrow \quad a_2 = (5-2)a_1 = 3(1) = 3,\ a_3 = (5-3)a_2 = 2(3) = 6,\ a_4 = (5-4)a_3 = 1(6) = 6,$ $a_5 = (5-5)a_4 = 0$, and all succeeding terms equal 0. Thus, $\sum\limits_{n=1}^{\infty} a_n = \sum\limits_{n=1}^{4} a_n = 1 + 3 + 6 + 6 = 16$.

51. $0.\overline{8} = \dfrac{8}{10} + \dfrac{8}{10^2} + \cdots$ is a geometric series with $a = \dfrac{8}{10}$ and $r = \dfrac{1}{10}$. It converges to $\dfrac{a}{1-r} = \dfrac{8/10}{1 - 1/10} = \dfrac{8}{9}$.

52. $0.\overline{46} = \dfrac{46}{100} + \dfrac{46}{100^2} + \cdots$ is a geometric series with $a = \dfrac{46}{100}$ and $r = \dfrac{1}{100}$. It converges to $\dfrac{a}{1-r} = \dfrac{46/100}{1 - 1/100} = \dfrac{46}{99}$.

53. $2.\overline{516} = 2 + \dfrac{516}{10^3} + \dfrac{516}{10^6} + \cdots$. Now $\dfrac{516}{10^3} + \dfrac{516}{10^6} + \cdots$ is a geometric series with $a = \dfrac{516}{10^3}$ and $r = \dfrac{1}{10^3}$. It converges to $\dfrac{a}{1-r} = \dfrac{516/10^3}{1 - 1/10^3} = \dfrac{516/10^3}{999/10^3} = \dfrac{516}{999}$. Thus, $2.\overline{516} = 2 + \dfrac{516}{999} = \dfrac{2514}{999} = \dfrac{838}{333}$.

54. $10.1\overline{35} = 10.1 + \dfrac{35}{10^3} + \dfrac{35}{10^5} + \cdots$. Now $\dfrac{35}{10^3} + \dfrac{35}{10^5} + \cdots$ is a geometric series with $a = \dfrac{35}{10^3}$ and $r = \dfrac{1}{10^2}$. It converges to $\dfrac{a}{1-r} = \dfrac{35/10^3}{1 - 1/10^2} = \dfrac{35/10^3}{99/10^2} = \dfrac{35}{990}$. Thus, $10.1\overline{35} = 10.1 + \dfrac{35}{990} = \dfrac{9999 + 35}{990} = \dfrac{10{,}034}{990} = \dfrac{5017}{495}$.

55. $1.234\overline{567} = 1.234 + \dfrac{567}{10^6} + \dfrac{567}{10^9} + \cdots$. Now $\dfrac{567}{10^6} + \dfrac{567}{10^9} + \cdots$ is a geometric series with $a = \dfrac{567}{10^6}$ and $r = \dfrac{1}{10^3}$. It converges to $\dfrac{a}{1-r} = \dfrac{567/10^6}{1 - 1/10^3} = \dfrac{567/10^6}{999/10^3} = \dfrac{567}{999{,}000} = \dfrac{21}{37{,}000}$. Thus,

$$1.234\overline{567} = 1.234 + \frac{21}{37{,}000} = \frac{1234}{1000} + \frac{21}{37{,}000} = \frac{45{,}658}{37{,}000} + \frac{21}{37{,}000} = \frac{45{,}679}{37{,}000}.$$

56. $5.\overline{71358} = 5 + \dfrac{71{,}358}{10^5} + \dfrac{71{,}358}{10^{10}} + \cdots$. Now $\dfrac{71{,}358}{10^5} + \dfrac{71{,}358}{10^{10}} + \cdots$ is a geometric series with $a = \dfrac{71{,}358}{10^5}$ and $r = \dfrac{1}{10^5}$. It converges to $\dfrac{a}{1-r} = \dfrac{71{,}358/10^5}{1 - 1/10^5} = \dfrac{71{,}358/10^5}{99{,}999/10^5} = \dfrac{71{,}358}{99{,}999} = \dfrac{23{,}786}{33{,}333}$. Thus,

$$5.\overline{71358} = 5 + \frac{23{,}786}{33{,}333} = \frac{166{,}665}{33{,}333} + \frac{23{,}786}{33{,}333} = \frac{190{,}451}{33{,}333}.$$

57. $\sum_{n=1}^{\infty}(-5)^n x^n = \sum_{n=1}^{\infty}(-5x)^n$ is a geometric series with $r = -5x$, so the series converges $\Leftrightarrow$ $|r| < 1$ $\Leftrightarrow$ $|-5x| < 1$ $\Leftrightarrow$ $|x| < \frac{1}{5}$, that is, $-\frac{1}{5} < x < \frac{1}{5}$. In that case, the sum of the series is $\dfrac{a}{1-r} = \dfrac{-5x}{1-(-5x)} = \dfrac{-5x}{1+5x}$.

58. $\sum_{n=1}^{\infty}(x+2)^n$ is a geometric series with $r = x+2$, so the series converges $\Leftrightarrow$ $|r| < 1$ $\Leftrightarrow$ $|x+2| < 1$ $\Leftrightarrow$ $-1 < x+2 < 1$ $\Leftrightarrow$ $-3 < x < -1$. In that case, the sum of the series is $\dfrac{a}{1-r} = \dfrac{x+2}{1-(x+2)} = \dfrac{x+2}{-x-1}$.

59. $\sum_{n=0}^{\infty}\dfrac{(x-2)^n}{3^n} = \sum_{n=0}^{\infty}\left(\dfrac{x-2}{3}\right)^n$ is a geometric series with $r = \dfrac{x-2}{3}$, so the series converges $\Leftrightarrow$ $|r| < 1$ $\Leftrightarrow$ $\left|\dfrac{x-2}{3}\right| < 1$ $\Leftrightarrow$ $-1 < \dfrac{x-2}{3} < 1$ $\Leftrightarrow$ $-3 < x-2 < 3$ $\Leftrightarrow$ $-1 < x < 5$. In that case, the sum of the series is $\dfrac{a}{1-r} = \dfrac{1}{1-\dfrac{x-2}{3}} = \dfrac{1}{\dfrac{3-(x-2)}{3}} = \dfrac{3}{5-x}$.

60. $\sum_{n=0}^{\infty}(-4)^n(x-5)^n = \sum_{n=0}^{\infty}[-4(x-5)]^n$ is a geometric series with $r = -4(x-5)$, so the series converges $\Leftrightarrow$ $|r| < 1$ $\Leftrightarrow$ $|-4(x-5)| < 1$ $\Leftrightarrow$ $|x-5| < \frac{1}{4}$ $\Leftrightarrow$ $-\frac{1}{4} < x-5 < \frac{1}{4}$ $\Leftrightarrow$ $\frac{19}{4} < x < \frac{21}{4}$. In that case, the sum of the series is $\dfrac{a}{1-r} = \dfrac{1}{1-[-4(x-5)]} = \dfrac{1}{4x-19}$.

61. $\sum_{n=0}^{\infty}\dfrac{2^n}{x^n} = \sum_{n=0}^{\infty}\left(\dfrac{2}{x}\right)^n$ is a geometric series with $r = \dfrac{2}{x}$, so the series converges $\Leftrightarrow$ $|r| < 1$ $\Leftrightarrow$ $\left|\dfrac{2}{x}\right| < 1$ $\Leftrightarrow$ $2 < |x|$ $\Leftrightarrow$ $x > 2$ or $x < -2$. In that case, the sum of the series is $\dfrac{a}{1-r} = \dfrac{1}{1-2/x} = \dfrac{x}{x-2}$.

62. $\sum_{n=0}^{\infty}\dfrac{\sin^n x}{3^n} = \sum_{n=0}^{\infty}\left(\dfrac{\sin x}{3}\right)^n$ is a geometric series with $r = \dfrac{\sin x}{3}$, so the series converges $\Leftrightarrow$ $|r| < 1$ $\Leftrightarrow$ $\left|\dfrac{\sin x}{3}\right| < 1$ $\Leftrightarrow$ $|\sin x| < 3$, which is true for all x. Thus, the sum of the series is $\dfrac{a}{1-r} = \dfrac{1}{1-(\sin x)/3} = \dfrac{3}{3-\sin x}$.

63. $\sum_{n=0}^{\infty}e^{nx} = \sum_{n=0}^{\infty}(e^x)^n$ is a geometric series with $r = e^x$, so the series converges $\Leftrightarrow$ $|r| < 1$ $\Leftrightarrow$ $|e^x| < 1$ $\Leftrightarrow$ $-1 < e^x < 1$ $\Leftrightarrow$ $0 < e^x < 1$ $\Leftrightarrow$ $x < 0$. In that case, the sum of the series is $\dfrac{a}{1-r} = \dfrac{1}{1-e^x}$.

64. Because $\dfrac{1}{n} \to 0$ and ln is continuous, we have $\lim_{n\to\infty} \ln\left(1+\dfrac{1}{n}\right) = \ln 1 = 0$.

We now show that the series $\sum_{n=1}^{\infty}\ln\left(1+\dfrac{1}{n}\right) = \sum_{n=1}^{\infty}\ln\left(\dfrac{n+1}{n}\right) = \sum_{n=1}^{\infty}[\ln(n+1)-\ln n]$ diverges.

$s_n = (\ln 2 - \ln 1) + (\ln 3 - \ln 2) + \cdots + (\ln(n+1) - \ln n) = \ln(n+1) - \ln 1 = \ln(n+1)$.

As $n \to \infty$, $s_n = \ln(n+1) \to \infty$, so the series diverges.

65. After defining f, We use `convert(f,parfrac);` in Maple, `Apart` in Mathematica, or `Expand Rational` and `Simplify` in Derive to find that the general term is $\dfrac{3n^2+3n+1}{(n^2+n)^3} = \dfrac{1}{n^3} - \dfrac{1}{(n+1)^3}$. So the nth partial sum is

$$s_n = \sum_{k=1}^{n}\left(\frac{1}{k^3} - \frac{1}{(k+1)^3}\right) = \left(1 - \frac{1}{2^3}\right) + \left(\frac{1}{2^3} - \frac{1}{3^3}\right) + \cdots + \left(\frac{1}{n^3} - \frac{1}{(n+1)^3}\right) = 1 - \frac{1}{(n+1)^3}$$

The series converges to $\lim\limits_{n\to\infty} s_n = 1$. This can be confirmed by directly computing the sum using `sum(f,n=1..infinity);` (in Maple), `Sum[f,{n,1,Infinity}]` (in Mathematica), or `Calculus Sum` (from 1 to ∞) and `Simplify` (in Derive).

66. See Exercise 65 for specific CAS commands.

$\dfrac{1}{n^5-5n^3+4n} = \dfrac{1}{24(n-2)} + \dfrac{1}{24(n+2)} - \dfrac{1}{6(n-1)} - \dfrac{1}{6(n+1)} + \dfrac{1}{4n}$. So the nth partial sum is

$$\begin{aligned} s_n &= \frac{1}{24}\sum_{k=3}^{n}\left(\frac{1}{k-2} - \frac{4}{k-1} + \frac{6}{k} - \frac{4}{k+1} + \frac{1}{k+2}\right) \\ &= \frac{1}{24}\left[\left(\frac{1}{1} - \frac{4}{2} + \frac{6}{3} - \frac{4}{4} + \frac{1}{5}\right) + \cdots + \left(\frac{1}{n-2} - \frac{4}{n-1} + \frac{6}{n} - \frac{4}{n+1} + \frac{1}{n+2}\right)\right] \end{aligned}$$

The terms with denominator 5 or greater cancel, except for a few terms with n in the denominator. So as $n \to \infty$,

$s_n \to \dfrac{1}{24}\left(\dfrac{1}{1} - \dfrac{3}{2} + \dfrac{3}{3} - \dfrac{1}{4}\right) = \dfrac{1}{24}\left(\dfrac{1}{4}\right) = \dfrac{1}{96}$.

67. For $n=1$, $a_1 = 0$ since $s_1 = 0$. For $n > 1$,

$$a_n = s_n - s_{n-1} = \frac{n-1}{n+1} - \frac{(n-1)-1}{(n-1)+1} = \frac{(n-1)n - (n+1)(n-2)}{(n+1)n} = \frac{2}{n(n+1)}$$

Also, $\sum\limits_{n=1}^{\infty} a_n = \lim\limits_{n\to\infty} s_n = \lim\limits_{n\to\infty} \dfrac{1-1/n}{1+1/n} = 1$.

68. $a_1 = s_1 = 3 - \frac{1}{2} = \frac{5}{2}$. For $n \neq 1$,

$$a_n = s_n - s_{n-1} = \left(3 - n2^{-n}\right) - \left[3 - (n-1)2^{-(n-1)}\right] = -\frac{n}{2^n} + \frac{n-1}{2^{n-1}} \cdot \frac{2}{2} = \frac{2(n-1)}{2^n} - \frac{n}{2^n} = \frac{n-2}{2^n}$$

Also, $\sum\limits_{n=1}^{\infty} a_n = \lim\limits_{n\to\infty} s_n = \lim\limits_{n\to\infty}\left(3 - \dfrac{n}{2^n}\right) = 3$ because $\lim\limits_{x\to\infty} \dfrac{x}{2^x} \overset{\text{H}}{=} \lim\limits_{x\to\infty} \dfrac{1}{2^x \ln 2} = 0$.

69. (a) The quantity of the drug in the body after the first tablet is 100 mg. After the second tablet, there is 100 mg plus 20% of the first 100-mg tablet; that is, $100 + 0.20(100) = 120$ mg. After the third tablet, the quantity is $100 + 0.20(120)$ or, equivalently, $100 + 100(0.20) + 100(0.20)^2$. Either expression gives us 124 mg.

(b) From part (a), we see that $Q_{n+1} = 100 + 0.20\,Q_n$.

(c) $$\begin{aligned} Q_n &= 100 + 100(0.20)^1 + 100(0.20)^2 + \cdots + 100(0.20)^{n-1} \\ &= \sum_{i=1}^{n} 100(0.20)^{i-1} \quad \text{[geometric with } a = 100 \text{ and } r = 0.20\text{]}. \end{aligned}$$

The quantity of the antibiotic that remains in the body in the long run is $\lim\limits_{n\to\infty} Q_n = \dfrac{100}{1-0.20} = \dfrac{100}{4/5} = 125$ mg.

70. (a) The concentration of the drug after the first injection is 1.5 mg/L. "Reduced by 90%" is the same as 10% remains, so the concentration after the second injection is $1.5 + 0.10(1.5) = 1.65\text{ mg/L}$. The concentration after the third injection is $1.5 + 0.10(1.65)$, or, equivalently, $1.5 + 1.5(0.10) + 1.5(0.10)^2$. Either expression gives us 1.665 mg/L.

(b) $C_n = 1.5 + 1.5(0.10)^1 + 1.5(0.10)^2 + \cdots + 1.5(0.10)^{n-1}$

$= \sum\limits_{i=1}^{n} 1.5(0.10)^{i-1}$ [geometric with $a = 1.5$ and $r = 0.10$].

By (3), $C_n = \dfrac{1.5[1-(0.10)^n]}{1-0.10} = \dfrac{1.5}{0.9}[1-(0.10)^n] = \dfrac{5}{3}[1-(0.10)^n]\text{ mg/L}$.

(c) The limiting value of the concentration is $\lim\limits_{n\to\infty} C_n = \lim\limits_{n\to\infty} \frac{5}{3}[1-(0.10)^n] = \frac{5}{3}(1-0) = \frac{5}{3}\text{ mg/L}$.

71. (a) The quantity of the drug in the body after the first tablet is 150 mg. After the second tablet, there is 150 mg plus 5% of the first 150-mg tablet, that is, $[150 + 150(0.05)]\text{ mg}$. After the third tablet, the quantity is $[150 + 150(0.05) + 150(0.05)^2] = 157.875\text{ mg}$. After n tablets, the quantity (in mg) is $150 + 150(0.05) + \cdots + 150(0.05)^{n-1}$. We can use Formula 3 to write this as $\dfrac{150(1-0.05^n)}{1-0.05} = \dfrac{3000}{19}(1-0.05^n)$.

(b) The number of milligrams remaining in the body in the long run is $\lim\limits_{n\to\infty}\left[\frac{3000}{19}(1-0.05^n)\right] = \frac{3000}{19}(1-0) \approx 157.895$, only 0.02 mg more than the amount after 3 tablets.

72. (a) The residual concentration just before the second injection is De^{-aT}; before the third, $De^{-aT} + De^{-a2T}$; before the $(n+1)$st, $De^{-aT} + De^{-a2T} + \cdots + De^{-anT}$. This sum is equal to $\dfrac{De^{-aT}\left(1-e^{-anT}\right)}{1-e^{-aT}}$ [Formula 3].

(b) The limiting pre-injection concentration is $\lim\limits_{n\to\infty}\dfrac{De^{-aT}\left(1-e^{-anT}\right)}{1-e^{-aT}} = \dfrac{De^{-aT}(1-0)}{1-e^{-aT}} \cdot \dfrac{e^{aT}}{e^{aT}} = \dfrac{D}{e^{aT}-1}$.

(c) $\dfrac{D}{e^{aT}-1} \ge C \quad\Rightarrow\quad D \ge C\left(e^{aT}-1\right)$, so the minimal dosage is $D = C\left(e^{aT}-1\right)$.

73. (a) The first step in the chain occurs when the local government spends D dollars. The people who receive it spend a fraction c of those D dollars, that is, Dc dollars. Those who receive the Dc dollars spend a fraction c of it, that is, Dc^2 dollars. Continuing in this way, we see that the total spending after n transactions is

$S_n = D + Dc + Dc^2 + \cdots + Dc^{n-1} = \dfrac{D(1-c^n)}{1-c}$ by (3).

(b) $\lim\limits_{n\to\infty} S_n = \lim\limits_{n\to\infty}\dfrac{D(1-c^n)}{1-c} = \dfrac{D}{1-c}\lim\limits_{n\to\infty}(1-c^n) = \dfrac{D}{1-c}$ $\left[\text{since } 0 < c < 1 \;\Rightarrow\; \lim\limits_{n\to\infty} c^n = 0\right]$

$= \dfrac{D}{s}$ [since $c + s = 1$] $= kD$ [since $k = 1/s$]

If $c = 0.8$, then $s = 1 - c = 0.2$ and the multiplier is $k = 1/s = 5$.

74. (a) Initially, the ball falls a distance H, then rebounds a distance rH, falls rH, rebounds r^2H, falls r^2H, etc. The total distance it travels is

$$H + 2rH + 2r^2H + 2r^3H + \cdots = H\left(1 + 2r + 2r^2 + 2r^3 + \cdots\right) = H\left[1 + 2r\left(1 + r + r^2 + \cdots\right)\right]$$
$$= H\left[1 + 2r\left(\frac{1}{1-r}\right)\right] = H\left(\frac{1+r}{1-r}\right) \text{ meters}$$

(b) From Example 3 in Section 2.1, we know that a ball falls $\frac{1}{2}gt^2$ meters in t seconds, where g is the gravitational acceleration. Thus, a ball falls h meters in $t = \sqrt{2h/g}$ seconds. The total travel time in seconds is

$$\sqrt{\frac{2H}{g}} + 2\sqrt{\frac{2H}{g}r} + 2\sqrt{\frac{2H}{g}r^2} + 2\sqrt{\frac{2H}{g}r^3} + \cdots = \sqrt{\frac{2H}{g}}\left[1 + 2\sqrt{r} + 2\sqrt{r}^{\,2} + 2\sqrt{r}^{\,3} + \cdots\right]$$
$$= \sqrt{\frac{2H}{g}}\left(1 + 2\sqrt{r}\left[1 + \sqrt{r} + \sqrt{r}^{\,2} + \cdots\right]\right)$$
$$= \sqrt{\frac{2H}{g}}\left[1 + 2\sqrt{r}\left(\frac{1}{1-\sqrt{r}}\right)\right] = \sqrt{\frac{2H}{g}}\,\frac{1+\sqrt{r}}{1-\sqrt{r}}$$

(c) It will help to make a chart of the time for each descent and each rebound of the ball, together with the velocity just before and just after each bounce. Recall that the time in seconds needed to fall h meters is $\sqrt{2h/g}$. The ball hits the ground with velocity $-g\sqrt{2h/g} = -\sqrt{2hg}$ (taking the upward direction to be positive) and rebounds with velocity $kg\sqrt{2h/g} = k\sqrt{2hg}$, taking time $k\sqrt{2h/g}$ to reach the top of its bounce, where its velocity is 0. At that point, its height is k^2h. All these results follow from the formulas for vertical motion with gravitational acceleration $-g$:
$\dfrac{d^2y}{dt^2} = -g \quad\Rightarrow\quad v = \dfrac{dy}{dt} = v_0 - gt \quad\Rightarrow\quad y = y_0 + v_0t - \frac{1}{2}gt^2.$

number of descent	time of descent	speed before bounce	speed after bounce	time of ascent	peak height
1	$\sqrt{2H/g}$	$\sqrt{2Hg}$	$k\sqrt{2Hg}$	$k\sqrt{2H/g}$	k^2H
2	$\sqrt{2k^2H/g}$	$\sqrt{2k^2Hg}$	$k\sqrt{2k^2Hg}$	$k\sqrt{2k^2H/g}$	k^4H
3	$\sqrt{2k^4H/g}$	$\sqrt{2k^4Hg}$	$k\sqrt{2k^4Hg}$	$k\sqrt{2k^4H/g}$	k^6H
$\cdots$	$\cdots$	$\cdots$	$\cdots$	$\cdots$	$\cdots$

The total travel time in seconds is

$$\sqrt{\frac{2H}{g}} + k\sqrt{\frac{2H}{g}} + k\sqrt{\frac{2H}{g}} + k^2\sqrt{\frac{2H}{g}} + k^2\sqrt{\frac{2H}{g}} + \cdots = \sqrt{\frac{2H}{g}}\left(1 + 2k + 2k^2 + 2k^3 + \cdots\right)$$
$$= \sqrt{\frac{2H}{g}}\left[1 + 2k(1 + k + k^2 + \cdots)\right]$$
$$= \sqrt{\frac{2H}{g}}\left[1 + 2k\left(\frac{1}{1-k}\right)\right] = \sqrt{\frac{2H}{g}}\,\frac{1+k}{1-k}$$

Another method: We could use part (b). At the top of the bounce, the height is $k^2h = rh$, so $\sqrt{r} = k$ and the result follows from part (b).

75. $\sum_{n=2}^{\infty}(1+c)^{-n}$ is a geometric series with $a=(1+c)^{-2}$ and $r=(1+c)^{-1}$, so the series converges when $\left|(1+c)^{-1}\right|<1 \Leftrightarrow |1+c|>1 \Leftrightarrow 1+c>1$ or $1+c<-1 \Leftrightarrow c>0$ or $c<-2$. We calculate the sum of the series and set it equal to 2: $\dfrac{(1+c)^{-2}}{1-(1+c)^{-1}}=2 \Leftrightarrow \left(\dfrac{1}{1+c}\right)^2=2-2\left(\dfrac{1}{1+c}\right) \Leftrightarrow 1=2(1+c)^2-2(1+c) \Leftrightarrow$ $2c^2+2c-1=0 \Leftrightarrow c=\frac{-2\pm\sqrt{12}}{4}=\frac{\pm\sqrt{3}-1}{2}$. However, the negative root is inadmissible because $-2<\frac{-\sqrt{3}-1}{2}<0$. So $c=\frac{\sqrt{3}-1}{2}$.

76. $\sum_{n=0}^{\infty}e^{nc}=\sum_{n=0}^{\infty}(e^c)^n$ is a geometric series with $a=(e^c)^0=1$ and $r=e^c$. If $e^c<1$, it has sum $\dfrac{1}{1-e^c}$, so $\dfrac{1}{1-e^c}=10 \Rightarrow$ $\frac{1}{10}=1-e^c \Rightarrow e^c=\frac{9}{10} \Rightarrow c=\ln\frac{9}{10}$.

77. $e^{s_n}=e^{1+\frac{1}{2}+\frac{1}{3}+\cdots+\frac{1}{n}}=e^1e^{1/2}e^{1/3}\cdots e^{1/n}>(1+1)\left(1+\frac{1}{2}\right)\left(1+\frac{1}{3}\right)\cdots\left(1+\frac{1}{n}\right) \qquad [e^x>1+x]$

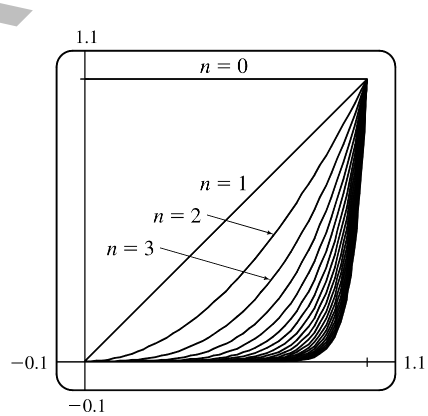
$$=\frac{2}{1}\frac{3}{2}\frac{4}{3}\cdots\frac{n+1}{n}=n+1$$

Thus, $e^{s_n}>n+1$ and $\lim_{n\to\infty}e^{s_n}=\infty$. Since $\{s_n\}$ is increasing, $\lim_{n\to\infty}s_n=\infty$, implying that the harmonic series is divergent.

78. The area between $y=x^{n-1}$ and $y=x^n$ for $0\le x\le 1$ is

$$\int_0^1\left(x^{n-1}-x^n\right)dx=\left[\frac{x^n}{n}-\frac{x^{n+1}}{n+1}\right]_0^1=\frac{1}{n}-\frac{1}{n+1}$$
$$=\frac{(n+1)-n}{n(n+1)}=\frac{1}{n(n+1)}$$

We can see from the diagram that as $n\to\infty$, the sum of the areas between the successive curves approaches the area of the unit square, that is, 1. So $\sum_{n=1}^{\infty}\dfrac{1}{n(n+1)}=1$.



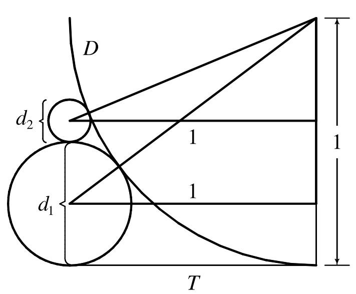
79. Let d_n be the diameter of C_n. We draw lines from the centers of the C_i to the center of D (or C), and using the Pythagorean Theorem, we can write

$1^2+\left(1-\frac{1}{2}d_1\right)^2=\left(1+\frac{1}{2}d_1\right)^2 \Leftrightarrow$

$1=\left(1+\frac{1}{2}d_1\right)^2-\left(1-\frac{1}{2}d_1\right)^2=2d_1$ [difference of squares] $\Rightarrow d_1=\frac{1}{2}$.

Similarly,

$$1=\left(1+\tfrac{1}{2}d_2\right)^2-\left(1-d_1-\tfrac{1}{2}d_2\right)^2=2d_2+2d_1-d_1^2-d_1d_2$$
$$=(2-d_1)(d_1+d_2) \quad \Leftrightarrow$$



$d_2 = \dfrac{1}{2-d_1} - d_1 = \dfrac{(1-d_1)^2}{2-d_1}$, $1 = \left(1+\frac{1}{2}d_3\right)^2 - \left(1-d_1-d_2-\frac{1}{2}d_3\right)^2 \;\Leftrightarrow\; d_3 = \dfrac{[1-(d_1+d_2)]^2}{2-(d_1+d_2)}$, and in general,

$d_{n+1} = \dfrac{\left(1-\sum_{i=1}^{n} d_i\right)^2}{2-\sum_{i=1}^{n} d_i}$. If we actually calculate d_2 and d_3 from the formulas above, we find that they are $\dfrac{1}{6} = \dfrac{1}{2\cdot 3}$ and

$\dfrac{1}{12} = \dfrac{1}{3\cdot 4}$ respectively, so we suspect that in general, $d_n = \dfrac{1}{n(n+1)}$. To prove this, we use induction: Assume that for all

$k \le n$, $d_k = \dfrac{1}{k(k+1)} = \dfrac{1}{k} - \dfrac{1}{k+1}$. Then $\sum\limits_{i=1}^{n} d_i = 1 - \dfrac{1}{n+1} = \dfrac{n}{n+1}$ [telescoping sum]. Substituting this into our

formula for d_{n+1}, we get $d_{n+1} = \dfrac{\left[1-\dfrac{n}{n+1}\right]^2}{2-\left(\dfrac{n}{n+1}\right)} = \dfrac{\dfrac{1}{(n+1)^2}}{\dfrac{n+2}{n+1}} = \dfrac{1}{(n+1)(n+2)}$, and the induction is complete.

Now, we observe that the partial sums $\sum_{i=1}^{n} d_i$ of the diameters of the circles approach 1 as $n \to \infty$; that is,

$\sum\limits_{n=1}^{\infty} a_n = \sum\limits_{n=1}^{\infty} \dfrac{1}{n(n+1)} = 1$, which is what we wanted to prove.

80. $|CD| = b\sin\theta$, $|DE| = |CD|\sin\theta = b\sin^2\theta$, $|EF| = |DE|\sin\theta = b\sin^3\theta, \ldots$. Therefore,

$|CD| + |DE| + |EF| + |FG| + \cdots = b\sum\limits_{n=1}^{\infty} \sin^n\theta = b\left(\dfrac{\sin\theta}{1-\sin\theta}\right)$ since this is a geometric series with $r = \sin\theta$

and $|\sin\theta| < 1$ $\left[\text{because } 0 < \theta < \frac{\pi}{2}\right]$.

81. The series $1-1+1-1+1-1+\cdots$ diverges (geometric series with $r=-1$) so we cannot say that $0 = 1-1+1-1+1-1+\cdots$.

82. If $\sum\limits_{n=1}^{\infty} a_n$ is convergent, then $\lim\limits_{n\to\infty} a_n = 0$ by Theorem 6, so $\lim\limits_{n\to\infty} \dfrac{1}{a_n} \ne 0$, and so $\sum\limits_{n=1}^{\infty} \dfrac{1}{a_n}$ is divergent by the Test for Divergence.

83. $\sum_{n=1}^{\infty} ca_n = \lim\limits_{n\to\infty} \sum_{i=1}^{n} ca_i = \lim\limits_{n\to\infty} c\sum_{i=1}^{n} a_i = c\lim\limits_{n\to\infty} \sum_{i=1}^{n} a_i = c\sum_{n=1}^{\infty} a_n$, which exists by hypothesis.

84. If $\sum ca_n$ were convergent, then $\sum(1/c)(ca_n) = \sum a_n$ would be also, by Theorem 8(i). But this is not the case, so $\sum ca_n$ must diverge.

85. Suppose on the contrary that $\sum(a_n+b_n)$ converges. Then $\sum(a_n+b_n)$ and $\sum a_n$ are convergent series. So by Theorem 8(iii), $\sum[(a_n+b_n)-a_n]$ would also be convergent. But $\sum[(a_n+b_n)-a_n] = \sum b_n$, a contradiction, since $\sum b_n$ is given to be divergent.

86. No. For example, take $\sum a_n = \sum n$ and $\sum b_n = \sum(-n)$, which both diverge, yet $\sum(a_n+b_n) = \sum 0$, which converges with sum 0.

87. The partial sums $\{s_n\}$ form an increasing sequence, since $s_n - s_{n-1} = a_n > 0$ for all n. Also, the sequence $\{s_n\}$ is bounded since $s_n \leq 1000$ for all n. So by the Monotonic Sequence Theorem, the sequence of partial sums converges, that is, the series $\sum a_n$ is convergent.

88. (a) $\text{RHS} = \dfrac{1}{f_{n-1}f_n} - \dfrac{1}{f_n f_{n+1}} = \dfrac{f_n f_{n+1} - f_n f_{n-1}}{f_n^2 f_{n-1} f_{n+1}} = \dfrac{f_{n+1} - f_{n-1}}{f_n f_{n-1} f_{n+1}} = \dfrac{(f_{n-1} + f_n) - f_{n-1}}{f_n f_{n-1} f_{n+1}} = \dfrac{1}{f_{n-1} f_{n+1}} = \text{LHS}$

(b) $$\sum_{n=2}^{\infty} \frac{1}{f_{n-1}f_{n+1}} = \sum_{n=2}^{\infty} \left(\frac{1}{f_{n-1}f_n} - \frac{1}{f_n f_{n+1}} \right) \quad \text{[from part (a)]}$$
$$= \lim_{n\to\infty} \left[\left(\frac{1}{f_1 f_2} - \frac{1}{f_2 f_3} \right) + \left(\frac{1}{f_2 f_3} - \frac{1}{f_3 f_4} \right) + \left(\frac{1}{f_3 f_4} - \frac{1}{f_4 f_5} \right) + \cdots + \left(\frac{1}{f_{n-1} f_n} - \frac{1}{f_n f_{n+1}} \right) \right]$$
$$= \lim_{n\to\infty} \left(\frac{1}{f_1 f_2} - \frac{1}{f_n f_{n+1}} \right) = \frac{1}{f_1 f_2} - 0 = \frac{1}{1\cdot 1} = 1 \quad \text{because } f_n \to \infty \text{ as } n \to \infty.$$

(c) $$\sum_{n=2}^{\infty} \frac{f_n}{f_{n-1}f_{n+1}} = \sum_{n=2}^{\infty} \left(\frac{f_n}{f_{n-1}f_n} - \frac{f_n}{f_n f_{n+1}} \right) \quad \text{[as above]}$$
$$= \sum_{n=2}^{\infty} \left(\frac{1}{f_{n-1}} - \frac{1}{f_{n+1}} \right)$$
$$= \lim_{n\to\infty} \left[\left(\frac{1}{f_1} - \frac{1}{f_3} \right) + \left(\frac{1}{f_2} - \frac{1}{f_4} \right) + \left(\frac{1}{f_3} - \frac{1}{f_5} \right) + \left(\frac{1}{f_4} - \frac{1}{f_6} \right) + \cdots + \left(\frac{1}{f_{n-1}} - \frac{1}{f_{n+1}} \right) \right]$$
$$= \lim_{n\to\infty} \left(\frac{1}{f_1} + \frac{1}{f_2} - \frac{1}{f_n} - \frac{1}{f_{n+1}} \right) = 1 + 1 - 0 - 0 = 2 \quad \text{because } f_n \to \infty \text{ as } n \to \infty.$$

89. (a) At the first step, only the interval $\left(\frac{1}{3}, \frac{2}{3}\right)$ (length $\frac{1}{3}$) is removed. At the second step, we remove the intervals $\left(\frac{1}{9}, \frac{2}{9}\right)$ and $\left(\frac{7}{9}, \frac{8}{9}\right)$, which have a total length of $2 \cdot \left(\frac{1}{3}\right)^2$. At the third step, we remove 2^2 intervals, each of length $\left(\frac{1}{3}\right)^3$. In general, at the nth step we remove 2^{n-1} intervals, each of length $\left(\frac{1}{3}\right)^n$, for a length of $2^{n-1} \cdot \left(\frac{1}{3}\right)^n = \frac{1}{3}\left(\frac{2}{3}\right)^{n-1}$. Thus, the total length of all removed intervals is $\sum\limits_{n=1}^{\infty} \frac{1}{3}\left(\frac{2}{3}\right)^{n-1} = \frac{1/3}{1-2/3} = 1$ $\left[\text{geometric series with } a = \frac{1}{3} \text{ and } r = \frac{2}{3}\right]$. Notice that at the nth step, the leftmost interval that is removed is $\left(\left(\frac{1}{3}\right)^n, \left(\frac{2}{3}\right)^n\right)$, so we never remove 0, and 0 is in the Cantor set. Also, the rightmost interval removed is $\left(1 - \left(\frac{2}{3}\right)^n, 1 - \left(\frac{1}{3}\right)^n\right)$, so 1 is never removed. Some other numbers in the Cantor set are $\frac{1}{3}$, $\frac{2}{3}$, $\frac{1}{9}$, $\frac{2}{9}$, $\frac{7}{9}$, and $\frac{8}{9}$.

(b) The area removed at the first step is $\frac{1}{9}$; at the second step, $8 \cdot \left(\frac{1}{9}\right)^2$; at the third step, $(8)^2 \cdot \left(\frac{1}{9}\right)^3$. In general, the area removed at the nth step is $(8)^{n-1}\left(\frac{1}{9}\right)^n = \frac{1}{9}\left(\frac{8}{9}\right)^{n-1}$, so the total area of all removed squares is
$$\sum_{n=1}^{\infty} \frac{1}{9}\left(\frac{8}{9}\right)^{n-1} = \frac{1/9}{1 - 8/9} = 1.$$

90. (a)

a_1	1	2	4	1	1	1000
a_2	2	3	1	4	1000	1
a_3	1.5	2.5	2.5	2.5	500.5	500.5
a_4	1.75	2.75	1.75	3.25	750.25	250.75
a_5	1.625	2.625	2.125	2.875	625.375	375.625
a_6	1.6875	2.6875	1.9375	3.0625	687.813	313.188
a_7	1.65625	2.65625	2.03125	2.96875	656.594	344.406
a_8	1.67188	2.67188	1.98438	3.01563	672.203	328.797
a_9	1.66406	2.66406	2.00781	2.99219	664.398	336.602
a_{10}	1.66797	2.66797	1.99609	3.00391	668.301	332.699
a_{11}	1.66602	2.66602	2.00195	2.99805	666.350	334.650
a_{12}	1.66699	2.66699	1.99902	3.00098	667.325	333.675

The limits seem to be $\frac{5}{3}, \frac{8}{3}$, 2, 3, 667, and 334. Note that the limits appear to be "weighted" more toward a_2. In general, we guess that the limit is $\dfrac{a_1 + 2a_2}{3}$.

(b) $a_{n+1} - a_n = \frac{1}{2}(a_n + a_{n-1}) - a_n = -\frac{1}{2}(a_n - a_{n-1}) = -\frac{1}{2}\left[\frac{1}{2}(a_{n-1} + a_{n-2}) - a_{n-1}\right]$

$$= -\tfrac{1}{2}\left[-\tfrac{1}{2}(a_{n-1} - a_{n-2})\right] = \cdots = \left(-\tfrac{1}{2}\right)^{n-1}(a_2 - a_1)$$

Note that we have used the formula $a_k = \frac{1}{2}(a_{k-1} + a_{k-2})$ a total of $n-1$ times in this calculation, once for each k between 3 and $n+1$. Now we can write

$$a_n = a_1 + (a_2 - a_1) + (a_3 - a_2) + \cdots + (a_{n-1} - a_{n-2}) + (a_n - a_{n-1})$$
$$= a_1 + \sum_{k=1}^{n-1}(a_{k+1} - a_k) = a_1 + \sum_{k=1}^{n-1}\left(-\tfrac{1}{2}\right)^{k-1}(a_2 - a_1)$$

and so

$$\lim_{n\to\infty} a_n = a_1 + (a_2 - a_1)\sum_{k=1}^{\infty}\left(-\tfrac{1}{2}\right)^{k-1} = a_1 + (a_2 - a_1)\left[\frac{1}{1 - (-1/2)}\right] = a_1 + \tfrac{2}{3}(a_2 - a_1) = \frac{a_1 + 2a_2}{3}.$$

91. (a) For $\displaystyle\sum_{n=1}^{\infty}\frac{n}{(n+1)!}$, $s_1 = \dfrac{1}{1\cdot 2} = \dfrac{1}{2}$, $s_2 = \dfrac{1}{2} + \dfrac{2}{1\cdot 2\cdot 3} = \dfrac{5}{6}$, $s_3 = \dfrac{5}{6} + \dfrac{3}{1\cdot 2\cdot 3\cdot 4} = \dfrac{23}{24}$,

$s_4 = \dfrac{23}{24} + \dfrac{4}{1\cdot 2\cdot 3\cdot 4\cdot 5} = \dfrac{119}{120}$. The denominators are $(n+1)!$, so a guess would be $s_n = \dfrac{(n+1)! - 1}{(n+1)!}$.

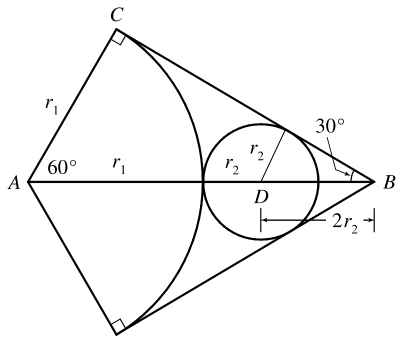
(b) For $n = 1$, $s_1 = \dfrac{1}{2} = \dfrac{2! - 1}{2!}$, so the formula holds for $n = 1$. Assume $s_k = \dfrac{(k+1)! - 1}{(k+1)!}$. Then

$$s_{k+1} = \frac{(k+1)! - 1}{(k+1)!} + \frac{k+1}{(k+2)!} = \frac{(k+1)! - 1}{(k+1)!} + \frac{k+1}{(k+1)!(k+2)} = \frac{(k+2)! - (k+2) + k + 1}{(k+2)!}$$
$$= \frac{(k+2)! - 1}{(k+2)!}$$

Thus, the formula is true for $n = k+1$. So by induction, the guess is correct.

(c) $\displaystyle\lim_{n\to\infty} s_n = \lim_{n\to\infty}\frac{(n+1)! - 1}{(n+1)!} = \lim_{n\to\infty}\left[1 - \frac{1}{(n+1)!}\right] = 1$ and so $\displaystyle\sum_{n=1}^{\infty}\frac{n}{(n+1)!} = 1$.

92.



Let r_1 = radius of the large circle, r_2 = radius of next circle, and so on. From the figure we have $\angle BAC = 60°$ and $\cos 60° = r_1/|AB|$, so $|AB| = 2r_1$ and $|DB| = 2r_2$. Therefore, $2r_1 = r_1 + r_2 + 2r_2 \Rightarrow r_1 = 3r_2$. In general, we have $r_{n+1} = \frac{1}{3}r_n$, so the total area is

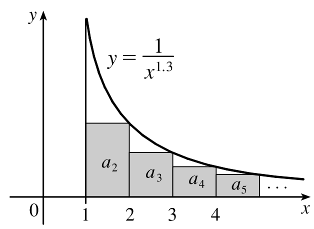
$$A = \pi r_1^2 + 3\pi r_2^2 + 3\pi r_3^2 + \cdots = \pi r_1^2 + 3\pi r_2^2\left(1 + \frac{1}{3^2} + \frac{1}{3^4} + \frac{1}{3^6} + \cdots\right)$$

$$= \pi r_1^2 + 3\pi r_2^2 \cdot \frac{1}{1 - 1/9} = \pi r_1^2 + \tfrac{27}{8}\pi r_2^2$$

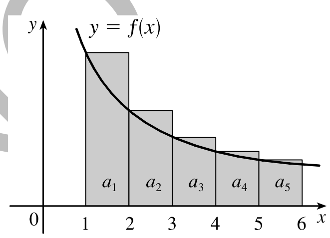
Since the sides of the triangle have length 1, $|BC| = \frac{1}{2}$ and $\tan 30° = \dfrac{r_1}{1/2}$. Thus, $r_1 = \dfrac{\tan 30°}{2} = \dfrac{1}{2\sqrt{3}} \Rightarrow r_2 = \dfrac{1}{6\sqrt{3}}$, so $A = \pi\left(\dfrac{1}{2\sqrt{3}}\right)^2 + \dfrac{27\pi}{8}\left(\dfrac{1}{6\sqrt{3}}\right)^2 = \dfrac{\pi}{12} + \dfrac{\pi}{32} = \dfrac{11\pi}{96}$. The area of the triangle is $\dfrac{\sqrt{3}}{4}$, so the circles occupy about 83.1% of the area of the triangle.

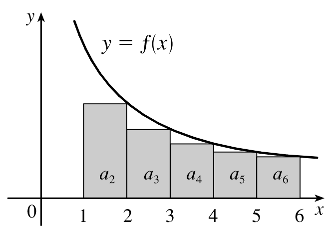
11.3 The Integral Test and Estimates of Sums

1. The picture shows that $a_2 = \dfrac{1}{2^{1.3}} < \displaystyle\int_1^2 \frac{1}{x^{1.3}}\,dx$, $a_3 = \dfrac{1}{3^{1.3}} < \displaystyle\int_2^3 \frac{1}{x^{1.3}}\,dx$, and so on, so $\displaystyle\sum_{n=2}^{\infty} \frac{1}{n^{1.3}} < \int_1^{\infty} \frac{1}{x^{1.3}}\,dx$. The integral converges by (7.8.2) with $p = 1.3 > 1$, so the series converges.



2. From the first figure, we see that $\int_1^6 f(x)\,dx < \sum_{i=1}^{5} a_i$. From the second figure, we see that $\sum_{i=2}^{6} a_i < \int_1^6 f(x)\,dx$. Thus, we have $\sum_{i=2}^{6} a_i < \int_1^6 f(x)\,dx < \sum_{i=1}^{5} a_i$.





3. The function $f(x) = x^{-3}$ is continuous, positive, and decreasing on $[1, \infty)$, so the Integral Test applies.

$$\int_1^{\infty} x^{-3}\,dx = \lim_{t\to\infty} \int_1^t x^{-3}\,dx = \lim_{t\to\infty}\left[\frac{x^{-2}}{-2}\right]_1^t = \lim_{t\to\infty}\left(-\frac{1}{2t^2} + \frac{1}{2}\right) = \frac{1}{2}.$$

Since this improper integral is convergent, the series $\displaystyle\sum_{n=1}^{\infty} n^{-3}$ is also convergent by the Integral Test.

4. The function $f(x) = x^{-0.3}$ is continuous, positive, and decreasing on $[1, \infty)$, so the Integral Test applies.

$$\int_1^\infty x^{-0.3}\,dx = \lim_{t\to\infty}\int_1^t x^{-0.3}\,dx = \lim_{t\to\infty}\left[\frac{x^{0.7}}{0.7}\right]_1^t = \lim_{t\to\infty}\left(\frac{t^{0.7}}{0.7} - \frac{1}{0.7}\right) = \infty.$$

Since this improper integral is divergent, the series $\sum\limits_{n=1}^{\infty} n^{-0.3}$ is also divergent by the Integral Test.

5. The function $f(x) = \dfrac{2}{5x-1}$ is continuous, positive, and decreasing on $[1, \infty)$, so the Integral Test applies.

$$\int_1^\infty \frac{2}{5x-1}\,dx = \lim_{t\to\infty}\int_1^t \frac{2}{5x-1}\,dx = \lim_{t\to\infty}\left[\frac{2}{5}\ln(5x-1)\right]_1^t = \lim_{t\to\infty}\left[\frac{2}{5}\ln(5t-1) - \frac{2}{5}\ln 4\right] = \infty.$$

Since this improper integral is divergent, the series $\sum\limits_{n=1}^{\infty} \dfrac{2}{5n-1}$ is also divergent by the Integral Test.

6. The function $f(x) = \dfrac{1}{(3x-1)^4}$ is continuous, positive, and decreasing on $[1, \infty)$, so the Integral Test applies.

$$\int_1^\infty \frac{1}{(3x-1)^4}\,dx = \lim_{t\to\infty}\int_1^t (3x-1)^{-4}\,dx = \lim_{t\to\infty}\left[\frac{1}{(-3)3}(3x-1)^{-3}\right]_1^t = \lim_{t\to\infty}\left[-\frac{1}{9(3t-1)^3} + \frac{1}{9\cdot 2^3}\right] = \frac{1}{72}.$$

Since this improper integral is convergent, the series $\sum\limits_{n=1}^{\infty} \dfrac{1}{(3n-1)^4}$ is also convergent by the Integral Test.

7. The function $f(x) = \dfrac{x}{x^2+1}$ is continuous, positive, and decreasing on $[1, \infty)$, so the Integral Test applies.

$\displaystyle\int_1^\infty \frac{x}{x^2+1}\,dx = \lim_{t\to\infty}\int_1^t \frac{x}{x^2+1}\,dx = \lim_{t\to\infty}\left[\frac{1}{2}\ln(x^2+1)\right]_1^t = \frac{1}{2}\lim_{t\to\infty}\left[\ln(t^2+1) - \ln 2\right] = \infty$. Since this improper integral is divergent, the series $\sum\limits_{n=1}^{\infty} \dfrac{n}{n^2+1}$ is also divergent by the Integral Test.

8. The function $f(x) = x^2 e^{-x^3}$ is continuous, positive, and decreasing ($\star$) on $[1, \infty)$, so the Integral Test applies.

$$\int_1^\infty x^2 e^{-x^3}\,dx = \lim_{t\to\infty}\int_1^t x^2 e^{-x^3}\,dx = \lim_{t\to\infty}\left[-\frac{1}{3}e^{-x^3}\right]_1^t = -\frac{1}{3}\lim_{t\to\infty}\left(e^{-t^3} - e^{-1}\right) = -\frac{1}{3}\left(0 - \frac{1}{e}\right) = \frac{1}{3e}.$$

Since this improper integral is convergent, the series $\sum\limits_{n=1}^{\infty} n^2 e^{-n^3}$ is also convergent by the Integral Test.

($\star$): $f'(x) = x^2 e^{-x^3}(-3x^2) + e^{-x^3}(2x) = xe^{-x^3}(-3x^3+2) = \dfrac{x(2-3x^3)}{e^{x^3}} < 0$ for $x > 1$

9. $\sum\limits_{n=1}^{\infty} \dfrac{1}{n^{\sqrt{2}}}$ is a p-series with $p = \sqrt{2} > 1$, so it converges by (1).

10. $\sum\limits_{n=3}^{\infty} n^{-0.9999} = \sum\limits_{n=3}^{\infty} \dfrac{1}{n^{0.9999}}$ is a p-series with $p = 0.9999 \le 1$, so it diverges by (1). The fact that the series begins with $n = 3$ is irrelevant when determining convergence.

11. $1 + \dfrac{1}{8} + \dfrac{1}{27} + \dfrac{1}{64} + \dfrac{1}{125} + \cdots = \sum\limits_{n=1}^{\infty} \dfrac{1}{n^3}$. This is a p-series with $p = 3 > 1$, so it converges by (1).

12. $\frac{1}{5}+\frac{1}{7}+\frac{1}{9}+\frac{1}{11}+\frac{1}{13}+\cdots=\sum_{n=1}^{\infty}\frac{1}{2n+3}$. The function $f(x)=\frac{1}{2x+3}$ is continuous, positive, and decreasing on $[1,\infty)$, so the Integral Test applies.

$\int_1^{\infty}\frac{1}{2x+3}\,dx=\lim_{t\to\infty}\int_1^t\frac{1}{2x+3}\,dx=\lim_{t\to\infty}\left[\frac{1}{2}\ln(2x+3)\right]_1^t=\lim_{t\to\infty}\left[\frac{1}{2}\ln(2t+3)-\frac{1}{2}\ln 5\right]=\infty$, so the series $\sum_{n=1}^{\infty}\frac{1}{2n+3}$ diverges.

13. $\frac{1}{3}+\frac{1}{7}+\frac{1}{11}+\frac{1}{15}+\frac{1}{19}+\cdots=\sum_{n=1}^{\infty}\frac{1}{4n-1}$. The function $f(x)=\frac{1}{4x-1}$ is continuous, positive, and decreasing on $[1,\infty)$, so the Integral Test applies.

$\int_1^{\infty}\frac{1}{4x-1}\,dx=\lim_{t\to\infty}\int_1^t\frac{1}{4x-1}\,dx=\lim_{t\to\infty}\left[\frac{1}{4}\ln(4x-1)\right]_1^t=\lim_{t\to\infty}\left[\frac{1}{4}\ln(4t-1)-\frac{1}{4}\ln 3\right]=\infty$, so the series $\sum_{n=1}^{\infty}\frac{1}{4n-1}$ diverges.

14. $1+\frac{1}{2\sqrt{2}}+\frac{1}{3\sqrt{3}}+\frac{1}{4\sqrt{4}}+\frac{1}{5\sqrt{5}}+\cdots=\sum_{n=1}^{\infty}\frac{1}{n\sqrt{n}}=\sum_{n=1}^{\infty}\frac{1}{n^{3/2}}$. This is a p-series with $p=\frac{3}{2}>1$, so it converges by (1).

15. $\sum_{n=1}^{\infty}\frac{\sqrt{n}+4}{n^2}=\sum_{n=1}^{\infty}\left(\frac{\sqrt{n}}{n^2}+\frac{4}{n^2}\right)=\sum_{n=1}^{\infty}\frac{1}{n^{3/2}}+\sum_{n=1}^{\infty}\frac{4}{n^2}$. $\sum_{n=1}^{\infty}\frac{1}{n^{3/2}}$ is a convergent p-series with $p=\frac{3}{2}>1$.

$\sum_{n=1}^{\infty}\frac{4}{n^2}=4\sum_{n=1}^{\infty}\frac{1}{n^2}$ is a constant multiple of a convergent p-series with $p=2>1$, so it converges. The sum of two convergent series is convergent, so the original series is convergent.

16. The function $f(x)=\frac{\sqrt{x}}{1+x^{3/2}}$ is continuous and positive on $[1,\infty)$.

$f'(x)=\frac{(1+x^{3/2})\left(\frac{1}{2}x^{-1/2}\right)-x^{1/2}\left(\frac{3}{2}x^{1/2}\right)}{(1+x^{3/2})^2}=\frac{\frac{1}{2}x^{-1/2}+\frac{1}{2}x-\frac{3}{2}x}{(1+x^{3/2})^2}=\frac{1-2x^{3/2}}{2\sqrt{x}(1+x^{3/2})^2}<0$ for $x\geq 1$, so f is decreasing on $[1,\infty)$, and the Integral Test applies.

$$\int_1^{\infty}\frac{\sqrt{x}}{1+x^{3/2}}\,dx=\lim_{t\to\infty}\int_1^t\frac{\sqrt{x}}{1+x^{3/2}}\,dx=\lim_{t\to\infty}\left[\frac{2}{3}\ln(1+x^{3/2})\right]_1^t \qquad \left[\begin{array}{c}\text{substitution}\\ \text{with } u=1+x^{3/2}\end{array}\right]$$
$$=\lim_{t\to\infty}\left[\frac{2}{3}\ln(1+t^{3/2})-\frac{2}{3}\ln 2\right]=\infty,$$

so the series $\sum_{n=1}^{\infty}\frac{\sqrt{n}}{1+n^{3/2}}$ diverges.

17. The function $f(x)=\frac{1}{x^2+4}$ is continuous, positive, and decreasing on $[1,\infty)$, so we can apply the Integral Test.

$$\int_1^{\infty}\frac{1}{x^2+4}\,dx=\lim_{t\to\infty}\int_1^t\frac{1}{x^2+4}\,dx=\lim_{t\to\infty}\left[\frac{1}{2}\tan^{-1}\frac{x}{2}\right]_1^t=\frac{1}{2}\lim_{t\to\infty}\left[\tan^{-1}\left(\frac{t}{2}\right)-\tan^{-1}\left(\frac{1}{2}\right)\right]$$
$$=\frac{1}{2}\left[\frac{\pi}{2}-\tan^{-1}\left(\frac{1}{2}\right)\right]$$

Therefore, the series $\sum_{n=1}^{\infty}\frac{1}{n^2+4}$ converges.

18. The function $f(x) = \dfrac{1}{x^2+2x+2}$ is continuous, positive, and decreasing on $[1, \infty)$, so the Integral Test applies.

$$\begin{aligned}\int_1^\infty \frac{1}{x^2+2x+2}\,dx &= \lim_{t\to\infty}\int_1^t \frac{1}{(x+1)^2+1}\,dx = \lim_{t\to\infty}\Big[\arctan(x+1)\Big]_1^t \\ &= \lim_{t\to\infty}[\arctan(t+1) - \arctan 2] = \frac{\pi}{2} - \arctan 2,\end{aligned}$$

so the series $\displaystyle\sum_{n=1}^\infty \frac{1}{n^2+2n+2}$ converges.

19. The function $f(x) = \dfrac{x^3}{x^4+4}$ is continuous and positive on $[2, \infty)$, and is also decreasing since

$f'(x) = \dfrac{(x^4+4)(3x^2) - x^3(4x^3)}{(x^4+4)^2} = \dfrac{12x^2 - x^6}{(x^4+4)^2} = \dfrac{x^2(12-x^4)}{(x^4+4)^2} < 0$ for $x > \sqrt[4]{12} \approx 1.86$, so we can use the Integral Test on $[2, \infty)$.

$\displaystyle\int_2^\infty \frac{x^3}{x^4+4}\,dx = \lim_{t\to\infty}\int_2^t \frac{x^3}{x^4+4}\,dx = \lim_{t\to\infty}\Big[\tfrac14\ln(x^4+4)\Big]_2^t = \lim_{t\to\infty}\Big[\tfrac14\ln(t^4+4) - \tfrac14\ln 20\Big] = \infty$, so the series $\displaystyle\sum_{n=2}^\infty \frac{n^3}{n^4+4}$ diverges, and it follows that $\displaystyle\sum_{n=1}^\infty \frac{n^3}{n^4+4}$ diverges as well.

20. The function $f(x) = \dfrac{3x-4}{x^2-2x} = \dfrac{2}{x} + \dfrac{1}{x-2}$ [by partial fractions] is continuous, positive, and decreasing on $[3, \infty)$ since it is the sum of two such functions, so we can apply the Integral Test.

$\displaystyle\int_3^\infty \frac{3x-4}{x^2-x}\,dx = \lim_{t\to\infty}\int_3^t \left[\frac{2}{x} + \frac{1}{x-2}\right]dx = \lim_{t\to\infty}\Big[2\ln x + \ln(x-2)\Big]_3^t = \lim_{t\to\infty}[2\ln t + \ln(t-2) - 2\ln 3] = \infty.$

The integral is divergent, so the series $\sum_{n=3}^\infty \dfrac{3n-4}{n^2-n}$ is divergent.

21. $f(x) = \dfrac{1}{x\ln x}$ is continuous and positive on $[2, \infty)$, and also decreasing since $f'(x) = -\dfrac{1+\ln x}{x^2(\ln x)^2} < 0$ for $x > 2$, so we can use the Integral Test. $\displaystyle\int_2^\infty \frac{1}{x\ln x}\,dx = \lim_{t\to\infty}[\ln(\ln x)]_2^t = \lim_{t\to\infty}[\ln(\ln t) - \ln(\ln 2)] = \infty$, so the series $\sum_{n=2}^\infty \dfrac{1}{n\ln n}$ diverges.

22. The function $f(x) = \dfrac{\ln x}{x^2}$ is continuous and positive on $[2, \infty)$, and also decreasing since

$f'(x) = \dfrac{x^2(1/x) - (\ln x)(2x)}{(x^2)^2} = \dfrac{x - 2x\ln x}{x^4} = \dfrac{1-2\ln x}{x^3} < 0$ for $x > e^{1/2} \approx 1.65$, so we can use the Integral Test on $[2, \infty)$.

$$\begin{aligned}\int_2^\infty \frac{\ln x}{x^2}\,dx &= \lim_{t\to\infty}\int_2^t \frac{\ln x}{x^2}\,dx = \lim_{t\to\infty}\left(\left[-\frac{\ln x}{x}\right]_2^t + \int_2^t \frac{1}{x^2}\,dx\right) \qquad \left[\begin{array}{c}\text{by parts with}\\ u = \ln x,\ dv = (1/x^2)\,dx\end{array}\right] \\ &= \lim_{t\to\infty}\left(-\frac{\ln t}{t} + \frac{\ln 2}{2} + \left[-\frac{1}{x}\right]_2^t\right) \overset{\text{H}}{=} \lim_{t\to\infty}\left(-\frac{1/t}{1} + \frac{\ln 2}{2} - \frac{1}{t} + \frac{1}{2}\right) = \frac{\ln 2 + 1}{2},\end{aligned}$$

so the series $\displaystyle\sum_{n=2}^\infty \frac{\ln n}{n^2}$ converges.

23. The function $f(x) = xe^{-x} = \dfrac{x}{e^x}$ is continuous and positive on $[1, \infty)$, and also decreasing since

$f'(x) = \dfrac{e^x \cdot 1 - xe^x}{(e^x)^2} = \dfrac{e^x(1-x)}{(e^x)^2} = \dfrac{1-x}{e^x} < 0$ for $x > 1$ [and $f(1) > f(2)$], so we can use the Integral Test on $[1, \infty)$.

$$\int_1^\infty xe^{-x}\,dx = \lim_{t\to\infty}\int_1^t xe^{-x}\,dx = \lim_{t\to\infty}\left(\left[-xe^{-x}\right]_1^t + \int_1^t e^{-x}\,dx\right) \qquad \left[\begin{array}{c}\text{by parts with}\\ u = x,\, dv = e^{-x}\,dx\end{array}\right]$$
$$= \lim_{t\to\infty}\left(-te^{-t} + e^{-1} + \left[-e^{-x}\right]_1^t\right) = \lim_{t\to\infty}\left(-\frac{t}{e^t} + \frac{1}{e} - \frac{1}{e^t} + \frac{1}{e}\right)$$
$$\overset{\text{H}}{=} \lim_{t\to\infty}\left(-\frac{1}{e^t} + \frac{1}{e} - 0 + \frac{1}{e}\right) = \frac{2}{e},$$

so the series $\sum\limits_{k=1}^\infty ke^{-k}$ converges.

24. The function $f(x) = xe^{-x^2} = \dfrac{x}{e^{x^2}}$ is continuous and positive on $[1, \infty)$, and also decreasing since

$f'(x) = \dfrac{e^{x^2}\cdot 1 - xe^{x^2}\cdot 2x}{(e^{x^2})^2} = \dfrac{1-2x^2}{e^{x^2}} < 0$ for $x > \sqrt{\frac{1}{2}} \approx 0.7$, so we can use the Integral Test on $[1, \infty)$.

$\displaystyle\int_1^\infty xe^{-x^2}\,dx = \lim_{t\to\infty}\int_1^t xe^{-x^2}\,dx = \lim_{t\to\infty}\left[-\tfrac{1}{2}e^{-x^2}\right]_1^t = \lim_{t\to\infty}\left(-\tfrac{1}{2}e^{-t^2} + \tfrac{1}{2}e^{-1}\right) = \frac{1}{2e}$, so the series $\sum\limits_{k=1}^\infty ke^{-k^2}$ converges.

25. The function $f(x) = \dfrac{1}{x^2+x^3} = \dfrac{1}{x^2} - \dfrac{1}{x} + \dfrac{1}{x+1}$ [by partial fractions] is continuous, positive and decreasing on $[1, \infty)$, so the Integral Test applies.

$$\int_1^\infty f(x)\,dx = \lim_{t\to\infty}\int_1^t\left(\frac{1}{x^2} - \frac{1}{x} + \frac{1}{x+1}\right)dx = \lim_{t\to\infty}\left[-\frac{1}{x} - \ln x + \ln(x+1)\right]_1^t$$
$$= \lim_{t\to\infty}\left[-\frac{1}{t} + \ln\frac{t+1}{t} + 1 - \ln 2\right] = 0 + 0 + 1 - \ln 2$$

The integral converges, so the series $\sum\limits_{n=1}^\infty \dfrac{1}{n^2+n^3}$ converges.

26. The function $f(x) = \dfrac{x}{x^4+1}$ is positive, continuous, and decreasing on $[1, \infty)$. [Note that

$f'(x) = \dfrac{x^4+1-4x^4}{(x^4+1)^2} = \dfrac{1-3x^4}{(x^4+1)^2} < 0$ on $[1, \infty)$.] Thus, we can apply the Integral Test.

$\displaystyle\int_1^\infty \frac{x}{x^4+1}\,dx = \lim_{t\to\infty}\int_1^t \frac{\frac{1}{2}(2x)}{1+(x^2)^2}\,dx = \lim_{t\to\infty}\left[\frac{1}{2}\tan^{-1}(x^2)\right]_1^t = \frac{1}{2}\lim_{t\to\infty}\left[\tan^{-1}(t^2) - \tan^{-1}1\right] = \frac{1}{2}\left(\frac{\pi}{2} - \frac{\pi}{4}\right) = \frac{\pi}{8}$

so the series $\sum\limits_{n=1}^\infty \dfrac{n}{n^4+1}$ converges.

27. The function $f(x) = \dfrac{\cos \pi x}{\sqrt{x}}$ is neither positive nor decreasing on $[1, \infty)$, so the hypotheses of the Integral Test are not satisfied for the series $\sum\limits_{n=1}^\infty \dfrac{\cos \pi n}{\sqrt{n}}$.

28. The function $f(x) = \dfrac{\cos^2 x}{1+x^2}$ is not decreasing on $[1, \infty)$, so the hypotheses of the Integral Test are not satisfied for the series $\sum\limits_{n=1}^{\infty} \dfrac{\cos^2 n}{1+n^2}$.

29. We have already shown (in Exercise 21) that when $p = 1$ the series $\sum\limits_{n=2}^{\infty} \dfrac{1}{n(\ln n)^p}$ diverges, so assume that $p \neq 1$.

$f(x) = \dfrac{1}{x(\ln x)^p}$ is continuous and positive on $[2, \infty)$, and $f'(x) = -\dfrac{p + \ln x}{x^2(\ln x)^{p+1}} < 0$ if $x > e^{-p}$, so that f is eventually decreasing and we can use the Integral Test.

$$\int_2^{\infty} \frac{1}{x(\ln x)^p}\,dx = \lim_{t\to\infty}\left[\frac{(\ln x)^{1-p}}{1-p}\right]_2^t \quad [\text{for } p \neq 1] \;=\; \lim_{t\to\infty}\left[\frac{(\ln t)^{1-p}}{1-p} - \frac{(\ln 2)^{1-p}}{1-p}\right]$$

This limit exists whenever $1 - p < 0 \quad\Leftrightarrow\quad p > 1$, so the series converges for $p > 1$.

30. $f(x) = \dfrac{1}{x \ln x\,[\ln(\ln x)]^p}$ is positive and continuous on $[3, \infty)$. For $p \geq 0$, f clearly decreases on $[3, \infty)$; and for $p < 0$, it can be verified that f is ultimately decreasing. Thus, we can apply the Integral Test.

$$I = \int_3^{\infty} \frac{dx}{x \ln x\,[\ln(\ln x)]^p} = \lim_{t\to\infty}\int_3^t \frac{[\ln(\ln x)]^{-p}}{x \ln x}\,dx = \lim_{t\to\infty}\left[\frac{[\ln(\ln x)]^{-p+1}}{-p+1}\right]_3^t \qquad [\text{for } p \neq 1]$$

$$= \lim_{t\to\infty}\left[\frac{[\ln(\ln t)]^{-p+1}}{-p+1} - \frac{[\ln(\ln 3)]^{-p+1}}{-p+1}\right],$$

which exists whenever $-p + 1 < 0 \quad\Leftrightarrow\quad p > 1$. If $p = 1$, then $I = \lim\limits_{t\to\infty}\big[\ln(\ln(\ln x))\big]_3^t = \infty$. Therefore, $\sum\limits_{n=3}^{\infty} \dfrac{1}{n \ln n\,[\ln(\ln n)]^p}$ converges for $p > 1$.

31. Clearly the series cannot converge if $p \geq -\frac{1}{2}$, because then $\lim\limits_{n\to\infty} n(1+n^2)^p \neq 0$. So assume $p < -\frac{1}{2}$. Then $f(x) = x(1+x^2)^p$ is continuous, positive, and eventually decreasing on $[1, \infty)$, and we can use the Integral Test.

$$\int_1^{\infty} x(1+x^2)^p\,dx = \lim_{t\to\infty}\left[\frac{1}{2}\cdot\frac{(1+x^2)^{p+1}}{p+1}\right]_1^t = \frac{1}{2(p+1)}\lim_{t\to\infty}\left[(1+t^2)^{p+1} - 2^{p+1}\right].$$

This limit exists and is finite $\quad\Leftrightarrow\quad p + 1 < 0 \quad\Leftrightarrow\quad p < -1$, so the series $\sum\limits_{n=1}^{\infty} n(1+n^2)^p$ converges whenever $p < -1$.

32. If $p \leq 0$, $\lim\limits_{n\to\infty} \dfrac{\ln n}{n^p} = \infty$ and the series diverges, so assume $p > 0$. $f(x) = \dfrac{\ln x}{x^p}$ is positive and continuous and $f'(x) < 0$ for $x > e^{1/p}$, so f is eventually decreasing and we can use the Integral Test. Integration by parts gives

$$\int_1^{\infty} \frac{\ln x}{x^p}\,dx = \lim_{t\to\infty}\left[\frac{x^{1-p}\,[(1-p)\ln x - 1]}{(1-p)^2}\right]_1^t \quad (\text{for } p \neq 1) \;=\; \frac{1}{(1-p)^2}\left[\lim_{t\to\infty} t^{1-p}\,[(1-p)\ln t - 1] + 1\right],$$ which exists whenever $1 - p < 0 \quad\Leftrightarrow\quad p > 1$. Thus, $\sum\limits_{n=1}^{\infty} \dfrac{\ln n}{n^p}$ converges $\quad\Leftrightarrow\quad p > 1$.

33. Since this is a p-series with $p = x$, $\zeta(x)$ is defined when $x > 1$. Unless specified otherwise, the domain of a function f is the set of real numbers x such that the expression for $f(x)$ makes sense and defines a real number. So, in the case of a series, it's the set of real numbers x such that the series is convergent.

34. (a) $\sum_{n=2}^{\infty} \frac{1}{n^2} = \sum_{n=1}^{\infty} \frac{1}{n^2} - \frac{1}{1^2}$ [subtract a_1] $= \frac{\pi^2}{6} - 1$

(b) $\sum_{n=3}^{\infty} \frac{1}{(n+1)^2} = \sum_{n=4}^{\infty} \frac{1}{n^2} = \sum_{n=1}^{\infty} \frac{1}{n^2} - \left(\frac{1}{1^2} + \frac{1}{2^2} + \frac{1}{3^2}\right) = \frac{\pi^2}{6} - \frac{49}{36}$

(c) $\sum_{n=1}^{\infty} \frac{1}{(2n)^2} = \sum_{n=1}^{\infty} \frac{1}{4n^2} = \frac{1}{4}\sum_{n=1}^{\infty} \frac{1}{n^2} = \frac{1}{4}\left(\frac{\pi^2}{6}\right) = \frac{\pi^2}{24}$

35. (a) $\sum_{n=1}^{\infty} \left(\frac{3}{n}\right)^4 = \sum_{n=1}^{\infty} \frac{81}{n^4} = 81 \sum_{n=1}^{\infty} \frac{1}{n^4} = 81\left(\frac{\pi^4}{90}\right) = \frac{9\pi^4}{10}$

(b) $\sum_{k=5}^{\infty} \frac{1}{(k-2)^4} = \frac{1}{3^4} + \frac{1}{4^4} + \frac{1}{5^4} + \cdots = \sum_{k=3}^{\infty} \frac{1}{k^4} = \frac{\pi^4}{90} - \left(\frac{1}{1^4} + \frac{1}{2^4}\right)$ [subtract a_1 and a_2] $= \frac{\pi^4}{90} - \frac{17}{16}$

36. (a) $f(x) = 1/x^4$ is positive and continuous and $f'(x) = -4/x^5$ is negative for $x > 0$, and so the Integral Test applies.

$\sum_{n=1}^{\infty} \frac{1}{n^4} \approx s_{10} = \frac{1}{1^4} + \frac{1}{2^4} + \frac{1}{3^4} + \cdots + \frac{1}{10^4} \approx 1.082037.$

$R_{10} \le \int_{10}^{\infty} \frac{1}{x^4}\,dx = \lim_{t\to\infty}\left[\frac{1}{-3x^3}\right]_{10}^{t} = \lim_{t\to\infty}\left(-\frac{1}{3t^3} + \frac{1}{3\,(10)^3}\right) = \frac{1}{3000}$, so the error is at most $0.000\overline{3}$.

(b) $s_{10} + \int_{11}^{\infty} \frac{1}{x^4}\,dx \le s \le s_{10} + \int_{10}^{\infty} \frac{1}{x^4}\,dx \quad\Rightarrow\quad s_{10} + \frac{1}{3(11)^3} \le s \le s_{10} + \frac{1}{3(10)^3} \quad\Rightarrow$

$1.082037 + 0.000250 = 1.082287 \le s \le 1.082037 + 0.000333 = 1.082370$, so we get $s \approx 1.08233$ with error ≤ 0.00005.

(c) The estimate in part (b) is $s \approx 1.08233$ with error ≤ 0.00005. The exact value given in Exercise 35 is $\pi^4/90 \approx 1.082323$. The difference is less than 0.00001.

(d) $R_n \le \int_{n}^{\infty} \frac{1}{x^4}\,dx = \frac{1}{3n^3}$. So $R_n < 0.00001 \quad\Rightarrow\quad \frac{1}{3n^3} < \frac{1}{10^5} \quad\Rightarrow\quad 3n^3 > 10^5 \quad\Rightarrow\quad n > \sqrt[3]{(10)^5/3} \approx 32.2$, that is, for $n > 32$.

37. (a) $f(x) = \frac{1}{x^2}$ is positive and continuous and $f'(x) = -\frac{2}{x^3}$ is negative for $x > 0$, and so the Integral Test applies.

$\sum_{n=1}^{\infty} \frac{1}{n^2} \approx s_{10} = \frac{1}{1^2} + \frac{1}{2^2} + \frac{1}{3^2} + \cdots + \frac{1}{10^2} \approx 1.549768.$

$R_{10} \le \int_{10}^{\infty} \frac{1}{x^2}\,dx = \lim_{t\to\infty}\left[\frac{-1}{x}\right]_{10}^{t} = \lim_{t\to\infty}\left(-\frac{1}{t} + \frac{1}{10}\right) = \frac{1}{10}$, so the error is at most 0.1.

(b) $s_{10} + \int_{11}^{\infty} \frac{1}{x^2}\,dx \le s \le s_{10} + \int_{10}^{\infty} \frac{1}{x^2}\,dx \quad \Rightarrow \quad s_{10} + \frac{1}{11} \le s \le s_{10} + \frac{1}{10} \quad \Rightarrow$

$1.549768 + 0.090909 = 1.640677 \le s \le 1.549768 + 0.1 = 1.649768$, so we get $s \approx 1.64522$ (the average of 1.640677 and 1.649768) with error ≤ 0.005 (the maximum of $1.649768 - 1.64522$ and $1.64522 - 1.640677$, rounded up).

(c) The estimate in part (b) is $s \approx 1.64522$ with error ≤ 0.005. The exact value given in Exercise 34 is $\pi^2/6 \approx 1.644934$. The difference is less than 0.0003.

(d) $R_n \le \int_n^{\infty} \frac{1}{x^2}\,dx = \frac{1}{n}$. So $R_n < 0.001$ if $\frac{1}{n} < \frac{1}{1000} \quad \Leftrightarrow \quad n > 1000$.

38. $f(x) = xe^{-2x}$ is continuous, positive, and decreasing on $[1, \infty)$, so the Integral Test applies. Using (2),

$$R_n \le \int_n^{\infty} xe^{-2x}\,dx = \lim_{t\to\infty}\left(\left[-\tfrac{1}{2}xe^{-2x}\right]_n^t + \int_n^t \tfrac{1}{2}e^{-2x}\,dx\right) \qquad \left[\begin{array}{c}\text{using parts with}\\ u = x,\, dv = e^{-2x}\,dx\end{array}\right]$$

$$= \lim_{t\to\infty}\left(\frac{-t}{2e^{2t}} + \frac{n}{2e^{2n}} - \frac{1}{4e^{2t}} + \frac{1}{4e^{2n}}\right) \overset{\text{H}}{=} 0 + \frac{n}{2e^{2n}} - 0 + \frac{1}{4e^{2n}} = \frac{2n+1}{4e^{2n}}$$

To be correct to four decimal places, we want $\frac{2n+1}{4e^{2n}} \le \frac{5}{10^5}$. This inequality is true for $n = 6$.

$s_6 = \sum_{n=1}^{6} \frac{n}{e^{2n}} = \frac{1}{e^2} + \frac{2}{e^4} + \frac{3}{e^6} + \frac{4}{e^8} + \frac{5}{e^{10}} + \frac{6}{e^{12}} \approx 0.1810.$

39. $f(x) = 1/(2x+1)^6$ is continuous, positive, and decreasing on $[1, \infty)$, so the Integral Test applies. Using (2),

$R_n \le \int_n^{\infty} (2x+1)^{-6}\,dx = \lim_{t\to\infty}\left[\frac{-1}{10(2x+1)^5}\right]_n^t = \frac{1}{10(2n+1)^5}$. To be correct to five decimal places, we want

$\frac{1}{10(2n+1)^5} \le \frac{5}{10^6} \quad \Leftrightarrow \quad (2n+1)^5 \ge 20{,}000 \quad \Leftrightarrow \quad n \ge \frac{1}{2}\left(\sqrt[5]{20{,}000} - 1\right) \approx 3.12$, so use $n = 4$.

$s_4 = \sum_{n=1}^{4} \frac{1}{(2n+1)^6} = \frac{1}{3^6} + \frac{1}{5^6} + \frac{1}{7^6} + \frac{1}{9^6} \approx 0.001\,446 \approx 0.00145.$

40. $f(x) = \frac{1}{x(\ln x)^2}$ is positive and continuous and $f'(x) = -\frac{\ln x + 2}{x^2(\ln x)^3}$ is negative for $x > 1$, so the Integral Test applies.

Using (2), we need $0.01 > \int_n^{\infty} \frac{dx}{x(\ln x)^2} = \lim_{t\to\infty}\left[\frac{-1}{\ln x}\right]_n^t = \frac{1}{\ln n}$. This is true for $n > e^{100}$, so we would have to add this many terms to find the sum of the series $\sum_{n=2}^{\infty} \frac{1}{n(\ln n)^2}$ to within 0.01, which would be problematic because $e^{100} \approx 2.7 \times 10^{43}$.

41. $\sum_{n=1}^{\infty} n^{-1.001} = \sum_{n=1}^{\infty} \frac{1}{n^{1.001}}$ is a convergent p-series with $p = 1.001 > 1$. Using (2), we get

$R_n \le \int_n^{\infty} x^{-1.001}\,dx = \lim_{t\to\infty}\left[\frac{x^{-0.001}}{-0.001}\right]_n^t = -1000 \lim_{t\to\infty}\left[\frac{1}{x^{0.001}}\right]_n^t = -1000\left(-\frac{1}{n^{0.001}}\right) = \frac{1000}{n^{0.001}}$. We want

$R_n < 0.000\,000\,005 \quad \Leftrightarrow \quad \dfrac{1000}{n^{0.001}} < 5 \times 10^{-9} \quad \Leftrightarrow \quad n^{0.001} > \dfrac{1000}{5 \times 10^{-9}} \quad \Leftrightarrow$

$n > \left(2 \times 10^{11}\right)^{1000} = 2^{1000} \times 10^{11{,}000} \approx 1.07 \times 10^{301} \times 10^{11{,}000} = 1.07 \times 10^{11{,}301}$.

42. (a) $f(x) = \left(\dfrac{\ln x}{x}\right)^2$ is continuous and positive for $x > 1$, and since $f'(x) = \dfrac{2\ln x\,(1 - \ln x)}{x^3} < 0$ for $x > e$, we can apply the Integral Test. Using a CAS, we get $\displaystyle\int_1^\infty \left(\frac{\ln x}{x}\right)^2 dx = 2$, so the series $\displaystyle\sum_{n=1}^\infty \left(\frac{\ln n}{n}\right)^2$ also converges.

(b) Since the Integral Test applies, the error in $s \approx s_n$ is $R_n \le \displaystyle\int_n^\infty \left(\frac{\ln x}{x}\right)^2 dx = \frac{(\ln n)^2 + 2\ln n + 2}{n}$.

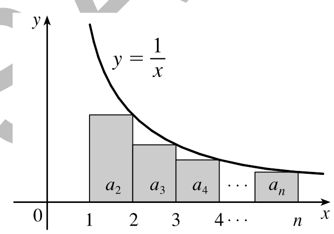
(c) By graphing the functions $y_1 = \dfrac{(\ln x)^2 + 2\ln x + 2}{x}$ and $y_2 = 0.05$, we see that $y_1 < y_2$ for $n \ge 1373$.

(d) Using the CAS to sum the first 1373 terms, we get $s_{1373} \approx 1.94$.

43. (a) From the figure, $a_2 + a_3 + \cdots + a_n \le \int_1^n f(x)\,dx$, so with

$f(x) = \dfrac{1}{x}$, $\dfrac{1}{2} + \dfrac{1}{3} + \dfrac{1}{4} + \cdots + \dfrac{1}{n} \le \displaystyle\int_1^n \frac{1}{x}\,dx = \ln n$.

Thus, $s_n = 1 + \dfrac{1}{2} + \dfrac{1}{3} + \dfrac{1}{4} + \cdots + \dfrac{1}{n} \le 1 + \ln n$.



(b) By part (a), $s_{10^6} \le 1 + \ln 10^6 \approx 14.82 < 15$ and

$s_{10^9} \le 1 + \ln 10^9 \approx 21.72 < 22$.

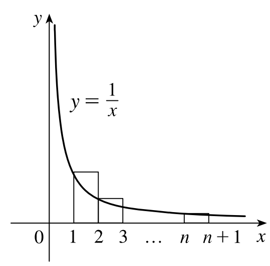
44. (a) The sum of the areas of the n rectangles in the graph to the right is

$1 + \dfrac{1}{2} + \dfrac{1}{3} + \cdots + \dfrac{1}{n}$. Now $\displaystyle\int_1^{n+1} \frac{dx}{x}$ is less than this sum because

the rectangles extend above the curve $y = 1/x$, so

$\displaystyle\int_1^{n+1} \frac{1}{x}\,dx = \ln(n+1) < 1 + \frac{1}{2} + \frac{1}{3} + \cdots + \frac{1}{n}$, and since

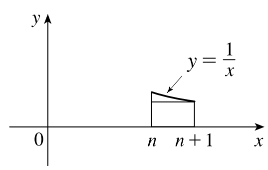
$\ln n < \ln(n+1)$, $0 < 1 + \dfrac{1}{2} + \dfrac{1}{3} + \cdots + \dfrac{1}{n} - \ln n = t_n$.



(b) The area under $f(x) = 1/x$ between $x = n$ and $x = n + 1$ is

$\displaystyle\int_n^{n+1} \frac{dx}{x} = \ln(n+1) - \ln n$, and this is clearly greater than the area of

the inscribed rectangle in the figure to the right $\left[\text{which is } \dfrac{1}{n+1}\right]$, so



$t_n - t_{n+1} = [\ln(n+1) - \ln n] - \dfrac{1}{n+1} > 0$, and so $t_n > t_{n+1}$, so $\{t_n\}$ is a decreasing sequence.

(c) We have shown that $\{t_n\}$ is decreasing and that $t_n > 0$ for all n. Thus, $0 < t_n \le t_1 = 1$, so $\{t_n\}$ is a bounded monotonic sequence, and hence converges by the Monotonic Sequence Theorem.

45. $b^{\ln n} = \left(e^{\ln b}\right)^{\ln n} = \left(e^{\ln n}\right)^{\ln b} = n^{\ln b} = \dfrac{1}{n^{-\ln b}}$. This is a p-series, which converges for all b such that $-\ln b > 1 \quad\Leftrightarrow$

$\ln b < -1 \quad\Leftrightarrow\quad b < e^{-1} \quad\Leftrightarrow\quad b < 1/e$ [with $b > 0$].

46. For the series $\sum\limits_{n=1}^{\infty}\left(\dfrac{c}{n} - \dfrac{1}{n+1}\right)$,

$$s_n = \sum_{i=1}^{n}\left(\frac{c}{i} - \frac{1}{i+1}\right) = \left(\frac{c}{1} - \frac{1}{2}\right) + \left(\frac{c}{2} - \frac{1}{3}\right) + \left(\frac{c}{3} - \frac{1}{4}\right) + \cdots + \left(\frac{c}{n} - \frac{1}{n+1}\right)$$

$$= \frac{c}{1} + \frac{c-1}{2} + \frac{c-1}{3} + \frac{c-1}{4} + \cdots + \frac{c-1}{n} - \frac{1}{n+1} = c + (c-1)\left(\frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \cdots + \frac{1}{n}\right) - \frac{1}{n+1}$$

Thus, $\sum\limits_{n=1}^{\infty}\left(\dfrac{c}{n} - \dfrac{1}{n+1}\right) = \lim\limits_{n\to\infty} s_n = \lim\limits_{n\to\infty}\left[c + (c-1)\sum\limits_{i=2}^{n}\dfrac{1}{i} - \dfrac{1}{n+1}\right]$. Since a constant multiple of a divergent series is divergent, the last limit exists only if $c - 1 = 0$, so the original series converges only if $c = 1$.

11.4 The Comparison Tests

1. (a) We cannot say anything about $\sum a_n$. If $a_n > b_n$ for all n and $\sum b_n$ is convergent, then $\sum a_n$ could be convergent or divergent. (See the note after Example 2.)

(b) If $a_n < b_n$ for all n, then $\sum a_n$ is convergent. [This is part (i) of the Comparison Test.]

2. (a) If $a_n > b_n$ for all n, then $\sum a_n$ is divergent. [This is part (ii) of the Comparison Test.]

(b) We cannot say anything about $\sum a_n$. If $a_n < b_n$ for all n and $\sum b_n$ is divergent, then $\sum a_n$ could be convergent or divergent.

3. $\dfrac{1}{n^3+8} < \dfrac{1}{n^3}$ for all $n \geq 1$, so $\sum\limits_{n=1}^{\infty}\dfrac{1}{n^3+8}$ converges by comparison with $\sum\limits_{n=1}^{\infty}\dfrac{1}{n^3}$, which converges because it is a p-series with $p = 3 > 1$.

4. $\dfrac{1}{\sqrt{n}-1} > \dfrac{1}{\sqrt{n}}$ for all $n \geq 2$, so $\sum\limits_{n=2}^{\infty}\dfrac{1}{\sqrt{n}-1}$ diverges by comparison with $\sum\limits_{n=2}^{\infty}\dfrac{1}{\sqrt{n}}$, which diverges because it is a p-series with $p = \frac{1}{2} \leq 1$.

5. $\dfrac{n+1}{n\sqrt{n}} > \dfrac{n}{n\sqrt{n}} = \dfrac{1}{\sqrt{n}}$ for all $n \geq 1$, so $\sum\limits_{n=1}^{\infty}\dfrac{n+1}{n\sqrt{n}}$ diverges by comparison with $\sum\limits_{n=1}^{\infty}\dfrac{1}{\sqrt{n}}$, which diverges because it is a p-series with $p = \frac{1}{2} \leq 1$.

6. $\dfrac{n-1}{n^3+1} < \dfrac{n}{n^3+1} < \dfrac{n}{n^3} = \dfrac{1}{n^2}$ for all $n \geq 1$, so $\sum\limits_{n=1}^{\infty}\dfrac{n-1}{n^3+1}$ converges by comparison with $\sum\limits_{n=1}^{\infty}\dfrac{1}{n^2}$, which converges because it is a p-series with $p = 2 > 1$.

7. $\dfrac{9^n}{3+10^n} < \dfrac{9^n}{10^n} = \left(\dfrac{9}{10}\right)^n$ for all $n \geq 1$. $\sum\limits_{n=1}^{\infty}\left(\frac{9}{10}\right)^n$ is a convergent geometric series $\left(|r| = \frac{9}{10} < 1\right)$, so $\sum\limits_{n=1}^{\infty}\dfrac{9^n}{3+10^n}$ converges by the Comparison Test.

8. $\dfrac{6^n}{5^n-1} > \dfrac{6^n}{5^n} = \left(\dfrac{6}{5}\right)^n$ for all $n \geq 1$. $\sum\limits_{n=1}^{\infty} \left(\frac{6}{5}\right)^n$ is a divergent geometric series $\left(|r| = \frac{6}{5} > 1\right)$, so $\sum\limits_{n=1}^{\infty} \dfrac{6^n}{5^n-1}$ diverges by the Comparison Test.

9. $\dfrac{\ln k}{k} > \dfrac{1}{k}$ for all k ≥ 3 [since $\ln k > 1$ for $k \geq 3$], so $\sum\limits_{k=3}^{\infty} \dfrac{\ln k}{k}$ diverges by comparison with $\sum\limits_{k=3}^{\infty} \dfrac{1}{k}$, which diverges because it is a p-series with $p = 1 \leq 1$ (the harmonic series). Thus, $\sum\limits_{k=1}^{\infty} \dfrac{\ln k}{k}$ diverges since a finite number of terms doesn't affect the convergence or divergence of a series.

10. $\dfrac{k \sin^2 k}{1+k^3} \leq \dfrac{k}{1+k^3} < \dfrac{k}{k^3} = \dfrac{1}{k^2}$ for all $k \geq 1$, so $\sum\limits_{k=1}^{\infty} \dfrac{k \sin^2 k}{1+k^3}$ converges by comparison with $\sum\limits_{k=1}^{\infty} \dfrac{1}{k^2}$, which converges because it is a p-series with $p = 2 > 1$.

11. $\dfrac{\sqrt[3]{k}}{\sqrt{k^3+4k+3}} < \dfrac{\sqrt[3]{k}}{\sqrt{k^3}} = \dfrac{k^{1/3}}{k^{3/2}} = \dfrac{1}{k^{7/6}}$ for all $k \geq 1$, so $\sum\limits_{k=1}^{\infty} \dfrac{\sqrt[3]{k}}{\sqrt{k^3+4k+3}}$ converges by comparison with $\sum\limits_{k=1}^{\infty} \dfrac{1}{k^{7/6}}$, which converges because it is a p-series with $p = \frac{7}{6} > 1$.

12. $\dfrac{(2k-1)(k^2-1)}{(k+1)(k^2+4)^2} < \dfrac{2k(k^2)}{k(k^2)^2} = \dfrac{2k^3}{k^5} = \dfrac{2}{k^2}$ for all $k \geq 1$, so $\sum\limits_{k=1}^{\infty} \dfrac{(2k-1)(k^2-1)}{(k+1)(k^2+4)^2}$ converges by comparison with $2\sum\limits_{k=1}^{\infty} \dfrac{1}{k^2}$, which converges because it is a constant multiple of a p-series with $p = 2 > 1$.

13. $\dfrac{1+\cos n}{e^n} < \dfrac{2}{e^n}$ for all $n \geq 1$. $\sum\limits_{n=1}^{\infty} \dfrac{2}{e^n}$ is a convergent geometric series ($|r| = \frac{1}{e} < 1$), so $\sum\limits_{n=1}^{\infty} \dfrac{1+\cos n}{e^n}$ converges by the Comparison Test.

14. $\dfrac{1}{\sqrt[3]{3n^4+1}} < \dfrac{1}{\sqrt[3]{3n^4}} < \dfrac{1}{\sqrt[3]{n^4}} = \dfrac{1}{n^{4/3}}$ for all $n \geq 1$, so $\sum\limits_{n=1}^{\infty} \dfrac{1}{\sqrt[3]{3n^4+1}}$ converges by comparison with $\sum\limits_{n=1}^{\infty} \dfrac{1}{n^{4/3}}$, which converges because it is a p-series with $p = \frac{4}{3} > 1$.

15. $\dfrac{4^{n+1}}{3^n-2} > \dfrac{4 \cdot 4^n}{3^n} = 4\left(\dfrac{4}{3}\right)^n$ for all $n \geq 1$. $\sum\limits_{n=1}^{\infty} 4\left(\dfrac{4}{3}\right)^n = 4\sum\limits_{n=1}^{\infty} \left(\dfrac{4}{3}\right)^n$ is a divergent geometric series $\left(|r| = \frac{4}{3} > 1\right)$, so $\sum\limits_{n=1}^{\infty} \dfrac{4^{n+1}}{3^n-2}$ diverges by the Comparison Test.

16. $\dfrac{1}{n^n} \leq \dfrac{1}{n^2}$ for all $n \geq 1$, so $\sum\limits_{n=1}^{\infty} \dfrac{1}{n^n}$ converges by comparison with $\sum\limits_{n=1}^{\infty} \dfrac{1}{n^2}$, which converges because it is a p-series with $p = 2 > 1$.

17. Use the Limit Comparison Test with $a_n = \dfrac{1}{\sqrt{n^2+1}}$ and $b_n = \dfrac{1}{n}$:

$\lim\limits_{n\to\infty} \dfrac{a_n}{b_n} = \lim\limits_{n\to\infty} \dfrac{n}{\sqrt{n^2+1}} = \lim\limits_{n\to\infty} \dfrac{1}{\sqrt{1+(1/n^2)}} = 1 > 0$. Since the harmonic series $\sum\limits_{n=1}^{\infty} \dfrac{1}{n}$ diverges, so does $\sum\limits_{n=1}^{\infty} \dfrac{1}{\sqrt{n^2+1}}$.

18. Use the Limit Comparison Test with $a_n = \dfrac{2}{\sqrt{n}+2}$ and $b_n = \dfrac{1}{\sqrt{n}}$:

$\lim\limits_{n\to\infty} \dfrac{a_n}{b_n} = \lim\limits_{n\to\infty} \dfrac{2\sqrt{n}}{\sqrt{n}+2} = \lim\limits_{n\to\infty} \dfrac{2}{1+2/\sqrt{n}} = 2 > 0$. Since $\sum\limits_{n=1}^{\infty} \dfrac{1}{\sqrt{n}}$ is a divergent p-series $[\,p = \frac{1}{2} \leq 1]$, the series $\sum\limits_{n=1}^{\infty} \dfrac{2}{\sqrt{n}+2}$ is also divergent.

19. Use the Limit Comparison Test with $a_n = \dfrac{n+1}{n^3+n}$ and $b_n = \dfrac{1}{n^2}$:

$\lim\limits_{n\to\infty} \dfrac{a_n}{b_n} = \lim\limits_{n\to\infty} \dfrac{(n+1)n^2}{n(n^2+1)} = \lim\limits_{n\to\infty} \dfrac{n^2+n}{n^2+1} = \lim\limits_{n\to\infty} \dfrac{1+1/n}{1+1/n^2} = 1 > 0$. Since $\sum\limits_{n=1}^{\infty} \dfrac{1}{n^2}$ is a convergent p-series $[p = 2 > 1]$, the series $\sum\limits_{n=1}^{\infty} \dfrac{n+1}{n^3+n}$ also converges.

20. Use the Limit Comparison Test with $a_n = \dfrac{n^2+n+1}{n^4+n^2}$ and $b_n = \dfrac{1}{n^2}$:

$\lim\limits_{n\to\infty} \dfrac{a_n}{b_n} = \lim\limits_{n\to\infty} \dfrac{(n^2+n+1)n^2}{n^2(n^2+1)} = \lim\limits_{n\to\infty} \dfrac{n^2+n+1}{n^2+1} = \lim\limits_{n\to\infty} \dfrac{1+1/n+1/n^2}{1+1/n^2} = 1 > 0$. Since $\sum\limits_{n=1}^{\infty} \dfrac{1}{n^2}$ is a convergent p-series $[p = 2 > 1]$, the series $\sum\limits_{n=1}^{\infty} \dfrac{n^2+n+1}{n^4+n^2}$ also converges.

21. Use the Limit Comparison Test with $a_n = \dfrac{\sqrt{1+n}}{2+n}$ and $b_n = \dfrac{1}{\sqrt{n}}$:

$\lim\limits_{n\to\infty} \dfrac{a_n}{b_n} = \lim\limits_{n\to\infty} \dfrac{\sqrt{1+n}\sqrt{n}}{2+n} = \lim\limits_{n\to\infty} \dfrac{\sqrt{n^2+n}/\sqrt{n^2}}{(2+n)/n} = \lim\limits_{n\to\infty} \dfrac{\sqrt{1+1/n}}{2/n+1} = 1 > 0$. Since $\sum\limits_{n=1}^{\infty} \dfrac{1}{\sqrt{n}}$ is a divergent p-series $[\,p = \frac{1}{2} \leq 1]$, the series $\sum\limits_{n=1}^{\infty} \dfrac{\sqrt{1+n}}{2+n}$ also diverges.

22. Use the Limit Comparison Test with $a_n = \dfrac{n+2}{(n+1)^3}$ and $b_n = \dfrac{1}{n^2}$:

$\lim\limits_{n\to\infty} \dfrac{a_n}{b_n} = \lim\limits_{n\to\infty} \dfrac{n^2(n+2)}{(n+1)^3} = \lim\limits_{n\to\infty} \dfrac{1+\frac{2}{n}}{\left(1+\frac{1}{n}\right)^3} = 1 > 0$. Since $\sum\limits_{n=3}^{\infty} \dfrac{1}{n^2}$ is a convergent (partial) p-series $[p = 2 > 1]$, the series $\sum\limits_{n=3}^{\infty} \dfrac{n+2}{(n+1)^3}$ also converges.

23. Use the Limit Comparison Test with $a_n = \dfrac{5+2n}{(1+n^2)^2}$ and $b_n = \dfrac{1}{n^3}$:

$\lim\limits_{n\to\infty} \dfrac{a_n}{b_n} = \lim\limits_{n\to\infty} \dfrac{n^3(5+2n)}{(1+n^2)^2} = \lim\limits_{n\to\infty} \dfrac{5n^3+2n^4}{(1+n^2)^2} \cdot \dfrac{1/n^4}{1/(n^2)^2} = \lim\limits_{n\to\infty} \dfrac{\frac{5}{n}+2}{\left(\frac{1}{n^2}+1\right)^2} = 2 > 0$. Since $\sum\limits_{n=1}^{\infty} \dfrac{1}{n^3}$ is a convergent p-series $[p = 3 > 1]$, the series $\sum\limits_{n=1}^{\infty} \dfrac{5+2n}{(1+n^2)^2}$ also converges.

24. $\dfrac{n+3^n}{n+2^n} > \dfrac{3^n}{n+2^n} > \dfrac{3^n}{2^n+2^n} = \dfrac{3^n}{2\cdot 2^n} = \dfrac{1}{2}\left(\dfrac{3}{2}\right)^n$, so the series $\displaystyle\sum_{n=1}^{\infty}\frac{n+3^n}{n+2^n}$ diverges by comparison with $\displaystyle\frac{1}{2}\sum_{n=1}^{\infty}\left(\frac{3}{2}\right)^n$, which is a constant multiple of a divergent geometric series $[|r| = \frac{3}{2} > 1]$. *Or:* Use the Limit Comparison Test with $a_n = \dfrac{n+3^n}{n+2^n}$ and $b_n = \left(\dfrac{3}{2}\right)^n$.

25. $\dfrac{e^n+1}{ne^n+1} \geq \dfrac{e^n+1}{ne^n+n} = \dfrac{e^n+1}{n(e^n+1)} = \dfrac{1}{n}$ for $n \geq 1$, so the series $\displaystyle\sum_{n=1}^{\infty}\frac{e^n+1}{ne^n+1}$ diverges by comparison with the divergent harmonic series $\displaystyle\sum_{n=1}^{\infty}\frac{1}{n}$. *Or:* Use the Limit Comparison Test with $a_n = \dfrac{e^n+1}{ne^n+1}$ and $b_n = \dfrac{1}{n}$.

26. If $a_n = \dfrac{1}{n\sqrt{n^2-1}}$ and $b_n = \dfrac{1}{n^2}$, then

$\displaystyle\lim_{n\to\infty}\frac{a_n}{b_n} = \lim_{n\to\infty}\frac{n^2}{n\sqrt{n^2-1}} = \lim_{n\to\infty}\frac{n/n}{\sqrt{n^2-1}/n} = \lim_{n\to\infty}\frac{1}{\sqrt{1-1/n^2}} = \frac{1}{1} = 1 > 0$, so $\displaystyle\sum_{n=2}^{\infty}\frac{1}{n\sqrt{n^2-1}}$ converges by the Limit Comparison Test with the convergent series $\displaystyle\sum_{n=2}^{\infty}\frac{1}{n^2}$.

27. Use the Limit Comparison Test with $a_n = \left(1+\dfrac{1}{n}\right)^2 e^{-n}$ and $b_n = e^{-n}$: $\displaystyle\lim_{n\to\infty}\frac{a_n}{b_n} = \lim_{n\to\infty}\left(1+\frac{1}{n}\right)^2 = 1 > 0$. Since $\displaystyle\sum_{n=1}^{\infty}e^{-n} = \sum_{n=1}^{\infty}\frac{1}{e^n}$ is a convergent geometric series $\left[|r| = \frac{1}{e} < 1\right]$, the series $\displaystyle\sum_{n=1}^{\infty}\left(1+\frac{1}{n}\right)^2 e^{-n}$ also converges.

28. $\dfrac{e^{1/n}}{n} > \dfrac{1}{n}$ for all $n \geq 1$, so $\displaystyle\sum_{n=1}^{\infty}\frac{e^{1/n}}{n}$ diverges by comparison with the harmonic series $\displaystyle\sum_{n=1}^{\infty}\frac{1}{n}$.

29. Clearly $n! = n(n-1)(n-2)\cdots(3)(2) \geq 2\cdot 2\cdot 2\cdot\cdots\cdot 2\cdot 2 = 2^{n-1}$, so $\dfrac{1}{n!} \leq \dfrac{1}{2^{n-1}}$. $\displaystyle\sum_{n=1}^{\infty}\frac{1}{2^{n-1}}$ is a convergent geometric series $\left[|r| = \frac{1}{2} < 1\right]$, so $\displaystyle\sum_{n=1}^{\infty}\frac{1}{n!}$ converges by the Comparison Test.

30. $\dfrac{n!}{n^n} = \dfrac{1\cdot 2\cdot 3\cdot\cdots\cdot(n-1)n}{n\cdot n\cdot n\cdot\cdots\cdot n\cdot n} \leq \dfrac{1}{n}\cdot\dfrac{2}{n}\cdot 1\cdot 1\cdot\cdots\cdot 1$ for $n \geq 2$, so since $\displaystyle\sum_{n=1}^{\infty}\frac{2}{n^2}$ converges $[p = 2 > 1]$, $\displaystyle\sum_{n=1}^{\infty}\frac{n!}{n^n}$ converges also by the Comparison Test.

31. Use the Limit Comparison Test with $a_n = \sin\left(\dfrac{1}{n}\right)$ and $b_n = \dfrac{1}{n}$. Then $\sum a_n$ and $\sum b_n$ are series with positive terms and

$\displaystyle\lim_{n\to\infty}\frac{a_n}{b_n} = \lim_{n\to\infty}\frac{\sin(1/n)}{1/n} = \lim_{\theta\to 0}\frac{\sin\theta}{\theta} = 1 > 0$. Since $\displaystyle\sum_{n=1}^{\infty}b_n$ is the divergent harmonic series, $\displaystyle\sum_{n=1}^{\infty}\sin(1/n)$ also diverges. [Note that we could also use l'Hospital's Rule to evaluate the limit:

$\displaystyle\lim_{x\to\infty}\frac{\sin(1/x)}{1/x} \overset{\text{H}}{=} \lim_{x\to\infty}\frac{\cos(1/x)\cdot\left(-1/x^2\right)}{-1/x^2} = \lim_{x\to\infty}\cos\frac{1}{x} = \cos 0 = 1.$]

32. Use the Limit Comparison Test with $a_n = \dfrac{1}{n^{1+1/n}}$ and $b_n = \dfrac{1}{n}$. $\displaystyle\lim_{n\to\infty}\frac{a_n}{b_n} = \lim_{n\to\infty}\frac{n}{n^{1+1/n}} = \lim_{n\to\infty}\frac{1}{n^{1/n}} = 1$

$\left[\text{since } \displaystyle\lim_{x\to\infty} x^{1/x} = 1 \text{ by l'Hospital's Rule}\right]$, so $\displaystyle\sum_{n=1}^{\infty}\frac{1}{n}$ diverges [harmonic series] $\Rightarrow$ $\displaystyle\sum_{n=1}^{\infty}\frac{1}{n^{1+1/n}}$ diverges.

33. $\displaystyle\sum_{n=1}^{10}\frac{1}{5+n^5} = \frac{1}{5+1^5} + \frac{1}{5+2^5} + \frac{1}{5+3^5} + \cdots + \frac{1}{5+10^5} \approx 0.19926$. Now $\dfrac{1}{5+n^5} < \dfrac{1}{n^5}$, so the error is

$$R_{10} \le T_{10} \le \int_{10}^{\infty}\frac{1}{x^5}\,dx = \lim_{t\to\infty}\int_{10}^{t} x^{-5}\,dx = \lim_{t\to\infty}\left[\frac{-1}{4x^4}\right]_{10}^{t} = \lim_{t\to\infty}\left(\frac{-1}{4t^4} + \frac{1}{40{,}000}\right) = \frac{1}{40{,}000} = 0.000\,025.$$

34. $\displaystyle\sum_{n=1}^{10}\frac{e^{1/n}}{n^4} = \frac{e^{1/1}}{1^4} + \frac{e^{1/2}}{2^4} + \frac{e^{1/3}}{3^4} + \cdots + \frac{e^{1/10}}{10^4} \approx 2.84748$. Now $\dfrac{e^{1/n}}{n^4} \le \dfrac{e}{n^4}$ for $n \ge 1$, so the error is

$$R_{10} \le T_{10} \le \int_{10}^{\infty}\frac{e}{x^4}\,dx = \lim_{t\to\infty}\int_{10}^{t} ex^{-4}\,dx = \lim_{t\to\infty}\left[\frac{-e}{3x^3}\right]_{10}^{t} = \lim_{t\to\infty}\left(\frac{-e}{3t^3} + \frac{e}{3000}\right) = \frac{e}{3000} \approx 0.000\,906.$$

35. $\displaystyle\sum_{n=1}^{10} 5^{-n}\cos^2 n = \frac{\cos^2 1}{5} + \frac{\cos^2 2}{5^2} + \frac{\cos^2 3}{5^3} + \cdots + \frac{\cos^2 10}{5^{10}} \approx 0.07393$. Now $\dfrac{\cos^2 n}{5^n} \le \dfrac{1}{5^n}$, so the error is

$$R_{10} \le T_{10} \le \int_{10}^{\infty}\frac{1}{5^x}\,dx = \lim_{t\to\infty}\int_{10}^{t} 5^{-x}\,dx = \lim_{t\to\infty}\left[-\frac{5^{-x}}{\ln 5}\right]_{10}^{t} = \lim_{t\to\infty}\left(-\frac{5^{-t}}{\ln 5} + \frac{5^{-10}}{\ln 5}\right) = \frac{1}{5^{10}\ln 5} < 6.4\times 10^{-8}.$$

36. $\displaystyle\sum_{n=1}^{10}\frac{1}{3^n+4^n} = \frac{1}{3^1+4^1} + \frac{1}{3^2+4^2} + \frac{1}{3^3+4^3} + \cdots + \frac{1}{3^{10}+4^{10}} \approx 0.19788$. Now $\dfrac{1}{3^n+4^n} < \dfrac{1}{3^n+3^n} = \dfrac{1}{2\cdot 3^n}$, so the error is

$$R_{10} \le T_{10} \le \int_{10}^{\infty}\frac{1}{2\cdot 3^x}\,dx = \lim_{t\to\infty}\int_{10}^{t}\frac{1}{2}\cdot 3^{-x}\,dx = \lim_{t\to\infty}\left[-\frac{1}{2}\,\frac{3^{-x}}{\ln 3}\right]_{10}^{t} = \lim_{t\to\infty}\left(-\frac{1}{2}\,\frac{3^{-t}}{\ln 3} + \frac{1}{2}\,\frac{3^{-10}}{\ln 3}\right)$$
$$= \frac{1}{2\cdot 3^{10}\ln 3} < 7.7\times 10^{-6}.$$

37. Since $\dfrac{d_n}{10^n} \le \dfrac{9}{10^n}$ for each n, and since $\displaystyle\sum_{n=1}^{\infty}\frac{9}{10^n}$ is a convergent geometric series $\left(|r| = \frac{1}{10} < 1\right)$, $0.d_1d_2d_3\ldots = \displaystyle\sum_{n=1}^{\infty}\frac{d_n}{10^n}$ will always converge by the Comparison Test.

38. Clearly, if $p < 0$ then the series diverges, since $\displaystyle\lim_{n\to\infty}\frac{1}{n^p\ln n} = \infty$. If $0 \le p \le 1$, then $n^p\ln n \le n\ln n$ $\Rightarrow$ $\dfrac{1}{n^p\ln n} \ge \dfrac{1}{n\ln n}$ and $\displaystyle\sum_{n=2}^{\infty}\frac{1}{n\ln n}$ diverges (Exercise 11.3.21), so $\displaystyle\sum_{n=2}^{\infty}\frac{1}{n^p\ln n}$ diverges. If $p > 1$, use the Limit Comparison Test with $a_n = \dfrac{1}{n^p\ln n}$ and $b_n = \dfrac{1}{n^p}$. $\displaystyle\sum_{n=2}^{\infty} b_n$ converges, and $\displaystyle\lim_{n\to\infty}\frac{a_n}{b_n} = \lim_{n\to\infty}\frac{1}{\ln n} = 0$, so $\displaystyle\sum_{n=2}^{\infty}\frac{1}{n^p\ln n}$ also converges. (Or use the Comparison Test, since $n^p\ln n > n^p$ for $n > e$.) In summary, the series converges if and only if $p > 1$.

39. Since $\sum a_n$ converges, $\displaystyle\lim_{n\to\infty} a_n = 0$, so there exists N such that $|a_n - 0| < 1$ for all $n > N$ $\Rightarrow$ $0 \le a_n < 1$ for all $n > N$ $\Rightarrow$ $0 \le a_n^2 \le a_n$. Since $\sum a_n$ converges, so does $\sum a_n^2$ by the Comparison Test.

40. (a) Since $\lim\limits_{n\to\infty}(a_n/b_n)=0$, there is a number $N>0$ such that $|a_n/b_n-0|<1$ for all $n>N$, and so $a_n<b_n$ since a_n and b_n are positive. Thus, since $\sum b_n$ converges, so does $\sum a_n$ by the Comparison Test.

(b) (i) If $a_n=\dfrac{\ln n}{n^3}$ and $b_n=\dfrac{1}{n^2}$, then $\lim\limits_{n\to\infty}\dfrac{a_n}{b_n}=\lim\limits_{n\to\infty}\dfrac{\ln n}{n}=\lim\limits_{x\to\infty}\dfrac{\ln x}{x}\overset{\text{H}}{=}\lim\limits_{x\to\infty}\dfrac{1/x}{1}=0$, so $\sum\limits_{n=1}^{\infty}\dfrac{\ln n}{n^3}$ converges by part (a).

(ii) If $a_n=\dfrac{\ln n}{\sqrt{n}e^n}$ and $b_n=\dfrac{1}{e^n}$, then $\lim\limits_{n\to\infty}\dfrac{a_n}{b_n}=\lim\limits_{n\to\infty}\dfrac{\ln n}{\sqrt{n}}=\lim\limits_{x\to\infty}\dfrac{\ln x}{\sqrt{x}}\overset{\text{H}}{=}\lim\limits_{x\to\infty}\dfrac{1/x}{1/(2\sqrt{x})}=\lim\limits_{x\to\infty}\dfrac{2}{\sqrt{x}}=0$. Now $\sum b_n$ is a convergent geometric series with ratio $r=1/e$ $[|r|<1]$, so $\sum a_n$ converges by part (a).

41. (a) Since $\lim\limits_{n\to\infty}\dfrac{a_n}{b_n}=\infty$, there is an integer N such that $\dfrac{a_n}{b_n}>1$ whenever $n>N$. (Take $M=1$ in Definition 11.1.5.) Then $a_n>b_n$ whenever $n>N$ and since $\sum b_n$ is divergent, $\sum a_n$ is also divergent by the Comparison Test.

(b) (i) If $a_n=\dfrac{1}{\ln n}$ and $b_n=\dfrac{1}{n}$ for $n\geq 2$, then $\lim\limits_{n\to\infty}\dfrac{a_n}{b_n}=\lim\limits_{n\to\infty}\dfrac{n}{\ln n}=\lim\limits_{x\to\infty}\dfrac{x}{\ln x}\overset{\text{H}}{=}\lim\limits_{x\to\infty}\dfrac{1}{1/x}=\lim\limits_{x\to\infty}x=\infty$, so by part (a), $\sum\limits_{n=2}^{\infty}\dfrac{1}{\ln n}$ is divergent.

(ii) If $a_n=\dfrac{\ln n}{n}$ and $b_n=\dfrac{1}{n}$, then $\sum\limits_{n=1}^{\infty}b_n$ is the divergent harmonic series and $\lim\limits_{n\to\infty}\dfrac{a_n}{b_n}=\lim\limits_{n\to\infty}\ln n=\lim\limits_{x\to\infty}\ln x=\infty$, so $\sum\limits_{n=1}^{\infty}a_n$ diverges by part (a).

42. Let $a_n=\dfrac{1}{n^2}$ and $b_n=\dfrac{1}{n}$. Then $\lim\limits_{n\to\infty}\dfrac{a_n}{b_n}=\lim\limits_{n\to\infty}\dfrac{1}{n}=0$, but $\sum b_n$ diverges while $\sum a_n$ converges.

43. $\lim\limits_{n\to\infty}na_n=\lim\limits_{n\to\infty}\dfrac{a_n}{1/n}$, so we apply the Limit Comparison Test with $b_n=\dfrac{1}{n}$. Since $\lim\limits_{n\to\infty}na_n>0$ we know that either both series converge or both series diverge, and we also know that $\sum\limits_{n=1}^{\infty}\dfrac{1}{n}$ diverges [p-series with $p=1$]. Therefore, $\sum a_n$ must be divergent.

44. First we observe that, by l'Hospital's Rule, $\lim\limits_{x\to 0}\dfrac{\ln(1+x)}{x}=\lim\limits_{x\to 0}\dfrac{1}{1+x}=1$. Also, if $\sum a_n$ converges, then $\lim\limits_{n\to\infty}a_n=0$ by Theorem 11.2.6. Therefore, $\lim\limits_{n\to\infty}\dfrac{\ln(1+a_n)}{a_n}=\lim\limits_{x\to 0}\dfrac{\ln(1+x)}{x}=1>0$. We are given that $\sum a_n$ is convergent and $a_n>0$. Thus, $\sum\ln(1+a_n)$ is convergent by the Limit Comparison Test.

45. Yes. Since $\sum a_n$ is a convergent series with positive terms, $\lim\limits_{n\to\infty}a_n=0$ by Theorem 11.2.6, and $\sum b_n=\sum\sin(a_n)$ is a series with positive terms (for large enough n). We have $\lim\limits_{n\to\infty}\dfrac{b_n}{a_n}=\lim\limits_{n\to\infty}\dfrac{\sin(a_n)}{a_n}=1>0$ by Theorem 3.3.2. Thus, $\sum b_n$ is also convergent by the Limit Comparison Test.

46. Yes. Since $\sum a_n$ converges, its terms approach 0 as $n\to\infty$, so for some integer N, $a_n\leq 1$ for all $n\geq N$. But then $\sum_{n=1}^{\infty}a_nb_n=\sum_{n=1}^{N-1}a_nb_n+\sum_{n=N}^{\infty}a_nb_n\leq\sum_{n=1}^{N-1}a_nb_n+\sum_{n=N}^{\infty}b_n$. The first term is a finite sum, and the second term converges since $\sum_{n=1}^{\infty}b_n$ converges. So $\sum a_nb_n$ converges by the Comparison Test.

11.5 Alternating Series

1. (a) An alternating series is a series whose terms are alternately positive and negative.

(b) An alternating series $\sum_{n=1}^{\infty} a_n = \sum_{n=1}^{\infty} (-1)^{n-1} b_n$, where $b_n = |a_n|$, converges if $0 < b_{n+1} \leq b_n$ for all n and $\lim_{n\to\infty} b_n = 0$. (This is the Alternating Series Test.)

(c) The error involved in using the partial sum s_n as an approximation to the total sum s is the remainder $R_n = s - s_n$ and the size of the error is smaller than b_{n+1}; that is, $|R_n| \leq b_{n+1}$. (This is the Alternating Series Estimation Theorem.)

2. $\frac{2}{3} - \frac{2}{5} + \frac{2}{7} - \frac{2}{9} + \frac{2}{11} - \cdots = \sum_{n=1}^{\infty} (-1)^{n+1} \frac{2}{2n+1}$. Now $b_n = \frac{2}{2n+1} > 0$, $\{b_n\}$ is decreasing, and $\lim_{n\to\infty} b_n = 0$, so the series converges by the Alternating Series Test.

3. $-\frac{2}{5} + \frac{4}{6} - \frac{6}{7} + \frac{8}{8} - \frac{10}{9} + \cdots = \sum_{n=1}^{\infty} (-1)^n \frac{2n}{n+4}$. Now $\lim_{n\to\infty} b_n = \lim_{n\to\infty} \frac{2n}{n+4} = \lim_{n\to\infty} \frac{2}{1+4/n} = \frac{2}{1} \neq 0$. Since $\lim_{n\to\infty} a_n \neq 0$ (in fact the limit does not exist), the series diverges by the Test for Divergence.

4. $\frac{1}{\ln 3} - \frac{1}{\ln 4} + \frac{1}{\ln 5} - \frac{1}{\ln 6} + \frac{1}{\ln 7} - \cdots = \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{\ln(n+2)}$. Now $b_n = \frac{1}{\ln(n+2)} > 0$, $\{b_n\}$ is decreasing, and $\lim_{n\to\infty} b_n = 0$, so the series converges by the Alternating Series Test.

5. $\sum_{n=1}^{\infty} a_n = \sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{3+5n} = \sum_{n=1}^{\infty} (-1)^{n-1} b_n$. Now $b_n = \frac{1}{3+5n} > 0$, $\{b_n\}$ is decreasing, and $\lim_{n\to\infty} b_n = 0$, so the series converges by the Alternating Series Test.

6. $\sum_{n=0}^{\infty} a_n = \sum_{n=0}^{\infty} \frac{(-1)^{n+1}}{\sqrt{n+1}} = \sum_{n=0}^{\infty} (-1)^{n+1} b_n$. Now $b_n = \frac{1}{\sqrt{n+1}} > 0$, $\{b_n\}$ is decreasing, and $\lim_{n\to\infty} b_n = 0$, so the series converges by the Alternating Series Test.

7. $\sum_{n=1}^{\infty} a_n = \sum_{n=1}^{\infty} (-1)^n \frac{3n-1}{2n+1} = \sum_{n=1}^{\infty} (-1)^n b_n$. Now $\lim_{n\to\infty} b_n = \lim_{n\to\infty} \frac{3-1/n}{2+1/n} = \frac{3}{2} \neq 0$. Since $\lim_{n\to\infty} a_n \neq 0$ (in fact the limit does not exist), the series diverges by the Test for Divergence.

8. $\sum_{n=1}^{\infty} a_n = \sum_{n=1}^{\infty} (-1)^n \frac{n^2}{n^2+n+1} = \sum_{n=1}^{\infty} (-1)^n b_n$. Now $\lim_{n\to\infty} b_n = \lim_{n\to\infty} \frac{n^2}{n^2+n+1} = \lim_{n\to\infty} \frac{1}{1+1/n+1/n^2} = 1 \neq 0$. Since $\lim_{n\to\infty} a_n \neq 0$, the series diverges by the Test for Divergence.

9. $\sum_{n=1}^{\infty} a_n = \sum_{n=1}^{\infty} (-1)^n e^{-n} = \sum_{n=1}^{\infty} (-1)^n b_n$. Now $b_n = \frac{1}{e^n} > 0$, $\{b_n\}$ is decreasing, and $\lim_{n\to\infty} b_n = 0$, so the series converges by the Alternating Series Test.

10. $b_n = \dfrac{\sqrt{n}}{2n+3} > 0$ for $n \geq 1$. $\{b_n\}$ is decreasing for $n \geq 2$ since

$$\left(\frac{\sqrt{x}}{2x+3}\right)' = \frac{(2x+3)\left(\frac{1}{2}x^{-1/2}\right) - x^{1/2}(2)}{(2x+3)^2} = \frac{\frac{1}{2}x^{-1/2}[(2x+3)-4x]}{(2x+3)^2} = \frac{3-2x}{2\sqrt{x}\,(2x+3)^2} < 0 \text{ for } x > \tfrac{3}{2}.$$

Also, $\lim\limits_{n\to\infty} b_n = \lim\limits_{n\to\infty} \dfrac{\sqrt{n}/\sqrt{n}}{(2n+3)/\sqrt{n}} = \lim\limits_{n\to\infty} \dfrac{1}{2\sqrt{n}+3/\sqrt{n}} = 0$. Thus, the series $\sum\limits_{n=1}^{\infty}(-1)^n \dfrac{\sqrt{n}}{2n+3}$ converges by the Alternating Series Test.

11. $b_n = \dfrac{n^2}{n^3+4} > 0$ for $n \geq 1$. $\{b_n\}$ is decreasing for $n \geq 2$ since

$\left(\dfrac{x^2}{x^3+4}\right)' = \dfrac{(x^3+4)(2x) - x^2(3x^2)}{(x^3+4)^2} = \dfrac{x(2x^3+8-3x^3)}{(x^3+4)^2} = \dfrac{x(8-x^3)}{(x^3+4)^2} < 0$ for $x > 2$. Also,

$\lim\limits_{n\to\infty} b_n = \lim\limits_{n\to\infty} \dfrac{1/n}{1+4/n^3} = 0$. Thus, the series $\sum\limits_{n=1}^{\infty}(-1)^{n+1}\dfrac{n^2}{n^3+4}$ converges by the Alternating Series Test.

12. $b_n = ne^{-n} = \dfrac{n}{e^n} > 0$ for $n \geq 1$. $\{b_n\}$ is decreasing for $n \geq 1$ since $(xe^{-x})' = x(-e^{-x}) + e^{-x} = e^{-x}(1-x) < 0$ for $x > 1$. Also, $\lim\limits_{n\to\infty} b_n = 0$ since $\lim\limits_{x\to\infty} \dfrac{x}{e^x} \overset{\text{H}}{=} \lim\limits_{x\to\infty} \dfrac{1}{e^x} = 0$. Thus, the series $\sum\limits_{n=1}^{\infty}(-1)^{n+1}ne^{-n}$ converges by the Alternating Series Test.

13. $\lim\limits_{n\to\infty} b_n = \lim\limits_{n\to\infty} e^{2/n} = e^0 = 1$, so $\lim\limits_{n\to\infty}(-1)^{n-1}e^{2/n}$ does not exist. Thus, the series $\sum\limits_{n=1}^{\infty}(-1)^{n-1}e^{2/n}$ diverges by the Test for Divergence.

14. $\lim\limits_{n\to\infty} b_n = \lim\limits_{n\to\infty} \arctan n = \frac{\pi}{2}$, so $\lim\limits_{n\to\infty}(-1)^{n-1}\arctan n$ does not exist. Thus, the series $\sum\limits_{n=1}^{\infty}(-1)^{n-1}\arctan n$ diverges by the Test for Divergence.

15. $a_n = \dfrac{\sin\left(n+\frac{1}{2}\right)\pi}{1+\sqrt{n}} = \dfrac{(-1)^n}{1+\sqrt{n}}$. Now $b_n = \dfrac{1}{1+\sqrt{n}} > 0$ for $n \geq 0$, $\{b_n\}$ is decreasing, and $\lim\limits_{n\to\infty} b_n = 0$, so the series $\sum\limits_{n=0}^{\infty}\dfrac{\sin\left(n+\frac{1}{2}\right)\pi}{1+\sqrt{n}}$ converges by the Alternating Series Test.

16. $a_n = \dfrac{n\cos n\pi}{2^n} = (-1)^n\dfrac{n}{2^n} = (-1)^n b_n$. $\{b_n\}$ is decreasing for $n \geq 2$ since

$(x2^{-x})' = x(-2^{-x}\ln 2) + 2^{-x} = 2^{-x}(1 - x\ln 2) < 0$ for $x > \dfrac{1}{\ln 2}$ [≈ 1.4]. Also, $\lim\limits_{n\to\infty} b_n = 0$ since

$\lim\limits_{x\to\infty}\dfrac{x}{2^x} \overset{\text{H}}{=} \lim\limits_{x\to\infty}\dfrac{1}{2^x\ln 2} = 0$. Thus, the series $\sum\limits_{n=1}^{\infty}\dfrac{n\cos n\pi}{2^n}$ converges by the Alternating Series Test.

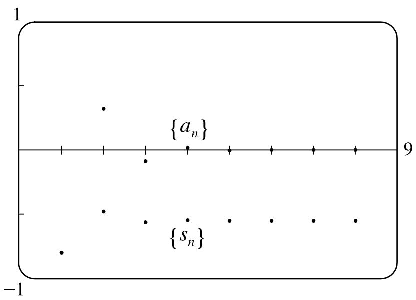
17. $\sum\limits_{n=1}^{\infty}(-1)^n\sin\left(\dfrac{\pi}{n}\right)$. $b_n = \sin\left(\dfrac{\pi}{n}\right) > 0$ for $n \geq 2$ and $\sin\left(\dfrac{\pi}{n}\right) \geq \sin\left(\dfrac{\pi}{n+1}\right)$, and $\lim\limits_{n\to\infty}\sin\left(\dfrac{\pi}{n}\right) = \sin 0 = 0$, so the series converges by the Alternating Series Test.

18. $\sum_{n=1}^{\infty}(-1)^n\cos\left(\frac{\pi}{n}\right)$. $\lim_{n\to\infty}\cos\left(\frac{\pi}{n}\right)=\cos(0)=1$, so $\lim_{n\to\infty}(-1)^n\cos\left(\frac{\pi}{n}\right)$ does not exist and the series diverges by the Test for Divergence.

19. $\frac{n^n}{n!}=\frac{n\cdot n\cdot\cdots\cdot n}{1\cdot 2\cdot\cdots\cdot n}\geq n \quad\Rightarrow\quad \lim_{n\to\infty}\frac{n^n}{n!}=\infty \quad\Rightarrow\quad \lim_{n\to\infty}\frac{(-1)^n n^n}{n!}$ does not exist. So the series $\sum_{n=1}^{\infty}(-1)^n\frac{n^n}{n!}$ diverges by the Test for Divergence.

20. $b_n=\frac{\sqrt{n+1}-\sqrt{n}}{1}\cdot\frac{\sqrt{n+1}+\sqrt{n}}{\sqrt{n+1}+\sqrt{n}}=\frac{(n+1)-n}{\sqrt{n+1}+\sqrt{n}}=\frac{1}{\sqrt{n+1}+\sqrt{n}}>0$ for $n\geq 1$. $\{b_n\}$ is decreasing and $\lim_{n\to\infty}b_n=0$, so the series $\sum_{n=1}^{\infty}(-1)^n\left(\sqrt{n+1}-\sqrt{n}\right)$ converges by the Alternating Series Test.

21.



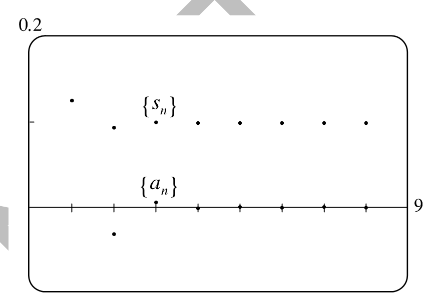
The graph gives us an estimate for the sum of the series $\sum_{n=1}^{\infty}\frac{(-0.8)^n}{n!}$ of -0.55.

$b_8=\frac{(0.8)^n}{8!}\approx 0.000\,004$, so

$$\sum_{n=1}^{\infty}\frac{(-0.8)^n}{n!}\approx s_7=\sum_{n=1}^{7}\frac{(-0.8)^n}{n!}$$
$$\approx -0.8+0.32-0.085\overline{3}+0.0170\overline{6}-0.002\,731+0.000\,364-0.000\,042\approx -0.5507$$

Adding b_8 to s_7 does not change the fourth decimal place of s_7, so the sum of the series, correct to four decimal places, is -0.5507.

22.



The graph gives us an estimate for the sum of the series $\sum_{n=1}^{\infty}(-1)^{n-1}\frac{n}{8^n}$ of 0.1.

$b_6=\frac{6}{8^6}\approx 0.000\,023$, so

$$\sum_{n=1}^{\infty}(-1)^{n-1}\frac{n}{8^n}\approx s_5=\sum_{n=1}^{5}(-1)^{n-1}\frac{n}{8^n}$$
$$\approx 0.125-0.03125+0.005\,859-0.000\,977+0.000\,153\approx 0.0988$$

Adding b_6 to s_5 does not change the fourth decimal place of s_5, so the sum of the series, correct to four decimal places, is 0.0988.

23. The series $\sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n^6}$ satisfies (i) of the Alternating Series Test because $\frac{1}{(n+1)^6} < \frac{1}{n^6}$ and (ii) $\lim_{n\to\infty} \frac{1}{n^6} = 0$, so the series is convergent. Now $b_5 = \frac{1}{5^6} = 0.000064 > 0.00005$ and $b_6 = \frac{1}{6^6} \approx 0.00002 < 0.00005$, so by the Alternating Series Estimation Theorem, $n = 5$. (That is, since the 6th term is less than the desired error, we need to add the first 5 terms to get the sum to the desired accuracy.)

24. The series $\sum_{n=1}^{\infty} \frac{\left(-\frac{1}{3}\right)^n}{n} = \sum_{n=1}^{\infty} (-1)^n \frac{1}{n3^n}$ satisfies (i) of the Alternating Series Test because $\frac{1}{(n+1)3^{n+1}} < \frac{1}{n3^n}$ and (ii) $\lim_{n\to\infty} \frac{1}{n3^n} = 0$, so the series is convergent. Now $b_5 = \frac{1}{5 \cdot 3^5} \approx 0.0008 > 0.0005$ and $b_6 = \frac{1}{6 \cdot 3^6} \approx 0.0002 < 0.0005$, so by the Alternating Series Estimation Theorem, $n = 5$. (That is, since the 6th term is less than the desired error, we need to add the first 5 terms to get the sum to the desired accuracy.)

25. The series $\sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{n^2 2^n}$ satisfies (i) of the Alternating Series Test because $\frac{1}{(n+1)^2 2^{n+1}} < \frac{1}{n^2 2^n}$ and (ii) $\lim_{n\to\infty} \frac{1}{n^2 2^n} = 0$, so the series is convergent. Now $b_5 = \frac{1}{5^2 2^5} = 0.00125 > 0.0005$ and $b_6 = \frac{1}{6^2 2^6} \approx 0.0004 < 0.0005$, so by the Alternating Series Estimation Theorem, $n = 5$. (That is, since the 6th term is less than the desired error, we need to add the first 5 terms to get the sum to the desired accuracy.)

26. The series $\sum_{n=1}^{\infty} \left(-\frac{1}{n}\right)^n = \sum_{n=1}^{\infty} (-1)^n \frac{1}{n^n}$ satisfies (i) of the Alternating Series Test because $\frac{1}{(n+1)^{n+1}} < \frac{1}{n^n}$ and (ii) $\lim_{n\to\infty} \frac{1}{n^n} = 0$, so the series is convergent. Now $b_5 = \frac{1}{5^5} = 0.00032 > 0.00005$ and $b_6 = \frac{1}{6^6} \approx 0.00002 < 0.00005$, so by the Alternating Series Estimation Theorem, $n = 5$. (That is, since the 6th term is less than the desired error, we need to add the first 5 terms to get the sum to the desired accuracy.)

27. $b_4 = \frac{1}{8!} = \frac{1}{40{,}320} \approx 0.000\,025$, so

$$\sum_{n=1}^{\infty} \frac{(-1)^n}{(2n)!} \approx s_3 = \sum_{n=1}^{3} \frac{(-1)^n}{(2n)!} = -\frac{1}{2} + \frac{1}{24} - \frac{1}{720} \approx -0.459\,722$$

Adding b_4 to s_3 does not change the fourth decimal place of s_3, so by the Alternating Series Estimation Theorem, the sum of the series, correct to four decimal places, is -0.4597.

28. $\sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n^6} \approx s_9 = \frac{1}{1^6} - \frac{1}{2^6} + \frac{1}{3^6} - \frac{1}{4^6} + \frac{1}{5^6} - \frac{1}{6^6} + \frac{1}{7^6} - \frac{1}{8^6} + \frac{1}{9^6} \approx 0.985\,552$. Subtracting $b_{10} = 1/10^6$ from s_9 does not change the fourth decimal place of s_9, so by the Alternating Series Estimation Theorem, the sum of the series, correct to four decimal places, is 0.9856.

29. $\sum_{n=1}^{\infty} (-1)^n n e^{-2n} \approx s_5 = -\frac{1}{e^2} + \frac{2}{e^4} - \frac{3}{e^6} + \frac{4}{e^8} - \frac{5}{e^{10}} \approx -0.105\,025$. Adding $b_6 = 6/e^{12} \approx 0.000\,037$ to s_5 does not change the fourth decimal place of s_5, so by the Alternating Series Estimation Theorem, the sum of the series, correct to four decimal places, is -0.1050.

30. $\displaystyle\sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{n4^n} \approx s_6 = \frac{1}{4} - \frac{1}{2\cdot 4^2} + \frac{1}{3\cdot 4^3} - \frac{1}{4\cdot 4^4} + \frac{1}{5\cdot 4^5} - \frac{1}{6\cdot 4^6} \approx 0.223136$. Adding $b_7 = \dfrac{1}{7\cdot 4^7} \approx 0.000\,0087$ to s_6 does not change the fourth decimal place of s_6, so by the Alternating Series Estimation Theorem, the sum of the series, correct to four decimal places, is 0.2231.

31. $\displaystyle\sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{n} = 1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \cdots + \frac{1}{49} - \frac{1}{50} + \frac{1}{51} - \frac{1}{52} + \cdots$. The 50th partial sum of this series is an underestimate, since $\displaystyle\sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{n} = s_{50} + \left(\frac{1}{51} - \frac{1}{52}\right) + \left(\frac{1}{53} - \frac{1}{54}\right) + \cdots$, and the terms in parentheses are all positive. The result can be seen geometrically in Figure 1.

32. If $p > 0$, $\dfrac{1}{(n+1)^p} \le \dfrac{1}{n^p}$ ($\{1/n^p\}$ is decreasing) and $\displaystyle\lim_{n\to\infty} \frac{1}{n^p} = 0$, so the series converges by the Alternating Series Test. If $p \le 0$, $\displaystyle\lim_{n\to\infty} \frac{(-1)^{n-1}}{n^p}$ does not exist, so the series diverges by the Test for Divergence. Thus, $\displaystyle\sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{n^p}$ converges $\Leftrightarrow$ $p > 0$.

33. Clearly $b_n = \dfrac{1}{n+p}$ is decreasing and eventually positive and $\displaystyle\lim_{n\to\infty} b_n = 0$ for any p. So the series $\displaystyle\sum_{n=1}^{\infty} \frac{(-1)^n}{n+p}$ converges (by the Alternating Series Test) for any p for which every b_n is defined, that is, $n + p \ne 0$ for $n \ge 1$, or p is not a negative integer.

34. Let $f(x) = \dfrac{(\ln x)^p}{x}$. Then $f'(x) = \dfrac{(\ln x)^{p-1}\,(p - \ln x)}{x^2} < 0$ if $x > e^p$ so f is eventually decreasing for every p. Clearly $\displaystyle\lim_{n\to\infty} \frac{(\ln n)^p}{n} = 0$ if $p \le 0$, and if $p > 0$ we can apply l'Hospital's Rule $[\![p+1]\!]$ times to get a limit of 0 as well. So the series $\displaystyle\sum_{n=2}^{\infty} (-1)^{n-1} \frac{(\ln n)^p}{n}$ converges for all p (by the Alternating Series Test).

35. $\sum b_{2n} = \sum 1/(2n)^2$ clearly converges (by comparison with the p-series for $p = 2$). So suppose that $\sum (-1)^{n-1}\, b_n$ converges. Then by Theorem 11.2.8(ii), so does $\sum \left[(-1)^{n-1} b_n + b_n\right] = 2\left(1 + \frac{1}{3} + \frac{1}{5} + \cdots\right) = 2\sum \dfrac{1}{2n-1}$. But this diverges by comparison with the harmonic series, a contradiction. Therefore, $\sum (-1)^{n-1}\, b_n$ must diverge. The Alternating Series Test does not apply since $\{b_n\}$ is not decreasing.

36. (a) We will prove this by induction. Let $P(n)$ be the proposition that $s_{2n} = h_{2n} - h_n$. $P(1)$ is the statement $s_2 = h_2 - h_1$, which is true since $1 - \frac{1}{2} = \left(1 + \frac{1}{2}\right) - 1$. So suppose that $P(n)$ is true. We will show that $P(n+1)$ must be true as a consequence.

$$\begin{aligned} h_{2n+2} - h_{n+1} &= \left(h_{2n} + \frac{1}{2n+1} + \frac{1}{2n+2}\right) - \left(h_n + \frac{1}{n+1}\right) = (h_{2n} - h_n) + \frac{1}{2n+1} - \frac{1}{2n+2} \\ &= s_{2n} + \frac{1}{2n+1} - \frac{1}{2n+2} = s_{2n+2} \end{aligned}$$

which is $P(n+1)$, and proves that $s_{2n} = h_{2n} - h_n$ for all n.

(b) We know that $h_{2n} - \ln(2n) \to \gamma$ and $h_n - \ln n \to \gamma$ as $n \to \infty$. So

$s_{2n} = h_{2n} - h_n = [h_{2n} - \ln(2n)] - (h_n - \ln n) + [\ln(2n) - \ln n]$, and

$\lim\limits_{n\to\infty} s_{2n} = \gamma - \gamma + \lim\limits_{n\to\infty} [\ln(2n) - \ln n] = \lim\limits_{n\to\infty} (\ln 2 + \ln n - \ln n) = \ln 2.$

11.6 Absolute Convergence and the Ratio and Root Tests

1. (a) Since $\lim\limits_{n\to\infty} \left|\dfrac{a_{n+1}}{a_n}\right| = 8 > 1$, part (b) of the Ratio Test tells us that the series $\sum a_n$ is divergent.

(b) Since $\lim\limits_{n\to\infty} \left|\dfrac{a_{n+1}}{a_n}\right| = 0.8 < 1$, part (a) of the Ratio Test tells us that the series $\sum a_n$ is absolutely convergent (and therefore convergent).

(c) Since $\lim\limits_{n\to\infty} \left|\dfrac{a_{n+1}}{a_n}\right| = 1$, the Ratio Test fails and the series $\sum a_n$ might converge or it might diverge.

2. $b_n = \dfrac{1}{\sqrt{n}} > 0$ for $n \geq 1$, $\{b_n\}$ is decreasing for $n \geq 1$, and $\lim\limits_{n\to\infty} b_n = 0$, so $\sum\limits_{n=1}^{\infty} \dfrac{(-1)^{n-1}}{\sqrt{n}}$ converges by the Alternating Series Test. To determine absolute convergence, note that $\sum\limits_{n=1}^{\infty} \dfrac{1}{\sqrt{n}}$ diverges because it is a p-series with $p = \frac{1}{2} \leq 1$. Thus, the series $\sum\limits_{n=1}^{\infty} \dfrac{(-1)^{n-1}}{\sqrt{n}}$ is conditionally convergent.

3. $b_n = \dfrac{1}{5n+1} > 0$ for $n \geq 0$, $\{b_n\}$ is decreasing for $n \geq 0$, and $\lim\limits_{n\to\infty} b_n = 0$, so $\sum\limits_{n=0}^{\infty} \dfrac{(-1)^n}{5n+1}$ converges by the Alternating Series Test. To determine absolute convergence, choose $a_n = \dfrac{1}{n}$ to get

$\lim\limits_{n\to\infty} \dfrac{a_n}{b_n} = \lim\limits_{n\to\infty} \dfrac{1/n}{1/(5n+1)} = \lim\limits_{n\to\infty} \dfrac{5n+1}{n} = 5 > 0$, so $\sum\limits_{n=1}^{\infty} \dfrac{1}{5n+1}$ diverges by the Limit Comparison Test with the harmonic series. Thus, the series $\sum\limits_{n=0}^{\infty} \dfrac{(-1)^n}{5n+1}$ is conditionally convergent.

4. $0 < \dfrac{1}{n^3+1} < \dfrac{1}{n^3}$ for $n \geq 1$ and $\sum\limits_{n=1}^{\infty} \dfrac{1}{n^3}$ is a convergent p-series ($p = 3 > 1$), so $\sum\limits_{n=1}^{\infty} \dfrac{1}{n^3+1}$ converges by comparison and the series $\sum\limits_{n=1}^{\infty} \dfrac{(-1)^n}{n^3+1}$ is absolutely convergent.

5. $0 < \left|\dfrac{\sin n}{2^n}\right| < \dfrac{1}{2^n}$ for $n \geq 1$ and $\sum\limits_{n=1}^{\infty} \dfrac{1}{2^n}$ is a convergent geometric series ($r = \frac{1}{2} < 1$), so $\sum\limits_{n=1}^{\infty} \left|\dfrac{\sin n}{2^n}\right|$ converges by comparison and the series $\sum\limits_{n=1}^{\infty} \dfrac{\sin n}{2^n}$ is absolutely convergent.

6. $b_n = \dfrac{n}{n^2+4} > 0$ for $n \geq 1$, $\{b_n\}$ is decreasing for $n \geq 2$, and $\lim\limits_{n\to\infty} b_n = 0$, so $\sum\limits_{n=1}^{\infty} (-1)^{n-1} \dfrac{n}{n^2+4}$ converges by the Alternating Series Test. To determine absolute convergence, choose $a_n = \dfrac{1}{n}$ to get

$\lim\limits_{n\to\infty}\dfrac{a_n}{b_n}=\lim\limits_{n\to\infty}\dfrac{1/n}{n/(n^2+4)}=\lim\limits_{n\to\infty}\dfrac{n^2+4}{n^2}=\lim\limits_{n\to\infty}\dfrac{1+4/n^2}{1}=1>0$, so $\sum\limits_{n=1}^{\infty}\dfrac{n}{n^2+4}$ diverges by the Limit Comparison Test with the harmonic series. Thus, the series $\sum\limits_{n=1}^{\infty}(-1)^{n-1}\dfrac{n}{n^2+4}$ is conditionally convergent.

7. $\lim\limits_{n\to\infty}\left|\dfrac{a_{n+1}}{a_n}\right|=\lim\limits_{n\to\infty}\left|\dfrac{n+1}{5^{n+1}}\cdot\dfrac{5^n}{n}\right|=\lim\limits_{n\to\infty}\left|\dfrac{1}{5}\cdot\dfrac{n+1}{n}\right|=\dfrac{1}{5}\lim\limits_{n\to\infty}\dfrac{1+1/n}{1}=\dfrac{1}{5}(1)=\dfrac{1}{5}<1$, so the series $\sum\limits_{n=1}^{\infty}\dfrac{n}{5^n}$ is absolutely convergent by the Ratio Test.

8. $\lim\limits_{n\to\infty}\left|\dfrac{a_{n+1}}{a_n}\right|=\lim\limits_{n\to\infty}\left|\dfrac{(-2)^{n+1}}{(n+1)^2}\cdot\dfrac{n^2}{(-2)^n}\right|=\lim\limits_{n\to\infty}\left|(-2)\dfrac{n^2}{(n+1)^2}\right|=2\lim\limits_{n\to\infty}\dfrac{1}{(1+1/n)^2}=2(1)=2>1$, so the series $\sum\limits_{n=1}^{\infty}\dfrac{(-2)^n}{n^2}$ is divergent by the Ratio Test.

9. $\lim\limits_{n\to\infty}\left|\dfrac{a_{n+1}}{a_n}\right|=\lim\limits_{n\to\infty}\left|\dfrac{(-1)^n3^{n+1}}{2^{n+1}(n+1)^3}\cdot\dfrac{2^nn^3}{(-1)^{n-1}3^n}\right|=\lim\limits_{n\to\infty}\left|\left(-\dfrac{3}{2}\right)\dfrac{n^3}{(n+1)^3}\right|=\dfrac{3}{2}\lim\limits_{n\to\infty}\dfrac{1}{(1+1/n)^3}=\dfrac{3}{2}(1)=\dfrac{3}{2}>1$, so the series $\sum\limits_{n=1}^{\infty}(-1)^{n-1}\dfrac{3^n}{2^nn^3}$ is divergent by the Ratio Test.

10. $\lim\limits_{n\to\infty}\left|\dfrac{a_{n+1}}{a_n}\right|=\lim\limits_{n\to\infty}\left|\dfrac{(-3)^{n+1}}{[2(n+1)+1]!}\cdot\dfrac{(2n+1)!}{(-3)^n}\right|=\lim\limits_{n\to\infty}\left|(-3)\dfrac{1}{(2n+3)(2n+2)}\right|=3\lim\limits_{n\to\infty}\dfrac{1}{(2n+3)(2n+2)}$

$=3(0)=0<1$

so the series $\sum\limits_{n=0}^{\infty}\dfrac{(-3)^n}{(2n+1)!}$ is absolutely convergent by the Ratio Test.

11. $\lim\limits_{k\to\infty}\left|\dfrac{a_{k+1}}{a_k}\right|=\lim\limits_{k\to\infty}\left|\dfrac{1}{(k+1)!}\cdot\dfrac{k!}{1}\right|=\lim\limits_{k\to\infty}\dfrac{1}{k+1}=0<1$, so the series $\sum\limits_{k=1}^{\infty}\dfrac{1}{k!}$ is absolutely convergent by the Ratio Test.

Since the terms of this series are positive, absolute convergence is the same as convergence.

12. $\lim\limits_{k\to\infty}\left|\dfrac{a_{k+1}}{a_k}\right|=\lim\limits_{k\to\infty}\left|\dfrac{(k+1)e^{-(k+1)}}{ke^{-k}}\right|=\lim\limits_{k\to\infty}\left(\dfrac{k+1}{k}\cdot e^{-1}\right)=\dfrac{1}{e}\lim\limits_{k\to\infty}\dfrac{1+1/k}{1}=\dfrac{1}{e}(1)=\dfrac{1}{e}<1$, so the series $\sum\limits_{k=1}^{\infty}ke^{-k}$ is absolutely convergent by the Ratio Test. Since the terms of this series are positive, absolute convergence is the same as convergence.

13. $\lim\limits_{n\to\infty}\left|\dfrac{a_{n+1}}{a_n}\right|=\lim\limits_{n\to\infty}\left[\dfrac{10^{n+1}}{(n+2)\,4^{2n+3}}\cdot\dfrac{(n+1)\,4^{2n+1}}{10^n}\right]=\lim\limits_{n\to\infty}\left(\dfrac{10}{4^2}\cdot\dfrac{n+1}{n+2}\right)=\dfrac{5}{8}<1$, so the series $\sum\limits_{n=1}^{\infty}\dfrac{10^n}{(n+1)4^{2n+1}}$ is absolutely convergent by the Ratio Test. Since the terms of this series are positive, absolute convergence is the same as convergence.

14. $\lim\limits_{n\to\infty}\left|\dfrac{a_{n+1}}{a_n}\right|=\lim\limits_{n\to\infty}\left[\dfrac{(n+1)!}{100^{n+1}}\cdot\dfrac{100^n}{n!}\right]=\lim\limits_{n\to\infty}\dfrac{n+1}{100}=\infty$, so the series $\sum\limits_{n=1}^{\infty}\dfrac{n!}{100^n}$ diverges by the Ratio Test.

15. $\lim\limits_{n\to\infty}\left|\dfrac{a_{n+1}}{a_n}\right|=\lim\limits_{n\to\infty}\left|\dfrac{(n+1)\pi^{n+1}}{(-3)^n}\cdot\dfrac{(-3)^{n-1}}{n\pi^n}\right|=\lim\limits_{n\to\infty}\left|\dfrac{\pi}{-3}\cdot\dfrac{n+1}{n}\right|=\dfrac{\pi}{3}\lim\limits_{n\to\infty}\dfrac{1+1/n}{1}=\dfrac{\pi}{3}(1)=\dfrac{\pi}{3}>1$, so the series $\sum\limits_{n=1}^{\infty}\dfrac{n\pi^n}{(-3)^{n-1}}$ diverges by the Ratio Test. *Or:* Since $\lim\limits_{n\to\infty}|a_n|=\infty$, the series diverges by the Test for Divergence.

16. $\lim\limits_{n\to\infty}\left|\dfrac{a_{n+1}}{a_n}\right| = \lim\limits_{n\to\infty}\left|\dfrac{(n+1)^{10}}{(-10)^{n+2}}\cdot\dfrac{(-10)^{n+1}}{n^{10}}\right| = \lim\limits_{n\to\infty}\left|\dfrac{1}{-10}\left(\dfrac{n+1}{n}\right)^{10}\right| = \dfrac{1}{10}\lim\limits_{n\to\infty}\left(1+\dfrac{1}{n}\right)^{10} = \dfrac{1}{10}(1) = \dfrac{1}{10} < 1,$

so the series $\sum\limits_{n=1}^{\infty}\dfrac{n^{10}}{(-10)^{n+1}}$ is absolutely convergent by the Ratio Test.

17. $\lim\limits_{n\to\infty}\left|\dfrac{a_{n+1}}{a_n}\right| = \lim\limits_{n\to\infty}\left|\dfrac{\cos[(n+1)\pi/3]}{(n+1)!}\cdot\dfrac{n!}{\cos(n\pi/3)}\right| = \lim\limits_{n\to\infty}\left|\dfrac{\cos[(n+1)\pi/3]}{(n+1)\cos(n\pi/3)}\right| = \lim\limits_{n\to\infty}\dfrac{c}{n+1} = 0 < 1$ (where

$0 < c \le 2$ for all positive integers n), so the series $\sum\limits_{n=1}^{\infty}\dfrac{\cos(n\pi/3)}{n!}$ is absolutely convergent by the Ratio Test.

18. $\lim\limits_{n\to\infty}\left|\dfrac{a_{n+1}}{a_n}\right| = \lim\limits_{n\to\infty}\left|\dfrac{(n+1)!}{(n+1)^{n+1}}\cdot\dfrac{n^n}{n!}\right| = \lim\limits_{n\to\infty}\dfrac{(n+1)n^n}{(n+1)^{n+1}} = \lim\limits_{n\to\infty}\dfrac{n^n}{(n+1)^n} = \lim\limits_{n\to\infty}\dfrac{1}{(1+1/n)^n} = \dfrac{1}{e} < 1$, so the

series $\sum\limits_{n=1}^{\infty}\dfrac{n!}{n^n}$ is absolutely convergent by the Ratio Test.

19. $\lim\limits_{n\to\infty}\left|\dfrac{a_{n+1}}{a_n}\right| = \lim\limits_{n\to\infty}\left|\dfrac{(n+1)^{100}100^{n+1}}{(n+1)!}\cdot\dfrac{n!}{n^{100}100^n}\right| = \lim\limits_{n\to\infty}\dfrac{100}{n+1}\left(\dfrac{n+1}{n}\right)^{100} = \lim\limits_{n\to\infty}\dfrac{100}{n+1}\left(1+\dfrac{1}{n}\right)^{100}$

$= 0\cdot 1 = 0 < 1$

so the series $\sum\limits_{n=1}^{\infty}\dfrac{n^{100}100^n}{n!}$ is absolutely convergent by the Ratio Test.

20. $\lim\limits_{n\to\infty}\left|\dfrac{a_{n+1}}{a_n}\right| = \lim\limits_{n\to\infty}\left|\dfrac{[2(n+1)]!}{[(n+1)!]^2}\cdot\dfrac{(n!)^2}{(2n)!}\right| = \lim\limits_{n\to\infty}\dfrac{(2n+2)(2n+1)}{(n+1)(n+1)} = \lim\limits_{n\to\infty}\dfrac{(2+2/n)(2+1/n)}{(1+1/n)(1+1/n)} = \dfrac{2\cdot 2}{1\cdot 1} = 4 > 1,$

so the series $\sum\limits_{n=1}^{\infty}\dfrac{(2n)!}{(n!)^2}$ diverges by the Ratio Test.

21. $\lim\limits_{n\to\infty}\left|\dfrac{a_{n+1}}{a_n}\right| = \lim\limits_{n\to\infty}\left|\dfrac{(-1)^n(n+1)!}{1\cdot 3\cdot 5\cdot\cdots\cdot(2n-1)(2n+1)}\cdot\dfrac{1\cdot 3\cdot 5\cdot\cdots\cdot(2n-1)}{(-1)^{n-1}n!}\right| = \lim\limits_{n\to\infty}\dfrac{n+1}{2n+1}$

$= \lim\limits_{n\to\infty}\dfrac{1+1/n}{2+1/n} = \dfrac{1}{2} < 1,$

so the series $1 - \dfrac{2!}{1\cdot 3} + \dfrac{3!}{1\cdot 3\cdot 5} - \dfrac{4!}{1\cdot 3\cdot 5\cdot 7} + \cdots + (-1)^{n-1}\dfrac{n!}{1\cdot 3\cdot 5\cdot\cdots\cdot(2n-1)} + \cdots$ is absolutely convergent by the Ratio Test.

22. $\dfrac{2}{3} + \dfrac{2\cdot 5}{3\cdot 5} + \dfrac{2\cdot 5\cdot 8}{3\cdot 5\cdot 7} + \dfrac{2\cdot 5\cdot 8\cdot 11}{3\cdot 5\cdot 7\cdot 9} + \cdots = \sum\limits_{n=1}^{\infty}\dfrac{2\cdot 5\cdot 8\cdot 11\cdot\cdots\cdot(3n-1)}{3\cdot 5\cdot 7\cdot 9\cdot\cdots\cdot(2n+1)}.$

$$\lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty}\left|\frac{2\cdot 5\cdot 8\cdot\cdots\cdot(3n-1)(3n+2)}{3\cdot 5\cdot 7\cdot\cdots\cdot(2n+1)(2n+3)}\cdot\frac{3\cdot 5\cdot 7\cdot\cdots\cdot(2n+1)}{2\cdot 5\cdot 8\cdot\cdots\cdot(3n-1)}\right|$$
$$= \lim_{n\to\infty}\frac{3n+2}{2n+3} = \lim_{n\to\infty}\frac{3+2/n}{2+3/n} = \frac{3}{2} > 1,$$

so the given series diverges by the Ratio Test.

23. $\lim\limits_{n\to\infty}\left|\dfrac{a_{n+1}}{a_n}\right| = \lim\limits_{n\to\infty}\left|\dfrac{2\cdot 4\cdot 6\cdot\cdots\cdot(2n)(2n+2)}{(n+1)!}\cdot\dfrac{n!}{2\cdot 4\cdot 6\cdot\cdots\cdot(2n)}\right| = \lim\limits_{n\to\infty}\dfrac{2n+2}{n+1} = \lim\limits_{n\to\infty}\dfrac{2(n+1)}{n+1} = 2 > 1$, so

the series $\sum\limits_{n=1}^{\infty}\dfrac{2\cdot 4\cdot 6\cdot\cdots\cdot(2n)}{n!}$ diverges by the Ratio Test.

24. $\lim\limits_{n\to\infty}\left|\dfrac{a_{n+1}}{a_n}\right| = \lim\limits_{n\to\infty}\left|\dfrac{2^{n+1}(n+1)!}{5\cdot 8\cdot 11\cdot\cdots\cdot(3n+2)(3n+5)}\cdot\dfrac{5\cdot 8\cdot 11\cdot\cdots\cdot(3n+2)}{2^n n!}\right| = \lim\limits_{n\to\infty}\dfrac{2(n+1)}{3n+5} = \dfrac{2}{3} < 1$, so the series $\sum\limits_{n=1}^{\infty}(-1)^n\dfrac{2^n n!}{5\cdot 8\cdot 11\cdot\cdots\cdot(3n+2)}$ is absolutely convergent by the Ratio Test.

25. $\lim\limits_{n\to\infty}\sqrt[n]{|a_n|} = \lim\limits_{n\to\infty}\dfrac{n^2+1}{2n^2+1} = \lim\limits_{n\to\infty}\dfrac{1+1/n^2}{2+1/n^2} = \dfrac{1}{2} < 1$, so the series $\sum\limits_{n=1}^{\infty}\left(\dfrac{n^2+1}{2n^2+1}\right)^n$ is absolutely convergent by the Root Test.

26. $\lim\limits_{n\to\infty}\sqrt[n]{|a_n|} = \lim\limits_{n\to\infty}\sqrt[n]{\left|\dfrac{(-2)^n}{n^n}\right|} = \lim\limits_{n\to\infty}\dfrac{2}{n} = 0 < 1$, so the series $\sum\limits_{n=1}^{\infty}\dfrac{(-2)^n}{n^n}$ is absolutely convergent by the Root Test.

27. $\lim\limits_{n\to\infty}\sqrt[n]{|a_n|} = \lim\limits_{n\to\infty}\sqrt[n]{\left|\dfrac{(-1)^{n-1}}{(\ln n)^n}\right|} = \lim\limits_{n\to\infty}\dfrac{1}{\ln n} = 0 < 1$, so the series $\sum\limits_{n=2}^{\infty}\dfrac{(-1)^{n-1}}{(\ln n)^n}$ is absolutely convergent by the Root Test.

28. $\lim\limits_{n\to\infty}\sqrt[n]{|a_n|} = \lim\limits_{n\to\infty}\sqrt[n]{\left|\left(\dfrac{-2n}{n+1}\right)^{5n}\right|} = \lim\limits_{n\to\infty}\dfrac{2^5\,n^5}{(n+1)^5} = 32\lim\limits_{n\to\infty}\dfrac{1}{\left(\dfrac{n+1}{n}\right)^5} = 32\lim\limits_{n\to\infty}\dfrac{1}{(1+1/n)^5}$

$= 32(1) = 32 > 1,$

so the series $\sum\limits_{n=1}^{\infty}\left(\dfrac{-2n}{n+1}\right)^{5n}$ diverges by the Root Test.

29. $\lim\limits_{n\to\infty}\sqrt[n]{|a_n|} = \lim\limits_{n\to\infty}\sqrt[n]{\left(1+\dfrac{1}{n}\right)^{n^2}} = \lim\limits_{n\to\infty}\left(1+\dfrac{1}{n}\right)^n = e > 1$ [by Equation 3.6.6], so the series $\sum\limits_{n=1}^{\infty}\left(1+\dfrac{1}{n}\right)^{n^2}$ diverges by the Root Test.

30. $\lim\limits_{n\to\infty}\sqrt[n]{|a_n|} = \lim\limits_{n\to\infty}\sqrt[n]{|(\arctan n)^n|} = \lim\limits_{n\to\infty}\arctan n = \frac{\pi}{2} > 1$, so the series $\sum\limits_{n=0}^{\infty}(\arctan n)^n$ diverges by the Root Test.

31. $\sum\limits_{n=2}^{\infty}\dfrac{(-1)^n}{\ln n}$ converges by the Alternating Series Test since $\lim\limits_{n\to\infty}\dfrac{1}{\ln n} = 0$ and $\left\{\dfrac{1}{\ln n}\right\}$ is decreasing. Now $\ln n < n$, so $\dfrac{1}{\ln n} > \dfrac{1}{n}$, and since $\sum\limits_{n=2}^{\infty}\dfrac{1}{n}$ is the divergent (partial) harmonic series, $\sum\limits_{n=2}^{\infty}\dfrac{1}{\ln n}$ diverges by the Comparison Test. Thus, $\sum\limits_{n=2}^{\infty}\dfrac{(-1)^n}{\ln n}$ is conditionally convergent.

32. $\lim\limits_{n\to\infty}\sqrt[n]{|a_n|} = \lim\limits_{n\to\infty}\sqrt[n]{\left|\left(\dfrac{1-n}{2+3n}\right)^n\right|} = \lim\limits_{n\to\infty}\dfrac{n-1}{3n+2} = \lim\limits_{n\to\infty}\dfrac{1-1/n}{3+2/n} = \dfrac{1}{3} < 1$, so the series $\sum\limits_{n=1}^{\infty}\left(\dfrac{1-n}{2+3n}\right)^n$ is absolutely convergent by the Root Test.

33. $\lim\limits_{n\to\infty}\left|\dfrac{a_{n+1}}{a_n}\right| = \lim\limits_{n\to\infty}\left|\dfrac{(-9)^{n+1}}{(n+1)10^{n+2}}\cdot\dfrac{n10^{n+1}}{(-9)^n}\right| = \lim\limits_{n\to\infty}\left|\dfrac{(-9)n}{10(n+1)}\right| = \dfrac{9}{10}\lim\limits_{n\to\infty}\dfrac{1}{1+1/n} = \dfrac{9}{10}(1) = \dfrac{9}{10} < 1$, so the series $\sum\limits_{n=1}^{\infty}\dfrac{(-9)^n}{n10^{n+1}}$ is absolutely convergent by the Ratio Test.

34. $\lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty}\left|\frac{(n+1)5^{2n+2}}{10^{n+2}}\cdot\frac{10^{n+1}}{n5^{2n}}\right| = \lim_{n\to\infty}\frac{5^2(n+1)}{10n} = \frac{5}{2}\lim_{n\to\infty}\left(1+\frac{1}{n}\right) = \frac{5}{2}(1) = \frac{5}{2} > 1$, so the series $\sum_{n=1}^{\infty}\frac{n5^{2n}}{10^{n+1}}$ diverges by the Ratio Test. *Or:* Since $\lim_{n\to\infty} a_n = \infty$, the series diverges by the Test for Divergence.

35. $\lim_{n\to\infty}\sqrt[n]{|a_n|} = \lim_{n\to\infty}\sqrt[n]{\left|\left(\frac{n}{\ln n}\right)^n\right|} = \lim_{n\to\infty}\frac{n}{\ln n} = \lim_{x\to\infty}\frac{x}{\ln x} \overset{\text{H}}{=} \lim_{x\to\infty}\frac{1}{1/x} = \lim_{x\to\infty} x = \infty$, so the series $\sum_{n=2}^{\infty}\left(\frac{n}{\ln n}\right)^n$ diverges by the Root Test.

36. $\left|\frac{\sin(n\pi/6)}{1+n\sqrt{n}}\right| \le \frac{1}{1+n\sqrt{n}} < \frac{1}{n^{3/2}}$, so the series $\sum_{n=1}^{\infty}\frac{\sin(n\pi/6)}{1+n\sqrt{n}}$ converges by comparison with the convergent p-series $\sum_{n=1}^{\infty}\frac{1}{n^{3/2}}$ ($p=\frac{3}{2}>1$). It follows that the given series is absolutely convergent.

37. $\left|\frac{(-1)^n\arctan n}{n^2}\right| < \frac{\pi/2}{n^2}$, so since $\sum_{n=1}^{\infty}\frac{\pi/2}{n^2} = \frac{\pi}{2}\sum_{n=1}^{\infty}\frac{1}{n^2}$ converges ($p=2>1$), the given series $\sum_{n=1}^{\infty}\frac{(-1)^n\arctan n}{n^2}$ converges absolutely by the Comparison Test.

38. The function $f(x) = \frac{1}{x\ln x}$ is continuous, positive, and decreasing on $[2,\infty)$.

$\int_2^{\infty}\frac{1}{x\ln x}\,dx = \lim_{t\to\infty}\int_2^t\frac{1}{x\ln x}\,dx = \lim_{t\to\infty}\left[\ln(\ln x)\right]_2^t = \lim_{t\to\infty}\left[(\ln(\ln t) - \ln(\ln 2)\right] = \infty$, so the series $\sum_{n=2}^{\infty}\frac{(-1)^n}{n\ln n}$ diverges by the Integral Test. Now $\{b_n\} = \left\{\frac{1}{n\ln n}\right\}$ with $n\ge 2$ is a decreasing sequence of positive terms and $\lim_{n\to\infty} b_n = 0$. Thus, $\sum_{n=2}^{\infty}\frac{(-1)^n}{n\ln n}$ converges by the Alternating Series Test. It follows that $\sum_{n=2}^{\infty}\frac{(-1)^n}{n\ln n}$ is conditionally convergent.

39. By the recursive definition, $\lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty}\left|\frac{5n+1}{4n+3}\right| = \frac{5}{4} > 1$, so the series diverges by the Ratio Test.

40. By the recursive definition, $\lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty}\left|\frac{2+\cos n}{\sqrt{n}}\right| = 0 < 1$, so the series converges absolutely by the Ratio Test.

41. The series $\sum_{n=1}^{\infty}\frac{b_n^n\cos n\pi}{n} = \sum_{n=1}^{\infty}(-1)^n\frac{b_n^n}{n}$, where $b_n > 0$ for $n\ge 1$ and $\lim_{n\to\infty} b_n = \frac{1}{2}$.

$\lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty}\left|\frac{(-1)^{n+1}b_n^{n+1}}{n+1}\cdot\frac{n}{(-1)^n b_n^n}\right| = \lim_{n\to\infty} b_n\frac{n}{n+1} = \frac{1}{2}(1) = \frac{1}{2} < 1$, so the series $\sum_{n=1}^{\infty}\frac{b_n^n\cos n\pi}{n}$ is absolutely convergent by the Ratio Test.

42.
$$\lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty}\left|\frac{(-1)^{n+1}(n+1)!}{(n+1)^{n+1}b_1b_2\cdots b_nb_{n+1}}\cdot\frac{n^nb_1b_2\cdots b_n}{(-1)^n\,n!}\right| = \lim_{n\to\infty}\left|\frac{(-1)(n+1)n^n}{b_{n+1}(n+1)^{n+1}}\right| = \lim_{n\to\infty}\frac{n^n}{b_{n+1}(n+1)^n}$$
$$= \lim_{n\to\infty}\frac{1}{b_{n+1}}\left(\frac{n}{n+1}\right)^n = \lim_{n\to\infty}\frac{1}{b_{n+1}}\left(\frac{1}{1+1/n}\right)^n = \lim_{n\to\infty}\frac{1}{b_{n+1}(1+1/n)^n} = \frac{1}{\frac{1}{2}e} = \frac{2}{e} < 1$$

so the series $\sum_{n=1}^{\infty}\frac{(-1)^n\,n!}{n^nb_1b_2b_3\cdots b_n}$ is absolutely convergent by the Ratio Test.

43. (a) $\lim_{n\to\infty}\left|\dfrac{1/(n+1)^3}{1/n^3}\right| = \lim_{n\to\infty}\dfrac{n^3}{(n+1)^3} = \lim_{n\to\infty}\dfrac{1}{(1+1/n)^3} = 1.$ Inconclusive

(b) $\lim_{n\to\infty}\left|\dfrac{(n+1)}{2^{n+1}}\cdot\dfrac{2^n}{n}\right| = \lim_{n\to\infty}\dfrac{n+1}{2n} = \lim_{n\to\infty}\left(\dfrac{1}{2}+\dfrac{1}{2n}\right) = \dfrac{1}{2}.$ Conclusive (convergent)

(c) $\lim_{n\to\infty}\left|\dfrac{(-3)^n}{\sqrt{n+1}}\cdot\dfrac{\sqrt{n}}{(-3)^{n-1}}\right| = 3\lim_{n\to\infty}\sqrt{\dfrac{n}{n+1}} = 3\lim_{n\to\infty}\sqrt{\dfrac{1}{1+1/n}} = 3.$ Conclusive (divergent)

(d) $\lim_{n\to\infty}\left|\dfrac{\sqrt{n+1}}{1+(n+1)^2}\cdot\dfrac{1+n^2}{\sqrt{n}}\right| = \lim_{n\to\infty}\left[\sqrt{1+\dfrac{1}{n}}\cdot\dfrac{1/n^2+1}{1/n^2+(1+1/n)^2}\right] = 1.$ Inconclusive

44. We use the Ratio Test:

$$\lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty}\left|\frac{[(n+1)!]^2/[k(n+1)]!}{(n!)^2/(kn)!}\right| = \lim_{n\to\infty}\left|\frac{(n+1)^2}{[k(n+1)]\,[k(n+1)-1]\cdots[kn+1]}\right|$$

Now if $k=1$, then this is equal to $\lim_{n\to\infty}\left|\dfrac{(n+1)^2}{(n+1)}\right| = \infty$, so the series diverges; if $k=2$, the limit is $\lim_{n\to\infty}\left|\dfrac{(n+1)^2}{(2n+2)(2n+1)}\right| = \dfrac{1}{4} < 1$, so the series converges, and if $k>2$, then the highest power of n in the denominator is larger than 2, and so the limit is 0, indicating convergence. So the series converges for $k \geq 2$.

45. (a) $\lim_{n\to\infty}\left|\dfrac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty}\left|\dfrac{x^{n+1}}{(n+1)!}\cdot\dfrac{n!}{x^n}\right| = \lim_{n\to\infty}\left|\dfrac{x}{n+1}\right| = |x|\lim_{n\to\infty}\dfrac{1}{n+1} = |x|\cdot 0 = 0 < 1$, so by the Ratio Test the series $\sum_{n=0}^{\infty}\dfrac{x^n}{n!}$ converges for all x.

(b) Since the series of part (a) always converges, we must have $\lim_{n\to\infty}\dfrac{x^n}{n!} = 0$ by Theorem 11.2.6.

46. (a)
$$\begin{aligned}R_n &= a_{n+1}+a_{n+2}+a_{n+3}+a_{n+4}+\cdots = a_{n+1}\left(1+\frac{a_{n+2}}{a_{n+1}}+\frac{a_{n+3}}{a_{n+1}}+\frac{a_{n+4}}{a_{n+1}}+\cdots\right)\\ &= a_{n+1}\left(1+\frac{a_{n+2}}{a_{n+1}}+\frac{a_{n+3}}{a_{n+2}}\frac{a_{n+2}}{a_{n+1}}+\frac{a_{n+4}}{a_{n+3}}\frac{a_{n+3}}{a_{n+2}}\frac{a_{n+2}}{a_{n+1}}+\cdots\right)\\ &= a_{n+1}\left(1+r_{n+1}+r_{n+2}r_{n+1}+r_{n+3}r_{n+2}r_{n+1}+\cdots\right) \quad (\star)\\ &\leq a_{n+1}\left(1+r_{n+1}+r_{n+1}^2+r_{n+1}^3+\cdots\right) \quad [\text{since } \{r_n\} \text{ is decreasing}] \quad = \frac{a_{n+1}}{1-r_{n+1}}\end{aligned}$$

(b) Note that since $\{r_n\}$ is increasing and $r_n \to L$ as $n\to\infty$, we have $r_n < L$ for all n. So, starting with equation $(\star)$,

$$R_n = a_{n+1}(1+r_{n+1}+r_{n+2}r_{n+1}+r_{n+3}r_{n+2}r_{n+1}+\cdots) \leq a_{n+1}\left(1+L+L^2+L^3+\cdots\right) = \frac{a_{n+1}}{1-L}.$$

47. (a) $s_5 = \sum_{n=1}^{5}\dfrac{1}{n2^n} = \dfrac{1}{2}+\dfrac{1}{8}+\dfrac{1}{24}+\dfrac{1}{64}+\dfrac{1}{160} = \dfrac{661}{960} \approx 0.68854.$ Now the ratios

$r_n = \dfrac{a_{n+1}}{a_n} = \dfrac{n2^n}{(n+1)2^{n+1}} = \dfrac{n}{2(n+1)}$ form an increasing sequence, since

$r_{n+1}-r_n = \dfrac{n+1}{2(n+2)} - \dfrac{n}{2(n+1)} = \dfrac{(n+1)^2-n(n+2)}{2(n+1)(n+2)} = \dfrac{1}{2(n+1)(n+2)} > 0.$ So by Exercise 46(b), the error in using s_5 is $R_5 \leq \dfrac{a_6}{1-\lim_{n\to\infty} r_n} = \dfrac{1/\left(6\cdot 2^6\right)}{1-1/2} = \dfrac{1}{192} \approx 0.00521.$

(b) The error in using s_n as an approximation to the sum is $R_n = \dfrac{a_{n+1}}{1-\frac{1}{2}} = \dfrac{2}{(n+1)2^{n+1}}$. We want $R_n < 0.00005 \quad \Leftrightarrow$

$\dfrac{1}{(n+1)2^n} < 0.00005 \quad \Leftrightarrow \quad (n+1)2^n > 20{,}000$. To find such an n we can use trial and error or a graph. We calculate

$(11+1)2^{11} = 24{,}576$, so $s_{11} = \sum\limits_{n=1}^{11} \dfrac{1}{n2^n} \approx 0.693109$ is within 0.00005 of the actual sum.

48. $s_{10} = \sum\limits_{n=1}^{10} \dfrac{n}{2^n} = \dfrac{1}{2} + \dfrac{2}{4} + \dfrac{3}{8} + \cdots + \dfrac{10}{1024} \approx 1.988$. The ratios $r_n = \dfrac{a_{n+1}}{a_n} = \dfrac{n+1}{2^{n+1}} \cdot \dfrac{2^n}{n} = \dfrac{n+1}{2n} = \dfrac{1}{2}\left(1 + \dfrac{1}{n}\right)$ form a decreasing sequence, and $r_{11} = \dfrac{11+1}{2(11)} = \dfrac{12}{22} = \dfrac{6}{11} < 1$, so by Exercise 46(a), the error in using s_{10} to approximate the sum of the series $\sum\limits_{n=1}^{\infty} \dfrac{n}{2^n}$ is $R_{10} \le \dfrac{a_{11}}{1-r_{11}} = \dfrac{\frac{11}{2048}}{1-\frac{6}{11}} = \dfrac{121}{10{,}240} \approx 0.0118$.

49. (i) Following the hint, we get that $|a_n| < r^n$ for $n \ge N$, and so since the geometric series $\sum_{n=1}^{\infty} r^n$ converges $[0 < r < 1]$, the series $\sum_{n=N}^{\infty} |a_n|$ converges as well by the Comparison Test, and hence so does $\sum_{n=1}^{\infty} |a_n|$, so $\sum_{n=1}^{\infty} a_n$ is absolutely convergent.

(ii) If $\lim\limits_{n\to\infty} \sqrt[n]{|a_n|} = L > 1$, then there is an integer N such that $\sqrt[n]{|a_n|} > 1$ for all $n \ge N$, so $|a_n| > 1$ for $n \ge N$. Thus, $\lim\limits_{n\to\infty} a_n \ne 0$, so $\sum_{n=1}^{\infty} a_n$ diverges by the Test for Divergence.

(iii) Consider $\sum\limits_{n=1}^{\infty} \dfrac{1}{n}$ [diverges] and $\sum\limits_{n=1}^{\infty} \dfrac{1}{n^2}$ [converges]. For each sum, $\lim\limits_{n\to\infty} \sqrt[n]{|a_n|} = 1$, so the Root Test is inconclusive.

50. (a) $$\lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty} \left| \frac{[4(n+1)]!\,[1103 + 26{,}390(n+1)]}{[(n+1)!]^4\, 396^{4(n+1)}} \cdot \frac{(n!)^4\, 396^{4n}}{(4n)!\,(1103 + 26{,}390n)} \right|$$

$$= \lim_{n\to\infty} \frac{(4n+4)(4n+3)(4n+2)(4n+1)(26{,}390n + 27{,}493)}{(n+1)^4\, 396^4\, (26{,}390n + 1103)} = \frac{4^4}{396^4} = \frac{1}{99^4} < 1,$$

so by the Ratio Test, the series $\sum\limits_{n=0}^{\infty} \dfrac{(4n)!\,(1103 + 26{,}390n)}{(n!)^4\, 396^{4n}}$ converges.

(b) $$\frac{1}{\pi} = \frac{2\sqrt{2}}{9801} \sum_{n=0}^{\infty} \frac{(4n)!\,(1103 + 26{,}390n)}{(n!)^4\, 396^{4n}}$$

With the first term $(n = 0)$, $\dfrac{1}{\pi} \approx \dfrac{2\sqrt{2}}{9801} \cdot \dfrac{1103}{1} \quad \Rightarrow \quad \pi \approx 3.141\,592\,73$, so we get 6 correct decimal places of π, which is 3.141 592 653 589 793 238 to 18 decimal places.

With the second term $(n = 1)$, $\dfrac{1}{\pi} \approx \dfrac{2\sqrt{2}}{9801}\left(\dfrac{1103}{1} + \dfrac{4!\,(1103 + 26{,}390)}{396^4}\right) \quad \Rightarrow \quad \pi \approx 3.141\,592\,653\,589\,793\,878$, so we get 15 correct decimal places of π.

51. (a) Since $\sum a_n$ is absolutely convergent, and since $\left|a_n^+\right| \le |a_n|$ and $\left|a_n^-\right| \le |a_n|$ (because a_n^+ and a_n^- each equal either a_n or 0), we conclude by the Comparison Test that both $\sum a_n^+$ and $\sum a_n^-$ must be absolutely convergent.

Or: Use Theorem 11.2.8.

(b) We will show by contradiction that both $\sum a_n^+$ and $\sum a_n^-$ must diverge. For suppose that $\sum a_n^+$ converged. Then so would $\sum\left(a_n^+ - \frac{1}{2}a_n\right)$ by Theorem 11.2.8. But $\sum\left(a_n^+ - \frac{1}{2}a_n\right) = \sum\left[\frac{1}{2}\left(a_n + |a_n|\right) - \frac{1}{2}a_n\right] = \frac{1}{2}\sum|a_n|$, which diverges because $\sum a_n$ is only conditionally convergent. Hence, $\sum a_n^+$ can't converge. Similarly, neither can $\sum a_n^-$.

52. Let $\sum b_n$ be the rearranged series constructed in the hint. [This series can be constructed by virtue of the result of Exercise 51(b).] This series will have partial sums s_n that oscillate in value back and forth across r. Since $\lim\limits_{n\to\infty} a_n = 0$ (by Theorem 11.2.6), and since the size of the oscillations $|s_n - r|$ is always less than $|a_n|$ because of the way $\sum b_n$ was constructed, we have that $\sum b_n = \lim\limits_{n\to\infty} s_n = r$.

53. Suppose that $\sum a_n$ is conditionally convergent.

(a) $\sum n^2 a_n$ is divergent: Suppose $\sum n^2 a_n$ converges. Then $\lim\limits_{n\to\infty} n^2 a_n = 0$ by Theorem 6 in Section 11.2, so there is an integer $N > 0$ such that $n > N \quad\Rightarrow\quad n^2|a_n| < 1$. For $n > N$, we have $|a_n| < \dfrac{1}{n^2}$, so $\sum\limits_{n>N} |a_n|$ converges by comparison with the convergent p-series $\sum\limits_{n>N} \dfrac{1}{n^2}$. In other words, $\sum a_n$ converges absolutely, contradicting the assumption that $\sum a_n$ is conditionally convergent. This contradiction shows that $\sum n^2 a_n$ diverges.

Remark: The same argument shows that $\sum n^p a_n$ diverges for any $p > 1$.

(b) $\sum\limits_{n=2}^{\infty} \dfrac{(-1)^n}{n \ln n}$ is conditionally convergent. It converges by the Alternating Series Test, but does not converge absolutely $\Bigg[$by the Integral Test, since the function $f(x) = \dfrac{1}{x \ln x}$ is continuous, positive, and decreasing on $[2, \infty)$ and $\displaystyle\int_2^\infty \frac{dx}{x \ln x} = \lim_{t\to\infty} \int_2^t \frac{dx}{x \ln x} = \lim_{t\to\infty}\Big[\ln(\ln x)\Big]_2^t = \infty\Bigg]$. Setting $a_n = \dfrac{(-1)^n}{n \ln n}$ for $n \ge 2$, we find that $\sum\limits_{n=2}^{\infty} n a_n = \sum\limits_{n=2}^{\infty} \dfrac{(-1)^n}{\ln n}$ converges by the Alternating Series Test.

It is easy to find conditionally convergent series $\sum a_n$ such that $\sum n a_n$ diverges. Two examples are $\sum\limits_{n=1}^{\infty} \dfrac{(-1)^{n-1}}{n}$ and $\sum\limits_{n=1}^{\infty} \dfrac{(-1)^{n-1}}{\sqrt{n}}$, both of which converge by the Alternating Series Test and fail to converge absolutely because $\sum |a_n|$ is a p-series with $p \le 1$. In both cases, $\sum n a_n$ diverges by the Test for Divergence.

11.7 Strategy for Testing Series

1. Use the Limit Comparison Test with $a_n = \dfrac{n^2-1}{n^3+1}$ and $b_n = \dfrac{1}{n}$:

$\displaystyle\lim_{n\to\infty} \frac{a_n}{b_n} = \lim_{n\to\infty} \frac{(n^2-1)n}{n^3+1} = \lim_{n\to\infty} \frac{n^3-n}{n^3+1} = \lim_{n\to\infty} \frac{1-1/n^2}{1+1/n^3} = 1 > 0$. Since $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n}$ is the divergent harmonic series, the series $\displaystyle\sum_{n=1}^{\infty} \frac{n^2-1}{n^3+1}$ also diverges.

2. $\dfrac{n-1}{n^3+1} < \dfrac{n}{n^3+1} < \dfrac{n}{n^3} = \dfrac{1}{n^2}$ for $n \geq 1$, so $\displaystyle\sum_{n=1}^{\infty} \frac{n-1}{n^3+1}$ converges by comparison with $\displaystyle\sum_{n=1}^{\infty} \frac{1}{n^2}$, which converges because it is a p-series with $p = 2 > 1$.

3. $\displaystyle\sum_{n=1}^{\infty} (-1)^n \frac{n^2-1}{n^3+1} = \sum_{n=1}^{\infty} (-1)^n b_n$. Now $b_n = \dfrac{n^2-1}{n^3+1} > 0$ for $n \geq 2$, $\{b_n\}$ is decreasing for $n \geq 2$, and $\displaystyle\lim_{n\to\infty} b_n = 0$, so the series $\displaystyle\sum_{n=1}^{\infty} (-1)^n \frac{n^2-1}{n^3+1}$ converges by the Alternating Series Test. By Exercise 1, $\displaystyle\sum_{n=1}^{\infty} \frac{n^2-1}{n^3+1}$ diverges, so the series $\displaystyle\sum_{n=1}^{\infty} (-1)^n \frac{n^2-1}{n^3+1}$ is conditionally convergent.

4. $\displaystyle\lim_{n\to\infty} |a_n| = \lim_{n\to\infty} \left|(-1)^n \frac{n^2-1}{n^2+1}\right| = \lim_{n\to\infty} \frac{1-1/n^2}{1+1/n^2} = 1 \neq 0$, so the series $\displaystyle\sum_{n=1}^{\infty} (-1)^n \frac{n^2-1}{n^2+1}$ diverges by the Test for Divergence. $\left[\text{Note that } \displaystyle\lim_{n\to\infty} (-1)^n \frac{n^2-1}{n^2+1} \text{ does not exist.}\right]$

5. $\displaystyle\lim_{x\to\infty} \frac{e^x}{x^2} \overset{\text{H}}{=} \lim_{x\to\infty} \frac{e^x}{2x} \overset{\text{H}}{=} \lim_{x\to\infty} \frac{e^x}{2} = \infty$, so $\displaystyle\lim_{n\to\infty} \frac{e^n}{n^2} = \infty$. Thus, the series $\displaystyle\sum_{n=1}^{\infty} \frac{e^n}{n^2}$ diverges by the Test for Divergence.

6. $\displaystyle\lim_{n\to\infty} \sqrt[n]{|a_n|} = \lim_{n\to\infty} \sqrt[n]{\frac{n^{2n}}{(1+n)^{3n}}} = \lim_{n\to\infty} \frac{n^2}{(1+n)^3} = \lim_{n\to\infty} \frac{1/n}{(1/n+1)^3} = \frac{0}{1} = 0 < 1$, so the series $\displaystyle\sum_{n=1}^{\infty} \frac{n^{2n}}{(1+n)^{3n}}$ converges by the Root Test.

7. Let $f(x) = \dfrac{1}{x\sqrt{\ln x}}$. Then f is positive, continuous, and decreasing on $[2, \infty)$, so we can apply the Integral Test.

Since $\displaystyle\int \frac{1}{x\sqrt{\ln x}}\,dx \left[\begin{matrix} u = \ln x, \\ du = dx/x \end{matrix}\right] = \int u^{-1/2}\,du = 2u^{1/2} + C = 2\sqrt{\ln x} + C$, we find

$\displaystyle\int_2^{\infty} \frac{dx}{x\sqrt{\ln x}} = \lim_{t\to\infty} \int_2^t \frac{dx}{x\sqrt{\ln x}} = \lim_{t\to\infty} \left[2\sqrt{\ln x}\right]_2^t = \lim_{t\to\infty} \left(2\sqrt{\ln t} - 2\sqrt{\ln 2}\right) = \infty$. Since the integral diverges, the given series $\displaystyle\sum_{n=2}^{\infty} \frac{1}{n\sqrt{\ln n}}$ diverges.

8. $\displaystyle\lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty} \left|\frac{(n+1)^4}{4^{n+1}} \cdot \frac{4^n}{n^4}\right| = \lim_{n\to\infty} \frac{(n+1)^4}{4n^4} = \frac{1}{4} \lim_{n\to\infty} \left(1 + \frac{1}{n}\right)^4 = \frac{1}{4}(1) = \frac{1}{4} < 1$, so the series $\displaystyle\sum_{n=1}^{\infty} (-1)^{n-1} \frac{n^4}{4^n}$ is absolutely convergent (and therefore convergent) by the Ratio Test.

9. $\lim\limits_{n\to\infty}\left|\dfrac{a_{n+1}}{a_n}\right| = \lim\limits_{n\to\infty}\left|\dfrac{\pi^{2n+2}}{(2n+2)!}\cdot\dfrac{(2n)!}{\pi^{2n}}\right| = \lim\limits_{n\to\infty}\dfrac{\pi^2}{(2n+2)(2n+1)} = 0 < 1$, so the series $\sum\limits_{n=0}^{\infty}(-1)^n\dfrac{\pi^{2n}}{(2n)!}$ is absolutely convergent (and therefore convergent) by the Ratio Test.

10. Let $f(x) = x^2e^{-x^3}$. Then f is continuous and positive on $[1,\infty)$, and $f'(x) = \dfrac{x(2-3x^3)}{e^{x^3}} < 0$ for $x \ge 1$, so f is decreasing on $[1,\infty)$ as well, and we can apply the Integral Test. $\int_1^\infty x^2e^{-x^3}\,dx = \lim\limits_{t\to\infty}\left[-\frac{1}{3}e^{-x^3}\right]_1^t = \frac{1}{3e}$, so the integral converges, and hence, the series converges.

11. $\sum\limits_{n=1}^{\infty}\left(\dfrac{1}{n^3}+\dfrac{1}{3^n}\right) = \sum\limits_{n=1}^{\infty}\dfrac{1}{n^3} + \sum\limits_{n=1}^{\infty}\left(\dfrac{1}{3}\right)^n$. The first series converges since it is a p-series with $p = 3 > 1$ and the second series converges since it is geometric with $|r| = \frac{1}{3} < 1$. The sum of two convergent series is convergent.

12. $\dfrac{1}{k\sqrt{k^2+1}} < \dfrac{1}{k\sqrt{k^2}} = \dfrac{1}{k^2}$, so $\sum\limits_{k=1}^{\infty}\dfrac{1}{k\sqrt{k^2+1}}$ converges by comparison with the convergent p-series $\sum\limits_{k=1}^{\infty}\dfrac{1}{k^2}$ $(p = 2 > 1)$.

13. $\lim\limits_{n\to\infty}\left|\dfrac{a_{n+1}}{a_n}\right| = \lim\limits_{n\to\infty}\left|\dfrac{3^{n+1}(n+1)^2}{(n+1)!}\cdot\dfrac{n!}{3^n n^2}\right| = \lim\limits_{n\to\infty}\dfrac{3(n+1)^2}{(n+1)n^2} = 3\lim\limits_{n\to\infty}\dfrac{n+1}{n^2} = 0 < 1$, so the series $\sum\limits_{n=1}^{\infty}\dfrac{3^n n^2}{n!}$ converges by the Ratio Test.

14. $\left|\dfrac{\sin 2n}{1+2^n}\right| \le \dfrac{1}{1+2^n} < \dfrac{1}{2^n} = \left(\dfrac{1}{2}\right)^n$, so the series $\sum\limits_{n=1}^{\infty}\left|\dfrac{\sin 2n}{1+2^n}\right|$ converges by comparison with the geometric series $\sum\limits_{n=1}^{\infty}\left(\dfrac{1}{2}\right)^n$ with $|r| = \frac{1}{2} < 1$. Thus, the series $\sum\limits_{n=1}^{\infty}\dfrac{\sin 2n}{1+2^n}$ converges absolutely, implying convergence.

15. $a_k = \dfrac{2^{k-1}3^{k+1}}{k^k} = \dfrac{2^k2^{-1}3^k3^1}{k^k} = \dfrac{3}{2}\left(\dfrac{2\cdot 3}{k}\right)^k$. By the Root Test, $\lim\limits_{k\to\infty}\sqrt[k]{\left(\dfrac{6}{k}\right)^k} = \lim\limits_{k\to\infty}\dfrac{6}{k} = 0 < 1$, so the series $\sum\limits_{k=1}^{\infty}\left(\dfrac{6}{k}\right)^k$ converges. It follows from Theorem 8(i) in Section 11.2 that the given series, $\sum\limits_{k=1}^{\infty}\dfrac{2^{k-1}3^{k+1}}{k^k} = \sum\limits_{k=1}^{\infty}\dfrac{3}{2}\left(\dfrac{6}{k}\right)^k$, also converges.

16. Use the Limit Comparison Test with $a_n = \dfrac{\sqrt{n^4+1}}{n^3+n}$ and $b_n = \dfrac{1}{n}$:

$\lim\limits_{n\to\infty}\dfrac{a_n}{b_n} = \lim\limits_{n\to\infty}\dfrac{n\sqrt{n^4+1}}{n(n^2+1)} = \lim\limits_{n\to\infty}\dfrac{\sqrt{n^4+1}/n^2}{(n^2+1)/n^2} = \lim\limits_{n\to\infty}\dfrac{\sqrt{1+1/n^4}}{1+1/n^2} = 1 > 0$. Since $\sum\limits_{n=1}^{\infty}\dfrac{1}{n}$ is the divergent harmonic series, the series $\sum\limits_{n=1}^{\infty}\dfrac{\sqrt{n^4+1}}{n^3+n}$ also diverges.

17.
$$\lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty}\left|\frac{1\cdot 3\cdot 5\cdot\cdots\cdot(2n-1)(2n+1)}{2\cdot 5\cdot 8\cdot\cdots\cdot(3n-1)(3n+2)}\cdot\frac{2\cdot 5\cdot 8\cdot\cdots\cdot(3n-1)}{1\cdot 3\cdot 5\cdot\cdots\cdot(2n-1)}\right| = \lim_{n\to\infty}\frac{2n+1}{3n+2}$$
$$= \lim_{n\to\infty}\frac{2+1/n}{3+2/n} = \frac{2}{3} < 1,$$

so the series $\sum\limits_{n=1}^{\infty}\dfrac{1\cdot 3\cdot 5\cdot\cdots\cdot(2n-1)}{2\cdot 5\cdot 8\cdot\cdots\cdot(3n-1)}$ converges by the Ratio Test.

18. $b_n = \dfrac{1}{\sqrt{n}-1}$ for $n \geq 2$. $\{b_n\}$ is a decreasing sequence of positive numbers and $\lim\limits_{n\to\infty} b_n = 0$, so $\sum\limits_{n=2}^{\infty} \dfrac{(-1)^{n-1}}{\sqrt{n}-1}$ converges by the Alternating Series Test.

19. Let $f(x) = \dfrac{\ln x}{\sqrt{x}}$. Then $f'(x) = \dfrac{2-\ln x}{2x^{3/2}} < 0$ when $\ln x > 2$ or $x > e^2$, so $\dfrac{\ln n}{\sqrt{n}}$ is decreasing for $n > e^2$.

By l'Hospital's Rule, $\lim\limits_{n\to\infty} \dfrac{\ln n}{\sqrt{n}} = \lim\limits_{n\to\infty} \dfrac{1/n}{1/\left(2\sqrt{n}\right)} = \lim\limits_{n\to\infty} \dfrac{2}{\sqrt{n}} = 0$, so the series $\sum\limits_{n=1}^{\infty} (-1)^n \dfrac{\ln n}{\sqrt{n}}$ converges by the Alternating Series Test.

20. $a_k = \dfrac{\sqrt[3]{k}-1}{k(\sqrt{k}+1)} < \dfrac{\sqrt[3]{k}}{k(\sqrt{k}+1)} < \dfrac{\sqrt[3]{k}}{k\sqrt{k}} = \dfrac{k^{1/3}}{k^{3/2}} = \dfrac{1}{k^{7/6}}$, so the series $\sum\limits_{k=1}^{\infty} \dfrac{\sqrt[3]{k}-1}{k(\sqrt{k}+1)}$ converges by comparison with the convergent p-series $\sum\limits_{k=1}^{\infty} \dfrac{1}{k^{7/6}}$ $\left(p = \frac{7}{6} > 1\right)$.

21. $\lim\limits_{n\to\infty} |a_n| = \lim\limits_{n\to\infty} \left|(-1)^n \cos(1/n^2)\right| = \lim\limits_{n\to\infty} \left|\cos(1/n^2)\right| = \cos 0 = 1$, so the series $\sum\limits_{n=1}^{\infty} (-1)^n \cos(1/n^2)$ diverges by the Test for Divergence.

22. $\lim\limits_{k\to\infty} |a_k| = \lim\limits_{k\to\infty} \left|\dfrac{1}{2+\sin k}\right| = \lim\limits_{k\to\infty} \dfrac{1}{2+\sin k}$, which does not exist (the terms vary between $\frac{1}{3}$ and 1). Thus, the series $\sum\limits_{k=1}^{\infty} \dfrac{1}{2+\sin k}$ diverges by the Test for Divergence.

23. Using the Limit Comparison Test with $a_n = \tan\left(\dfrac{1}{n}\right)$ and $b_n = \dfrac{1}{n}$, we have

$\lim\limits_{n\to\infty} \dfrac{a_n}{b_n} = \lim\limits_{n\to\infty} \dfrac{\tan(1/n)}{1/n} = \lim\limits_{x\to\infty} \dfrac{\tan(1/x)}{1/x} \overset{\text{H}}{=} \lim\limits_{x\to\infty} \dfrac{\sec^2(1/x)\cdot(-1/x^2)}{-1/x^2} = \lim\limits_{x\to\infty} \sec^2(1/x) = 1^2 = 1 > 0$. Since $\sum\limits_{n=1}^{\infty} b_n$ is the divergent harmonic series, $\sum\limits_{n=1}^{\infty} a_n$ is also divergent.

24. $\lim\limits_{n\to\infty} a_n = \lim\limits_{n\to\infty} \left(n \sin \dfrac{1}{n}\right) = \lim\limits_{n\to\infty} \dfrac{\sin(1/n)}{1/n} = \lim\limits_{x\to 0^+} \dfrac{\sin x}{x} = 1 \neq 0$, so the series $\sum\limits_{n=1}^{\infty} n\sin(1/n)$ diverges by the Test for Divergence.

25. Use the Ratio Test. $\lim\limits_{n\to\infty} \left|\dfrac{a_{n+1}}{a_n}\right| = \lim\limits_{n\to\infty} \left|\dfrac{(n+1)!}{e^{(n+1)^2}} \cdot \dfrac{e^{n^2}}{n!}\right| = \lim\limits_{n\to\infty} \dfrac{(n+1)n!\cdot e^{n^2}}{e^{n^2+2n+1}n!} = \lim\limits_{n\to\infty} \dfrac{n+1}{e^{2n+1}} = 0 < 1$, so $\sum\limits_{n=1}^{\infty} \dfrac{n!}{e^{n^2}}$ converges.

26. $\lim\limits_{n\to\infty} \left|\dfrac{a_{n+1}}{a_n}\right| = \lim\limits_{n\to\infty} \dfrac{a_{n+1}}{a_n} = \lim\limits_{n\to\infty} \left(\dfrac{n^2+2n+2}{5^{n+1}} \cdot \dfrac{5^n}{n^2+1}\right) = \lim\limits_{n\to\infty} \left(\dfrac{1+2/n+2/n^2}{1+1/n^2} \cdot \dfrac{1}{5}\right) = \dfrac{1}{5} < 1$, so $\sum\limits_{n=1}^{\infty} \dfrac{n^2+1}{5^n}$ converges by the Ratio Test.

27. $\displaystyle\int_2^{\infty} \frac{\ln x}{x^2}\,dx = \lim_{t\to\infty} \left[-\frac{\ln x}{x} - \frac{1}{x}\right]_1^t$ [using integration by parts] $\overset{\text{H}}{=} 1$. So $\sum\limits_{n=1}^{\infty} \dfrac{\ln n}{n^2}$ converges by the Integral Test, and since $\dfrac{k\ln k}{(k+1)^3} < \dfrac{k\ln k}{k^3} = \dfrac{\ln k}{k^2}$, the given series $\sum\limits_{k=1}^{\infty} \dfrac{k\ln k}{(k+1)^3}$ converges by the Comparison Test.

28. Since $\left\{\dfrac{1}{n}\right\}$ is a decreasing sequence, $e^{1/n} \leq e^{1/1} = e$ for all $n \geq 1$, and $\sum\limits_{n=1}^{\infty} \dfrac{e}{n^2}$ converges ($p = 2 > 1$), so $\sum\limits_{n=1}^{\infty} \dfrac{e^{1/n}}{n^2}$ converges by the Comparison Test. (Or use the Integral Test.)

29. $\sum\limits_{n=1}^{\infty} a_n = \sum\limits_{n=1}^{\infty} (-1)^n \dfrac{1}{\cosh n} = \sum\limits_{n=1}^{\infty} (-1)^n\, b_n$. Now $b_n = \dfrac{1}{\cosh n} > 0$, $\{b_n\}$ is decreasing, and $\lim\limits_{n\to\infty} b_n = 0$, so the series converges by the Alternating Series Test.

Or: Write $\dfrac{1}{\cosh n} = \dfrac{2}{e^n + e^{-n}} < \dfrac{2}{e^n}$ and $\sum\limits_{n=1}^{\infty} \dfrac{1}{e^n}$ is a convergent geometric series, so $\sum\limits_{n=1}^{\infty} \dfrac{1}{\cosh n}$ is convergent by the Comparison Test. So $\sum\limits_{n=1}^{\infty} (-1)^n \dfrac{1}{\cosh n}$ is absolutely convergent and therefore convergent.

30. Let $f(x) = \dfrac{\sqrt{x}}{x+5}$. Then $f(x)$ is continuous and positive on $[1, \infty)$, and since $f'(x) = \dfrac{5 - x}{2\sqrt{x}\,(x+5)^2} < 0$ for $x > 5$, $f(x)$ is eventually decreasing, so we can use the Alternating Series Test. $\lim\limits_{n\to\infty} \dfrac{\sqrt{n}}{n+5} = \lim\limits_{n\to\infty} \dfrac{1}{n^{1/2} + 5n^{-1/2}} = 0$, so the series $\sum\limits_{j=1}^{\infty} (-1)^j \dfrac{\sqrt{j}}{j+5}$ converges.

31. $\lim\limits_{k\to\infty} a_k = \lim\limits_{k\to\infty} \dfrac{5^k}{3^k + 4^k} = $ [divide by 4^k] $\lim\limits_{k\to\infty} \dfrac{(5/4)^k}{(3/4)^k + 1} = \infty$ since $\lim\limits_{k\to\infty} \left(\dfrac{3}{4}\right)^k = 0$ and $\lim\limits_{k\to\infty} \left(\dfrac{5}{4}\right)^k = \infty$.

Thus, $\sum\limits_{k=1}^{\infty} \dfrac{5^k}{3^k + 4^k}$ diverges by the Test for Divergence.

32. $\lim\limits_{n\to\infty} \sqrt[n]{|a_n|} = \lim\limits_{n\to\infty} \sqrt[n]{\left|\dfrac{(n!)^n}{n^{4n}}\right|} = \lim\limits_{n\to\infty} \dfrac{n!}{n^4} = \lim\limits_{n\to\infty} \left[\dfrac{n}{n} \cdot \dfrac{n-1}{n} \cdot \dfrac{n-2}{n} \cdot \dfrac{n-3}{n} \cdot (n-4)!\right]$

$$= \lim_{n\to\infty} \left[\left(1 - \frac{1}{n}\right)\left(1 - \frac{2}{n}\right)\left(1 - \frac{3}{n}\right)(n-4)!\right] = \infty,$$

so the series $\sum\limits_{n=1}^{\infty} \dfrac{(n!)^n}{n^{4n}}$ diverges by the Root Test.

33. $\lim\limits_{n\to\infty} \sqrt[n]{|a_n|} = \lim\limits_{n\to\infty} \left(\dfrac{n}{n+1}\right)^{n^2/n} = \lim\limits_{n\to\infty} \dfrac{1}{[(n+1)/n]^n} = \dfrac{1}{\lim\limits_{n\to\infty} (1 + 1/n)^n} = \dfrac{1}{e} < 1$, so the series $\sum\limits_{n=1}^{\infty} \left(\dfrac{n}{n+1}\right)^{n^2}$ converges by the Root Test.

34. $0 \leq n\cos^2 n \leq n$, so $\dfrac{1}{n + n\cos^2 n} \geq \dfrac{1}{n+n} = \dfrac{1}{2n}$. Thus, $\sum\limits_{n=1}^{\infty} \dfrac{1}{n + n\cos^2 n}$ diverges by comparison with $\sum\limits_{n=1}^{\infty} \dfrac{1}{2n}$, which is a constant multiple of the (divergent) harmonic series.

35. $a_n = \dfrac{1}{n^{1+1/n}} = \dfrac{1}{n \cdot n^{1/n}}$, so let $b_n = \dfrac{1}{n}$ and use the Limit Comparison Test. $\lim\limits_{n\to\infty} \dfrac{a_n}{b_n} = \lim\limits_{n\to\infty} \dfrac{1}{n^{1/n}} = 1 > 0$ [see Exercise 4.4.63], so the series $\sum\limits_{n=1}^{\infty} \dfrac{1}{n^{1+1/n}}$ diverges by comparison with the divergent harmonic series.

36. Note that $(\ln n)^{\ln n} = \left(e^{\ln \ln n}\right)^{\ln n} = \left(e^{\ln n}\right)^{\ln \ln n} = n^{\ln \ln n}$ and $\ln \ln n \to \infty$ as $n \to \infty$, so $\ln \ln n > 2$ for sufficiently large n. For these n we have $(\ln n)^{\ln n} > n^2$, so $\dfrac{1}{(\ln n)^{\ln n}} < \dfrac{1}{n^2}$. Since $\sum\limits_{n=2}^{\infty} \dfrac{1}{n^2}$ converges $[p = 2 > 1]$, so does $\sum\limits_{n=2}^{\infty} \dfrac{1}{(\ln n)^{\ln n}}$ by the Comparison Test.

37. $\lim\limits_{n\to\infty} \sqrt[n]{|a_n|} = \lim\limits_{n\to\infty} (2^{1/n} - 1) = 1 - 1 = 0 < 1$, so the series $\sum\limits_{n=1}^{\infty} \left(\sqrt[n]{2} - 1\right)^n$ converges by the Root Test.

38. Use the Limit Comparison Test with $a_n = \sqrt[n]{2} - 1$ and $b_n = 1/n$. Then

$$\lim_{n\to\infty} \frac{a_n}{b_n} = \lim_{n\to\infty} \frac{2^{1/n} - 1}{1/n} = \lim_{x\to\infty} \frac{2^{1/x} - 1}{1/x} \overset{\text{H}}{=} \lim_{x\to\infty} \frac{2^{1/x} \cdot \ln 2 \cdot (-1/x^2)}{-1/x^2} = \lim_{x\to\infty} (2^{1/x} \cdot \ln 2) = 1 \cdot \ln 2 = \ln 2 > 0.$$

So since $\sum\limits_{n=1}^{\infty} b_n$ diverges (harmonic series), so does $\sum\limits_{n=1}^{\infty} \left(\sqrt[n]{2} - 1\right)$.

Alternate solution: $\sqrt[n]{2} - 1 = \dfrac{1}{2^{(n-1)/n} + 2^{(n-2)/n} + 2^{(n-3)/n} + \cdots + 2^{1/n} + 1}$ [rationalize the numerator] $\geq \dfrac{1}{2n}$, and since $\sum\limits_{n=1}^{\infty} \dfrac{1}{2n} = \dfrac{1}{2} \sum\limits_{n=1}^{\infty} \dfrac{1}{n}$ diverges (harmonic series), so does $\sum\limits_{n=1}^{\infty} \left(\sqrt[n]{2} - 1\right)$ by the Comparison Test.

11.8 Power Series

1. A power series is a series of the form $\sum_{n=0}^{\infty} c_n x^n = c_0 + c_1 x + c_2 x^2 + c_3 x^3 + \cdots$, where x is a variable and the c_n's are constants called the coefficients of the series.

More generally, a series of the form $\sum_{n=0}^{\infty} c_n (x - a)^n = c_0 + c_1(x - a) + c_2(x - a)^2 + \cdots$ is called a power series in $(x - a)$ or a power series centered at a or a power series about a, where a is a constant.

2. (a) Given the power series $\sum_{n=0}^{\infty} c_n (x - a)^n$, the radius of convergence is:

(i) 0 if the series converges only when $x = a$

(ii) ∞ if the series converges for all x, or

(iii) a positive number R such that the series converges if $|x - a| < R$ and diverges if $|x - a| > R$.

In most cases, R can be found by using the Ratio Test.

(b) The interval of convergence of a power series is the interval that consists of all values of x for which the series converges. Corresponding to the cases in part (a), the interval of convergence is: (i) the single point $\{a\}$, (ii) all real numbers; that is, the real number line $(-\infty, \infty)$, or (iii) an interval with endpoints $a - R$ and $a + R$ which can contain neither, either, or both of the endpoints. In this case, we must test the series for convergence at each endpoint to determine the interval of convergence.

3. If $a_n = (-1)^n n x^n$, then

$$\lim_{n\to\infty} \left| \frac{a_{n+1}}{a_n} \right| = \lim_{n\to\infty} \left| \frac{(-1)^{n+1}(n+1)x^{n+1}}{(-1)^n\, n x^n} \right| = \lim_{n\to\infty} \left| (-1) \frac{n+1}{n} x \right| = \lim_{n\to\infty} \left[\left(1 + \frac{1}{n}\right) |x| \right] = |x|.$$

By the Ratio Test, the series $\sum\limits_{n=1}^{\infty} (-1)^n n x^n$ converges when $|x| < 1$, so the radius of convergence $R = 1$. Now we'll check the endpoints, that is,

$x = \pm 1$. Both series $\sum_{n=1}^{\infty} (-1)^n n(\pm 1)^n = \sum_{n=1}^{\infty} (\mp 1)^n n$ diverge by the Test for Divergence since $\lim_{n\to\infty} |(\mp 1)^n n| = \infty$. Thus, the interval of convergence is $I = (-1, 1)$.

4. If $a_n = \dfrac{(-1)^n x^n}{\sqrt[3]{n}}$, then

$$\lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty} \left|\frac{(-1)^{n+1} x^{n+1}}{\sqrt[3]{n+1}} \cdot \frac{\sqrt[3]{n}}{(-1)^n x^n}\right| = \lim_{n\to\infty} \left|\frac{(-1)x\sqrt[3]{n}}{\sqrt[3]{n+1}}\right| = \lim_{n\to\infty} \sqrt[3]{\frac{1}{1+1/n}}\,|x| = |x|.$$ By the Ratio Test, the series $\sum_{n=1}^{\infty} \dfrac{(-1)^n x^n}{\sqrt[3]{n}}$ converges when $|x| < 1$, so $R = 1$. When $x = 1$, the series $\sum_{n=1}^{\infty} \dfrac{(-1)^n}{\sqrt[3]{n}}$ converges by the Alternating Series Test. When $x = -1$, the series $\sum_{n=1}^{\infty} \dfrac{1}{\sqrt[3]{n}}$ diverges since it is a p-series $\left(p = \frac{1}{3} \le 1\right)$. Thus, the interval of convergence is $(-1, 1]$.

5. If $a_n = \dfrac{x^n}{2n-1}$, then $\lim_{n\to\infty} \left|\dfrac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty} \left|\dfrac{x^{n+1}}{2n+1} \cdot \dfrac{2n-1}{x^n}\right| = \lim_{n\to\infty} \left(\dfrac{2n-1}{2n+1}|x|\right) = \lim_{n\to\infty} \left(\dfrac{2-1/n}{2+1/n}|x|\right) = |x|$. By the Ratio Test, the series $\sum_{n=1}^{\infty} \dfrac{x^n}{2n-1}$ converges when $|x| < 1$, so $R = 1$. When $x = 1$, the series $\sum_{n=1}^{\infty} \dfrac{1}{2n-1}$ diverges by comparison with $\sum_{n=1}^{\infty} \dfrac{1}{2n}$ since $\dfrac{1}{2n-1} > \dfrac{1}{2n}$ and $\dfrac{1}{2}\sum_{n=1}^{\infty} \dfrac{1}{n}$ diverges since it is a constant multiple of the harmonic series. When $x = -1$, the series $\sum_{n=1}^{\infty} \dfrac{(-1)^n}{2n-1}$ converges by the Alternating Series Test. Thus, the interval of convergence is $[-1, 1)$.

6. If $a_n = \dfrac{(-1)^n x^n}{n^2}$, then

$$\lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty} \left|\frac{(-1)^{n+1} x^{n+1}}{(n+1)^2} \cdot \frac{n^2}{(-1)^n x^n}\right| = \lim_{n\to\infty} \left|\frac{(-1)xn^2}{(n+1)^2}\right| = \lim_{n\to\infty} \left[\left(\frac{n}{n+1}\right)^2 |x|\right] = 1^2 \cdot |x| = |x|.$$

By the Ratio Test, the series $\sum_{n=1}^{\infty} \dfrac{(-1)^n x^n}{n^2}$ converges when $|x| < 1$, so $R = 1$. When $x = 1$, the series $\sum_{n=1}^{\infty} \dfrac{(-1)^n}{n^2}$ converges by the Alternating Series Test. When $x = -1$, the series $\sum_{n=1}^{\infty} \dfrac{1}{n^2}$ converges since it is a p-series with $p = 2 > 1$. Thus, the interval of convergence is $[-1, 1]$.

7. If $a_n = \dfrac{x^n}{n!}$, then $\lim_{n\to\infty} \left|\dfrac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty} \left|\dfrac{x^{n+1}}{(n+1)!} \cdot \dfrac{n!}{x^n}\right| = \lim_{n\to\infty} \left|\dfrac{x}{n+1}\right| = |x| \lim_{n\to\infty} \dfrac{1}{n+1} = |x| \cdot 0 = 0 < 1$ for *all* real x. So, by the Ratio Test, $R = \infty$ and $I = (-\infty, \infty)$.

8. Here the Root Test is easier. If $a_n = n^n x^n$, then $\lim_{n\to\infty} \sqrt[n]{|a_n|} = \lim_{n\to\infty} n\,|x| = \infty$ if $x \ne 0$, so $R = 0$ and $I = \{0\}$.

9. If $a_n = \dfrac{x^n}{n^4\, 4^n}$, then

$$\lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty} \left|\frac{x^{n+1}}{(n+1)^4\, 4^{n+1}} \cdot \frac{n^4\, 4^n}{x^n}\right| = \lim_{n\to\infty} \left|\frac{n^4}{(n+1)^4} \cdot \frac{x}{4}\right| = \lim_{n\to\infty} \left(\frac{n}{n+1}\right)^4 \frac{|x|}{4} = 1^4 \cdot \frac{|x|}{4} = \frac{|x|}{4}.$$ By the Ratio Test, the series $\sum_{n=1}^{\infty} \dfrac{x^n}{n^4\, 4^n}$ converges when $\dfrac{|x|}{4} < 1 \;\Leftrightarrow\; |x| < 4$, so $R = 4$. When $x = 4$, the series $\sum_{n=1}^{\infty} \dfrac{1}{n^4}$

converges since it is a p-series ($p = 4 > 1$). When $x = -4$, the series $\sum\limits_{n=1}^{\infty} \frac{(-1)^n}{n^4}$ converges by the Alternating Series Test. Thus, the interval of convergence is $[-4, 4]$.

10. If $a_n = 2^n n^2 x^n$, then $\lim\limits_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \lim\limits_{n\to\infty} \left|\frac{2^{n+1}(n+1)^2 x^{n+1}}{2^n n^2 x^n}\right| = \lim\limits_{n\to\infty} 2\left(\frac{n+1}{n}\right)^2 |x| = 2\,|x|$. By the Ratio Test, the series $\sum\limits_{n=1}^{\infty} 2^n n^2 x^n$ converges when $2\,|x| < 1 \quad\Leftrightarrow\quad |x| < \frac{1}{2}$, so $R = \frac{1}{2}$. When $x = \pm\frac{1}{2}$, both series $\sum\limits_{n=1}^{\infty} 2^n n^2 \left(\pm\frac{1}{2}\right)^n = \sum\limits_{n=1}^{\infty} (\pm 1)^n n^2$ diverge by the Test for Divergence since $\lim\limits_{n\to\infty} \left|(\pm 1)^n n^2\right| = \infty$. Thus, the interval of convergence is $\left(-\frac{1}{2}, \frac{1}{2}\right)$.

11. If $a_n = \frac{(-1)^n\, 4^n}{\sqrt{n}}\, x^n$, then $\lim\limits_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \lim\limits_{n\to\infty} \left|\frac{(-1)^{n+1}\, 4^{n+1}\, x^{n+1}}{\sqrt{n+1}} \cdot \frac{\sqrt{n}}{(-1)^n\, 4^n\, x^n}\right| = \lim\limits_{n\to\infty} \sqrt{\frac{n}{n+1}} \cdot 4\,|x| = 4\,|x|$.

By the Ratio Test, the series $\sum\limits_{n=1}^{\infty} \frac{(-1)^n\, 4^n}{\sqrt{n}}\, x^n$ converges when $4\,|x| < 1 \quad\Leftrightarrow\quad |x| < \frac{1}{4}$, so $R = \frac{1}{4}$. When $x = \frac{1}{4}$, the series $\sum\limits_{n=1}^{\infty} \frac{(-1)^n}{\sqrt{n}}$ converges by the Alternating Series Test. When $x = -\frac{1}{4}$, the series $\sum\limits_{n=1}^{\infty} \frac{1}{\sqrt{n}}$ diverges since it is a p-series $\left(p = \frac{1}{2} \le 1\right)$. Thus, the interval of convergence is $\left(-\frac{1}{4}, \frac{1}{4}\right]$.

12. If $a_n = \sum\limits_{n=1}^{\infty} \frac{(-1)^{n-1}}{n 5^n}\, x^n$, then $\lim\limits_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \lim\limits_{n\to\infty} \left|\frac{(-1)^n x^{n+1}}{(n+1)\, 5^{n+1}} \cdot \frac{n 5^n}{(-1)^{n-1} x^n}\right| = \lim\limits_{n\to\infty} \left(\frac{n}{n+1}\right) \frac{|x|}{5} = 1 \cdot \frac{|x|}{5} = \frac{|x|}{5}$.

By the Ratio Test, the series $\sum\limits_{n=1}^{\infty} \frac{(-1)^{n-1}}{n 5^n}\, x^n$ converges when $\frac{|x|}{5} < 1 \quad\Leftrightarrow\quad |x| < 5$, so $R = 5$. When $x = 5$, the series $\sum\limits_{n=1}^{\infty} \frac{(-1)^{n-1}}{n}$ converges by the Alternating Series Test. When $x = -5$, the series $\sum\limits_{n=1}^{\infty} \frac{-1}{n}$ diverges since it is a constant multiple of the harmonic series. Thus, the interval of convergence is $(-5, 5]$.

13. If $a_n = \frac{n}{2^n(n^2+1)}\, x^n$, then

$$\lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty} \left|\frac{(n+1)x^{n+1}}{2^{n+1}(n^2+2n+2)} \cdot \frac{2^n(n^2+1)}{n\,x^n}\right| = \lim_{n\to\infty} \frac{n^3+n^2+n+1}{n^3+2n^2+2n} \cdot \frac{|x|}{2}$$
$$= \lim_{n\to\infty} \frac{1+1/n+1/n^2+1/n^3}{1+2/n+2/n^2} \cdot \frac{|x|}{2} = \frac{|x|}{2}$$

By the Ratio Test, the series $\sum\limits_{n=1}^{\infty} \frac{n}{2^n(n^2+1)}\, x^n$ converges when $\frac{|x|}{2} < 1 \quad\Leftrightarrow\quad |x| < 2$, so $R = 2$. When $x = 2$, the series $\sum\limits_{n=1}^{\infty} \frac{n}{n^2+1}$ diverges by the Limit Comparison Test with $b_n = \frac{1}{n}$. When $x = -2$, the series $\sum\limits_{n=1}^{\infty} \frac{(-1)^n n}{n^2+1}$ converges by the Alternating Series Test. Thus, the interval of convergence is $[-2, 2)$.

14. If $a_n = \frac{x^{2n}}{n!}$, then $\lim\limits_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \lim\limits_{n\to\infty} \left|\frac{x^{2n+2}}{(n+1)!} \cdot \frac{n!}{x^{2n}}\right| = \lim\limits_{n\to\infty} \frac{\left|x^2\right|}{n+1} = 0 < 1$ for *all* real x. So, by the Ratio Test, $R = \infty$ and $I = (-\infty, \infty)$.

15. If $a_n = \dfrac{(x-2)^n}{n^2+1}$, then $\lim\limits_{n\to\infty}\left|\dfrac{a_{n+1}}{a_n}\right| = \lim\limits_{n\to\infty}\left|\dfrac{(x-2)^{n+1}}{(n+1)^2+1}\cdot\dfrac{n^2+1}{(x-2)^n}\right| = |x-2|\lim\limits_{n\to\infty}\dfrac{n^2+1}{(n+1)^2+1} = |x-2|$. By the Ratio Test, the series $\sum\limits_{n=0}^{\infty}\dfrac{(x-2)^n}{n^2+1}$ converges when $|x-2|<1$ $[R=1]$ $\Leftrightarrow$ $-1<x-2<1$ $\Leftrightarrow$ $1<x<3$. When $x=1$, the series $\sum\limits_{n=0}^{\infty}(-1)^n\dfrac{1}{n^2+1}$ converges by the Alternating Series Test; when $x=3$, the series $\sum\limits_{n=0}^{\infty}\dfrac{1}{n^2+1}$ converges by comparison with the p-series $\sum\limits_{n=1}^{\infty}\dfrac{1}{n^2}$ $[p=2>1]$. Thus, the interval of convergence is $I=[1,3]$.

16. If $a_n = \dfrac{(-1)^n}{(2n-1)2^n}(x-1)^n$, then

$\lim\limits_{n\to\infty}\left|\dfrac{a_{n+1}}{a_n}\right| = \lim\limits_{n\to\infty}\left|\dfrac{(-1)^{n+1}(x-1)^{n+1}}{(2n+1)\,2^{n+1}}\cdot\dfrac{(2n-1)\,2^n}{(-1)^n(x-1)^n}\right| = \lim\limits_{n\to\infty}\dfrac{2n-1}{2n+1}\cdot\dfrac{|x-1|}{2} = \dfrac{|x-1|}{2}$. By the Ratio Test, the series $\sum\limits_{n=1}^{\infty}\dfrac{(-1)^n}{(2n-1)\,2^n}(x-1)^n$ converges when $\dfrac{|x-1|}{2}<1$ $\Leftrightarrow$ $|x-1|<2$ $[R=2]$ $\Leftrightarrow$ $-2<x-1<2$ $\Leftrightarrow$ $-1<x<3$. When $x=3$, the series $\sum\limits_{n=1}^{\infty}\dfrac{(-1)^n}{2n-1}$ converges by the Alternating Series Test. When $x=-1$, the series $\sum\limits_{n=1}^{\infty}\dfrac{1}{2n-1}$ diverges by the Limit Comparison Test with $b_n=\dfrac{1}{n}$. Thus, the interval of convergence is $(-1,3]$.

17. If $a_n = \dfrac{(x+2)^n}{2^n\,\ln n}$, then $\lim\limits_{n\to\infty}\left|\dfrac{(x+2)^{n+1}}{2^{n+1}\ln(n+1)}\cdot\dfrac{2^n\ln n}{(x+2)^n}\right| = \lim\limits_{n\to\infty}\dfrac{\ln n}{\ln(n+1)}\cdot\dfrac{|x+2|}{2} = \dfrac{|x+2|}{2}$ since

$\lim\limits_{n\to\infty}\dfrac{\ln n}{\ln(n+1)} = \lim\limits_{x\to\infty}\dfrac{\ln x}{\ln(x+1)} \overset{\text{H}}{=} \lim\limits_{x\to\infty}\dfrac{1/x}{1/(x+1)} = \lim\limits_{x\to\infty}\dfrac{x+1}{x} = \lim\limits_{x\to\infty}\left(1+\dfrac{1}{x}\right) = 1$. By the Ratio Test, the series $\sum\limits_{n=2}^{\infty}\dfrac{(x+2)^n}{2^n\,\ln n}$ converges when $\dfrac{|x+2|}{2}<1$ $\Leftrightarrow$ $|x+2|<2$ $[R=2]$ $\Leftrightarrow$ $-2<x+2<2$ $\Leftrightarrow$ $-4<x<0$. When $x=-4$, the series $\sum\limits_{n=2}^{\infty}\dfrac{(-1)^n}{\ln n}$ converges by the Alternating Series Test. When $x=0$, the series $\sum\limits_{n=2}^{\infty}\dfrac{1}{\ln n}$ diverges by the Limit Comparison Test with $b_n=\dfrac{1}{n}$ (or by comparison with the harmonic series). Thus, the interval of convergence is $[-4,0)$.

18. If $a_n = \dfrac{\sqrt{n}}{8^n}(x+6)^n$, then

$$\lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty}\left|\frac{\sqrt{n+1}\,(x+6)^{n+1}}{8^{n+1}}\cdot\frac{8^n}{\sqrt{n}(x+6)^n}\right| = \lim_{n\to\infty}\sqrt{\frac{n+1}{n}}\cdot\frac{|x+6|}{8}$$
$$= \lim_{n\to\infty}\sqrt{1+\frac{1}{n}}\cdot\frac{|x+6|}{8} = \frac{|x+6|}{8}$$

By the Ratio Test, the series $\sum\limits_{n=1}^{\infty}\dfrac{\sqrt{n}}{8^n}(x+6)^n$ converges when $\dfrac{|x+6|}{8}<1$ $\Leftrightarrow$ $|x+6|<8$ $[R=8]$ $\Leftrightarrow$ $-8<x+6<8$ $\Leftrightarrow$ $-14<x<2$. When $x=2$, the series $\sum\limits_{n=1}^{\infty}\sqrt{n}$ diverges by the Test for Divergence since $\lim\limits_{n\to\infty}|a_n| = \lim\limits_{n\to\infty}\sqrt{n} = \infty > 0$. Similarly, when $x=-14$, the series $\sum\limits_{n=1}^{\infty}(-1)^n\sqrt{n}$ diverges. Thus, the interval of convergence is $(-14,2)$.

19. If $a_n = \dfrac{(x-2)^n}{n^n}$, then $\lim_{n\to\infty} \sqrt[n]{|a_n|} = \lim_{n\to\infty} \dfrac{|x-2|}{n} = 0$, so the series converges for all x (by the Root Test). $R = \infty$ and $I = (-\infty, \infty)$.

20. If $a_n = \dfrac{(2x-1)^n}{5^n\sqrt{n}}$, then

$$\lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty}\left|\frac{(2x-1)^{n+1}}{5^{n+1}\sqrt{n+1}}\cdot\frac{5^n\sqrt{n}}{(2x-1)^n}\right| = \lim_{n\to\infty}\frac{|2x-1|}{5}\sqrt{\frac{n}{n+1}} = \lim_{n\to\infty}\frac{|2x-1|}{5}\sqrt{\frac{1}{1+1/n}} = \frac{|2x-1|}{5}.$$

By the Ratio Test, the series $\sum_{n=1}^{\infty}\dfrac{(2x-1)^n}{5^n\sqrt{n}}$ converges when $\dfrac{|2x-1|}{5} < 1 \Leftrightarrow |2x-1| < 5 \Leftrightarrow \left|x-\frac{1}{2}\right| < \frac{5}{2} \Leftrightarrow$ $-\frac{5}{2} < x - \frac{1}{2} < \frac{5}{2} \Leftrightarrow -2 < x < 3$, so $R = \frac{5}{2}$. When $x = 3$, the series $\sum_{n=1}^{\infty}\dfrac{1}{\sqrt{n}}$ is a divergent p-series $\left(p = \frac{1}{2} \le 1\right)$. When $x = -2$, the series $\sum_{n=1}^{\infty}\dfrac{(-1)^n}{\sqrt{n}}$ converges by the Alternating Series Test. Thus, the interval of convergence is $I = [-2, 3)$.

21. $a_n = \dfrac{n}{b^n}(x-a)^n$, where $b > 0$.

$$\lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty}\frac{(n+1)\,|x-a|^{n+1}}{b^{n+1}}\cdot\frac{b^n}{n\,|x-a|^n} = \lim_{n\to\infty}\left(1+\frac{1}{n}\right)\frac{|x-a|}{b} = \frac{|x-a|}{b}.$$

By the Ratio Test, the series converges when $\dfrac{|x-a|}{b} < 1 \Leftrightarrow |x-a| < b$ [so $R = b$] $\Leftrightarrow -b < x-a < b \Leftrightarrow$ $a - b < x < a + b$. When $|x-a| = b$, $\lim_{n\to\infty}|a_n| = \lim_{n\to\infty} n = \infty$, so the series diverges. Thus, $I = (a-b, a+b)$.

22. $a_n = \dfrac{b^n}{\ln n}(x-a)^n$, where $b > 0$.

$$\lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty}\left|\frac{b^{n+1}(x-a)^{n+1}}{\ln(n+1)}\cdot\frac{\ln n}{b^n(x-a)^n}\right| = \lim_{n\to\infty}\frac{\ln n}{\ln(n+1)}\cdot b\,|x-a| = b\,|x-a| \text{ since}$$

$\lim_{n\to\infty}\dfrac{\ln n}{\ln(n+1)} = \lim_{n\to\infty}\dfrac{\ln x}{\ln(x+1)} \overset{\text{H}}{=} \lim_{x\to\infty}\dfrac{1/x}{1/(x+1)} = \lim_{x\to\infty}\dfrac{x+1}{x} \overset{\text{H}}{=} \lim_{x\to\infty}\dfrac{1}{1} = 1$. By the Ratio Test, the series $\sum_{n=2}^{\infty}\dfrac{b^n}{\ln n}(x-a)^n$ converges when $b\,|x-a| < 1 \Leftrightarrow |x-a| < \dfrac{1}{b} \Leftrightarrow -\dfrac{1}{b} < x-a < \dfrac{1}{b} \Leftrightarrow a - \dfrac{1}{b} < x < a + \dfrac{1}{b}$, so $R = \dfrac{1}{b}$. When $x = a + \dfrac{1}{b}$, the series $\sum_{n=2}^{\infty}\dfrac{1}{\ln n}$ diverges by comparison with the divergent p-series $\sum_{n=2}^{\infty}\dfrac{1}{n}$ since $\dfrac{1}{\ln n} > \dfrac{1}{n}$ for $n \ge 2$. When $x = a - \dfrac{1}{b}$, the series $\sum_{n=2}^{\infty}\dfrac{(-1)^n}{\ln n}$ converges by the Alternating Series Test. Thus, the interval of convergence is $I = \left[a - \dfrac{1}{b}, a + \dfrac{1}{b}\right)$.

23. If $a_n = n!\,(2x-1)^n$, then $\lim_{n\to\infty}\left|\dfrac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty}\left|\dfrac{(n+1)!\,(2x-1)^{n+1}}{n!(2x-1)^n}\right| = \lim_{n\to\infty}(n+1)\,|2x-1| \to \infty$ as $n \to \infty$ for all $x \ne \frac{1}{2}$. Since the series diverges for all $x \ne \frac{1}{2}$, $R = 0$ and $I = \left\{\frac{1}{2}\right\}$.

24. $a_n = \dfrac{n^2x^n}{2 \cdot 4 \cdot 6 \cdot \cdots \cdot (2n)} = \dfrac{n^2x^n}{2^n n!} = \dfrac{nx^n}{2^n(n-1)!}$, so

$\lim\limits_{n\to\infty}\left|\dfrac{a_{n+1}}{a_n}\right| = \lim\limits_{n\to\infty}\dfrac{(n+1)\,|x|^{n+1}}{2^{n+1}n!}\cdot\dfrac{2^n(n-1)!}{n\,|x|^n} = \lim\limits_{n\to\infty}\dfrac{n+1}{n^2}\dfrac{|x|}{2} = 0$. Thus, by the Ratio Test, the series converges for *all* real x and we have $R = \infty$ and $I = (-\infty, \infty)$.

25. If $a_n = \dfrac{(5x-4)^n}{n^3}$, then

$$\lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty}\left|\frac{(5x-4)^{n+1}}{(n+1)^3}\cdot\frac{n^3}{(5x-4)^n}\right| = \lim_{n\to\infty}|5x-4|\left(\frac{n}{n+1}\right)^3 = \lim_{n\to\infty}|5x-4|\left(\frac{1}{1+1/n}\right)^3$$
$$= |5x-4|\cdot 1 = |5x-4|$$

By the Ratio Test, $\sum\limits_{n=1}^{\infty}\dfrac{(5x-4)^n}{n^3}$ converges when $|5x-4| < 1 \iff \left|x-\frac{4}{5}\right| < \frac{1}{5} \iff -\frac{1}{5} < x - \frac{4}{5} < \frac{1}{5} \iff$ $\frac{3}{5} < x < 1$, so $R = \frac{1}{5}$. When $x = 1$, the series $\sum\limits_{n=1}^{\infty}\dfrac{1}{n^3}$ is a convergent p-series ($p = 3 > 1$). When $x = \frac{3}{5}$, the series $\sum\limits_{n=1}^{\infty}\dfrac{(-1)^n}{n^3}$ converges by the Alternating Series Test. Thus, the interval of convergence is $I = \left[\frac{3}{5}, 1\right]$.

26. If $a_n = \dfrac{x^{2n}}{n\,(\ln n)^2}$, then $\lim\limits_{n\to\infty}\left|\dfrac{a_{n+1}}{a_n}\right| = \lim\limits_{n\to\infty}\left|\dfrac{x^{2n+2}}{(n+1)[\ln(n+1)]^2}\cdot\dfrac{n\,(\ln n)^2}{x^{2n}}\right| = \left|x^2\right|\lim\limits_{n\to\infty}\dfrac{n\,(\ln n)^2}{(n+1)[\ln(n+1)]^2} = x^2$.

By the Ratio Test, the series $\sum\limits_{n=2}^{\infty}\dfrac{x^{2n}}{n\,(\ln n)^2}$ converges when $x^2 < 1 \iff |x| < 1$, so $R = 1$. When $x = \pm 1$, $x^{2n} = 1$, the series $\sum\limits_{n=2}^{\infty}\dfrac{1}{n\,(\ln n)^2}$ converges by the Integral Test (see Exercise 11.3.22). Thus, the interval of convergence is $I = [-1, 1]$.

27. If $a_n = \dfrac{x^n}{1 \cdot 3 \cdot 5 \cdot \cdots \cdot (2n-1)}$, then

$\lim\limits_{n\to\infty}\left|\dfrac{a_{n+1}}{a_n}\right| = \lim\limits_{n\to\infty}\left|\dfrac{x^{n+1}}{1 \cdot 3 \cdot 5 \cdot \cdots \cdot (2n-1)(2n+1)}\cdot\dfrac{1 \cdot 3 \cdot 5 \cdot \cdots \cdot (2n-1)}{x^n}\right| = \lim\limits_{n\to\infty}\dfrac{|x|}{2n+1} = 0 < 1$. Thus, by the Ratio Test, the series $\sum\limits_{n=1}^{\infty}\dfrac{x^n}{1 \cdot 3 \cdot 5 \cdot \cdots \cdot (2n-1)}$ converges for *all* real x and we have $R = \infty$ and $I = (-\infty, \infty)$.

28. If $a_n = \dfrac{n!\,x^n}{1 \cdot 3 \cdot 5 \cdot \cdots \cdot (2n-1)}$, then

$\lim\limits_{n\to\infty}\left|\dfrac{a_{n+1}}{a_n}\right| = \lim\limits_{n\to\infty}\left|\dfrac{(n+1)!\,x^{n+1}}{1 \cdot 3 \cdot 5 \cdot \cdots \cdot (2n-1)(2n+1)}\cdot\dfrac{1 \cdot 3 \cdot 5 \cdot \cdots \cdot (2n-1)}{n!\,x^n}\right| = \lim\limits_{n\to\infty}\dfrac{(n+1)\,|x|}{2n+1} = \frac{1}{2}\,|x|$.

By the Ratio Test, the series $\sum\limits_{n=1}^{\infty}a_n$ converges when $\frac{1}{2}\,|x| < 1 \Rightarrow |x| < 2$, so $R = 2$. When $x = \pm 2$,

$|a_n| = \dfrac{n!\,2^n}{1 \cdot 3 \cdot 5 \cdot \cdots \cdot (2n-1)} = \dfrac{[1 \cdot 2 \cdot 3 \cdot \cdots \cdot n]\,2^n}{[1 \cdot 3 \cdot 5 \cdot \cdots \cdot (2n-1)]} = \dfrac{2 \cdot 4 \cdot 6 \cdot \cdots \cdot 2n}{1 \cdot 3 \cdot 5 \cdot \cdots \cdot (2n-1)} > 1$, so both endpoint series diverge by the Test for Divergence. Thus, the interval of convergence is $I = (-2, 2)$.

29. (a) We are given that the power series $\sum_{n=0}^{\infty} c_n x^n$ is convergent for $x = 4$. So by Theorem 4, it must converge for at least $-4 < x \leq 4$. In particular, it converges when $x = -2$; that is, $\sum_{n=0}^{\infty} c_n(-2)^n$ is convergent.

(b) It does not follow that $\sum_{n=0}^{\infty} c_n(-4)^n$ is necessarily convergent. [See the comments after Theorem 4 about convergence at the endpoint of an interval. An example is $c_n = (-1)^n/(n4^n)$.]

30. We are given that the power series $\sum_{n=0}^{\infty} c_n x^n$ is convergent for $x = -4$ and divergent when $x = 6$. So by Theorem 4 it converges for at least $-4 \le x < 4$ and diverges for at least $x \ge 6$ and $x < -6$. Therefore:

(a) It converges when $x = 1$; that is, $\sum c_n$ is convergent.

(b) It diverges when $x = 8$; that is, $\sum c_n 8^n$ is divergent.

(c) It converges when $x = -3$; that is, $\sum c_n(-3^n)$ is convergent.

(d) It diverges when $x = -9$; that is, $\sum c_n(-9)^n = \sum(-1)^n c_n 9^n$ is divergent.

31. If $a_n = \dfrac{(n!)^k}{(kn)!}x^n$, then

$$\begin{aligned}\lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| &= \lim_{n\to\infty}\frac{[(n+1)!]^k\,(kn)!}{(n!)^k\,[k(n+1)]!}\,|x| = \lim_{n\to\infty}\frac{(n+1)^k}{(kn+k)(kn+k-1)\cdots(kn+2)(kn+1)}\,|x| \\ &= \lim_{n\to\infty}\left[\frac{(n+1)}{(kn+1)}\frac{(n+1)}{(kn+2)}\cdots\frac{(n+1)}{(kn+k)}\right]|x| \\ &= \lim_{n\to\infty}\left[\frac{n+1}{kn+1}\right]\lim_{n\to\infty}\left[\frac{n+1}{kn+2}\right]\cdots\lim_{n\to\infty}\left[\frac{n+1}{kn+k}\right]|x| \\ &= \left(\frac{1}{k}\right)^k |x| < 1 \quad\Leftrightarrow\quad |x| < k^k \text{ for convergence, and the radius of convergence is } R = k^k.\end{aligned}$$

32. (a) Note that the four intervals in parts (a)–(d) have midpoint $m = \frac{1}{2}(p+q)$ and radius of convergence $r = \frac{1}{2}(q-p)$. We also know that the power series $\sum_{n=0}^{\infty} x^n$ has interval of convergence $(-1,1)$. To change the radius of convergence to r, we can change x^n to $\left(\dfrac{x}{r}\right)^n$. To shift the midpoint of the interval of convergence, we can replace x with $x-m$. Thus, a power series whose interval of convergence is (p,q) is $\sum_{n=0}^{\infty}\left(\dfrac{x-m}{r}\right)^n$, where $m = \frac{1}{2}(p+q)$ and $r = \frac{1}{2}(q-p)$.

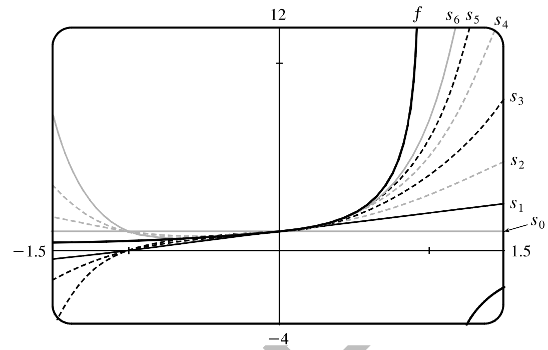
(b) Similar to Example 2, we know that $\sum_{n=1}^{\infty}\dfrac{x^n}{n}$ has interval of convergence $[-1,1)$. By introducing the factor $(-1)^n$ in a_n, the interval of convergence changes to $(-1,1]$. Now change the midpoint and radius as in part (a) to get $\sum_{n=1}^{\infty}(-1)^n\dfrac{1}{n}\left(\dfrac{x-m}{r}\right)^n$ as a power series whose interval of convergence is $(p,q]$.

(c) As in part (b), $\sum_{n=1}^{\infty}\dfrac{1}{n}\left(\dfrac{x-m}{r}\right)^n$ is a power series whose interval of convergence is $[p,q)$.

(d) If we increase the exponent on n (to say, $n = 2$), in the power series in part (c), then when $x = q$, the power series $\sum_{n=1}^{\infty}\dfrac{1}{n^2}\left(\dfrac{x-m}{r}\right)^n$ will converge by comparison to the p-series with $p = 2 > 1$, and the interval of convergence will be $[p,q]$.

33. No. If a power series is centered at a, its interval of convergence is symmetric about a. If a power series has an infinite radius of convergence, then its interval of convergence must be $(-\infty,\infty)$, not $[0,\infty)$.

34. The partial sums of the series $\sum_{n=0}^{\infty} x^n$ definitely do not converge to $f(x) = 1/(1-x)$ for $x \geq 1$, since f is undefined at $x = 1$ and negative on $(1, \infty)$, while all the partial sums are positive on this interval. The partial sums also fail to converge to f for $x \leq -1$, since $0 < f(x) < 1$ on this interval, while the partial sums are either larger than 1 or less than 0. The partial sums seem to converge to f on $(-1, 1)$. This graphical evidence is consistent with what we know about geometric series: convergence for $|x| < 1$, divergence for $|x| \geq 1$ (see Examples 2 and 7 in Section 11.2).

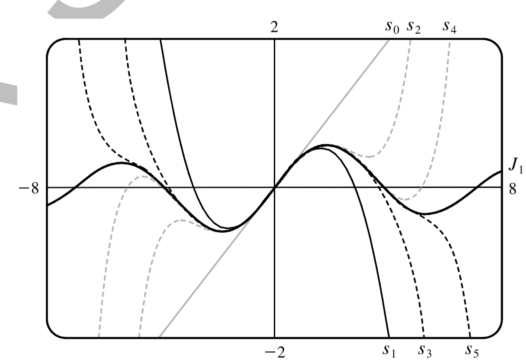


35. (a) If $a_n = \dfrac{(-1)^n x^{2n+1}}{n!(n+1)!\,2^{2n+1}}$, then

$$\lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty}\left|\frac{x^{2n+3}}{(n+1)!(n+2)!\,2^{2n+3}}\cdot\frac{n!(n+1)!\,2^{2n+1}}{x^{2n+1}}\right| = \left(\frac{x}{2}\right)^2 \lim_{n\to\infty}\frac{1}{(n+1)(n+2)} = 0 \text{ for all } x.$$

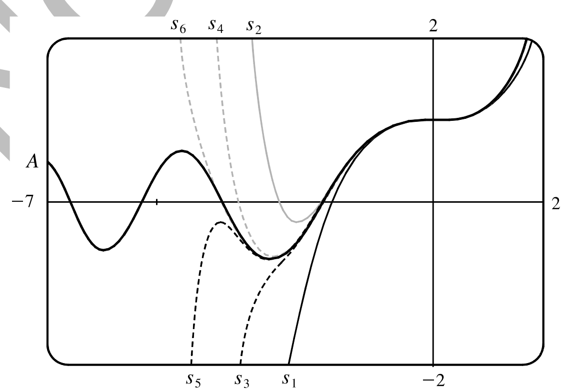
So $J_1(x)$ converges for all x and its domain is $(-\infty, \infty)$.

(b), (c) The initial terms of $J_1(x)$ up to $n = 5$ are $a_0 = \dfrac{x}{2}$, $a_1 = -\dfrac{x^3}{16}$, $a_2 = \dfrac{x^5}{384}$, $a_3 = -\dfrac{x^7}{18{,}432}$, $a_4 = \dfrac{x^9}{1{,}474{,}560}$, and $a_5 = -\dfrac{x^{11}}{176{,}947{,}200}$. The partial sums seem to approximate $J_1(x)$ well near the origin, but as $|x|$ increases, we need to take a large number of terms to get a good approximation.



36. (a) $A(x) = 1 + \sum\limits_{n=1}^{\infty} a_n$, where $a_n = \dfrac{x^{3n}}{2\cdot 3\cdot 5\cdot 6\cdot\cdots\cdot(3n-1)(3n)}$, so $\lim\limits_{n\to\infty}\left|\dfrac{a_{n+1}}{a_n}\right| = |x|^3 \lim\limits_{n\to\infty}\dfrac{1}{(3n+2)(3n+3)} = 0$ for all x, so the domain is $\mathbb{R}$.

(b), (c)



$s_0 = 1$ has been omitted from the graph. The partial sums seem to approximate $A(x)$ well near the origin, but as $|x|$ increases, we need to take a large number of terms to get a good approximation.

To plot A, we must first define $A(x)$ for the CAS. Note that for $n \geq 1$, the denominator of a_n is

$2 \cdot 3 \cdot 5 \cdot 6 \cdot \cdots \cdot (3n-1) \cdot 3n = \dfrac{(3n)!}{1 \cdot 4 \cdot 7 \cdot \cdots \cdot (3n-2)} = \dfrac{(3n)!}{\prod_{k=1}^{n}(3k-2)}$, so $a_n = \dfrac{\prod_{k=1}^{n}(3k-2)}{(3n)!}x^{3n}$ and thus

$A(x) = 1 + \sum\limits_{n=1}^{\infty} \dfrac{\prod_{k=1}^{n}(3k-2)}{(3n)!}x^{3n}$. Both Maple and Mathematica are able to plot A if we define it this way, and Derive is able to produce a similar graph using a suitable partial sum of $A(x)$.

Derive, Maple and Mathematica all have two initially known Airy functions, called `AI·SERIES(z,m)` and `BI·SERIES(z,m)` from `BESSEL.MTH` in Derive and `AiryAi` and `AiryBi` in Maple and Mathematica (just `Ai` and `Bi` in older versions of Maple). However, it is very difficult to solve for A in terms of the CAS's Airy functions, although in fact $A(x) = \dfrac{\sqrt{3}\,\texttt{AiryAi}(x) + \texttt{AiryBi}(x)}{\sqrt{3}\,\texttt{AiryAi}(0) + \texttt{AiryBi}(0)}$.

37. $s_{2n-1} = 1 + 2x + x^2 + 2x^3 + x^4 + 2x^5 + \cdots + x^{2n-2} + 2x^{2n-1}$

$= 1(1+2x) + x^2(1+2x) + x^4(1+2x) + \cdots + x^{2n-2}(1+2x) = (1+2x)(1 + x^2 + x^4 + \cdots + x^{2n-2})$

$= (1+2x)\dfrac{1-x^{2n}}{1-x^2}$ [by (11.2.3) with $r = x^2$] $\to \dfrac{1+2x}{1-x^2}$ as $n \to \infty$ by (11.2.4), when $|x| < 1$.

Also $s_{2n} = s_{2n-1} + x^{2n} \to \dfrac{1+2x}{1-x^2}$ since $x^{2n} \to 0$ for $|x| < 1$. Therefore, $s_n \to \dfrac{1+2x}{1-x^2}$ since s_{2n} and s_{2n-1} both approach $\dfrac{1+2x}{1-x^2}$ as $n \to \infty$. Thus, the interval of convergence is $(-1, 1)$ and $f(x) = \dfrac{1+2x}{1-x^2}$.

38. $s_{4n-1} = c_0 + c_1x + c_2x^2 + c_3x^3 + c_0x^4 + c_1x^5 + c_2x^6 + c_3x^7 + \cdots + c_3x^{4n-1}$

$= \left(c_0 + c_1x + c_2x^2 + c_3x^3\right)\left(1 + x^4 + x^8 + \cdots + x^{4n-4}\right) \to \dfrac{c_0 + c_1x + c_2x^2 + c_3x^3}{1-x^4}$ as $n \to \infty$

[by (11.2.4) with $r = x^4$] for $|x^4| < 1 \quad \Leftrightarrow \quad |x| < 1$. Also $s_{4n}, s_{4n+1}, s_{4n+2}$ have the same limits (for example, $s_{4n} = s_{4n-1} + c_0x^{4n}$ and $x^{4n} \to 0$ for $|x| < 1$). So if at least one of c_0, c_1, c_2, and c_3 is nonzero, then the interval of convergence is $(-1, 1)$ and $f(x) = \dfrac{c_0 + c_1x + c_2x^2 + c_3x^3}{1-x^4}$.

39. We use the Root Test on the series $\sum c_nx^n$. We need $\lim\limits_{n\to\infty} \sqrt[n]{|c_nx^n|} = |x| \lim\limits_{n\to\infty} \sqrt[n]{|c_n|} = c\,|x| < 1$ for convergence, or $|x| < 1/c$, so $R = 1/c$.

40. Suppose $c_n \neq 0$. Applying the Ratio Test to the series $\sum c_n(x-a)^n$, we find that

$L = \lim\limits_{n\to\infty}\left|\dfrac{a_{n+1}}{a_n}\right| = \lim\limits_{n\to\infty}\left|\dfrac{c_{n+1}(x-a)^{n+1}}{c_n(x-a)^n}\right| = \lim\limits_{n\to\infty}\dfrac{|x-a|}{|c_n/c_{n+1}|}(*) = \dfrac{|x-a|}{\lim\limits_{n\to\infty}|c_n/c_{n+1}|}$ (if $\lim\limits_{n\to\infty}|c_n/c_{n+1}| \neq 0$), so the series converges when $\dfrac{|x-a|}{\lim\limits_{n\to\infty}|c_n/c_{n+1}|} < 1 \quad \Leftrightarrow \quad |x-a| < \lim\limits_{n\to\infty}\left|\dfrac{c_n}{c_{n+1}}\right|$. Thus, $R = \lim\limits_{n\to\infty}\left|\dfrac{c_n}{c_{n+1}}\right|$. If $\lim\limits_{n\to\infty}\left|\dfrac{c_n}{c_{n+1}}\right| = 0$ and $|x-a| \neq 0$, then $(*)$ shows that $L = \infty$ and so the series diverges, and hence, $R = 0$. Thus, in all cases, $R = \lim\limits_{n\to\infty}\left|\dfrac{c_n}{c_{n+1}}\right|$.

41. For $2 < x < 3$, $\sum c_nx^n$ diverges and $\sum d_nx^n$ converges. By Exercise 11.2.85, $\sum(c_n + d_n)\,x^n$ diverges. Since both series converge for $|x| < 2$, the radius of convergence of $\sum(c_n + d_n)\,x^n$ is 2.

42. Since $\sum c_n x^n$ converges whenever $|x| < R$, $\sum c_n x^{2n} = \sum c_n \left(x^2\right)^n$ converges whenever $\left|x^2\right| < R \quad \Leftrightarrow \quad |x| < \sqrt{R}$, so the second series has radius of convergence $\sqrt{R}$.

11.9 Representations of Functions as Power Series

1. If $f(x) = \sum\limits_{n=0}^{\infty} c_n x^n$ has radius of convergence 10, then $f'(x) = \sum\limits_{n=1}^{\infty} n c_n x^{n-1}$ also has radius of convergence 10 by Theorem 2.

2. If $f(x) = \sum\limits_{n=0}^{\infty} b_n x^n$ converges on $(-2, 2)$, then $\int f(x)\,dx = C + \sum\limits_{n=0}^{\infty} \dfrac{b_n}{n+1} x^{n+1}$ has the same radius of convergence (by Theorem 2), but may not have the same interval of convergence—it may happen that the integrated series converges at an endpoint (or both endpoints).

3. Our goal is to write the function in the form $\dfrac{1}{1-r}$, and then use Equation (1) to represent the function as a sum of a power series. $f(x) = \dfrac{1}{1+x} = \dfrac{1}{1-(-x)} = \sum\limits_{n=0}^{\infty} (-x)^n = \sum\limits_{n=0}^{\infty} (-1)^n x^n$ with $|-x| < 1 \quad \Leftrightarrow \quad |x| < 1$, so $R = 1$ and $I = (-1, 1)$.

4. $f(x) = \dfrac{5}{1-4x^2} = 5\left(\dfrac{1}{1-4x^2}\right) = 5 \sum\limits_{n=0}^{\infty} (4x^2)^n = 5 \sum\limits_{n=0}^{\infty} 4^n x^{2n}$. The series converges when $\left|4x^2\right| < 1 \quad \Leftrightarrow$ $|x|^2 < \frac{1}{4} \quad \Leftrightarrow \quad |x| < \frac{1}{2}$, so $R = \frac{1}{2}$ and $I = \left(-\frac{1}{2}, \frac{1}{2}\right)$.

5. $f(x) = \dfrac{2}{3-x} = \dfrac{2}{3}\left(\dfrac{1}{1-x/3}\right) = \dfrac{2}{3} \sum\limits_{n=0}^{\infty} \left(\dfrac{x}{3}\right)^n$ or, equivalently, $2 \sum\limits_{n=0}^{\infty} \dfrac{1}{3^{n+1}} x^n$. The series converges when $\left|\dfrac{x}{3}\right| < 1$, that is, when $|x| < 3$, so $R = 3$ and $I = (-3, 3)$.

6. $f(x) = \dfrac{4}{2x+3} = \dfrac{4}{3}\left(\dfrac{1}{1+2x/3}\right) = \dfrac{4}{3}\left(\dfrac{1}{1-(-2x/3)}\right) = \dfrac{4}{3} \sum\limits_{n=0}^{\infty} \left(-\dfrac{2x}{3}\right)^n$ or, equivalently, $\sum\limits_{n=0}^{\infty} (-1)^n \dfrac{2^{n+2}}{3^{n+1}} x^n$. The series converges when $\left|-\dfrac{2x}{3}\right| < 1$, that is, when $|x| < \frac{3}{2}$, so $R = \frac{3}{2}$ and $I = \left(-\frac{3}{2}, \frac{3}{2}\right)$.

7. $f(x) = \dfrac{x^2}{x^4+16} = \dfrac{x^2}{16}\left(\dfrac{1}{1+x^4/16}\right) = \dfrac{x^2}{16}\left(\dfrac{1}{1-[-(x/2)]^4}\right) = \dfrac{x^2}{16} \sum\limits_{n=0}^{\infty} \left[-\left(\dfrac{x}{2}\right)^4\right]^n$ or, equivalently, $\sum\limits_{n=0}^{\infty} \dfrac{(-1)^n x^{4n+2}}{2^{4n+4}}$. The series converges when $\left|-\left(\dfrac{x}{2}\right)^4\right| < 1 \quad \Rightarrow \quad \left|\dfrac{x}{2}\right| < 1 \quad \Rightarrow \quad |x| < 2$, so $R = 2$ and $I = (-2, 2)$.

8. $f(x) = \dfrac{x}{2x^2+1} = x\left(\dfrac{1}{1-(-2x^2)}\right) = x \sum\limits_{n=0}^{\infty} (-2x^2)^n$ or, equivalently, $\sum\limits_{n=0}^{\infty} (-1)^n 2^n x^{2n+1}$. The series converges when $\left|-2x^2\right| < 1 \quad \Rightarrow \quad \left|x^2\right| < \frac{1}{2} \quad \Rightarrow \quad |x| < \dfrac{1}{\sqrt{2}}$, so $R = \dfrac{1}{\sqrt{2}}$ and $I = \left(-\dfrac{1}{\sqrt{2}}, \dfrac{1}{\sqrt{2}}\right)$.

9. $f(x) = \dfrac{x-1}{x+2} = \dfrac{x+2-3}{x+2} = 1 - \dfrac{3}{x+2} = 1 - \dfrac{3/2}{x/2+1} = 1 - \dfrac{3}{2} \cdot \dfrac{1}{1-(-x/2)}$

$$= 1 - \frac{3}{2}\sum_{n=0}^{\infty}\left(-\frac{x}{2}\right)^n = 1 - \frac{3}{2} - \frac{3}{2}\sum_{n=1}^{\infty}\left(-\frac{x}{2}\right)^n = -\frac{1}{2} - \sum_{n=1}^{\infty}\frac{(-1)^n\,3x^n}{2^{n+1}}.$$

The geometric series $\sum_{n=0}^{\infty}\left(-\frac{x}{2}\right)^n$ converges when $\left|-\frac{x}{2}\right| < 1 \quad\Leftrightarrow\quad |x| < 2$, so $R = 2$ and $I = (-2, 2)$.

Alternatively, you could write $f(x) = 1 - 3\left(\dfrac{1}{x+2}\right)$ and use the series for $\dfrac{1}{x+2}$ found in Example 2.

10. $f(x) = \dfrac{a}{x^2+a^2} \quad [a > 0] \quad = \dfrac{a}{a^2}\left[\dfrac{1}{1-(-x^2/a^2)}\right] = \dfrac{1}{a}\sum_{n=0}^{\infty}\left(-\dfrac{x^2}{a^2}\right)^n = \sum_{n=0}^{\infty}\dfrac{(-1)^n x^{2n}}{a^{2n+1}}$. The geometric series $\sum_{n=0}^{\infty}\left(-\dfrac{x^2}{a^2}\right)^n$ converges when $\left|-\dfrac{x^2}{a^2}\right| < 1 \quad\Leftrightarrow\quad |x| < a$, so $R = a$ and $I = (-a, a)$.

11. $f(x) = \dfrac{2x-4}{x^2-4x+3} = \dfrac{2x-4}{(x-1)(x-3)} = \dfrac{A}{x-1} + \dfrac{B}{x-3} \quad\Rightarrow\quad 2x-4 = A(x-3) + B(x-1)$. Let $x = 1$ to get $-2 = -2A \quad\Leftrightarrow\quad A = 1$ and $x = 3$ to get $2 = 2B \quad\Leftrightarrow\quad B = 1$. Thus,

$$\frac{2x-4}{x^2-4x+3} = \frac{1}{x-1} + \frac{1}{x-3} = \frac{-1}{1-x} + \frac{1}{-3}\left[\frac{1}{1-(x/3)}\right] = -\sum_{n=0}^{\infty}x^n - \frac{1}{3}\sum_{n=0}^{\infty}\left(\frac{x}{3}\right)^n = \sum_{n=0}^{\infty}\left(-1-\frac{1}{3^{n+1}}\right)x^n.$$

We represented f as the sum of two geometric series; the first converges for $x \in (-1, 1)$ and the second converges for $x \in (-3, 3)$. Thus, the sum converges for $x \in (-1, 1) = I$.

12. $f(x) = \dfrac{2x+3}{x^2+3x+2} = \dfrac{2x+3}{(x+1)(x+2)} = \dfrac{A}{x+1} + \dfrac{B}{x+2} \quad\Rightarrow\quad 2x+3 = A(x+2) + B(x+1)$. Let $x = -1$ to get $1 = A$ and $x = -2$ to get $-1 = -B \quad\Leftrightarrow\quad B = 1$. Thus,

$$\frac{2x+3}{x^2+3x+2} = \frac{1}{x+1} + \frac{1}{x+2} = \frac{1}{1-(-x)} + \frac{1}{2}\left[\frac{1}{1-(-x/2)}\right]$$

$$= \sum_{n=0}^{\infty}(-x)^n + \frac{1}{2}\sum_{n=0}^{\infty}\left(-\frac{x}{2}\right)^n = \sum_{n=0}^{\infty}\left[(-1)^n\left(1+\frac{1}{2^{n+1}}\right)\right]x^n$$

We represented f as the sum of two geometric series; the first converges for $x \in (-1, 1)$ and the second converges for $x \in (-2, 2)$. Thus, the sum converges for $x \in (-1, 1) = I$.

13. (a) $f(x) = \dfrac{1}{(1+x)^2} = \dfrac{d}{dx}\left(\dfrac{-1}{1+x}\right) = -\dfrac{d}{dx}\left[\sum_{n=0}^{\infty}(-1)^n x^n\right]$ [from Exercise 3]

$$= \sum_{n=1}^{\infty}(-1)^{n+1}nx^{n-1} \quad \text{[from Theorem 2(i)]} \quad = \sum_{n=0}^{\infty}(-1)^n(n+1)x^n \text{ with } R = 1.$$

In the last step, note that we *decreased* the initial value of the summation variable n by 1, and then *increased* each occurrence of n in the term by 1 [also note that $(-1)^{n+2} = (-1)^n$].

(b) $f(x) = \dfrac{1}{(1+x)^3} = -\dfrac{1}{2}\dfrac{d}{dx}\left[\dfrac{1}{(1+x)^2}\right] = -\dfrac{1}{2}\dfrac{d}{dx}\left[\sum_{n=0}^{\infty}(-1)^n(n+1)x^n\right]$ [from part (a)]

$$= -\tfrac{1}{2}\sum_{n=1}^{\infty}(-1)^n(n+1)nx^{n-1} = \tfrac{1}{2}\sum_{n=0}^{\infty}(-1)^n(n+2)(n+1)x^n \text{ with } R = 1.$$

(c) $f(x) = \dfrac{x^2}{(1+x)^3} = x^2 \cdot \dfrac{1}{(1+x)^3} = x^2 \cdot \dfrac{1}{2}\sum_{n=0}^{\infty}(-1)^n(n+2)(n+1)x^n$ [from part (b)]

$$= \frac{1}{2}\sum_{n=0}^{\infty}(-1)^n(n+2)(n+1)x^{n+2}$$

[continued]

To write the power series with x^n rather than x^{n+2}, we will *decrease* each occurrence of n in the term by 2 and *increase* the initial value of the summation variable by 2. This gives us $\frac{1}{2}\sum_{n=2}^{\infty}(-1)^n(n)(n-1)x^n$ with $R = 1$.

14. (a) $\int \frac{1}{1-x}\,dx = -\ln(1-x) + C$ and

$$\int \frac{1}{1-x}\,dx = \int (1 + x + x^2 + \cdots)\,dx = \left(x + \frac{x^2}{2} + \frac{x^3}{3} + \cdots\right) + C = \sum_{n=1}^{\infty}\frac{x^n}{n} + C \text{ for } |x| < 1.$$

So $-\ln(1-x) = \sum_{n=1}^{\infty}\frac{x^n}{n} + C$ and letting $x = 0$ gives $0 = C$. Thus, $f(x) = \ln(1-x) = -\sum_{n=1}^{\infty}\frac{x^n}{n}$ with $R = 1$.

(b) $f(x) = x\ln(1-x) = -x\sum_{n=1}^{\infty}\frac{x^n}{n} = -\sum_{n=1}^{\infty}\frac{x^{n+1}}{n}$.

(c) Letting $x = \frac{1}{2}$ gives $\ln\frac{1}{2} = -\sum_{n=1}^{\infty}\frac{(1/2)^n}{n} \quad\Rightarrow\quad \ln 1 - \ln 2 = -\sum_{n=1}^{\infty}\frac{1^n}{n2^n} \quad\Rightarrow\quad \ln 2 = \sum_{n=1}^{\infty}\frac{1}{n2^n}$.

15. $f(x) = \ln(5-x) = -\int\frac{dx}{5-x} = -\frac{1}{5}\int\frac{dx}{1-x/5} = -\frac{1}{5}\int\left[\sum_{n=0}^{\infty}\left(\frac{x}{5}\right)^n\right]dx = C - \frac{1}{5}\sum_{n=0}^{\infty}\frac{x^{n+1}}{5^n(n+1)} = C - \sum_{n=1}^{\infty}\frac{x^n}{n5^n}$

Putting $x = 0$, we get $C = \ln 5$. The series converges for $|x/5| < 1 \quad\Leftrightarrow\quad |x| < 5$, so $R = 5$.

16. $f(x) = x^2\tan^{-1}(x^3) = x^2\sum_{n=0}^{\infty}(-1)^n\frac{(x^3)^{2n+1}}{2n+1}$ [by Example 7] $= \sum_{n=0}^{\infty}(-1)^n\frac{x^{6n+3+2}}{2n+1} = \sum_{n=0}^{\infty}(-1)^n\frac{x^{6n+5}}{2n+1}$ for

$\left|x^3\right| < 1 \quad\Leftrightarrow\quad |x| < 1$, so $R = 1$.

17. We know that $\frac{1}{1+4x} = \frac{1}{1-(-4x)} = \sum_{n=0}^{\infty}(-4x)^n$. Differentiating, we get

$$\frac{-4}{(1+4x)^2} = \sum_{n=1}^{\infty}(-4)^n nx^{n-1} = \sum_{n=0}^{\infty}(-4)^{n+1}(n+1)x^n, \text{ so}$$

$$f(x) = \frac{x}{(1+4x)^2} = \frac{-x}{4}\cdot\frac{-4}{(1+4x)^2} = \frac{-x}{4}\sum_{n=0}^{\infty}(-4)^{n+1}(n+1)x^n = \sum_{n=0}^{\infty}(-1)^n4^n(n+1)x^{n+1}$$

for $|-4x| < 1 \quad\Leftrightarrow\quad |x| < \frac{1}{4}$, so $R = \frac{1}{4}$.

18. $\frac{1}{2-x} = \frac{1}{2(1-x/2)} = \frac{1}{2}\sum_{n=0}^{\infty}\left(\frac{x}{2}\right)^n = \sum_{n=0}^{\infty}\frac{1}{2^{n+1}}x^n$. Now $\frac{d}{dx}\left(\frac{1}{2-x}\right) = \frac{d}{dx}\left(\sum_{n=0}^{\infty}\frac{1}{2^{n+1}}x^n\right) \quad\Rightarrow$

$$\frac{1}{(2-x)^2} = \sum_{n=1}^{\infty}\frac{1}{2^{n+1}}nx^{n-1} \text{ and } \frac{d}{dx}\left(\frac{1}{(2-x)^2}\right) = \frac{d}{dx}\left(\sum_{n=1}^{\infty}\frac{1}{2^{n+1}}nx^{n-1}\right) \quad\Rightarrow$$

$$\frac{2}{(2-x)^3} = \sum_{n=2}^{\infty}\frac{1}{2^{n+1}}n(n-1)x^{n-2} = \sum_{n=0}^{\infty}\frac{(n+2)(n+1)}{2^{n+3}}x^n.$$

Thus, $f(x) = \left(\frac{x}{2-x}\right)^3 = \frac{x^3}{(2-x)^3} = \frac{x^3}{2}\cdot\frac{2}{(2-x)^3} = \frac{x^3}{2}\sum_{n=0}^{\infty}\frac{(n+2)(n+1)}{2^{n+3}}x^n = \sum_{n=0}^{\infty}\frac{(n+2)(n+1)}{2^{n+4}}x^{n+3}$

for $\left|\frac{x}{2}\right| < 1 \quad\Leftrightarrow\quad |x| < 2$, so $R = 2$.

19. By Example 5, $\dfrac{1}{(1-x)^2} = \sum\limits_{n=0}^{\infty}(n+1)x^n$. Thus,

$$f(x) = \frac{1+x}{(1-x)^2} = \frac{1}{(1-x)^2} + \frac{x}{(1-x)^2} = \sum_{n=0}^{\infty}(n+1)x^n + \sum_{n=0}^{\infty}(n+1)x^{n+1}$$

$$= \sum_{n=0}^{\infty}(n+1)x^n + \sum_{n=1}^{\infty}nx^n \qquad \text{[make the starting values equal]}$$

$$= 1 + \sum_{n=1}^{\infty}[(n+1)+n]x^n = 1 + \sum_{n=1}^{\infty}(2n+1)x^n = \sum_{n=0}^{\infty}(2n+1)x^n \text{ with } R=1.$$

20. By Example 5, $\dfrac{1}{(1-x)^2} = \sum\limits_{n=0}^{\infty}(n+1)x^n$, so

$$\frac{d}{dx}\left(\frac{1}{(1-x)^2}\right) = \frac{d}{dx}\left(\sum_{n=0}^{\infty}(n+1)x^n\right) \quad \Rightarrow \quad \frac{2}{(1-x)^3} = \sum_{n=1}^{\infty}(n+1)nx^{n-1}. \text{ Thus,}$$

$$f(x) = \frac{x^2+x}{(1-x)^3} = \frac{x^2}{(1-x)^3} + \frac{x}{(1-x)^3} = \frac{x^2}{2}\cdot\frac{2}{(1-x)^3} + \frac{x}{2}\cdot\frac{2}{(1-x)^3}$$

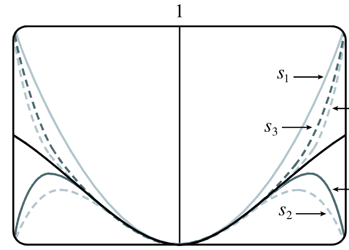
$$= \frac{x^2}{2}\sum_{n=1}^{\infty}(n+1)nx^{n-1} + \frac{x}{2}\sum_{n=1}^{\infty}(n+1)nx^{n-1} = \sum_{n=1}^{\infty}\frac{(n+1)n}{2}x^{n+1} + \sum_{n=1}^{\infty}\frac{(n+1)n}{2}x^n$$

$$= \sum_{n=2}^{\infty}\frac{n(n-1)}{2}x^n + \sum_{n=1}^{\infty}\frac{(n+1)n}{2}x^n \qquad \text{[make the exponents on } x \text{ equal by changing an index]}$$

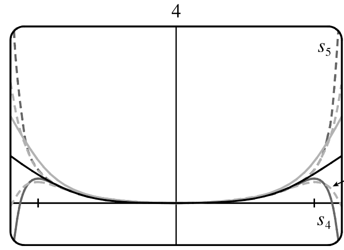
$$= \sum_{n=2}^{\infty}\frac{n^2-n}{2}x^n + x + \sum_{n=2}^{\infty}\frac{n^2+n}{2}x^n \qquad \text{[make the starting values equal]}$$

$$= x + \sum_{n=2}^{\infty}n^2x^n = \sum_{n=1}^{\infty}n^2x^n \text{ with } R=1.$$

21. $f(x) = \dfrac{x^2}{x^2+1} = x^2\left(\dfrac{1}{1-(-x^2)}\right) = x^2\sum\limits_{n=0}^{\infty}(-x^2)^n = \sum\limits_{n=0}^{\infty}(-1)^n x^{2n+2}$. This series converges when $\left|-x^2\right| < 1 \Leftrightarrow$ $x^2 < 1 \Leftrightarrow |x| < 1$, so $R = 1$. The partial sums are $s_1 = x^2$, $s_2 = s_1 - x^4$, $s_3 = s_2 + x^6$, $s_4 = s_3 - x^8$, $s_5 = s_4 + x^{10}$, ... Note that s_1 corresponds to the first term of the infinite sum, regardless of the value of the summation variable and the value of the exponent. As n increases, $s_n(x)$ approximates f better on the interval of convergence, which is $(-1, 1)$.



22. From Example 6, we have $\ln(1+x) = \sum\limits_{n=1}^{\infty}(-1)^{n-1}\dfrac{x^n}{n}$ with $|x| < 1$, so $f(x) = \ln(1+x^4) = \sum\limits_{n=1}^{\infty}(-1)^{n-1}\dfrac{x^{4n}}{n}$ with $\left|x^4\right| < 1 \Leftrightarrow |x| < 1$ $[R = 1]$. The partial sums are $s_1 = x^4$, $s_2 = s_1 - \frac{1}{2}x^8$, $s_3 = s_2 + \frac{1}{3}x^{12}$, $s_4 = s_3 - \frac{1}{4}x^{16}$, $s_5 = s_4 + \frac{1}{5}x^{20}$, ... Note that s_1 corresponds to the first term of the infinite sum, regardless of the value of the summation variable and the value of the exponent. As n increases, $s_n(x)$ approximates f better on the interval of convergence, which is $[-1, 1]$. (When $x = \pm 1$, the series is the convergent alternating harmonic series.)



23. $f(x) = \ln\left(\dfrac{1+x}{1-x}\right) = \ln(1+x) - \ln(1-x) = \displaystyle\int \frac{dx}{1+x} + \int \frac{dx}{1-x} = \int \frac{dx}{1-(-x)} + \int \frac{dx}{1-x}$

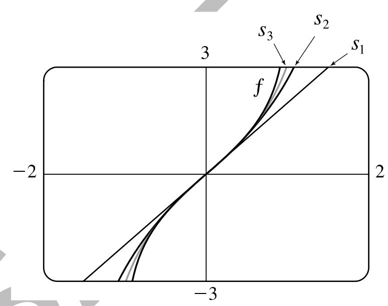
$$= \int \left[\sum_{n=0}^{\infty} (-1)^n x^n + \sum_{n=0}^{\infty} x^n\right] dx = \int [(1 - x + x^2 - x^3 + x^4 - \cdots) + (1 + x + x^2 + x^3 + x^4 + \cdots)]\, dx$$

$$= \int (2 + 2x^2 + 2x^4 + \cdots)\, dx = \int \sum_{n=0}^{\infty} 2x^{2n}\, dx = C + \sum_{n=0}^{\infty} \frac{2x^{2n+1}}{2n+1}$$

But $f(0) = \ln \frac{1}{1} = 0$, so $C = 0$ and we have $f(x) = \displaystyle\sum_{n=0}^{\infty} \frac{2x^{2n+1}}{2n+1}$ with $R = 1$. If $x = \pm 1$, then $f(x) = \pm 2 \displaystyle\sum_{n=0}^{\infty} \frac{1}{2n+1}$, which both diverge by the Limit Comparison Test with $b_n = \dfrac{1}{n}$.

The partial sums are $s_1 = \dfrac{2x}{1}$, $s_2 = s_1 + \dfrac{2x^3}{3}$, $s_3 = s_2 + \dfrac{2x^5}{5}$, ...

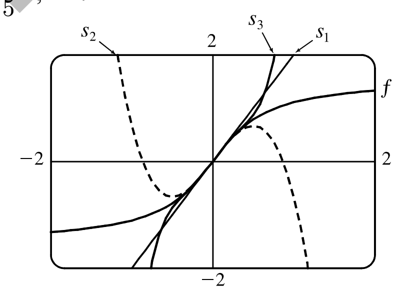
As n increases, $s_n(x)$ approximates f better on the interval of convergence, which is $(-1, 1)$.



24. $f(x) = \tan^{-1}(2x) = 2\displaystyle\int \frac{dx}{1+4x^2} = 2\int \sum_{n=0}^{\infty} (-1)^n \left(4x^2\right)^n dx = 2\int \sum_{n=0}^{\infty} (-1)^n 4^n x^{2n}\, dx$

$$= C + 2\sum_{n=0}^{\infty} \frac{(-1)^n 4^n x^{2n+1}}{2n+1} = \sum_{n=0}^{\infty} \frac{(-1)^n 2^{2n+1} x^{2n+1}}{2n+1} \qquad [f(0) = \tan^{-1} 0 = 0, \text{ so } C = 0]$$

The series converges when $\left|4x^2\right| < 1 \quad \Leftrightarrow \quad |x| < \frac{1}{2}$, so $R = \frac{1}{2}$. If $x = \pm\frac{1}{2}$, then $f(x) = \displaystyle\sum_{n=0}^{\infty} (-1)^n \frac{1}{2n+1}$ and $f(x) = \displaystyle\sum_{n=0}^{\infty} (-1)^{n+1} \frac{1}{2n+1}$, respectively. Both series converge by the Alternating Series Test. The partial sums are $s_1 = \dfrac{2x}{1}$, $s_2 = s_1 - \dfrac{2^3 x^3}{3}$, $s_3 = s_2 + \dfrac{2^5 x^5}{5}$, ...



As n increases, $s_n(x)$ approximates f better on the interval of convergence, which is $\left[-\frac{1}{2}, \frac{1}{2}\right]$.

25. $\dfrac{t}{1-t^8} = t \cdot \dfrac{1}{1-t^8} = t\displaystyle\sum_{n=0}^{\infty} (t^8)^n = \sum_{n=0}^{\infty} t^{8n+1} \quad \Rightarrow \quad \int \frac{t}{1-t^8}\, dt = C + \sum_{n=0}^{\infty} \frac{t^{8n+2}}{8n+2}$. The series for $\dfrac{1}{1-t^8}$ converges when $\left|t^8\right| < 1 \quad \Leftrightarrow \quad |t| < 1$, so $R = 1$ for that series and also the series for $t/(1-t^8)$. By Theorem 2, the series for $\displaystyle\int \frac{t}{1-t^8}\, dt$ also has $R = 1$.

26. $\dfrac{t}{1+t^3} = t \cdot \dfrac{1}{1-(-t^3)} = t\sum_{n=0}^{\infty}(-t^3)^n = \sum_{n=0}^{\infty}(-1)^n t^{3n+1} \quad\Rightarrow\quad \displaystyle\int \frac{t}{1+t^3}\,dt = C + \sum_{n=0}^{\infty}(-1)^n \frac{t^{3n+2}}{3n+2}$. The series for $\dfrac{1}{1+t^3}$ converges when $\left|-t^3\right| < 1 \quad\Leftrightarrow\quad |t| < 1$, so $R = 1$ for that series and also for the series $\dfrac{t}{1+t^3}$. By Theorem 2, the series for $\displaystyle\int \frac{t}{1+t^3}\,dt$ also has $R = 1$.

27. From Example 6, $\ln(1+x) = \sum_{n=1}^{\infty}(-1)^{n-1}\dfrac{x^n}{n}$ for $|x| < 1$, so $x^2\ln(1+x) = \sum_{n=1}^{\infty}(-1)^{n-1}\dfrac{x^{n+2}}{n}$ and $\displaystyle\int x^2\ln(1+x)\,dx = C + \sum_{n=1}^{\infty}(-1)^{n-1}\frac{x^{n+3}}{n(n+3)}$. $R = 1$ for the series for $\ln(1+x)$, so $R = 1$ for the series representing $x^2\ln(1+x)$ as well. By Theorem 2, the series for $\displaystyle\int x^2\ln(1+x)\,dx$ also has $R = 1$.

28. From Example 7, $\tan^{-1}x = \sum_{n=0}^{\infty}(-1)^n\dfrac{x^{2n+1}}{2n+1}$ for $|x| < 1$, so $\dfrac{\tan^{-1}x}{x} = \sum_{n=0}^{\infty}(-1)^n\dfrac{x^{2n}}{2n+1}$ and $\displaystyle\int \frac{\tan^{-1}x}{x}\,dx = C + \sum_{n=0}^{\infty}(-1)^n\frac{x^{2n+1}}{(2n+1)^2}$. $R = 1$ for the series for $\tan^{-1}x$, so $R = 1$ for the series representing $\dfrac{\tan^{-1}x}{x}$ as well. By Theorem 2, the series for $\displaystyle\int\frac{\tan^{-1}x}{x}\,dx$ also has $R = 1$.

29. $\dfrac{x}{1+x^3} = x\left[\dfrac{1}{1-(-x^3)}\right] = x\sum_{n=0}^{\infty}(-x^3)^n = \sum_{n=0}^{\infty}(-1)^n x^{3n+1} \quad\Rightarrow$

$\displaystyle\int \frac{x}{1+x^3}\,dx = \int \sum_{n=0}^{\infty}(-1)^n x^{3n+1}\,dx = C + \sum_{n=0}^{\infty}(-1)^n\frac{x^{3n+2}}{3n+2}$. Thus,

$I = \displaystyle\int_0^{0.3}\frac{x}{1+x^3}\,dx = \left[\frac{x^2}{2} - \frac{x^5}{5} + \frac{x^8}{8} - \frac{x^{11}}{11} + \cdots\right]_0^{0.3} = \frac{(0.3)^2}{2} - \frac{(0.3)^5}{5} + \frac{(0.3)^8}{8} - \frac{(0.3)^{11}}{11} + \cdots$.

The series is alternating, so if we use the first three terms, the error is at most $(0.3)^{11}/11 \approx 1.6\times 10^{-7}$. So $I \approx (0.3)^2/2 - (0.3)^5/5 + (0.3)^8/8 \approx 0.044\,522$ to six decimal places.

30. We substitute $x/2$ for x in Example 7, and find that

$$\begin{aligned}\int \arctan(x/2)\,dx &= \int \sum_{n=0}^{\infty}(-1)^n\frac{(x/2)^{2n+1}}{2n+1}\,dx = \int \sum_{n=0}^{\infty}(-1)^n\frac{x^{2n+1}}{2^{2n+1}(2n+1)}\,dx \\ &= C + \sum_{n=0}^{\infty}(-1)^n\frac{x^{2n+2}}{2^{2n+1}(2n+1)(2n+2)}\end{aligned}$$

Thus,

$$\begin{aligned}I = \int_0^{1/2}\arctan(x/2)\,dx &= \left[\frac{x^2}{2(1)(2)} - \frac{x^4}{2^3(3)(4)} + \frac{x^6}{2^5(5)(6)} - \frac{x^8}{2^7(7)(8)} + \frac{x^{10}}{2^9(9)(10)} - \cdots\right]_0^{1/2} \\ &= \frac{1}{2^3(1)(2)} - \frac{1}{2^7(3)(4)} + \frac{1}{2^{11}(5)(6)} - \frac{1}{2^{15}(7)(8)} + \frac{1}{2^{19}(9)(10)} - \cdots\end{aligned}$$

[continued]

The series is alternating, so if we use four terms, the error is at most $1/(2^{19} \cdot 90) \approx 2.1 \times 10^{-8}$. So

$I \approx \dfrac{1}{16} - \dfrac{1}{1536} + \dfrac{1}{61{,}440} - \dfrac{1}{1{,}835{,}008} \approx 0.061\,865$ to six decimal places.

Remark: The sum of the first three terms gives us the same answer to six decimal places, but the error is at most $1/1{,}835{,}008 \approx 5.5 \times 10^{-7}$, slightly too large to guarantee the desired accuracy.

31. We substitute x^2 for x in Example 6, and find that

$$\int x\ln(1+x^2)\,dx = \int x\sum_{n=1}^{\infty}(-1)^{n-1}\frac{(x^2)^n}{n}\,dx = \int \sum_{n=1}^{\infty}(-1)^{n-1}\frac{x^{2n+1}}{n}\,dx = C + \sum_{n=1}^{\infty}(-1)^{n-1}\frac{x^{2n+2}}{n(2n+2)}$$

Thus,

$$I \approx \int_0^{0.2} x\ln(1+x^2)\,dx = \left[\frac{x^4}{1(4)} - \frac{x^6}{2(6)} + \frac{x^8}{3(8)} - \frac{x^{10}}{4(10)} + \cdots\right]_0^{0.2} = \frac{(0.2)^4}{4} - \frac{(0.2)^6}{12} + \frac{(0.2)^8}{24} - \frac{(0.2)^{10}}{40} + \cdots$$

The series is alternating, so if we use two terms, the error is at most $(0.2)^8/24 \approx 1.1 \times 10^{-7}$. So

$I \approx \dfrac{(0.2)^4}{4} - \dfrac{(0.2)^6}{12} \approx 0.000\,395$ to six decimal places.

32. $$\int_0^{0.3} \frac{x^2}{1+x^4}\,dx = \int_0^{0.3} x^2\sum_{n=0}^{\infty}(-1)^n x^{4n}\,dx = \sum_{n=0}^{\infty}\left[\frac{(-1)^n x^{4n+3}}{4n+3}\right]_0^{0.3} = \sum_{n=0}^{\infty}\frac{(-1)^n\,3^{4n+3}}{(4n+3)10^{4n+3}}$$
$$= \frac{3^3}{3\times 10^3} - \frac{3^7}{7\times 10^7} + \frac{3^{11}}{11\times 10^{11}} - \cdots$$

The series is alternating, so if we use only two terms, the error is at most $\dfrac{3^{11}}{11\times 10^{11}} \approx 0.000\,000\,16$. So, to six decimal places, $\displaystyle\int_0^{0.3}\frac{x^2}{1+x^4}\,dx \approx \frac{3^3}{3\times 10^3} - \frac{3^7}{7\times 10^7} \approx 0.008\,969$.

33. By Example 7, $\arctan x = x - \dfrac{x^3}{3} + \dfrac{x^5}{5} - \dfrac{x^7}{7} + \cdots$, so $\arctan 0.2 = 0.2 - \dfrac{(0.2)^3}{3} + \dfrac{(0.2)^5}{5} - \dfrac{(0.2)^7}{7} + \cdots$.

The series is alternating, so if we use three terms, the error is at most $\dfrac{(0.2)^7}{7} \approx 0.000\,002$.

Thus, to five decimal places, $\arctan 0.2 \approx 0.2 - \dfrac{(0.2)^3}{3} + \dfrac{(0.2)^5}{5} \approx 0.197\,40$.

34. $f(x) = \displaystyle\sum_{n=0}^{\infty}\frac{(-1)^n x^{2n}}{(2n)!} \quad\Rightarrow\quad f'(x) = \sum_{n=1}^{\infty}\frac{(-1)^n 2n x^{2n-1}}{(2n)!}$ [the first term disappears], so

$$f''(x) = \sum_{n=1}^{\infty}\frac{(-1)^n(2n)(2n-1)x^{2n-2}}{(2n)!} = \sum_{n=1}^{\infty}\frac{(-1)^n x^{2(n-1)}}{[2(n-1)]!} = \sum_{n=0}^{\infty}\frac{(-1)^{n+1}x^{2n}}{(2n)!} \quad \text{[substituting } n+1 \text{ for } n\text{]}$$
$$= -\sum_{n=0}^{\infty}\frac{(-1)^n x^{2n}}{(2n)!} = -f(x) \quad\Rightarrow\quad f''(x) + f(x) = 0.$$

35. (a) $J_0(x) = \sum_{n=0}^{\infty} \frac{(-1)^n x^{2n}}{2^{2n}(n!)^2}$, $J_0'(x) = \sum_{n=1}^{\infty} \frac{(-1)^n 2nx^{2n-1}}{2^{2n}(n!)^2}$, and $J_0''(x) = \sum_{n=1}^{\infty} \frac{(-1)^n 2n(2n-1)x^{2n-2}}{2^{2n}(n!)^2}$, so

$$\begin{aligned} x^2 J_0''(x) + xJ_0'(x) + x^2 J_0(x) &= \sum_{n=1}^{\infty} \frac{(-1)^n 2n(2n-1)x^{2n}}{2^{2n}(n!)^2} + \sum_{n=1}^{\infty} \frac{(-1)^n 2nx^{2n}}{2^{2n}(n!)^2} + \sum_{n=0}^{\infty} \frac{(-1)^n x^{2n+2}}{2^{2n}(n!)^2} \\ &= \sum_{n=1}^{\infty} \frac{(-1)^n 2n(2n-1)x^{2n}}{2^{2n}(n!)^2} + \sum_{n=1}^{\infty} \frac{(-1)^n 2nx^{2n}}{2^{2n}(n!)^2} + \sum_{n=1}^{\infty} \frac{(-1)^{n-1} x^{2n}}{2^{2n-2}\left[(n-1)!\right]^2} \\ &= \sum_{n=1}^{\infty} \frac{(-1)^n 2n(2n-1)x^{2n}}{2^{2n}(n!)^2} + \sum_{n=1}^{\infty} \frac{(-1)^n 2nx^{2n}}{2^{2n}(n!)^2} + \sum_{n=1}^{\infty} \frac{(-1)^n(-1)^{-1}2^2n^2x^{2n}}{2^{2n}(n!)^2} \\ &= \sum_{n=1}^{\infty} (-1)^n \left[\frac{2n(2n-1) + 2n - 2^2n^2}{2^{2n}(n!)^2}\right] x^{2n} \\ &= \sum_{n=1}^{\infty} (-1)^n \left[\frac{4n^2 - 2n + 2n - 4n^2}{2^{2n}(n!)^2}\right] x^{2n} = 0 \end{aligned}$$

(b) $$\int_0^1 J_0(x)\,dx = \int_0^1 \left[\sum_{n=0}^{\infty} \frac{(-1)^n x^{2n}}{2^{2n}(n!)^2}\right] dx = \int_0^1 \left(1 - \frac{x^2}{4} + \frac{x^4}{64} - \frac{x^6}{2304} + \cdots\right) dx$$

$$= \left[x - \frac{x^3}{3\cdot 4} + \frac{x^5}{5\cdot 64} - \frac{x^7}{7\cdot 2304} + \cdots\right]_0^1 = 1 - \frac{1}{12} + \frac{1}{320} - \frac{1}{16{,}128} + \cdots$$

Since $\frac{1}{16{,}128} \approx 0.000062$, it follows from The Alternating Series Estimation Theorem that, correct to three decimal places, $\int_0^1 J_0(x)\,dx \approx 1 - \frac{1}{12} + \frac{1}{320} \approx 0.920$.

36. (a) $J_1(x) = \sum_{n=0}^{\infty} \frac{(-1)^n x^{2n+1}}{n!\,(n+1)!\,2^{2n+1}}$, $J_1'(x) = \sum_{n=0}^{\infty} \frac{(-1)^n (2n+1)\,x^{2n}}{n!\,(n+1)!\,2^{2n+1}}$, and $J_1''(x) = \sum_{n=1}^{\infty} \frac{(-1)^n (2n+1)\,(2n)\,x^{2n-1}}{n!\,(n+1)!\,2^{2n+1}}$.

$$\begin{aligned} &x^2 J_1''(x) + xJ_1'(x) + \left(x^2 - 1\right) J_1(x) \\ &\quad= \sum_{n=1}^{\infty} \frac{(-1)^n (2n+1)(2n)x^{2n+1}}{n!\,(n+1)!\,2^{2n+1}} + \sum_{n=0}^{\infty} \frac{(-1)^n (2n+1)x^{2n+1}}{n!\,(n+1)!\,2^{2n+1}} \\ &\qquad + \sum_{n=0}^{\infty} \frac{(-1)^n x^{2n+3}}{n!\,(n+1)!\,2^{2n+1}} - \sum_{n=0}^{\infty} \frac{(-1)^n x^{2n+1}}{n!\,(n+1)!\,2^{2n+1}} \\ &\quad= \sum_{n=1}^{\infty} \frac{(-1)^n (2n+1)(2n)x^{2n+1}}{n!\,(n+1)!\,2^{2n+1}} + \sum_{n=0}^{\infty} \frac{(-1)^n (2n+1)x^{2n+1}}{n!\,(n+1)!\,2^{2n+1}} \\ &\qquad - \sum_{n=1}^{\infty} \frac{(-1)^n x^{2n+1}}{(n-1)!\,n!\,2^{2n-1}} - \sum_{n=0}^{\infty} \frac{(-1)^n x^{2n+1}}{n!\,(n+1)!\,2^{2n+1}} \qquad \left[\begin{array}{c}\text{Replace } n \text{ with } n-1 \\ \text{in the third term}\end{array}\right] \\ &\quad= \frac{x}{2} - \frac{x}{2} + \sum_{n=1}^{\infty} (-1)^n \left[\frac{(2n+1)(2n) + (2n+1) - (n)(n+1)2^2 - 1}{n!\,(n+1)!\,2^{2n+1}}\right] x^{2n+1} = 0 \end{aligned}$$

(b) $J_0(x) = \sum_{n=0}^{\infty} \frac{(-1)^n x^{2n}}{2^{2n}\,(n!)^2} \quad \Rightarrow$

$$J_0'(x) = \sum_{n=1}^{\infty} \frac{(-1)^n (2n)x^{2n-1}}{2^{2n}\,(n!)^2} = \sum_{n=0}^{\infty} \frac{(-1)^{n+1}\,2(n+1)x^{2n+1}}{2^{2n+2}\left[(n+1)!\right]^2} \qquad [\text{Replace } n \text{ with } n+1]$$

$$= -\sum_{n=0}^{\infty} \frac{(-1)^n x^{2n+1}}{2^{2n+1}(n+1)!\,n!} \qquad [\text{cancel 2 and } n+1\text{; take } -1 \text{ outside sum}] \quad = -J_1(x)$$

37. (a) $f(x) = \sum_{n=0}^{\infty} \frac{x^n}{n!} \quad \Rightarrow \quad f'(x) = \sum_{n=1}^{\infty} \frac{nx^{n-1}}{n!} = \sum_{n=1}^{\infty} \frac{x^{n-1}}{(n-1)!} = \sum_{n=0}^{\infty} \frac{x^n}{n!} = f(x)$

(b) By Theorem 9.4.2, the only solution to the differential equation $df(x)/dx = f(x)$ is $f(x) = Ke^x$, but $f(0) = 1$, so $K = 1$ and $f(x) = e^x$.

Or: We could solve the equation $df(x)/dx = f(x)$ as a separable differential equation.

38. $\frac{|\sin nx|}{n^2} \le \frac{1}{n^2}$, so $\sum_{n=1}^{\infty} \frac{\sin nx}{n^2}$ converges by the Comparison Test. $\frac{d}{dx}\left(\frac{\sin nx}{n^2}\right) = \frac{\cos nx}{n}$, so when $x = 2k\pi$ [k an integer], $\sum_{n=1}^{\infty} f_n'(x) = \sum_{n=1}^{\infty} \frac{\cos(2kn\pi)}{n} = \sum_{n=1}^{\infty} \frac{1}{n}$, which diverges [harmonic series]. $f_n''(x) = -\sin nx$, so $\sum_{n=1}^{\infty} f_n''(x) = -\sum_{n=1}^{\infty} \sin nx$, which converges only if $\sin nx = 0$, or $x = k\pi$ [k an integer].

39. If $a_n = \frac{x^n}{n^2}$, then by the Ratio Test, $\lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty} \left|\frac{x^{n+1}}{(n+1)^2} \cdot \frac{n^2}{x^n}\right| = |x| \lim_{n\to\infty} \left(\frac{n}{n+1}\right)^2 = |x| < 1$ for convergence, so $R = 1$. When $x = \pm 1$, $\sum_{n=1}^{\infty} \left|\frac{x^n}{n^2}\right| = \sum_{n=1}^{\infty} \frac{1}{n^2}$ which is a convergent p-series ($p = 2 > 1$), so the interval of convergence for f is $[-1, 1]$. By Theorem 2, the radii of convergence of f' and f'' are both 1, so we need only check the endpoints. $f(x) = \sum_{n=1}^{\infty} \frac{x^n}{n^2} \quad \Rightarrow \quad f'(x) = \sum_{n=1}^{\infty} \frac{nx^{n-1}}{n^2} = \sum_{n=0}^{\infty} \frac{x^n}{n+1}$, and this series diverges for $x = 1$ (harmonic series) and converges for $x = -1$ (Alternating Series Test), so the interval of convergence is $[-1, 1)$. $f''(x) = \sum_{n=1}^{\infty} \frac{nx^{n-1}}{n+1}$ diverges at both 1 and -1 (Test for Divergence) since $\lim_{n\to\infty} \frac{n}{n+1} = 1 \ne 0$, so its interval of convergence is $(-1, 1)$.

40. (a) $\sum_{n=1}^{\infty} nx^{n-1} = \sum_{n=0}^{\infty} \frac{d}{dx} x^n = \frac{d}{dx}\left[\sum_{n=0}^{\infty} x^n\right] = \frac{d}{dx}\left[\frac{1}{1-x}\right] = -\frac{1}{(1-x)^2}(-1) = \frac{1}{(1-x)^2}$, $|x| < 1$.

(b) (i) $\sum_{n=1}^{\infty} nx^n = x \sum_{n=1}^{\infty} nx^{n-1} = x\left[\frac{1}{(1-x)^2}\right]$ [from part (a)] $= \frac{x}{(1-x)^2}$ for $|x| < 1$.

(ii) Put $x = \frac{1}{2}$ in (i): $\sum_{n=1}^{\infty} \frac{n}{2^n} = \sum_{n=1}^{\infty} n\left(\frac{1}{2}\right)^n = \frac{1/2}{(1-1/2)^2} = 2$.

(c) (i)
$$\sum_{n=2}^{\infty} n(n-1)x^n = x^2 \sum_{n=2}^{\infty} n(n-1)x^{n-2} = x^2 \frac{d}{dx}\left[\sum_{n=1}^{\infty} nx^{n-1}\right] = x^2 \frac{d}{dx} \frac{1}{(1-x)^2}$$
$$= x^2 \frac{2}{(1-x)^3} = \frac{2x^2}{(1-x)^3} \text{ for } |x| < 1.$$

(ii) Put $x = \frac{1}{2}$ in (i): $\sum_{n=2}^{\infty} \frac{n^2 - n}{2^n} = \sum_{n=2}^{\infty} n(n-1)\left(\frac{1}{2}\right)^n = \frac{2(1/2)^2}{(1-1/2)^3} = 4$.

(iii) From (b)(ii) and (c)(ii), we have $\sum_{n=1}^{\infty} \frac{n^2}{2^n} = \sum_{n=1}^{\infty} \frac{n^2 - n}{2^n} + \sum_{n=1}^{\infty} \frac{n}{2^n} = 4 + 2 = 6$.

41. By Example 7, $\tan^{-1} x = \sum_{n=0}^{\infty} (-1)^n \frac{x^{2n+1}}{2n+1}$ for $|x| < 1$. In particular, for $x = \frac{1}{\sqrt{3}}$, we

have $\frac{\pi}{6} = \tan^{-1}\left(\frac{1}{\sqrt{3}}\right) = \sum_{n=0}^{\infty} (-1)^n \frac{\left(1/\sqrt{3}\right)^{2n+1}}{2n+1} = \sum_{n=0}^{\infty} (-1)^n \left(\frac{1}{3}\right)^n \frac{1}{\sqrt{3}} \frac{1}{2n+1}$, so

$\pi = \frac{6}{\sqrt{3}} \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n+1)3^n} = 2\sqrt{3} \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n+1)3^n}$.

42. (a) $\int_0^{1/2} \frac{dx}{x^2 - x + 1} = \int_0^{1/2} \frac{dx}{(x - 1/2)^2 + 3/4}$ $\quad \left[x - \frac{1}{2} = \frac{\sqrt{3}}{2}u,\ u = \frac{2}{\sqrt{3}}\left(x - \frac{1}{2}\right),\ dx = \frac{\sqrt{3}}{2}\,du\right]$

$$= \int_{-1/\sqrt{3}}^{0} \frac{\left(\sqrt{3}/2\right) du}{(3/4)(u^2+1)} = \frac{2\sqrt{3}}{3}\left[\tan^{-1} u\right]_{-1/\sqrt{3}}^{0} = \frac{2}{\sqrt{3}}\left[0 - \left(-\frac{\pi}{6}\right)\right] = \frac{\pi}{3\sqrt{3}}$$

(b) $\frac{1}{x^3+1} = \frac{1}{(x+1)(x^2-x+1)} \quad \Rightarrow$

$$\frac{1}{x^2-x+1} = (x+1)\left(\frac{1}{1+x^3}\right) = (x+1)\frac{1}{1-(-x^3)} = (x+1)\sum_{n=0}^{\infty}(-1)^n x^{3n}$$

$$= \sum_{n=0}^{\infty}(-1)^n x^{3n+1} + \sum_{n=0}^{\infty}(-1)^n x^{3n} \quad \text{for } |x| < 1 \quad \Rightarrow$$

$$\int \frac{dx}{x^2-x+1} = C + \sum_{n=0}^{\infty}(-1)^n \frac{x^{3n+2}}{3n+2} + \sum_{n=0}^{\infty}(-1)^n \frac{x^{3n+1}}{3n+1} \text{ for } |x| < 1 \quad \Rightarrow$$

$$\int_0^{1/2} \frac{dx}{x^2-x+1} = \sum_{n=0}^{\infty}(-1)^n\left[\frac{1}{4\cdot 8^n(3n+2)} + \frac{1}{2\cdot 8^n(3n+1)}\right] = \frac{1}{4}\sum_{n=0}^{\infty}\frac{(-1)^n}{8^n}\left(\frac{2}{3n+1} + \frac{1}{3n+2}\right).$$

By part (a), this equals $\frac{\pi}{3\sqrt{3}}$, so $\pi = \frac{3\sqrt{3}}{4}\sum_{n=0}^{\infty}\frac{(-1)^n}{8^n}\left(\frac{2}{3n+1} + \frac{1}{3n+2}\right)$.

11.10 Taylor and Maclaurin Series

1. Using Theorem 5 with $\sum_{n=0}^{\infty} b_n(x-5)^n$, $b_n = \frac{f^{(n)}(a)}{n!}$, so $b_8 = \frac{f^{(8)}(5)}{8!}$.

2. (a) Using Equation 6, a power series expansion of f at 1 must have the form $f(1) + f'(1)(x-1) + \cdots$. Comparing to the given series, $1.6 - 0.8(x-1) + \cdots$, we must have $f'(1) = -0.8$. But from the graph, $f'(1)$ is positive. Hence, the given series is *not* the Taylor series of f centered at 1.

(b) A power series expansion of f at 2 must have the form $f(2) + f'(2)(x-2) + \frac{1}{2}f''(2)(x-2)^2 + \cdots$. Comparing to the given series, $2.8 + 0.5(x-2) + 1.5(x-2)^2 - 0.1(x-2)^3 + \cdots$, we must have $\frac{1}{2}f''(2) = 1.5$; that is, $f''(2)$ is positive. But from the graph, f is concave downward near $x = 2$, so $f''(2)$ must be negative. Hence, the given series is *not* the Taylor series of f centered at 2.

3. Since $f^{(n)}(0) = (n+1)!$, Equation 7 gives the Maclaurin series

$\sum_{n=0}^{\infty} \frac{f^{(n)}(0)}{n!}x^n = \sum_{n=0}^{\infty} \frac{(n+1)!}{n!}x^n = \sum_{n=0}^{\infty}(n+1)x^n$. Applying the Ratio Test with $a_n = (n+1)x^n$ gives us

$\lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty}\left|\frac{(n+2)x^{n+1}}{(n+1)x^n}\right| = |x|\lim_{n\to\infty}\frac{n+2}{n+1} = |x|\cdot 1 = |x|$. For convergence, we must have $|x|<1$, so the radius of convergence $R=1$.

4. Since $f^{(n)}(4) = \frac{(-1)^n\,n!}{3^n(n+1)}$, Equation 6 gives the Taylor series

$\sum_{n=0}^{\infty}\frac{f^{(n)}(4)}{n!}(x-4)^n = \sum_{n=0}^{\infty}\frac{(-1)^n\,n!}{3^n(n+1)\,n!}(x-4)^n = \sum_{n=0}^{\infty}\frac{(-1)^n}{3^n(n+1)}(x-4)^n$, which is the Taylor series for f centered at 4. Apply the Ratio Test to find the radius of convergence R.

$$\begin{aligned}\lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| &= \lim_{n\to\infty}\left|\frac{(-1)^{n+1}(x-4)^{n+1}}{3^{n+1}(n+2)}\cdot\frac{3^n(n+1)}{(-1)^n(x-4)^n}\right| = \lim_{n\to\infty}\left|\frac{(-1)(x-4)(n+1)}{3(n+2)}\right| \\ &= \frac{1}{3}|x-4|\lim_{n\to\infty}\frac{n+1}{n+2} = \frac{1}{3}|x-4|\end{aligned}$$

For convergence, $\frac{1}{3}|x-4|<1 \quad\Leftrightarrow\quad |x-4|<3$, so $R=3$.

5.

n	$f^{(n)}(x)$	$f^{(n)}(0)$
0	xe^x	0
1	$(x+1)e^x$	1
2	$(x+2)e^x$	2
3	$(x+3)e^x$	3
4	$(x+4)e^x$	4

Using Equation 6 with $n=0$ to 4 and $a=0$, we get

$$\begin{aligned}\sum_{n=0}^{4}\frac{f^{(n)}(0)}{n!}(x-0)^n &= \frac{0}{0!}x^0 + \frac{1}{1!}x^1 + \frac{2}{2!}x^2 + \frac{3}{3!}x^3 + \frac{4}{4!}x^4 \\ &= x + x^2 + \tfrac{1}{2}x^3 + \tfrac{1}{6}x^4\end{aligned}$$

6.

n	$f^{(n)}(x)$	$f^{(n)}(2)$
0	$\frac{1}{1+x}$	$\frac{1}{3}$
1	$-\frac{1}{(1+x)^2}$	$-\frac{1}{9}$
2	$\frac{2}{(1+x)^3}$	$\frac{2}{27}$
3	$-\frac{6}{(1+x)^4}$	$-\frac{6}{81}$

$$\begin{aligned}\sum_{n=0}^{3}\frac{f^{(n)}(2)}{n!}(x-2)^n &= \frac{\frac{1}{3}}{0!}(x-2)^0 - \frac{\frac{1}{9}}{1!}(x-2)^1 \\ &\quad + \frac{\frac{2}{27}}{2!}(x-2)^2 - \frac{\frac{6}{81}}{3!}(x-2)^3 \\ &= \tfrac{1}{3} - \tfrac{1}{9}(x-2) + \tfrac{1}{27}(x-2)^2 - \tfrac{1}{81}(x-2)^3\end{aligned}$$

7.

n	$f^{(n)}(x)$	$f^{(n)}(8)$
0	$\sqrt[3]{x}$	2
1	$\frac{1}{3x^{2/3}}$	$\frac{1}{12}$
2	$-\frac{2}{9x^{5/3}}$	$-\frac{2}{288}$
3	$\frac{10}{27x^{8/3}}$	$\frac{10}{6912}$

$$\begin{aligned}\sum_{n=0}^{3}\frac{f^{(n)}(8)}{n!}(x-8)^n &= \frac{2}{0!}(x-8)^0 + \frac{\frac{1}{12}}{1!}(x-8)^1 \\ &\quad - \frac{\frac{2}{288}}{2!}(x-8)^2 + \frac{\frac{10}{6912}}{3!}(x-8)^3 \\ &= 2 + \tfrac{1}{12}(x-8) - \tfrac{1}{288}(x-8)^2 + \tfrac{5}{20{,}736}(x-8)^3\end{aligned}$$

8.

n	$f^{(n)}(x)$	$f^{(n)}(1)$
0	$\ln x$	0
1	$1/x$	1
2	$-1/x^2$	-1
3	$2/x^3$	2
4	$-6/x^4$	-6

$$\sum_{n=0}^{4} \frac{f^{(n)}(1)}{n!}(x-1)^n = \frac{0}{0!}(x-1)^0 + \frac{1}{1!}(x-1)^1 - \frac{1}{2!}(x-1)^2 + \frac{2}{3!}(x-1)^3 - \frac{6}{4!}(x-1)^4$$
$$= (x-1) - \tfrac{1}{2}(x-1)^2 + \tfrac{1}{3}(x-1)^3 - \tfrac{1}{4}(x-1)^4$$

9.

n	$f^{(n)}(x)$	$f^{(n)}(\pi/6)$
0	$\sin x$	$1/2$
1	$\cos x$	$\sqrt{3}/2$
2	$-\sin x$	$-1/2$
3	$-\cos x$	$-\sqrt{3}/2$

$$\sum_{n=0}^{3} \frac{f^{(n)}(\pi/6)}{n!}\left(x-\frac{\pi}{6}\right)^n = \frac{1/2}{0!}\left(x-\frac{\pi}{6}\right)^0 + \frac{\sqrt{3}/2}{1!}\left(x-\frac{\pi}{6}\right)^1 - \frac{1/2}{2!}\left(x-\frac{\pi}{6}\right)^2 - \frac{\sqrt{3}/2}{3!}\left(x-\frac{\pi}{6}\right)^3$$
$$= \frac{1}{2} + \frac{\sqrt{3}}{2}\left(x-\frac{\pi}{6}\right) - \frac{1}{4}\left(x-\frac{\pi}{6}\right)^2 - \frac{\sqrt{3}}{12}\left(x-\frac{\pi}{6}\right)^3$$

10.

n	$f^{(n)}(x)$	$f^{(n)}(0)$
0	$\cos^2 x$	1
1	$-2\cos x\,\sin x = -\sin 2x$	0
2	$-2\cos 2x$	-2
3	$4\sin 2x$	0
4	$8\cos 2x$	8
5	$-16\sin 2x$	0
6	$-32\cos 2x$	-32

$$\sum_{n=0}^{6} \frac{f^{(n)}(0)}{n!}(x-0)^n = \frac{1}{0!}x^0 - \frac{2}{2!}x^2 + \frac{8}{4!}x^4 - \frac{32}{6!}x^6$$
$$= 1 - x^2 + \tfrac{1}{3}x^4 - \tfrac{2}{45}x^6$$

11.

n	$f^{(n)}(x)$	$f^{(n)}(0)$
0	$(1-x)^{-2}$	1
1	$2(1-x)^{-3}$	2
2	$6(1-x)^{-4}$	6
3	$24(1-x)^{-5}$	24
4	$120(1-x)^{-6}$	120
$\vdots$	$\vdots$	$\vdots$

$$(1-x)^{-2} = f(0) + f'(0)x + \frac{f''(0)}{2!}x^2 + \frac{f'''(0)}{3!}x^3 + \frac{f^{(4)}(0)}{4!}x^4 + \cdots$$
$$= 1 + 2x + \tfrac{6}{2}x^2 + \tfrac{24}{6}x^3 + \tfrac{120}{24}x^4 + \cdots$$
$$= 1 + 2x + 3x^2 + 4x^3 + 5x^4 + \cdots = \sum_{n=0}^{\infty}(n+1)x^n$$

$$\lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty}\left|\frac{(n+2)x^{n+1}}{(n+1)x^n}\right| = |x|\lim_{n\to\infty}\frac{n+2}{n+1} = |x|\,(1) = |x| < 1$$

for convergence, so $R = 1$.

12.

n	$f^{(n)}(x)$	$f^{(n)}(0)$
0	$\ln(1+x)$	0
1	$(1+x)^{-1}$	1
2	$-(1+x)^{-2}$	-1
3	$2(1+x)^{-3}$	2
4	$-6(1+x)^{-4}$	-6
5	$24(1+x)^{-5}$	24
$\vdots$	$\vdots$	$\vdots$

$$\begin{aligned}\ln(1+x) &= f(0)+f'(0)x+\frac{f''(0)}{2!}x^2 \\ &\quad + \frac{f'''(0)}{3!}x^3+\frac{f^{(4)}(0)}{4!}x^4+\frac{f^{(5)}(0)}{5!}x^5+\cdots \\ &= 0+x-\tfrac{1}{2}x^2+\tfrac{2}{6}x^3-\tfrac{6}{24}x^4+\tfrac{24}{120}x^5-\cdots \\ &= x-\frac{x^2}{2}+\frac{x^3}{3}-\frac{x^4}{4}+\frac{x^5}{5}-\cdots=\sum_{n=1}^{\infty}\frac{(-1)^{n-1}}{n}x^n\end{aligned}$$

$\lim\limits_{n\to\infty}\left|\dfrac{a_{n+1}}{a_n}\right| = \lim\limits_{n\to\infty}\left|\dfrac{x^{n+1}}{n+1}\cdot\dfrac{n}{x^n}\right| = \lim\limits_{n\to\infty}\dfrac{|x|}{1+1/n} = |x| < 1$ for convergence, so $R=1$.

Notice that the answer agrees with the entry for $\ln(1+x)$ in Table 1, but we obtained it by a different method. (Compare with Example 11.9.6.)

13.

n	$f^{(n)}(x)$	$f^{(n)}(0)$
0	$\cos x$	1
1	$-\sin x$	0
2	$-\cos x$	-1
3	$\sin x$	0
4	$\cos x$	1
$\vdots$	$\vdots$	$\vdots$

$$\begin{aligned}\cos x &= f(0)+f'(0)x+\frac{f''(0)}{2!}x^2+\frac{f'''(0)}{3!}x^3+\frac{f^{(4)}(0)}{4!}x^4+\cdots \\ &= 1-\frac{1}{2!}x^2+\frac{1}{4!}x^4-\cdots \\ &= \sum_{n=0}^{\infty}(-1)^n\frac{x^{2n}}{(2n)!} \qquad \text{[Equal to (16).]}\end{aligned}$$

$\lim\limits_{n\to\infty}\left|\dfrac{a_{n+1}}{a_n}\right| = \lim\limits_{n\to\infty}\left|\dfrac{x^{2n+2}}{(2n+2)!}\cdot\dfrac{(2n)!}{x^{2n}}\right| = \lim\limits_{n\to\infty}\dfrac{x^2}{(2n+2)(2n+1)} = 0 < 1$ for all x, so $R=\infty$.

14.

n	$f^{(n)}(x)$	$f^{(n)}(0)$
0	e^{-2x}	1
1	$-2e^{-2x}$	-2
2	$4e^{-2x}$	4
3	$-8e^{-2x}$	-8
4	$16e^{-2x}$	16
$\vdots$	$\vdots$	$\vdots$

$$e^{-2x}=\sum_{n=0}^{\infty}\frac{f^{(n)}(0)}{n!}x^n=\sum_{n=0}^{\infty}\frac{(-2)^n}{n!}x^n.$$

$$\lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty}\left|\frac{(-2)^{n+1}x^{n+1}}{(n+1)!}\cdot\frac{n!}{(-2)^n x^n}\right| = \lim_{n\to\infty}\frac{2\,|x|}{n+1} = 0<1 \quad \text{for all } x, \text{ so } R=\infty.$$

15.

n	$f^{(n)}(x)$	$f^{(n)}(0)$
0	2^x	1
1	$2^x(\ln 2)$	$\ln 2$
2	$2^x(\ln 2)^2$	$(\ln 2)^2$
3	$2^x(\ln 2)^3$	$(\ln 2)^3$
4	$2^x(\ln 2)^4$	$(\ln 2)^4$
$\vdots$	$\vdots$	$\vdots$

$$2^x=\sum_{n=0}^{\infty}\frac{f^{(n)}(0)}{n!}x^n=\sum_{n=0}^{\infty}\frac{(\ln 2)^n}{n!}x^n.$$

$$\lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty}\left|\frac{(\ln 2)^{n+1}x^{n+1}}{(n+1)!}\cdot\frac{n!}{(\ln 2)^n x^n}\right| = \lim_{n\to\infty}\frac{(\ln 2)\,|x|}{n+1} = 0<1 \quad \text{for all } x, \text{ so } R=\infty.$$

16.

n	$f^{(n)}(x)$	$f^{(n)}(0)$
0	$x\cos x$	0
1	$-x\sin x + \cos x$	1
2	$-x\cos x - 2\sin x$	0
3	$x\sin x - 3\cos x$	-3
4	$x\cos x + 4\sin x$	0
5	$-x\sin x + 5\cos x$	5
6	$-x\cos x - 6\sin x$	0
7	$x\sin x - 7\cos x$	-7
$\vdots$	$\vdots$	$\vdots$

$$\begin{aligned} x\cos x &= f(0) + f'(0)x + \frac{f''(0)}{2!}x^2 + \frac{f'''(0)}{3!}x^3 + \frac{f^{(4)}(0)}{4!}x^4 + \cdots \\ &= 0 + 1x + 0 - \frac{3}{3!}x^3 + 0 + \frac{5}{5!}x^5 + 0 - \frac{7}{7!}x^7 + \cdots \\ &= x - \frac{1}{2!}x^3 + \frac{1}{4!}x^5 - \frac{1}{6!}x^7 + \cdots \\ &= \sum_{n=0}^{\infty} (-1)^n \frac{1}{(2n)!} x^{2n+1} \end{aligned}$$

$$\begin{aligned} \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| &= \lim_{n\to\infty}\left|\frac{(-1)^{n+1}x^{2n+3}}{(2n+2)!}\cdot\frac{(2n)!}{(-1)^n x^{2n+1}}\right| \\ &= \lim_{n\to\infty}\frac{x^2}{(2n+2)(2n+1)} = 0 < 1 \quad \text{for all } x, \text{ so } R = \infty. \end{aligned}$$

17.

n	$f^{(n)}(x)$	$f^{(n)}(0)$
0	$\sinh x$	0
1	$\cosh x$	1
2	$\sinh x$	0
3	$\cosh x$	1
4	$\sinh x$	0
$\vdots$	$\vdots$	$\vdots$

$$f^{(n)}(0) = \begin{cases} 0 & \text{if } n \text{ is even} \\ 1 & \text{if } n \text{ is odd} \end{cases} \qquad \text{so } \sinh x = \sum_{n=0}^{\infty}\frac{x^{2n+1}}{(2n+1)!}.$$

Use the Ratio Test to find R. If $a_n = \dfrac{x^{2n+1}}{(2n+1)!}$, then

$$\begin{aligned} \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| &= \lim_{n\to\infty}\left|\frac{x^{2n+3}}{(2n+3)!}\cdot\frac{(2n+1)!}{x^{2n+1}}\right| = x^2\cdot\lim_{n\to\infty}\frac{1}{(2n+3)(2n+2)} \\ &= 0 < 1 \quad \text{for all } x, \text{ so } R = \infty. \end{aligned}$$

18.

n	$f^{(n)}(x)$	$f^{(n)}(0)$
0	$\cosh x$	1
1	$\sinh x$	0
2	$\cosh x$	1
3	$\sinh x$	0
$\vdots$	$\vdots$	$\vdots$

$$f^{(n)}(0) = \begin{cases} 1 & \text{if } n \text{ is even} \\ 0 & \text{if } n \text{ is odd} \end{cases} \qquad \text{so } \cosh x = \sum_{n=0}^{\infty}\frac{x^{2n}}{(2n)!}.$$

Use the Ratio Test to find R. If $a_n = \dfrac{x^{2n}}{(2n)!}$, then

$$\begin{aligned} \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| &= \lim_{n\to\infty}\left|\frac{x^{2n+2}}{(2n+2)!}\cdot\frac{(2n)!}{x^{2n}}\right| = x^2\cdot\lim_{n\to\infty}\frac{1}{(2n+2)(2n+1)} \\ &= 0 < 1 \quad \text{for all } x, \text{ so } R = \infty. \end{aligned}$$

19.

n	$f^{(n)}(x)$	$f^{(n)}(2)$
0	$x^5 + 2x^3 + x$	50
1	$5x^4 + 6x^2 + 1$	105
2	$20x^3 + 12x$	184
3	$60x^2 + 12$	252
4	$120x$	240
5	120	120
6	0	0
7	0	0
$\vdots$	$\vdots$	$\vdots$

$f^{(n)}(x) = 0$ for $n \geq 6$, so f has a finite expansion about $a = 2$.

$$\begin{aligned} f(x) = x^5 + 2x^3 + x &= \sum_{n=0}^{5}\frac{f^{(n)}(2)}{n!}(x-2)^n \\ &= \frac{50}{0!}(x-2)^0 + \frac{105}{1!}(x-2)^1 + \frac{184}{2!}(x-2)^2 + \frac{252}{3!}(x-2)^3 \\ &\quad + \frac{240}{4!}(x-2)^4 + \frac{120}{5!}(x-2)^5 \\ &= 50 + 105(x-2) + 92(x-2)^2 + 42(x-2)^3 \\ &\quad + 10(x-2)^4 + (x-2)^5 \end{aligned}$$

A finite series converges for all x, so $R = \infty$.

20.

n	$f^{(n)}(x)$	$f^{(n)}(-2)$
0	$x^6 - x^4 + 2$	50
1	$6x^5 - 4x^3$	-160
2	$30x^4 - 12x^2$	432
3	$120x^3 - 24x$	-912
4	$360x^2 - 24$	1416
5	$720x$	-1440
6	720	720
7	0	0
8	0	0
⋮	⋮	⋮

$f^{(n)}(x) = 0$ for $n \geq 7$, so f has a finite expansion about $a = -2$.

$$\begin{aligned} f(x) = x^6 - x^4 + 2 &= \sum_{n=0}^{6} \frac{f^{(n)}(-2)}{n!}\,(x+2)^n \\ &= \frac{50}{0!}\,(x+2)^0 - \frac{160}{1!}\,(x+2)^1 + \frac{432}{2!}\,(x+2)^2 - \frac{912}{3!}\,(x+2)^3 \\ &\qquad + \frac{1416}{4!}\,(x+2)^4 - \frac{1440}{5!}\,(x+2)^5 + \frac{720}{6!}\,(x+2)^6 \\ &= 50 - 160(x+2) + 216(x+2)^2 - 152(x+2)^3 + 59(x+2)^4 - 12(x+2)^5 + (x+2)^6 \end{aligned}$$

A finite series converges for all x, so $R = \infty$.

21.

n	$f^{(n)}(x)$	$f^{(n)}(2)$
0	$\ln x$	$\ln 2$
1	$1/x$	$1/2$
2	$-1/x^2$	$-1/2^2$
3	$2/x^3$	$2/2^3$
4	$-6/x^4$	$-6/2^4$
5	$24/x^5$	$24/2^5$
⋮	⋮	⋮

$$\begin{aligned} f(x) = \ln x &= \sum_{n=0}^{\infty} \frac{f^{(n)}(2)}{n!}\,(x-2)^n \\ &= \frac{\ln 2}{0!}\,(x-2)^0 + \frac{1}{1!\,2^1}\,(x-2)^1 + \frac{-1}{2!\,2^2}\,(x-2)^2 + \frac{2}{3!\,2^3}\,(x-2)^3 \\ &\qquad + \frac{-6}{4!\,2^4}\,(x-2)^4 + \frac{24}{5!\,2^5}\,(x-2)^5 + \cdots \\ &= \ln 2 + \sum_{n=1}^{\infty} (-1)^{n+1} \frac{(n-1)!}{n!\,2^n}\,(x-2)^n \\ &= \ln 2 + \sum_{n=1}^{\infty} (-1)^{n+1} \frac{1}{n\,2^n}\,(x-2)^n \end{aligned}$$

$$\lim_{n\to\infty} \left| \frac{a_{n+1}}{a_n} \right| = \lim_{n\to\infty} \left| \frac{(-1)^{n+2}(x-2)^{n+1}}{(n+1)\,2^{n+1}} \cdot \frac{n\,2^n}{(-1)^{n+1}(x-2)^n} \right| = \lim_{n\to\infty} \left| \frac{(-1)(x-2)n}{(n+1)2} \right| = \lim_{n\to\infty} \left(\frac{n}{n+1} \right) \frac{|x-2|}{2}$$

$= \dfrac{|x-2|}{2} < 1$ for convergence, so $|x-2| < 2$ and $R = 2$.

22.

n	$f^{(n)}(x)$	$f^{(n)}(-3)$
0	$1/x$	$-1/3$
1	$-1/x^2$	$-1/3^2$
2	$2/x^3$	$-2/3^3$
3	$-6/x^4$	$-6/3^4$
4	$24/x^5$	$-24/3^5$
$\vdots$	$\vdots$	$\vdots$

$$\begin{aligned} f(x) = \frac{1}{x} &= \sum_{n=0}^{\infty} \frac{f^{(n)}(-3)}{n!}(x+3)^n \\ &= \frac{-1/3}{0!}(x+3)^0 + \frac{-1/3^2}{1!}(x+3)^1 + \frac{-2/3^3}{2!}(x+3)^2 \\ &\qquad + \frac{-6/3^4}{3!}(x+3)^3 + \frac{-24/3^5}{4!}(x+3)^4 + \cdots \\ &= \sum_{n=0}^{\infty} \frac{-n!/3^{n+1}}{n!}(x+3)^n = -\sum_{n=0}^{\infty} \frac{(x+3)^n}{3^{n+1}} \end{aligned}$$

$$\lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty}\left|\frac{(x+3)^{n+1}}{3^{n+2}}\cdot\frac{3^{n+1}}{(x+3)^n}\right| = \lim_{n\to\infty}\frac{|x+3|}{3} = \frac{|x+3|}{3} < 1 \quad \text{for convergence,}$$

so $|x+3| < 3$ and $R = 3$.

23.

n	$f^{(n)}(x)$	$f^{(n)}(3)$
0	e^{2x}	e^6
1	$2e^{2x}$	$2e^6$

4	$-\frac{15}{16}x^{-7/2}$	$-\frac{15}{16}\cdot\frac{1}{4^7}$
$\vdots$	$\vdots$	$\vdots$

$$\begin{aligned} f(x) = \sqrt{x} &= \sum_{n=0}^{\infty}\frac{f^{(n)}(16)}{n!}(x-16)^n \\ &= \frac{4}{0!}(x-16)^0 + \frac{1}{2}\cdot\frac{1}{4}\cdot\frac{1}{1!}(x-16)^1 - \frac{1}{4}\cdot\frac{1}{4^3}\cdot\frac{1}{2!}(x-16)^2 \\ &\quad + \frac{3}{8}\cdot\frac{1}{4^5}\cdot\frac{1}{3!}(x-16)^3 - \frac{15}{16}\cdot\frac{1}{4^7}\cdot\frac{1}{4!}(x-16)^4 + \cdots \\ &= 4 + \frac{1}{8}(x-16) + \sum_{n=2}^{\infty}(-1)^{n-1}\frac{1\cdot3\cdot5\cdot\cdots\cdot(2n-3)}{2^n4^{2n-1}\,n!}(x-16)^n \\ &= 4 + \frac{1}{8}(x-16) + \sum_{n=2}^{\infty}(-1)^{n-1}\frac{1\cdot3\cdot5\cdot\cdots\cdot(2n-3)}{2^{5n-2}\,n!}(x-16)^n \end{aligned}$$

$$\begin{aligned} \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| &= \lim_{n\to\infty}\left|\frac{(-1)^n\,1\cdot3\cdot5\cdot\cdots\cdot(2n-1)(x-16)^{n+1}}{2^{5n+3}(n+1)!}\cdot\frac{2^{5n-2}n!}{(-1)^{n-1}\,1\cdot3\cdot5\cdot\cdots\cdot(2n-3)(x-16)^n}\right| \\ &= \lim_{n\to\infty}\frac{(2n-1)\,|x-16|}{2^5(n+1)} = \frac{|x-16|}{32}\lim_{n\to\infty}\frac{2-1/n}{1+1/n} = \frac{|x-16|}{32}\cdot 2 \\ &= \frac{|x-16|}{16} < 1 \quad \text{for convergence, so } |x-16| < 16 \text{ and } R = 16. \end{aligned}$$

27. If $f(x) = \cos x$, then $f^{(n+1)}(x) = \pm\sin x$ or $\pm\cos x$. In each case, $\left|f^{(n+1)}(x)\right| \le 1$, so by Formula 9 with $a = 0$ and $M = 1$, $|R_n(x)| \le \frac{1}{(n+1)!}|x|^{n+1}$. Thus, $|R_n(x)| \to 0$ as $n \to \infty$ by Equation 10. So $\lim_{n\to\infty} R_n(x) = 0$ and, by Theorem 8, the series in Exercise 13 represents $\cos x$ for all x.

28. If $f(x) = \sin x$, then $f^{(n+1)}(x) = \pm\sin x$ or $\pm\cos x$. In each case, $\left|f^{(n+1)}(x)\right| \le 1$, so by Formula 9 with $a = 0$ and $M = 1$, $|R_n(x)| \le \frac{1}{(n+1)!}|x-\pi|^{n+1}$. Thus, $|R_n(x)| \to 0$ as $n \to \infty$ by Equation 10. So $\lim_{n\to\infty} R_n(x) \to 0$ and, by Theorem 8, the series in Exercise 25 represents $\sin x$ for all x.

29. If $f(x) = \sinh x$, then for all n, $f^{(n+1)}(x) = \cosh x$ or $\sinh x$. Since $|\sinh x| < |\cosh x| = \cosh x$ for all x, we have $\left|f^{(n+1)}(x)\right| \le \cosh x$ for all n. If d is any positive number and $|x| \le d$, then $\left|f^{(n+1)}(x)\right| \le \cosh x \le \cosh d$, so by Formula 9 with $a = 0$ and $M = \cosh d$, we have $|R_n(x)| \le \dfrac{\cosh d}{(n+1)!}\,|x|^{n+1}$. It follows that $|R_n(x)| \to 0$ as $n \to \infty$ for $|x| \le d$ (by Equation 10). But d was an arbitrary positive number. So by Theorem 8, the series represents $\sinh x$ for all x.

30. If $f(x) = \cosh x$, then for all n, $f^{(n+1)}(x) = \cosh x$ or $\sinh x$. Since $|\sinh x| < |\cosh x| = \cosh x$ for all x, we have $\left|f^{(n+1)}(x)\right| \le \cosh x$ for all n. If d is any positive number and $|x| \le d$, then $\left|f^{(n+1)}(x)\right| \le \cosh x \le \cosh d$, so by Formula 9 with $a = 0$ and $M = \cosh d$, we have $|R_n(x)| \le \dfrac{\cosh d}{(n+1)!}\,|x|^{n+1}$. It follows that $|R_n(x)| \to 0$ as $n \to \infty$ for $|x| \le d$ (by Equation 10). But d was an arbitrary positive number. So by Theorem 8, the series represents $\cosh x$ for all x.

31. $$\sqrt[4]{1-x} = [1+(-x)]^{1/4} = \sum_{n=0}^{\infty}\binom{1/4}{n}(-x)^n = 1 + \tfrac{1}{4}(-x) + \frac{\frac{1}{4}\left(-\frac{3}{4}\right)}{2!}(-x)^2 + \frac{\frac{1}{4}\left(-\frac{3}{4}\right)\left(-\frac{7}{4}\right)}{3!}(-x)^3 + \cdots$$
$$= 1 - \frac{1}{4}x + \sum_{n=2}^{\infty}\frac{(-1)^{n-1}(-1)^n\cdot[3\cdot 7\cdot\cdots\cdot(4n-5)]}{4^n\cdot n!}x^n$$
$$= 1 - \frac{1}{4}x - \sum_{n=2}^{\infty}\frac{3\cdot 7\cdot\cdots\cdot(4n-5)}{4^n\cdot n!}x^n$$

and $|-x| < 1 \quad\Leftrightarrow\quad |x| < 1$, so $R = 1$.

32. $$\sqrt[3]{8+x} = \sqrt[3]{8\left(1+\frac{x}{8}\right)} = 2\left(1+\frac{x}{8}\right)^{1/3} = 2\sum_{n=0}^{\infty}\binom{1/3}{n}\left(\frac{x}{8}\right)^n$$
$$= 2\left[1 + \frac{1}{3}\left(\frac{x}{8}\right) + \frac{\frac{1}{3}\left(-\frac{2}{3}\right)}{2!}\left(\frac{x}{8}\right)^2 + \frac{\frac{1}{3}\left(-\frac{2}{3}\right)\left(-\frac{5}{3}\right)}{3!}\left(\frac{x}{8}\right)^3 + \cdots\right]$$
$$= 2\left[1 + \frac{1}{24}x + \sum_{n=2}^{\infty}\frac{(-1)^{n-1}\cdot[2\cdot 5\cdot\cdots\cdot(3n-4)]}{3^n\cdot 8^n\cdot n!}x^n\right]$$
$$= 2 + \frac{1}{12}x + 2\sum_{n=2}^{\infty}\frac{(-1)^{n-1}[2\cdot 5\cdot\cdots\cdot(3n-4)]}{24^n\cdot n!}x^n$$

and $\left|\dfrac{x}{8}\right| < 1 \quad\Leftrightarrow\quad |x| < 8$, so $R = 8$.

33. $\dfrac{1}{(2+x)^3} = \dfrac{1}{[2(1+x/2)]^3} = \dfrac{1}{8}\left(1+\dfrac{x}{2}\right)^{-3} = \dfrac{1}{8}\displaystyle\sum_{n=0}^{\infty}\binom{-3}{n}\left(\frac{x}{2}\right)^n$. The binomial coefficient is

$$\binom{-3}{n} = \frac{(-3)(-4)(-5)\cdot\cdots\cdot(-3-n+1)}{n!} = \frac{(-3)(-4)(-5)\cdot\cdots\cdot[-(n+2)]}{n!}$$
$$= \frac{(-1)^n\cdot 2\cdot 3\cdot 4\cdot 5\cdot\cdots\cdot(n+1)(n+2)}{2\cdot n!} = \frac{(-1)^n(n+1)(n+2)}{2}$$

Thus, $\dfrac{1}{(2+x)^3} = \dfrac{1}{8}\displaystyle\sum_{n=0}^{\infty}\frac{(-1)^n(n+1)(n+2)}{2}\frac{x^n}{2^n} = \sum_{n=0}^{\infty}\frac{(-1)^n(n+1)(n+2)x^n}{2^{n+4}}$ for $\left|\dfrac{x}{2}\right| < 1 \quad\Leftrightarrow\quad |x| < 2$, so $R = 2$.

34. $(1+x)^{3/4} = \sum_{n=0}^{\infty} \binom{\frac{3}{4}}{n} x^n = 1 + \frac{3}{4}x + \frac{\frac{3}{4}\left(-\frac{1}{4}\right)}{2!}x^2 + \frac{\frac{3}{4}\left(-\frac{1}{4}\right)\left(-\frac{5}{4}\right)}{3!}x^3 + \cdots$

$$= 1 + \frac{3}{4}x + \sum_{n=2}^{\infty} \frac{(-1)^{n-1} \cdot 3 \cdot [1 \cdot 5 \cdot 9 \cdot \cdots \cdot (4n-7)]}{4^n \cdot n!} x^n$$

for $|x| < 1$, so $R = 1$.

35. $\arctan x = \sum_{n=0}^{\infty} (-1)^n \frac{x^{2n+1}}{2n+1}$, so $f(x) = \arctan(x^2) = \sum_{n=0}^{\infty} (-1)^n \frac{(x^2)^{2n+1}}{2n+1} = \sum_{n=0}^{\infty} (-1)^n \frac{1}{2n+1} x^{4n+2}$, $R = 1$.

36. $\sin x = \sum_{n=0}^{\infty} (-1)^n \frac{x^{2n+1}}{(2n+1)!}$, so $f(x) = \sin\left(\frac{\pi}{4}x\right) = \sum_{n=0}^{\infty} (-1)^n \frac{\left(\frac{\pi}{4}x\right)^{2n+1}}{(2n+1)!} = \sum_{n=0}^{\infty} (-1)^n \frac{\pi^{2n+1}}{4^{2n+1}(2n+1)!} x^{2n+1}$, $R = \infty$.

37. $\cos x = \sum_{n=0}^{\infty} (-1)^n \frac{x^{2n}}{(2n)!} \Rightarrow \cos 2x = \sum_{n=0}^{\infty} (-1)^n \frac{(2x)^{2n}}{(2n)!} = \sum_{n=0}^{\infty} (-1)^n \frac{2^{2n} x^{2n}}{(2n)!}$, so

$f(x) = x \cos 2x = \sum_{n=0}^{\infty} (-1)^n \frac{2^{2n}}{(2n)!} x^{2n+1}$, $R = \infty$.

38. $e^x = \sum_{n=0}^{\infty} \frac{x^n}{n!}$, so $f(x) = e^{3x} - e^{2x} = \sum_{n=0}^{\infty} \frac{(3x)^n}{n!} - \sum_{n=0}^{\infty} \frac{(2x)^n}{n!} = \sum_{n=0}^{\infty} \frac{3^n x^n}{n!} - \sum_{n=0}^{\infty} \frac{2^n x^n}{n!} = \sum_{n=0}^{\infty} \frac{3^n - 2^n}{n!} x^n$, $R = \infty$.

39. $\cos x = \sum_{n=0}^{\infty} (-1)^n \frac{x^{2n}}{(2n)!} \Rightarrow \cos\left(\frac{1}{2}x^2\right) = \sum_{n=0}^{\infty} (-1)^n \frac{\left(\frac{1}{2}x^2\right)^{2n}}{(2n)!} = \sum_{n=0}^{\infty} (-1)^n \frac{x^{4n}}{2^{2n}(2n)!}$, so

$f(x) = x\cos\left(\frac{1}{2}x^2\right) = \sum_{n=0}^{\infty} (-1)^n \frac{1}{2^{2n}(2n)!} x^{4n+1}$, $R = \infty$.

40. $\ln(1+x) = \sum_{n=1}^{\infty} (-1)^{n-1} \frac{x^n}{n} \Rightarrow \ln(1+x^3) = \sum_{n=1}^{\infty} (-1)^{n-1} \frac{x^{3n}}{n}$, so $f(x) = x^2 \ln(1+x^3) = \sum_{n=1}^{\infty} (-1)^{n-1} \frac{x^{3n+2}}{n}$,

$R = 1$.

41. We must write the binomial in the form (1+ expression), so we'll factor out a 4.

$$\frac{x}{\sqrt{4+x^2}} = \frac{x}{\sqrt{4(1+x^2/4)}} = \frac{x}{2\sqrt{1+x^2/4}} = \frac{x}{2}\left(1+\frac{x^2}{4}\right)^{-1/2} = \frac{x}{2}\sum_{n=0}^{\infty}\binom{-\frac{1}{2}}{n}\left(\frac{x^2}{4}\right)^n$$

$$= \frac{x}{2}\left[1 + \left(-\tfrac{1}{2}\right)\frac{x^2}{4} + \frac{\left(-\frac{1}{2}\right)\left(-\frac{3}{2}\right)}{2!}\left(\frac{x^2}{4}\right)^2 + \frac{\left(-\frac{1}{2}\right)\left(-\frac{3}{2}\right)\left(-\frac{5}{2}\right)}{3!}\left(\frac{x^2}{4}\right)^3 + \cdots\right]$$

$$= \frac{x}{2} + \frac{x}{2}\sum_{n=1}^{\infty}(-1)^n \frac{1 \cdot 3 \cdot 5 \cdot \cdots \cdot (2n-1)}{2^n \cdot 4^n \cdot n!} x^{2n}$$

$$= \frac{x}{2} + \sum_{n=1}^{\infty}(-1)^n \frac{1 \cdot 3 \cdot 5 \cdot \cdots \cdot (2n-1)}{n!\, 2^{3n+1}} x^{2n+1} \text{ and } \frac{x^2}{4} < 1 \;\Leftrightarrow\; \frac{|x|}{2} < 1 \;\Leftrightarrow\; |x| < 2, \quad \text{so } R = 2.$$

42. $\dfrac{x^2}{\sqrt{2+x}} = \dfrac{x^2}{\sqrt{2\,(1+x/2)}} = \dfrac{x^2}{\sqrt{2}}\left(1+\dfrac{x}{2}\right)^{-1/2} = \dfrac{x^2}{\sqrt{2}}\displaystyle\sum_{n=0}^{\infty}\binom{-\frac{1}{2}}{n}\left(\dfrac{x}{2}\right)^n$

$$= \frac{x^2}{\sqrt{2}}\left[1+\left(-\tfrac{1}{2}\right)\left(\frac{x}{2}\right)+\frac{\left(-\frac{1}{2}\right)\left(-\frac{3}{2}\right)}{2!}\left(\frac{x}{2}\right)^2+\frac{\left(-\frac{1}{2}\right)\left(-\frac{3}{2}\right)\left(-\frac{5}{2}\right)}{3!}\left(\frac{x}{2}\right)^3+\cdots\right]$$

$$= \frac{x^2}{\sqrt{2}}+\frac{x^2}{\sqrt{2}}\sum_{n=1}^{\infty}(-1)^n\frac{1\cdot 3\cdot 5\cdot\cdots\cdot(2n-1)}{n!\,2^{2n}}x^n$$

$$= \frac{x^2}{\sqrt{2}}+\sum_{n=1}^{\infty}(-1)^n\frac{1\cdot 3\cdot 5\cdot\cdots\cdot(2n-1)}{n!\,2^{2n+1/2}}x^{n+2} \text{ and } \left|\frac{x}{2}\right|<1 \quad\Leftrightarrow\quad |x|<2, \quad \text{so } R=2.$$

43. $\sin^2 x = \dfrac{1}{2}(1-\cos 2x) = \dfrac{1}{2}\left[1-\displaystyle\sum_{n=0}^{\infty}\dfrac{(-1)^n(2x)^{2n}}{(2n)!}\right] = \dfrac{1}{2}\left[1-1-\displaystyle\sum_{n=1}^{\infty}\dfrac{(-1)^n(2x)^{2n}}{(2n)!}\right] = \displaystyle\sum_{n=1}^{\infty}\dfrac{(-1)^{n+1}2^{2n-1}x^{2n}}{(2n)!}$,

$R=\infty$

44. $\dfrac{x-\sin x}{x^3} = \dfrac{1}{x^3}\left[x-\displaystyle\sum_{n=0}^{\infty}\dfrac{(-1)^n x^{2n+1}}{(2n+1)!}\right] = \dfrac{1}{x^3}\left[x-x-\displaystyle\sum_{n=1}^{\infty}\dfrac{(-1)^n x^{2n+1}}{(2n+1)!}\right] = \dfrac{1}{x^3}\left[-\displaystyle\sum_{n=0}^{\infty}\dfrac{(-1)^{n+1}x^{2n+3}}{(2n+3)!}\right]$

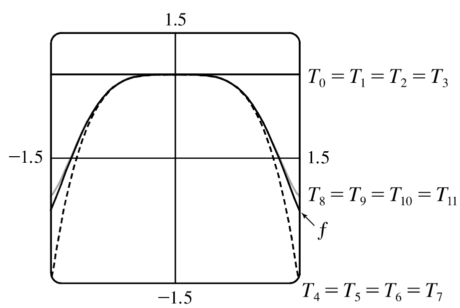
$$= \frac{1}{x^3}\sum_{n=0}^{\infty}\frac{(-1)^n x^{2n+3}}{(2n+3)!} = \sum_{n=0}^{\infty}\frac{(-1)^n x^{2n}}{(2n+3)!}$$

and this series also gives the required value at $x=0$ (namely $1/6$); $R=\infty$.

45. $\cos x \overset{(16)}{=} \displaystyle\sum_{n=0}^{\infty}(-1)^n\dfrac{x^{2n}}{(2n)!} \quad\Rightarrow$

$$f(x)=\cos(x^2)=\sum_{n=0}^{\infty}\frac{(-1)^n\,(x^2)^{2n}}{(2n)!}=\sum_{n=0}^{\infty}\frac{(-1)^n x^{4n}}{(2n)!}$$
$$=1-\tfrac{1}{2}x^4+\tfrac{1}{24}x^8-\tfrac{1}{720}x^{12}+\cdots$$

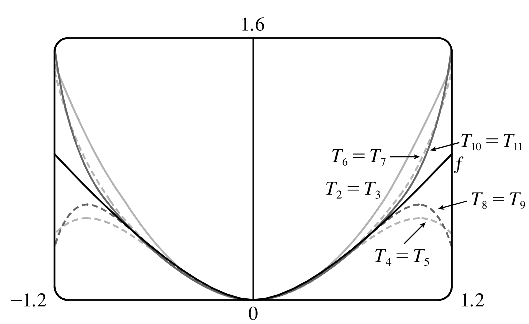
The series for $\cos x$ converges for all x, so the same is true of the series for $f(x)$, that is, $R=\infty$. Notice that, as n increases, $T_n(x)$ becomes a better approximation to $f(x)$.



46. $\ln(1+x)=\displaystyle\sum_{n=1}^{\infty}(-1)^{n-1}\dfrac{x^n}{n} \quad\Rightarrow$

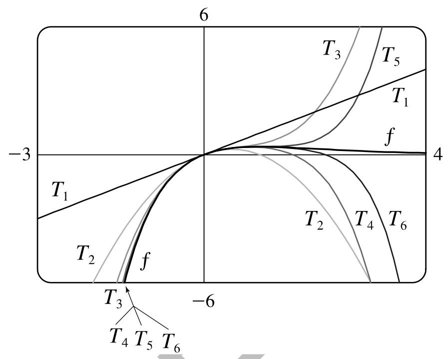
$$f(x)=\ln(1+x^2)=\sum_{n=1}^{\infty}\frac{(-1)^{n-1}(x^2)^n}{n}=\sum_{n=1}^{\infty}\frac{(-1)^{n-1}x^{2n}}{n}$$
$$=x^2-\tfrac{1}{2}x^4+\tfrac{1}{3}x^6-\tfrac{1}{4}x^8+\cdots$$

The series for $\ln(1+x)$ has $R=1$ and $\left|x^2\right|<1 \quad\Leftrightarrow\quad |x|<1$, so the series for $f(x)$ also has $R=1$. From the graphs of f and the first few Taylor polynomials, we see that $T_n(x)$ provides a closer fit to $f(x)$ near 0 as n increases.



47. $e^x \overset{(11)}{=} \sum_{n=0}^{\infty} \frac{x^n}{n!}$, so $e^{-x} = \sum_{n=0}^{\infty} \frac{(-x)^n}{n!} = \sum_{n=0}^{\infty} (-1)^n \frac{x^n}{n!}$, so

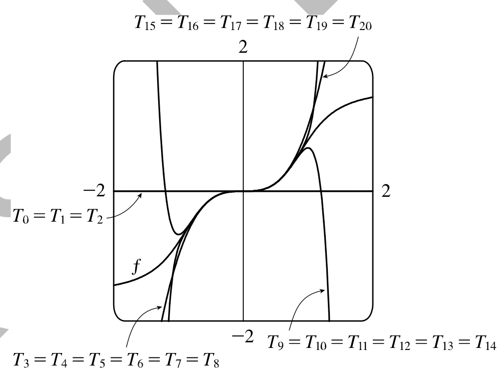
$$f(x) = xe^{-x} = \sum_{n=0}^{\infty} (-1)^n \frac{1}{n!} x^{n+1}$$
$$= x - x^2 + \tfrac{1}{2}x^3 - \tfrac{1}{6}x^4 + \tfrac{1}{24}x^5 - \tfrac{1}{120}x^6 + \cdots$$
$$= \sum_{n=1}^{\infty} (-1)^{n-1} \frac{x^n}{(n-1)!}$$



The series for e^x converges for all x, so the same is true of the series for $f(x)$; that is, $R = \infty$. From the graphs of f and the first few Taylor polynomials, we see that $T_n(x)$ provides a closer fit to $f(x)$ near 0 as n increases.

48. From Table 1, $\tan^{-1} x = \sum_{n=0}^{\infty} (-1)^n \frac{x^{2n+1}}{2n+1}$, so

$$f(x) = \tan^{-1}(x^3) = \sum_{n=0}^{\infty} (-1)^n \frac{(x^3)^{2n+1}}{2n+1} = \sum_{n=0}^{\infty} (-1)^n \frac{x^{6n+3}}{2n+1}$$
$$= x^3 - \tfrac{1}{3}x^9 + \tfrac{1}{5}x^{15} - \tfrac{1}{7}x^{21} + \cdots$$



The series for $\tan^{-1} x$ has $R = 1$ and $|x^3| < 1 \Leftrightarrow |x| < 1$, so the series for $f(x)$ also has $R = 1$. From the graphs of f and the first few Taylor polynomials, we see that $T_n(x)$ provides a closer fit to $f(x)$ near 0 as n increases.

49. $5^\circ = 5^\circ \left(\frac{\pi}{180^\circ}\right) = \frac{\pi}{36}$ radians and $\cos x = \sum_{n=0}^{\infty} (-1)^n \frac{x^{2n}}{(2n)!} = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \cdots$, so

$\cos\frac{\pi}{36} = 1 - \frac{(\pi/36)^2}{2!} + \frac{(\pi/36)^4}{4!} - \frac{(\pi/36)^6}{6!} + \cdots$. Now $1 - \frac{(\pi/36)^2}{2!} \approx 0.99619$ and adding $\frac{(\pi/36)^4}{4!} \approx 2.4 \times 10^{-6}$ does not affect the fifth decimal place, so $\cos 5^\circ \approx 0.99619$ by the Alternating Series Estimation Theorem.

50. $1/\sqrt[10]{e} = e^{-1/10}$ and $e^x = \sum_{n=0}^{\infty} \frac{x^n}{n!} = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \cdots$, so

$e^{-1/10} = 1 - \frac{1}{10} + \frac{(1/10)^2}{2!} - \frac{(1/10)^3}{3!} + \frac{(1/10)^4}{4!} - \frac{(1/10)^5}{5!} + \cdots$. Now

$1 - \frac{1}{10} + \frac{(1/10)^2}{2!} - \frac{(1/10)^3}{3!} + \frac{(1/10)^4}{4!} \approx 0.90484$ and subtracting $\frac{(1/10)^5}{5!} \approx 8.3 \times 10^{-8}$ does not affect the fifth decimal place, so $e^{-1/10} \approx 0.90484$ by the Alternating Series Estimation Theorem.

51. (a) $1/\sqrt{1-x^2} = \left[1 + (-x^2)\right]^{-1/2} = 1 + \left(-\frac{1}{2}\right)(-x^2) + \frac{\left(-\frac{1}{2}\right)\left(-\frac{3}{2}\right)}{2!}(-x^2)^2 + \frac{\left(-\frac{1}{2}\right)\left(-\frac{3}{2}\right)\left(-\frac{5}{2}\right)}{3!}(-x^2)^3 + \cdots$

$$= 1 + \sum_{n=1}^{\infty} \frac{1 \cdot 3 \cdot 5 \cdot \cdots \cdot (2n-1)}{2^n \cdot n!} x^{2n}$$

(b) $\sin^{-1} x = \int \frac{1}{\sqrt{1-x^2}}\, dx = C + x + \sum_{n=1}^{\infty} \frac{1 \cdot 3 \cdot 5 \cdot \cdots \cdot (2n-1)}{(2n+1)2^n \cdot n!} x^{2n+1}$

$$= x + \sum_{n=1}^{\infty} \frac{1 \cdot 3 \cdot 5 \cdot \cdots \cdot (2n-1)}{(2n+1)2^n \cdot n!} x^{2n+1} \quad \text{since } 0 = \sin^{-1} 0 = C.$$

52. (a) $1/\sqrt[4]{1+x} = (1+x)^{-1/4} = \sum\limits_{n=0}^{\infty} \binom{-\frac{1}{4}}{n} x^n = 1 - \frac{1}{4}x + \frac{\left(-\frac{1}{4}\right)\left(-\frac{5}{4}\right)}{2!}x^2 + \frac{\left(-\frac{1}{4}\right)\left(-\frac{5}{4}\right)\left(-\frac{9}{4}\right)}{3!}x^3 + \cdots$

$$= 1 - \frac{1}{4}x + \sum_{n=2}^{\infty} (-1)^n \frac{1 \cdot 5 \cdot 9 \cdot \cdots \cdot (4n-3)}{4^n \cdot n!} x^n$$

(b) $1/\sqrt[4]{1+x} = 1 - \frac{1}{4}x + \frac{5}{32}x^2 - \frac{15}{128}x^3 + \frac{195}{2048}x^4 - \cdots$. $1/\sqrt[4]{1.1} = 1/\sqrt[4]{1+0.1}$, so let $x = 0.1$. The sum of the first four terms is then $1 - \frac{1}{4}(0.1) + \frac{5}{32}(0.1)^2 - \frac{15}{128}(0.1)^3 \approx 0.976$. The fifth term is $\frac{195}{2048}(0.1)^4 \approx 0.000\,009\,5$, which does not affect the third decimal place of the sum, so we have $1/\sqrt[4]{1.1} \approx 0.976$. (Note that the third decimal place of the sum of the first three terms is affected by the fourth term, so we need to use more than three terms for the sum.)

53. $\sqrt{1+x^3} = (1+x^3)^{1/2} = \sum\limits_{n=0}^{\infty} \binom{\frac{1}{2}}{n} (x^3)^n = \sum\limits_{n=0}^{\infty} \binom{\frac{1}{2}}{n} x^{3n} \quad\Rightarrow\quad \int \sqrt{1+x^3}\,dx = C + \sum\limits_{n=0}^{\infty} \binom{\frac{1}{2}}{n} \frac{x^{3n+1}}{3n+1}$, with $R = 1$.

54. $\sin x = \sum\limits_{n=0}^{\infty} (-1)^n \frac{x^{2n+1}}{(2n+1)!} \quad\Rightarrow\quad \sin(x^2) = \sum\limits_{n=0}^{\infty} (-1)^n \frac{(x^2)^{2n+1}}{(2n+1)!} = \sum\limits_{n=0}^{\infty} (-1)^n \frac{x^{4n+2}}{(2n+1)!} \quad\Rightarrow$

$x^2 \sin(x^2) = \sum\limits_{n=0}^{\infty} (-1)^n \frac{x^{4n+4}}{(2n+1)!} \quad\Rightarrow\quad \int x^2 \sin(x^2)\,dx = C + \sum\limits_{n=0}^{\infty} (-1)^n \frac{x^{4n+5}}{(2n+1)!(4n+5)}$, with $R = \infty$.

55. $\cos x \overset{(16)}{=} \sum\limits_{n=0}^{\infty} (-1)^n \frac{x^{2n}}{(2n)!} \quad\Rightarrow\quad \cos x - 1 = \sum\limits_{n=1}^{\infty} (-1)^n \frac{x^{2n}}{(2n)!} \quad\Rightarrow\quad \frac{\cos x - 1}{x} = \sum\limits_{n=1}^{\infty} (-1)^n \frac{x^{2n-1}}{(2n)!} \quad\Rightarrow$

$\int \frac{\cos x - 1}{x}\,dx = C + \sum\limits_{n=1}^{\infty} (-1)^n \frac{x^{2n}}{2n \cdot (2n)!}$, with $R = \infty$.

56. $\arctan x = \sum\limits_{n=0}^{\infty} (-1)^n \frac{x^{2n+1}}{2n+1} \quad\Rightarrow\quad \arctan(x^2) = \sum\limits_{n=0}^{\infty} (-1)^n \frac{(x^2)^{2n+1}}{2n+1} = \sum\limits_{n=0}^{\infty} (-1)^n \frac{x^{4n+2}}{2n+1} \quad\Rightarrow$

$\int \arctan(x^2)\,dx = C + \sum\limits_{n=0}^{\infty} (-1)^n \frac{x^{4n+3}}{(2n+1)(4n+3)}$, with $R = 1$.

57. $\arctan x = \sum\limits_{n=0}^{\infty} (-1)^n \frac{x^{2n+1}}{2n+1}$ for $|x| < 1$, so $x^3 \arctan x = \sum\limits_{n=0}^{\infty} (-1)^n \frac{x^{2n+4}}{2n+1}$ for $|x| < 1$ and

$\int x^3 \arctan x\,dx = C + \sum\limits_{n=0}^{\infty} (-1)^n \frac{x^{2n+5}}{(2n+1)(2n+5)}$. Since $\frac{1}{2} < 1$, we have

$\int_0^{1/2} x^3 \arctan x\,dx = \sum\limits_{n=0}^{\infty} (-1)^n \frac{(1/2)^{2n+5}}{(2n+1)(2n+5)} = \frac{(1/2)^5}{1 \cdot 5} - \frac{(1/2)^7}{3 \cdot 7} + \frac{(1/2)^9}{5 \cdot 9} - \frac{(1/2)^{11}}{7 \cdot 11} + \cdots$. Now

$\frac{(1/2)^5}{1 \cdot 5} - \frac{(1/2)^7}{3 \cdot 7} + \frac{(1/2)^9}{5 \cdot 9} \approx 0.0059$ and subtracting $\frac{(1/2)^{11}}{7 \cdot 11} \approx 6.3 \times 10^{-6}$ does not affect the fourth decimal place,

so $\int_0^{1/2} x^3 \arctan x\,dx \approx 0.0059$ by the Alternating Series Estimation Theorem.

58. $\sin x = \sum\limits_{n=0}^{\infty} (-1)^n \frac{x^{2n+1}}{(2n+1)!}$ for all x, so $\sin(x^4) = \sum\limits_{n=0}^{\infty} (-1)^n \frac{x^{8n+4}}{(2n+1)!}$ for all x and

$\int \sin(x^4)\,dx = C + \sum\limits_{n=0}^{\infty} (-1)^n \frac{x^{8n+5}}{(2n+1)!\,(8n+5)}$. Thus,

$\int_0^1 \sin(x^4)\,dx = \sum\limits_{n=0}^{\infty} (-1)^n \dfrac{1}{(2n+1)!\,(8n+5)} = \dfrac{1}{1!\cdot 5} - \dfrac{1}{3!\cdot 13} + \dfrac{1}{5!\cdot 21} - \dfrac{1}{7!\cdot 29} + \cdots$. Now

$\dfrac{1}{1!\cdot 5} - \dfrac{1}{3!\cdot 13} + \dfrac{1}{5!\cdot 21} \approx 0.1876$ and subtracting $\dfrac{1}{7!\cdot 29} \approx 6.84\times 10^{-6}$ does not affect the fourth decimal place, so

$\int_0^1 \sin(x^4)\,dx \approx 0.1876$ by the Alternating Series Estimation Theorem.

59. $\sqrt{1+x^4} = (1+x^4)^{1/2} = \sum\limits_{n=0}^{\infty} \binom{\frac{1}{2}}{n} (x^4)^n$, so $\int \sqrt{1+x^4}\,dx = C + \sum\limits_{n=0}^{\infty} \binom{\frac{1}{2}}{n} \dfrac{x^{4n+1}}{4n+1}$ and hence, since $0.4 < 1$,

we have

$$\begin{aligned} I &= \int_0^{0.4} \sqrt{1+x^4}\,dx = \sum_{n=0}^{\infty} \binom{\frac{1}{2}}{n} \frac{(0.4)^{4n+1}}{4n+1} \\ &= (1)\frac{(0.4)^1}{0!} + \frac{\frac{1}{2}}{1!}\frac{(0.4)^5}{5} + \frac{\frac{1}{2}\left(-\frac{1}{2}\right)}{2!}\frac{(0.4)^9}{9} + \frac{\frac{1}{2}\left(-\frac{1}{2}\right)\left(-\frac{3}{2}\right)}{3!}\frac{(0.4)^{13}}{13} + \frac{\frac{1}{2}\left(-\frac{1}{2}\right)\left(-\frac{3}{2}\right)\left(-\frac{5}{2}\right)}{4!}\frac{(0.4)^{17}}{17} + \cdots \\ &= 0.4 + \frac{(0.4)^5}{10} - \frac{(0.4)^9}{72} + \frac{(0.4)^{13}}{208} - \frac{5(0.4)^{17}}{2176} + \cdots \end{aligned}$$

Now $\dfrac{(0.4)^9}{72} \approx 3.6\times 10^{-6} < 5\times 10^{-6}$, so by the Alternating Series Estimation Theorem, $I \approx 0.4 + \dfrac{(0.4)^5}{10} \approx 0.40102$ (correct to five decimal places).

60. $\int_0^{0.5} x^2 e^{-x^2}\,dx = \int_0^{0.5} \sum\limits_{n=0}^{\infty} \dfrac{(-1)^n x^{2n+2}}{n!}\,dx = \sum\limits_{n=0}^{\infty} \left[\dfrac{(-1)^n x^{2n+3}}{n!(2n+3)}\right]_0^{1/2} = \sum\limits_{n=0}^{\infty} \dfrac{(-1)^n}{n!(2n+3)2^{2n+3}}$ and since the term

with $n=2$ is $\dfrac{1}{1792} < 0.001$, we use $\sum\limits_{n=0}^{1} \dfrac{(-1)^n}{n!(2n+3)2^{2n+3}} = \dfrac{1}{24} - \dfrac{1}{160} \approx 0.0354$.

61. $$\begin{aligned} \lim_{x\to 0} \frac{x - \ln(1+x)}{x^2} &= \lim_{x\to 0} \frac{x - \left(x - \frac{1}{2}x^2 + \frac{1}{3}x^3 - \frac{1}{4}x^4 + \frac{1}{5}x^5 - \cdots\right)}{x^2} = \lim_{x\to 0} \frac{\frac{1}{2}x^2 - \frac{1}{3}x^3 + \frac{1}{4}x^4 - \frac{1}{5}x^5 + \cdots}{x^2} \\ &= \lim_{x\to 0} \left(\tfrac{1}{2} - \tfrac{1}{3}x + \tfrac{1}{4}x^2 - \tfrac{1}{5}x^3 + \cdots\right) = \tfrac{1}{2} \end{aligned}$$

since power series are continuous functions.

62. $$\begin{aligned} \lim_{x\to 0} \frac{1-\cos x}{1+x-e^x} &= \lim_{x\to 0} \frac{1 - \left(1 - \frac{1}{2!}x^2 + \frac{1}{4!}x^4 - \frac{1}{6!}x^6 + \cdots\right)}{1 + x - \left(1 + x + \frac{1}{2!}x^2 + \frac{1}{3!}x^3 + \frac{1}{4!}x^4 + \frac{1}{5!}x^5 + \frac{1}{6!}x^6 + \cdots\right)} \\ &= \lim_{x\to 0} \frac{\frac{1}{2!}x^2 - \frac{1}{4!}x^4 + \frac{1}{6!}x^6 - \cdots}{-\frac{1}{2!}x^2 - \frac{1}{3!}x^3 - \frac{1}{4!}x^4 - \frac{1}{5!}x^5 - \frac{1}{6!}x^6 - \cdots} \\ &= \lim_{x\to 0} \frac{\frac{1}{2!} - \frac{1}{4!}x^2 + \frac{1}{6!}x^4 - \cdots}{-\frac{1}{2!} - \frac{1}{3!}x - \frac{1}{4!}x^2 - \frac{1}{5!}x^3 - \frac{1}{6!}x^4 - \cdots} = \frac{\frac{1}{2} - 0}{-\frac{1}{2} - 0} = -1 \end{aligned}$$

since power series are continuous functions.

63. $$\begin{aligned} \lim_{x\to 0} \frac{\sin x - x + \frac{1}{6}x^3}{x^5} &= \lim_{x\to 0} \frac{\left(x - \frac{1}{3!}x^3 + \frac{1}{5!}x^5 - \frac{1}{7!}x^7 + \cdots\right) - x + \frac{1}{6}x^3}{x^5} \\ &= \lim_{x\to 0} \frac{\frac{1}{5!}x^5 - \frac{1}{7!}x^7 + \cdots}{x^5} = \lim_{x\to 0} \left(\frac{1}{5!} - \frac{x^2}{7!} + \frac{x^4}{9!} - \cdots\right) = \frac{1}{5!} = \frac{1}{120} \end{aligned}$$

since power series are continuous functions.

64. $\displaystyle \lim_{x\to 0} \frac{\sqrt{1+x} - 1 - \frac{1}{2}x}{x^2} = \lim_{x\to 0} \frac{\left(1 + \frac{1}{2}x - \frac{1}{8}x^2 + \frac{1}{16}x^3 - \cdots\right) - 1 - \frac{1}{2}x}{x^2} = \lim_{x\to 0} \frac{-\frac{1}{8}x^2 + \frac{1}{16}x^3 - \cdots}{x^2}$

$\displaystyle = \lim_{x\to 0} \left(-\tfrac{1}{8} + \tfrac{1}{16}x - \cdots\right) = -\tfrac{1}{8}$ since power series are continuous functions.

65. $\displaystyle \lim_{x\to 0} \frac{x^3 - 3x + 3\tan^{-1} x}{x^5} = \lim_{x\to 0} \frac{x^3 - 3x + 3\left(x - \frac{1}{3}x^3 + \frac{1}{5}x^5 - \frac{1}{7}x^7 + \cdots\right)}{x^5}$

$\displaystyle = \lim_{x\to 0} \frac{x^3 - 3x + 3x - x^3 + \frac{3}{5}x^5 - \frac{3}{7}x^7 + \cdots}{x^5} = \lim_{x\to 0} \frac{\frac{3}{5}x^5 - \frac{3}{7}x^7 + \cdots}{x^5}$

$\displaystyle = \lim_{x\to 0} \left(\tfrac{3}{5} - \tfrac{3}{7}x^2 + \cdots\right) = \tfrac{3}{5}$ since power series are continuous functions.

66. $\displaystyle \lim_{x\to 0} \frac{\tan x - x}{x^3} = \lim_{x\to 0} \frac{\left(x + \frac{1}{3}x^3 + \frac{2}{15}x^5 + \cdots\right) - x}{x^3} = \lim_{x\to 0} \frac{\frac{1}{3}x^3 + \frac{2}{15}x^5 + \cdots}{x^3} = \lim_{x\to 0} \left(\tfrac{1}{3} + \tfrac{2}{15}x^2 + \cdots\right) = \tfrac{1}{3}$

since power series are continuous functions.

67. From Equation 11, we have $e^{-x^2} = 1 - \dfrac{x^2}{1!} + \dfrac{x^4}{2!} - \dfrac{x^6}{3!} + \cdots$ and we know that $\cos x = 1 - \dfrac{x^2}{2!} + \dfrac{x^4}{4!} - \cdots$ from Equation 16. Therefore, $e^{-x^2} \cos x = \left(1 - x^2 + \frac{1}{2}x^4 - \cdots\right)\left(1 - \frac{1}{2}x^2 + \frac{1}{24}x^4 - \cdots\right)$. Writing only the terms with degree ≤ 4, we get $e^{-x^2} \cos x = 1 - \frac{1}{2}x^2 + \frac{1}{24}x^4 - x^2 + \frac{1}{2}x^4 + \frac{1}{2}x^4 + \cdots = 1 - \frac{3}{2}x^2 + \frac{25}{24}x^4 + \cdots$.

68. $\displaystyle \sec x = \frac{1}{\cos x} \overset{(16)}{=} \frac{1}{1 - \frac{1}{2}x^2 + \frac{1}{24}x^4 - \cdots}$.

$$
\begin{array}{r|l}
 & 1 + \frac{1}{2}x^2 + \frac{5}{24}x^4 + \cdots \\
\hline
1 - \frac{1}{2}x^2 + \frac{1}{24}x^4 - \cdots & 1 \\
 & 1 - \frac{1}{2}x^2 + \frac{1}{24}x^4 - \cdots \\
\hline
 & \qquad \frac{1}{2}x^2 - \frac{1}{24}x^4 + \cdots \\
 & \qquad \frac{1}{2}x^2 - \frac{1}{4}x^4 + \cdots \\
\hline
 & \qquad\qquad \frac{5}{24}x^4 + \cdots \\
 & \qquad\qquad \frac{5}{24}x^4 + \cdots \\
\hline
 & \qquad\qquad\qquad \cdots
\end{array}
$$

From the long division above, $\sec x = 1 + \frac{1}{2}x^2 + \frac{5}{24}x^4 + \cdots$.

69. $\displaystyle \frac{x}{\sin x} \overset{(15)}{=} \frac{x}{x - \frac{1}{6}x^3 + \frac{1}{120}x^5 - \cdots}$.

$$
\begin{array}{r|l}
 & 1 + \frac{1}{6}x^2 + \frac{7}{360}x^4 + \cdots \\
\hline
x - \frac{1}{6}x^3 + \frac{1}{120}x^5 - \cdots & x \\
 & x - \frac{1}{6}x^3 + \frac{1}{120}x^5 - \cdots \\
\hline
 & \qquad \frac{1}{6}x^3 - \frac{1}{120}x^5 + \cdots \\
 & \qquad \frac{1}{6}x^3 - \frac{1}{36}x^5 + \cdots \\
\hline
 & \qquad\qquad \frac{7}{360}x^5 + \cdots \\
 & \qquad\qquad \frac{7}{360}x^5 + \cdots \\
\hline
 & \qquad\qquad\qquad \cdots
\end{array}
$$

From the long division above, $\dfrac{x}{\sin x} = 1 + \frac{1}{6}x^2 + \frac{7}{360}x^4 + \cdots$.

70. From Table 1, we have $e^x = 1 + \frac{x}{1!} + \frac{x^2}{2!} + \frac{x^3}{3!} + \cdots$ and that $\ln(1+x) = x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \cdots$. Therefore,

$y = e^x \ln(1+x) = \left(1 + \frac{x}{1!} + \frac{x^2}{2!} + \frac{x^3}{3!} + \cdots\right)\left(x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \cdots\right)$. Writing only terms with degree ≤ 3,

we get $e^x \ln(1+x) = x - \frac{1}{2}x^2 + \frac{1}{3}x^3 + x^2 - \frac{1}{2}x^3 + \frac{1}{2}x^3 + \cdots = x + \frac{1}{2}x^2 + \frac{1}{3}x^3 + \cdots$.

71. $y = (\arctan x)^2 = \left(x - \frac{1}{3}x^3 + \frac{1}{5}x^5 - \frac{1}{7}x^7 + \cdots\right)\left(x - \frac{1}{3}x^3 + \frac{1}{5}x^5 - \frac{1}{7}x^7 + \cdots\right)$. Writing only the terms with degree ≤ 6, we get $(\arctan x)^2 = x^2 - \frac{1}{3}x^4 + \frac{1}{5}x^6 - \frac{1}{3}x^4 + \frac{1}{9}x^6 + \frac{1}{5}x^6 + \cdots = x^2 - \frac{2}{3}x^4 + \frac{23}{45}x^6 + \cdots$.

72. $y = e^x \sin^2 x = (e^x \sin x)\sin x = \left(x + x^2 + \frac{1}{3}x^3 + \cdots\right)\left(x - \frac{1}{6}x^3 + \cdots\right)$ [from Example 13]. Writing only the terms with degree ≤ 4, we get $e^x \sin^2 x = x^2 - \frac{1}{6}x^4 + x^3 + \frac{1}{3}x^4 + \cdots = x^2 + x^3 + \frac{1}{6}x^4 + \cdots$.

73. $\sum\limits_{n=0}^{\infty} (-1)^n \frac{x^{4n}}{n!} = \sum\limits_{n=0}^{\infty} \frac{(-x^4)^n}{n!} = e^{-x^4}$, by (11).

74. $\sum\limits_{n=0}^{\infty} \frac{(-1)^n \pi^{2n}}{6^{2n}(2n)!} = \sum\limits_{n=0}^{\infty} (-1)^n \frac{\left(\frac{\pi}{6}\right)^{2n}}{(2n)!} = \cos\frac{\pi}{6} = \frac{\sqrt{3}}{2}$, by (16).

75. $\sum\limits_{n=1}^{\infty} (-1)^{n-1} \frac{3^n}{n5^n} = \sum\limits_{n=1}^{\infty} (-1)^{n-1} \frac{(3/5)^n}{n} = \ln\left(1 + \frac{3}{5}\right)$ [from Table 1] $= \ln\frac{8}{5}$

76. $\sum\limits_{n=0}^{\infty} \frac{3^n}{5^n\, n!} = \sum\limits_{n=0}^{\infty} \frac{(3/5)^n}{n!} = e^{3/5}$, by (11).

77. $\sum\limits_{n=0}^{\infty} \frac{(-1)^n \pi^{2n+1}}{4^{2n+1}(2n+1)!} = \sum\limits_{n=0}^{\infty} \frac{(-1)^n \left(\frac{\pi}{4}\right)^{2n+1}}{(2n+1)!} = \sin\frac{\pi}{4} = \frac{1}{\sqrt{2}}$, by (15).

78. $1 - \ln 2 + \frac{(\ln 2)^2}{2!} - \frac{(\ln 2)^3}{3!} + \cdots = \sum\limits_{n=0}^{\infty} \frac{(-\ln 2)^n}{n!} = e^{-\ln 2} = \left(e^{\ln 2}\right)^{-1} = 2^{-1} = \frac{1}{2}$, by (11).

79. $3 + \frac{9}{2!} + \frac{27}{3!} + \frac{81}{4!} + \cdots = \frac{3^1}{1!} + \frac{3^2}{2!} + \frac{3^3}{3!} + \frac{3^4}{4!} + \cdots = \sum\limits_{n=1}^{\infty} \frac{3^n}{n!} = \sum\limits_{n=0}^{\infty} \frac{3^n}{n!} - 1 = e^3 - 1$, by (11).

80. $\frac{1}{1\cdot 2} - \frac{1}{3\cdot 2^3} + \frac{1}{5\cdot 2^5} - \frac{1}{7\cdot 2^7} + \cdots = \sum\limits_{n=0}^{\infty} (-1)^n \frac{1}{(2n+1)2^{2n+1}} = \sum\limits_{n=0}^{\infty} (-1)^n \frac{(1/2)^{2n+1}}{2n+1} = \tan^{-1}\left(\frac{1}{2}\right)$ [from Table 1]

81. If p is an nth-degree polynomial, then $p^{(i)}(x) = 0$ for $i > n$, so its Taylor series at a is $p(x) = \sum\limits_{i=0}^{n} \frac{p^{(i)}(a)}{i!}(x-a)^i$.

Put $x - a = 1$, so that $x = a + 1$. Then $p(a+1) = \sum\limits_{i=0}^{n} \frac{p^{(i)}(a)}{i!}$.

This is true for any a, so replace a by x: $p(x+1) = \sum\limits_{i=0}^{n} \frac{p^{(i)}(x)}{i!}$

82. The coefficient of x^{58} in the Maclaurin series of $f(x) = (1+x^3)^{30}$ is $\frac{f^{(58)}(0)}{58!}$. But the binomial series for $f(x)$ is

$(1+x^3)^{30} = \sum\limits_{n=0}^{\infty} \binom{30}{n} x^{3n}$, so it involves only powers of x that are multiples of 3 and therefore the coefficient of x^{58} is 0.

So $f^{(58)}(0) = 0$.

83. Assume that $|f'''(x)| \le M$, so $f'''(x) \le M$ for $a \le x \le a + d$. Now $\int_a^x f'''(t)\,dt \le \int_a^x M\,dt \Rightarrow$

$f''(x) - f''(a) \le M(x-a) \Rightarrow f''(x) \le f''(a) + M(x-a)$. Thus, $\int_a^x f''(t)\,dt \le \int_a^x [f''(a) + M(t-a)]\,dt \Rightarrow$

$f'(x) - f'(a) \le f''(a)(x-a) + \frac{1}{2}M(x-a)^2 \Rightarrow f'(x) \le f'(a) + f''(a)(x-a) + \frac{1}{2}M(x-a)^2 \Rightarrow$

$\int_a^x f'(t)\,dt \le \int_a^x \left[f'(a) + f''(a)(t-a) + \frac{1}{2}M(t-a)^2\right] dt \Rightarrow$

$f(x) - f(a) \le f'(a)(x-a) + \frac{1}{2}f''(a)(x-a)^2 + \frac{1}{6}M(x-a)^3$. So

$f(x) - f(a) - f'(a)(x-a) - \frac{1}{2}f''(a)(x-a)^2 \le \frac{1}{6}M(x-a)^3$. But

$R_2(x) = f(x) - T_2(x) = f(x) - f(a) - f'(a)(x-a) - \frac{1}{2}f''(a)(x-a)^2$, so $R_2(x) \le \frac{1}{6}M(x-a)^3$.

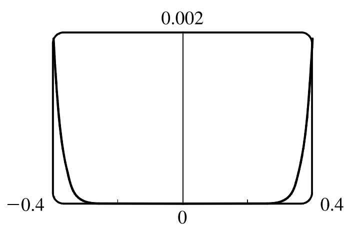
A similar argument using $f'''(x) \ge -M$ shows that $R_2(x) \ge -\frac{1}{6}M(x-a)^3$. So $|R_2(x_2)| \le \frac{1}{6}M\,|x-a|^3$.

Although we have assumed that $x > a$, a similar calculation shows that this inequality is also true if $x < a$.

84. (a) $f(x) = \begin{cases} e^{-1/x^2} & \text{if } x \ne 0 \\ 0 & \text{if } x = 0 \end{cases}$ so $f'(0) = \lim\limits_{x\to 0} \dfrac{f(x) - f(0)}{x - 0} = \lim\limits_{x\to 0} \dfrac{e^{-1/x^2}}{x} = \lim\limits_{x\to 0} \dfrac{1/x}{e^{1/x^2}} = \lim\limits_{x\to 0} \dfrac{x}{2e^{1/x^2}} = 0$

(using l'Hospital's Rule and simplifying in the penultimate step). Similarly, we can use the definition of the derivative and l'Hospital's Rule to show that $f''(0) = 0$, $f^{(3)}(0) = 0, \ldots, f^{(n)}(0) = 0$, so that the Maclaurin series for f consists entirely of zero terms. But since $f(x) \ne 0$ except for $x = 0$, we see that f cannot equal its Maclaurin series except at $x = 0$.

(b)



From the graph, it seems that the function is extremely flat at the origin. In fact, it could be said to be "infinitely flat" at $x = 0$, since all of its derivatives are 0 there.

85. (a) $g(x) = \sum\limits_{n=0}^{\infty} \dbinom{k}{n} x^n \Rightarrow g'(x) = \sum\limits_{n=1}^{\infty} \dbinom{k}{n} n x^{n-1}$, so

$$\begin{aligned}
(1+x)g'(x) &= (1+x)\sum_{n=1}^{\infty} \binom{k}{n} n x^{n-1} = \sum_{n=1}^{\infty} \binom{k}{n} n x^{n-1} + \sum_{n=1}^{\infty} \binom{k}{n} n x^n \\
&= \sum_{n=0}^{\infty} \binom{k}{n+1} (n+1) x^n + \sum_{n=0}^{\infty} \binom{k}{n} n x^n \qquad \left[\begin{array}{c}\text{Replace } n \text{ with } n+1 \\ \text{in the first series}\end{array}\right] \\
&= \sum_{n=0}^{\infty} (n+1) \frac{k(k-1)(k-2)\cdots(k-n+1)(k-n)}{(n+1)!} x^n + \sum_{n=0}^{\infty} \left[(n)\frac{k(k-1)(k-2)\cdots(k-n+1)}{n!}\right] x^n \\
&= \sum_{n=0}^{\infty} \frac{(n+1)k(k-1)(k-2)\cdots(k-n+1)}{(n+1)!} \left[(k-n) + n\right] x^n \\
&= k\sum_{n=0}^{\infty} \frac{k(k-1)(k-2)\cdots(k-n+1)}{n!} x^n = k\sum_{n=0}^{\infty} \binom{k}{n} x^n = kg(x)
\end{aligned}$$

Thus, $g'(x) = \dfrac{kg(x)}{1+x}$.

(b) $h(x) = (1+x)^{-k}\,g(x) \quad \Rightarrow$

$$\begin{aligned} h'(x) &= -k(1+x)^{-k-1}g(x) + (1+x)^{-k}\,g'(x) && \text{[Product Rule]} \\ &= -k(1+x)^{-k-1}g(x) + (1+x)^{-k}\,\frac{kg(x)}{1+x} && \text{[from part (a)]} \\ &= -k(1+x)^{-k-1}g(x) + k(1+x)^{-k-1}g(x) = 0 \end{aligned}$$

(c) From part (b) we see that $h(x)$ must be constant for $x \in (-1, 1)$, so $h(x) = h(0) = 1$ for $x \in (-1, 1)$.

Thus, $h(x) = 1 = (1+x)^{-k}\,g(x) \quad \Leftrightarrow \quad g(x) = (1+x)^k$ for $x \in (-1, 1)$.

86. Using the binomial series to expand $\sqrt{1+x}$ as a power series as in Example 9, we get

$\sqrt{1+x} = (1+x)^{1/2} = 1 + \dfrac{x}{2} + \displaystyle\sum_{n=2}^{\infty} \frac{(-1)^{n-1}1 \cdot 3 \cdot 5 \cdot \cdots \cdot (2n-3)x^n}{2^n \cdot n!}$, so

$\left(1-x^2\right)^{1/2} = 1 - \dfrac{1}{2}x^2 - \displaystyle\sum_{n=2}^{\infty} \frac{1 \cdot 3 \cdot 5 \cdot \cdots \cdot (2n-3)}{2^n \cdot n!} x^{2n}$ and

$\sqrt{1 - e^2 \sin^2\theta} = 1 - \dfrac{1}{2}e^2 \sin^2\theta - \displaystyle\sum_{n=2}^{\infty} \frac{1 \cdot 3 \cdot 5 \cdot \cdots \cdot (2n-3)}{2^n \cdot n!} e^{2n} \sin^{2n}\theta$. Thus,

$$\begin{aligned} L &= 4a \int_0^{\pi/2} \sqrt{1 - e^2\sin^2\theta}\, d\theta = 4a \int_0^{\pi/2} \left(1 - \frac{1}{2}e^2\sin^2\theta - \sum_{n=2}^{\infty} \frac{1 \cdot 3 \cdot 5 \cdot \cdots \cdot (2n-3)}{2^n \cdot n!} e^{2n}\sin^{2n}\theta\right) d\theta \\ &= 4a\left[\frac{\pi}{2} - \frac{e^2}{2}S_1 - \sum_{n=2}^{\infty} \frac{1 \cdot 3 \cdot 5 \cdot \cdots \cdot (2n-3)}{n!}\left(\frac{e^2}{2}\right)^n S_n\right] \end{aligned}$$

where $S_n = \displaystyle\int_0^{\pi/2} \sin^{2n}\theta\, d\theta = \frac{1 \cdot 3 \cdot 5 \cdot \cdots \cdot (2n-1)}{2 \cdot 4 \cdot 6 \cdot \cdots \cdot 2n}\frac{\pi}{2}$ by Exercise 7.1.50.

$$\begin{aligned} L &= 4a\left(\frac{\pi}{2}\right)\left[1 - \frac{e^2}{2} \cdot \frac{1}{2} - \sum_{n=2}^{\infty} \frac{1 \cdot 3 \cdot 5 \cdot \cdots \cdot (2n-3)}{n!}\left(\frac{e^2}{2}\right)^n \frac{1 \cdot 3 \cdot 5 \cdot \cdots \cdot (2n-1)}{2 \cdot 4 \cdot 6 \cdot \cdots \cdot 2n}\right] \\ &= 2\pi a\left[1 - \frac{e^2}{4} - \sum_{n=2}^{\infty} \frac{e^{2n}}{2^n} \cdot \frac{1^2 \cdot 3^2 \cdot 5^2 \cdot \cdots \cdot (2n-3)^2(2n-1)}{n! \cdot 2^n \cdot n!}\right] \\ &= 2\pi a\left[1 - \frac{e^2}{4} - \sum_{n=2}^{\infty} \frac{e^{2n}}{4^n}\left(\frac{1 \cdot 3 \cdot \cdots \cdot (2n-3)}{n!}\right)^2 (2n-1)\right] \\ &= 2\pi a\left[1 - \frac{e^2}{4} - \frac{3e^4}{64} - \frac{5e^6}{256} - \cdots\right] = \frac{\pi a}{128}\left(256 - 64e^2 - 12e^4 - 5e^6 - \cdots\right) \end{aligned}$$

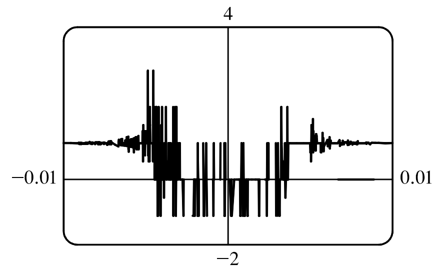
LABORATORY PROJECT An Elusive Limit

1. $f(x) = \dfrac{n(x)}{d(x)} = \dfrac{\sin(\tan x) - \tan(\sin x)}{\arcsin(\arctan x) - \arctan(\arcsin x)}$

The table of function values were obtained using Maple with 10 digits of precision. The results of this project will vary depending on the CAS and precision level. It appears that as $x \to 0^+$, $f(x) \to \frac{10}{3}$. Since f is an even function, we have $f(x) \to \frac{10}{3}$ as $x \to 0$.

x	$f(x)$
1	1.1838
0.1	0.9821
0.01	2.0000
0.001	3.3333
0.0001	3.3333

2. The graph is inconclusive about the limit of f as $x \to 0$.



3. The limit has the indeterminate form $\frac{0}{0}$. Applying l'Hospital's Rule, we obtain the form $\frac{0}{0}$ six times. Finally, on the seventh application we obtain $\lim\limits_{x\to 0} \dfrac{n^{(7)}(x)}{d^{(7)}(x)} = \dfrac{-168}{-168} = 1$.

4. $$\lim_{x\to 0} f(x) = \lim_{x\to 0} \frac{n(x)}{d(x)} \overset{\text{CAS}}{=} \lim_{x\to 0} \frac{-\frac{1}{30}x^7 - \frac{29}{756}x^9 + \cdots}{-\frac{1}{30}x^7 + \frac{13}{756}x^9 + \cdots}$$

$$= \lim_{x\to 0} \frac{\left(-\frac{1}{30}x^7 - \frac{29}{756}x^9 + \cdots\right)/x^7}{\left(-\frac{1}{30}x^7 + \frac{13}{756}x^9 + \cdots\right)/x^7} = \lim_{x\to 0} \frac{-\frac{1}{30} - \frac{29}{756}x^2 + \cdots}{-\frac{1}{30} + \frac{13}{756}x^2 + \cdots} = \frac{-\frac{1}{30}}{-\frac{1}{30}} = 1$$

Note that $n^{(7)}(x) = d^{(7)}(x) = -\frac{7!}{30} = -\frac{5040}{30} = -168$, which agrees with the result in Problem 3.

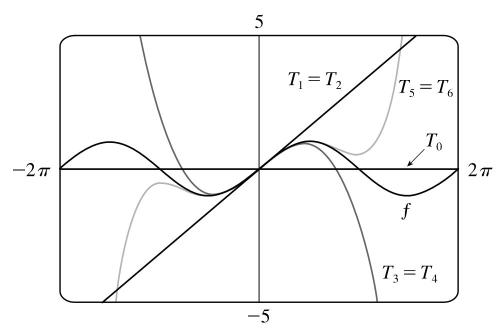
5. The limit command gives the result that $\lim\limits_{x\to 0} f(x) = 1$.

6. The strange results (with only 10 digits of precision) must be due to the fact that the terms being subtracted in the numerator and denominator are very close in value when $|x|$ is small. Thus, the differences are imprecise (have few correct digits).

11.11 Applications of Taylor Polynomials

1. (a)

n	$f^{(n)}(x)$	$f^{(n)}(0)$	$T_n(x)$
0	$\sin x$	0	0
1	$\cos x$	1	x
2	$-\sin x$	0	x
3	$-\cos x$	-1	$x - \frac{1}{6}x^3$
4	$\sin x$	0	$x - \frac{1}{6}x^3$
5	$\cos x$	1	$x - \frac{1}{6}x^3 + \frac{1}{120}x^5$



Note: $T_n(x) = \sum\limits_{k=0}^{n} \dfrac{f^{(k)}(0)}{k!}\, x^k$

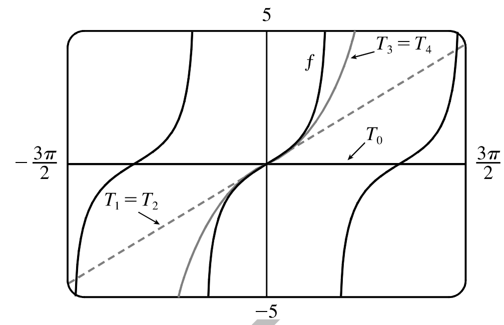
(b)

x	f	$T_0(x)$	$T_1(x) = T_2(x)$	$T_3(x) = T_4(x)$	$T_5(x)$
$\frac{\pi}{4}$	0.7071	0	0.7854	0.7047	0.7071
$\frac{\pi}{2}$	1	0	1.5708	0.9248	1.0045
π	0	0	3.1416	-2.0261	0.5240

(c) As n increases, $T_n(x)$ is a good approximation to $f(x)$ on a larger and larger interval.

2. (a)

n	$f^{(n)}(x)$	$f^{(n)}(0)$	$T_n(x)$
0	$\tan x$	0	0
1	$\sec^2 x$	1	x
2	$2\sec^2 x\,\tan x$	0	x
3	$4\sec^2 x\,\tan^2 x + 2\sec^4 x$	2	$x + \frac{1}{3}x^3$



(b)

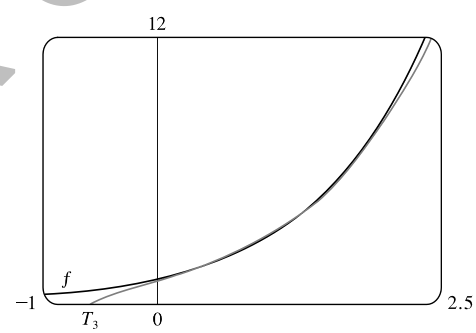
x	f	$T_0(x)$	$T_1(x) = T_2(x)$	$T_3(x)$
$\frac{\pi}{6}$	0.5774	0	0.5236	0.5714
$\frac{\pi}{4}$	1	0	0.7854	0.9469
$\frac{\pi}{3}$	1.7321	0	1.0472	1.4300

Note: $T_n(x) = \sum_{k=0}^{n} \frac{f^{(k)}(0)}{k!} x^k$

(c) As n increases, $T_n(x)$ is a good approximation to $f(x)$ on a larger and larger interval. Because the Taylor polynomials are continuous, they cannot approximate the infinite discontinuities at $x = \pm\pi/2$. They can only approximate $\tan x$ on $(-\pi/2, \pi/2)$.

3.

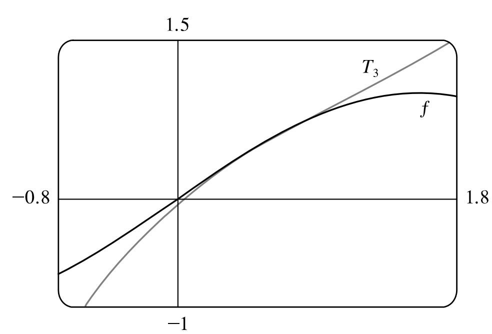
n	$f^{(n)}(x)$	$f^{(n)}(1)$
0	e^x	e
1	e^x	e
2	e^x	e
3	e^x	e



$$T_3(x) = \sum_{n=0}^{3} \frac{f^{(n)}(1)}{n!}(x-1)^n$$
$$= \frac{e}{0!}(x-1)^0 + \frac{e}{1!}(x-1)^1 + \frac{e}{2!}(x-1)^2 + \frac{e}{3!}(x-1)^3$$
$$= e + e(x-1) + \tfrac{1}{2}e(x-1)^2 + \tfrac{1}{6}e(x-1)^3$$

4.

n	$f^{(n)}(x)$	$f^{(n)}(\pi/6)$
0	$\sin x$	$1/2$
1	$\cos x$	$\sqrt{3}/2$
2	$-\sin x$	$-1/2$
3	$-\cos x$	$-\sqrt{3}/2$

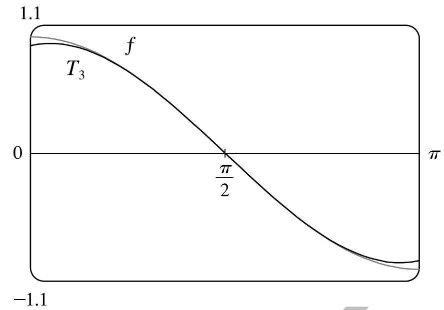


$$T_3(x) = \sum_{n=0}^{3} \frac{f^{(n)}(\pi/6)}{n!}\left(x - \frac{\pi}{6}\right)^n$$
$$= \frac{1/2}{0!}\left(x-\frac{\pi}{6}\right)^0 + \frac{\sqrt{3}/2}{1!}\left(x-\frac{\pi}{6}\right)^1 - \frac{1/2}{2!}\left(x-\frac{\pi}{6}\right)^2 + \frac{\sqrt{3}/2}{3!}\left(x-\frac{\pi}{6}\right)^3$$
$$= \frac{1}{2} + \frac{\sqrt{3}}{2}\left(x-\frac{\pi}{6}\right) - \frac{1}{4}\left(x-\frac{\pi}{6}\right)^2 - \frac{\sqrt{3}}{12}\left(x-\frac{\pi}{6}\right)^3$$

5.

n	$f^{(n)}(x)$	$f^{(n)}(\pi/2)$
0	$\cos x$	0
1	$-\sin x$	-1
2	$-\cos x$	0
3	$\sin x$	1

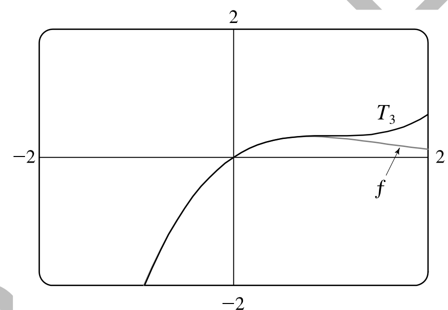
$$T_3(x) = \sum_{n=0}^{3} \frac{f^{(n)}(\pi/2)}{n!}\left(x - \tfrac{\pi}{2}\right)^n$$
$$= -\left(x - \tfrac{\pi}{2}\right) + \tfrac{1}{6}\left(x - \tfrac{\pi}{2}\right)^3$$



6.

n	$f^{(n)}(x)$	$f^{(n)}(0)$
0	$e^{-x}\sin x$	0
1	$e^{-x}(\cos x - \sin x)$	1
2	$-2e^{-x}\cos x$	-2
3	$2e^{-x}(\cos x + \sin x)$	2

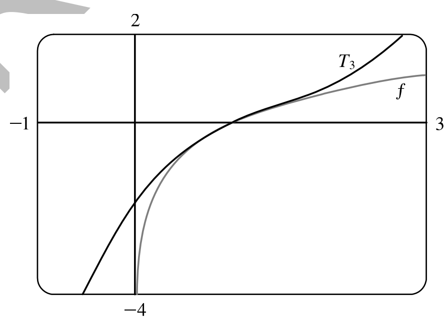
$$T_3(x) = \sum_{n=0}^{3} \frac{f^{(n)}(0)}{n!}x^n = x - x^2 + \tfrac{1}{3}x^3$$



7.

n	$f^{(n)}(x)$	$f^{(n)}(1)$
0	$\ln x$	0
1	$1/x$	1
2	$-1/x^2$	-1
3	$2/x^3$	2

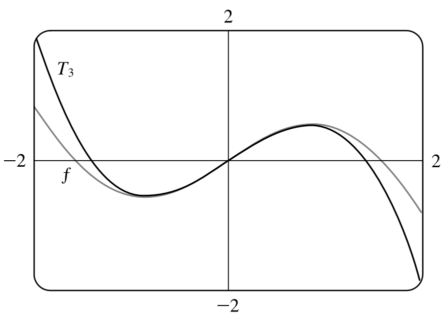
$$T_3(x) = \sum_{n=0}^{3} \frac{f^{(n)}(1)}{n!}(x-1)^n$$
$$= 0 + \frac{1}{1!}(x-1) + \frac{-1}{2!}(x-1)^2 + \frac{2}{3!}(x-1)^3$$
$$= (x-1) - \tfrac{1}{2}(x-1)^2 + \tfrac{1}{3}(x-1)^3$$



8.

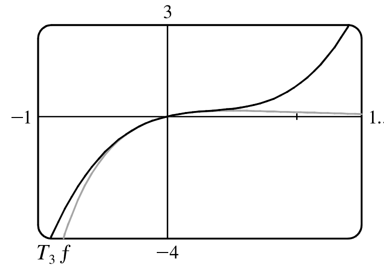
n	$f^{(n)}(x)$	$f^{(n)}(0)$
0	$x\cos x$	0
1	$-x\sin x + \cos x$	1
2	$-x\cos x - 2\sin x$	0
3	$x\sin x - 3\cos x$	-3

$$T_3(x) = \sum_{n=0}^{3} \frac{f^{(n)}(0)}{n!}x^n$$
$$= 0 + \frac{1}{1!}x + 0 + \frac{-3}{3!}x^3 = x - \frac{1}{2}x^3$$



9.

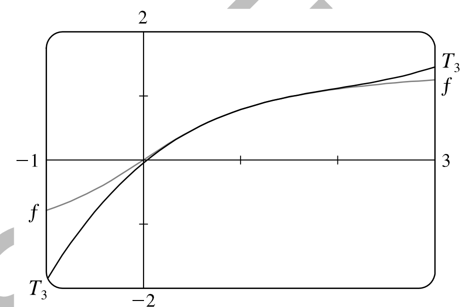
n	$f^{(n)}(x)$	$f^{(n)}(0)$
0	xe^{-2x}	0
1	$(1-2x)e^{-2x}$	1
2	$4(x-1)e^{-2x}$	-4
3	$4(3-2x)e^{-2x}$	12



$$T_3(x) = \sum_{n=0}^{3} \frac{f^{(n)}(0)}{n!} x^n = \tfrac{0}{1} \cdot 1 + \tfrac{1}{1}x^1 + \tfrac{-4}{2}x^2 + \tfrac{12}{6}x^3 = x - 2x^2 + 2x^3$$

10.

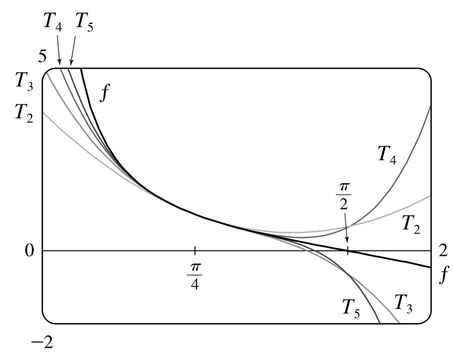
n	$f^{(n)}(x)$	$f^{(n)}(1)$
0	$\tan^{-1} x$	$\frac{\pi}{4}$
1	$\dfrac{1}{1+x^2}$	$\frac{1}{2}$
2	$\dfrac{-2x}{(1+x^2)^2}$	$-\frac{1}{2}$
3	$\dfrac{6x^2-2}{(1+x^2)^3}$	$\frac{1}{2}$



$$T_3(x) = \sum_{n=0}^{3} \frac{f^{(n)}(1)}{n!}(x-1)^n = \frac{\pi}{4} + \frac{1/2}{1}(x-1)^1 + \frac{-1/2}{2}(x-1)^2 + \frac{1/2}{6}(x-1)^3$$
$$= \tfrac{\pi}{4} + \tfrac{1}{2}(x-1) - \tfrac{1}{4}(x-1)^2 + \tfrac{1}{12}(x-1)^3$$

11. You may be able to simply find the Taylor polynomials for $f(x) = \cot x$ using your CAS. We will list the values of $f^{(n)}(\pi/4)$ for $n = 0$ to $n = 5$.

n	0	1	2	3	4	5
$f^{(n)}(\pi/4)$	1	-2	4	-16	80	-512

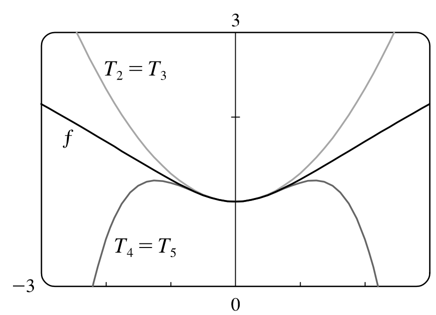


$$T_5(x) = \sum_{n=0}^{5} \frac{f^{(n)}(\pi/4)}{n!}\left(x - \tfrac{\pi}{4}\right)^n$$
$$= 1 - 2\left(x - \tfrac{\pi}{4}\right) + 2\left(x - \tfrac{\pi}{4}\right)^2 - \tfrac{8}{3}\left(x - \tfrac{\pi}{4}\right)^3 + \tfrac{10}{3}\left(x - \tfrac{\pi}{4}\right)^4 - \tfrac{64}{15}\left(x - \tfrac{\pi}{4}\right)^5$$

For $n = 2$ to $n = 5$, $T_n(x)$ is the polynomial consisting of all the terms up to and including the $\left(x - \frac{\pi}{4}\right)^n$ term.

12. You may be able to simply find the Taylor polynomials for $f(x) = \sqrt[3]{1+x^2}$ using your CAS. We will list the values of $f^{(n)}(0)$ for $n = 0$ to $n = 5$.

n	0	1	2	3	4	5
$f^{(n)}(0)$	1	0	$\frac{2}{3}$	0	$-\frac{8}{3}$	0



$$T_5(x) = \sum_{n=0}^{5} \frac{f^{(n)}(0)}{n!} x^n = 1 + \tfrac{1}{3}x^2 - \tfrac{1}{9}x^4$$

For $n = 2$ to $n = 5$, $T_n(x)$ is the polynomial consisting of all the terms up to and including the x^n term. Note that $T_2 = T_3$ and $T_4 = T_5$.

13. (a)

n	$f^{(n)}(x)$	$f^{(n)}(1)$
0	$1/x$	1
1	$-1/x^2$	-1
2	$2/x^3$	2
3	$-6/x^4$	

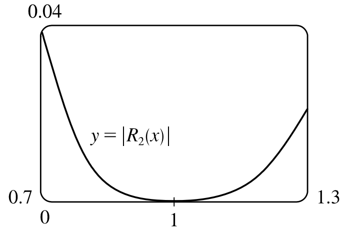
$$\begin{aligned} f(x) = 1/x &\approx T_2(x) \\ &= \frac{1}{0!}(x-1)^0 - \frac{1}{1!}(x-1)^1 + \frac{2}{2!}(x-1)^2 \\ &= 1 - (x-1) + (x-1)^2 \end{aligned}$$

(b) $|R_2(x)| \le \frac{M}{3!}|x-1|^3$, where $|f'''(x)| \le M$. Now $0.7 \le x \le 1.3 \Rightarrow |x-1| \le 0.3 \Rightarrow |x-1|^3 \le 0.027$.

Since $|f'''(x)|$ is decreasing on $[0.7, 1.3]$, we can take $M = |f'''(0.7)| = 6/(0.7)^4$, so

$|R_2(x)| \le \frac{6/(0.7)^4}{6}(0.027) = 0.112\,453\,1$.

(c)



From the graph of $|R_2(x)| = \left|\frac{1}{x} - T_2(x)\right|$, it seems that the error is less than $0.038\,571$ on $[0.7, 1.3]$.

14. (a)

n	$f^{(n)}(x)$	$f^{(n)}(4)$
0	$x^{-1/2}$	$\frac{1}{2}$
1	$-\frac{1}{2}x^{-3/2}$	$-\frac{1}{16}$
2	$\frac{3}{4}x^{-5/2}$	$\frac{3}{128}$
3	$-\frac{15}{8}x^{-7/2}$	

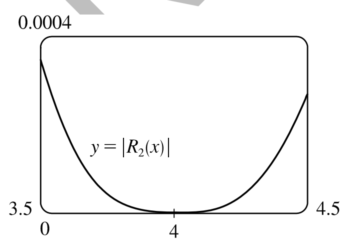
$$\begin{aligned} f(x) = x^{-1/2} &\approx T_2(x) \\ &= \frac{1/2}{0!}(x-4)^0 - \frac{1/16}{1!}(x-4)^1 + \frac{3/128}{2!}(x-4)^2 \\ &= \tfrac{1}{2} - \tfrac{1}{16}(x-4) + \tfrac{3}{256}(x-4)^2 \end{aligned}$$

(b) $|R_2(x)| \le \frac{M}{3!}|x-4|^3$, where $|f'''(x)| \le M$. Now $3.5 \le x \le 4.5 \Rightarrow |x-4| \le 0.5 \Rightarrow |x-4|^3 \le 0.125$.

Since $|f'''(x)|$ is decreasing on $[3.5, 4.5]$, we can take $M = |f'''(3.5)| = \frac{15}{8(3.5)^{7/2}}$, so

$|R_2(x)| \le \frac{15}{6 \cdot 8(3.5)^{7/2}}(0.125) \approx 0.000\,487$.

(c)



From the graph of $|R_2(x)| = \left|x^{-1/2} - T_2(x)\right|$, it seems that the error is less than $0.000\,343$ on $[3.5, 4.5]$.

15.

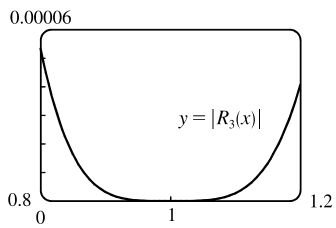
n	$f^{(n)}(x)$	$f^{(n)}(1)$
0	$x^{2/3}$	1
1	$\frac{2}{3}x^{-1/3}$	$\frac{2}{3}$
2	$-\frac{2}{9}x^{-4/3}$	$-\frac{2}{9}$
3	$\frac{8}{27}x^{-7/3}$	$\frac{8}{27}$
4	$-\frac{56}{81}x^{-10/3}$	

(a) $f(x) = x^{2/3} \approx T_3(x) = 1 + \frac{2}{3}(x-1) - \frac{2/9}{2!}(x-1)^2 + \frac{8/27}{3!}(x-1)^3$
$= 1 + \frac{2}{3}(x-1) - \frac{1}{9}(x-1)^2 + \frac{4}{81}(x-1)^3$

(b) $|R_3(x)| \le \frac{M}{4!}|x-1|^4$, where $\left|f^{(4)}(x)\right| \le M$. Now $0.8 \le x \le 1.2 \Rightarrow |x-1| \le 0.2 \Rightarrow |x-1|^4 \le 0.0016$. Since $\left|f^{(4)}(x)\right|$ is decreasing on $[0.8, 1.2]$, we can take $M = \left|f^{(4)}(0.8)\right| = \frac{56}{81}(0.8)^{-10/3}$, so

$|R_3(x)| \le \dfrac{\frac{56}{81}(0.8)^{-10/3}}{24}(0.0016) \approx 0.000\,096\,97.$

(c)



From the graph of $|R_3(x)| = \left|x^{2/3} - T_3(x)\right|$, it seems that the error is less than $0.000\,053\,3$ on $[0.8, 1.2]$.

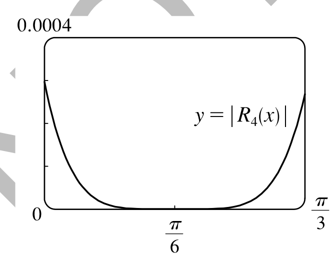
16.

n	$f^{(n)}(x)$	$f^{(n)}(\pi/6)$
0	$\sin x$	$1/2$
1	$\cos x$	$\sqrt{3}/2$
2	$-\sin x$	$-1/2$
3	$-\cos x$	$-\sqrt{3}/2$
4	$\sin x$	$1/2$
5	$\cos x$	

(a) $f(x) = \sin x \approx T_4(x)$
$= \frac{1}{2} + \frac{\sqrt{3}}{2}\left(x - \frac{\pi}{6}\right) - \frac{1}{4}\left(x - \frac{\pi}{6}\right)^2 - \frac{\sqrt{3}}{12}\left(x - \frac{\pi}{6}\right)^3 + \frac{1}{48}\left(x - \frac{\pi}{6}\right)^4$

(b) $|R_4(x)| \le \frac{M}{5!}\left|x - \frac{\pi}{6}\right|^5$, where $\left|f^{(5)}(x)\right| \le M$. Now $0 \le x \le \frac{\pi}{3} \Rightarrow -\frac{\pi}{6} \le x - \frac{\pi}{6} \le \frac{\pi}{6} \Rightarrow \left|x - \frac{\pi}{6}\right| \le \frac{\pi}{6} \Rightarrow$
$\left|x - \frac{\pi}{6}\right|^5 \le \left(\frac{\pi}{6}\right)^5$. Since $\left|f^{(5)}(x)\right|$ is decreasing on $\left[0, \frac{\pi}{3}\right]$, we can take $M = \left|f^{(5)}(0)\right| = \cos 0 = 1$, so
$|R_4(x)| \le \frac{1}{5!}\left(\frac{\pi}{6}\right)^5 \approx 0.000\,328.$

(c)



From the graph of $|R_4(x)| = |\sin x - T_4(x)|$, it seems that the error is less than $0.000\,297$ on $\left[0, \frac{\pi}{3}\right]$.

17.

n	$f^{(n)}(x)$	$f^{(n)}(0)$
0	$\sec x$	1
1	$\sec x\, \tan x$	0
2	$\sec x\,(2\sec^2 x - 1)$	1
3	$\sec x\, \tan x\,(6\sec^2 x - 1)$	

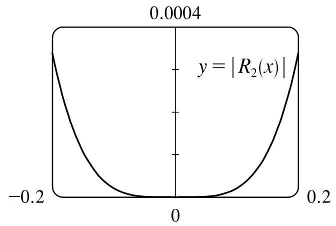
(a) $f(x) = \sec x \approx T_2(x) = 1 + \frac{1}{2}x^2$

(b) $|R_2(x)| \le \frac{M}{3!}|x|^3$, where $\left|f^{(3)}(x)\right| \le M$. Now $-0.2 \le x \le 0.2 \Rightarrow |x| \le 0.2 \Rightarrow |x|^3 \le (0.2)^3$.

$f^{(3)}(x)$ is an odd function and it is increasing on $[0, 0.2]$ since $\sec x$ and $\tan x$ are increasing on $[0, 0.2]$,

so $\left|f^{(3)}(x)\right| \le f^{(3)}(0.2) \approx 1.085\,158\,892$. Thus, $|R_2(x)| \le \frac{f^{(3)}(0.2)}{3!}(0.2)^3 \approx 0.001\,447$.

(c)



From the graph of $|R_2(x)| = |\sec x - T_2(x)|$, it seems that the error is less than $0.000\,339$ on $[-0.2, 0.2]$.

18.

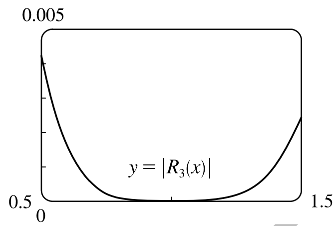
n	$f^{(n)}(x)$	$f^{(n)}(1)$
0	$\ln(1+2x)$	$\ln 3$
1	$2/(1+2x)$	$\frac{2}{3}$
2	$-4/(1+2x)^2$	$-\frac{4}{9}$
3	$16/(1+2x)^3$	$\frac{16}{27}$
4	$-96/(1+2x)^4$	

(a) $f(x) = \ln(1+2x) \approx T_3(x)$

$$= \ln 3 + \tfrac{2}{3}(x-1) - \frac{4/9}{2!}(x-1)^2 + \frac{16/27}{3!}(x-1)^3$$

(b) $|R_3(x)| \le \frac{M}{4!}|x-1|^4$, where $\left|f^{(4)}(x)\right| \le M$. Now $0.5 \le x \le 1.5 \Rightarrow$ $-0.5 \le x-1 \le 0.5 \Rightarrow |x-1| \le 0.5 \Rightarrow |x-1|^4 \le \frac{1}{16}$, and letting $x = 0.5$ gives $M = 6$, so $|R_3(x)| \le \frac{6}{4!} \cdot \frac{1}{16} = \frac{1}{64} = 0.015\,625$.

(c)



From the graph of $|R_3(x)| = |\ln(1+2x) - T_3(x)|$, it seems that the error is less than 0.005 on $[0.5, 1.5]$.

19.

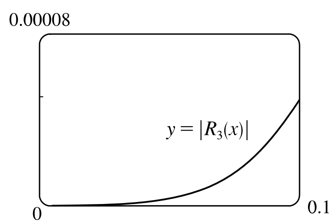
n	$f^{(n)}(x)$	$f^{(n)}(0)$
0	e^{x^2}	1
1	$e^{x^2}(2x)$	0
2	$e^{x^2}(2+4x^2)$	2
3	$e^{x^2}(12x+8x^3)$	0
4	$e^{x^2}(12+48x^2+16x^4)$	

(a) $f(x) = e^{x^2} \approx T_3(x) = 1 + \frac{2}{2!}x^2 = 1 + x^2$

(b) $|R_3(x)| \le \frac{M}{4!}|x|^4$, where $\left|f^{(4)}(x)\right| \le M$. Now $0 \le x \le 0.1 \Rightarrow$ $x^4 \le (0.1)^4$, and letting $x = 0.1$ gives

$$|R_3(x)| \le \frac{e^{0.01}(12 + 0.48 + 0.0016)}{24}(0.1)^4 \approx 0.00006.$$

(c)



From the graph of $|R_3(x)| = \left|e^{x^2} - T_3(x)\right|$, it appears that the error is less than $0.000\,051$ on $[0, 0.1]$.

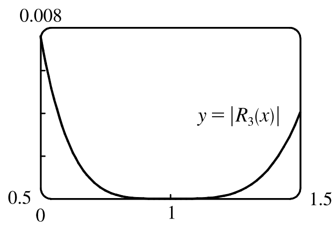
20.

n	$f^{(n)}(x)$	$f^{(n)}(1)$
0	$x \ln x$	0
1	$\ln x + 1$	1
2	$1/x$	1
3	$-1/x^2$	-1
4	$2/x^3$	

(a) $f(x) = x \ln x \approx T_3(x) = (x-1) + \frac{1}{2}(x-1)^2 - \frac{1}{6}(x-1)^3$

(b) $|R_3(x)| \le \dfrac{M}{4!}|x-1|^4$, where $\left|f^{(4)}(x)\right| \le M$. Now $0.5 \le x \le 1.5 \Rightarrow$ $|x-1| \le \frac{1}{2} \Rightarrow |x-1|^4 \le \frac{1}{16}$. Since $\left|f^{(4)}(x)\right|$ is decreasing on $[0.5, 1.5]$, we can take $M = \left|f^{(4)}(0.5)\right| = 2/(0.5)^3 = 16$, so $|R_3(x)| \le \frac{16}{24}(1/16) = \frac{1}{24} = 0.041\overline{6}$.

(c)



From the graph of $|R_3(x)| = |x \ln x - T_3(x)|$, it seems that the error is less than 0.0076 on $[0.5, 1.5]$.

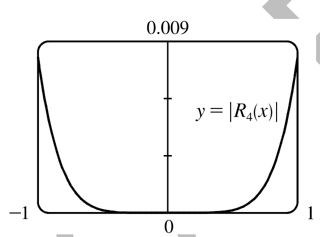
21.

n	$f^{(n)}(x)$	$f^{(n)}(0)$
0	$x \sin x$	0
1	$\sin x + x \cos x$	0
2	$2\cos x - x \sin x$	2
3	$-3\sin x - x\cos x$	0
4	$-4\cos x + x \sin x$	-4
5	$5 \sin x + x \cos x$	

(a) $f(x) = x \sin x \approx T_4(x) = \dfrac{2}{2!}(x-0)^2 + \dfrac{-4}{4!}(x-0)^4 = x^2 - \dfrac{1}{6}x^4$

(b) $|R_4(x)| \le \dfrac{M}{5!}|x|^5$, where $\left|f^{(5)}(x)\right| \le M$. Now $-1 \le x \le 1 \Rightarrow$ $|x| \le 1$, and a graph of $f^{(5)}(x)$ shows that $\left|f^{(5)}(x)\right| \le 5$ for $-1 \le x \le 1$. Thus, we can take $M = 5$ and get $|R_4(x)| \le \dfrac{5}{5!} \cdot 1^5 = \dfrac{1}{24} = 0.041\overline{6}$.

(c)



From the graph of $|R_4(x)| = |x \sin x - T_4(x)|$, it seems that the error is less than 0.0082 on $[-1, 1]$.

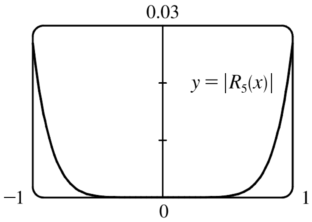
22.

n	$f^{(n)}(x)$	$f^{(n)}(0)$
0	$\sinh 2x$	0
1	$2\cosh 2x$	2
2	$4 \sinh 2x$	0
3	$8 \cosh 2x$	8
4	$16 \sinh 2x$	0
5	$32 \cosh 2x$	32
6	$64 \sinh 2x$	

(a) $f(x) = \sinh 2x \approx T_5(x) = 2x + \frac{8}{3!}x^3 + \frac{32}{5!}x^5 = 2x + \frac{4}{3}x^3 + \frac{4}{15}x^5$

(b) $|R_5(x)| \le \frac{M}{6!}|x|^6$, where $\left|f^{(6)}(x)\right| \le M$. For x in $[-1, 1]$, we have $|x| \le 1$. Since $f^{(6)}(x)$ is an increasing odd function on $[-1, 1]$, we see that $\left|f^{(6)}(x)\right| \le f^{(6)}(1) = 64 \sinh 2 = 32(e^2 - e^{-2}) \approx 232.119$, so we can take $M = 232.12$ and get $|R_5(x)| \le \frac{232.12}{720} \cdot 1^6 \approx 0.3224$.

(c)



From the graph of $|R_5(x)| = |\sinh 2x - T_5(x)|$, it seems that the error is less than 0.027 on $[-1, 1]$.

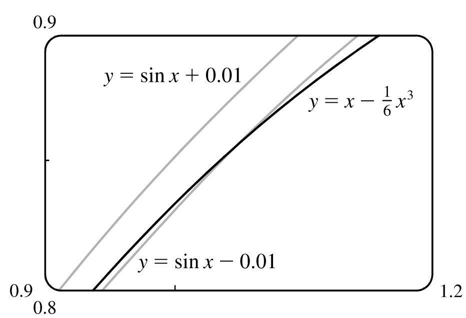
23. From Exercise 5, $\cos x = -\left(x - \frac{\pi}{2}\right) + \frac{1}{6}\left(x - \frac{\pi}{2}\right)^3 + R_3(x)$, where $|R_3(x)| \leq \dfrac{M}{4!}\left|x - \frac{\pi}{2}\right|^4$ with $\left|f^{(4)}(x)\right| = |\cos x| \leq M = 1$. Now $x = 80° = (90° - 10°) = \left(\frac{\pi}{2} - \frac{\pi}{18}\right) = \frac{4\pi}{9}$ radians, so the error is $\left|R_3\left(\frac{4\pi}{9}\right)\right| \leq \frac{1}{24}\left(\frac{\pi}{18}\right)^4 \approx 0.000\,039$, which means our estimate would *not* be accurate to five decimal places. However, $T_3 = T_4$, so we can use $\left|R_4\left(\frac{4\pi}{9}\right)\right| \leq \frac{1}{120}\left(\frac{\pi}{18}\right)^5 \approx 0.000\,001$. Therefore, to five decimal places, $\cos 80° \approx -\left(-\frac{\pi}{18}\right) + \frac{1}{6}\left(-\frac{\pi}{18}\right)^3 \approx 0.17365$.

24. From Exercise 16, $\sin x = \frac{1}{2} + \frac{\sqrt{3}}{2}\left(x - \frac{\pi}{6}\right) - \frac{1}{4}\left(x - \frac{\pi}{6}\right)^2 - \frac{\sqrt{3}}{12}\left(x - \frac{\pi}{6}\right)^3 + \frac{1}{48}\left(x - \frac{\pi}{6}\right)^4 + R_4(x)$, where $|R_4(x)| \leq \dfrac{M}{5!}\left|x - \frac{\pi}{6}\right|^5$ with $\left|f^{(5)}(x)\right| = |\cos x| \leq M = 1$. Now $x = 38° = (30° + 8°) = \left(\frac{\pi}{6} + \frac{2\pi}{45}\right)$ radians, so the error is $\left|R_4\left(\frac{38\pi}{180}\right)\right| \leq \frac{1}{120}\left(\frac{2\pi}{45}\right)^5 \approx 0.000\,000\,44$, which means our estimate will be accurate to five decimal places. Therefore, to five decimal places, $\sin 38° = \frac{1}{2} + \frac{\sqrt{3}}{2}\left(\frac{2\pi}{45}\right) - \frac{1}{4}\left(\frac{2\pi}{45}\right)^2 - \frac{\sqrt{3}}{12}\left(\frac{2\pi}{45}\right)^3 + \frac{1}{48}\left(\frac{2\pi}{45}\right)^4 \approx 0.61566$.

25. All derivatives of e^x are e^x, so $|R_n(x)| \leq \dfrac{e^x}{(n+1)!}|x|^{n+1}$, where $0 < x < 0.1$. Letting $x = 0.1$, $R_n(0.1) \leq \dfrac{e^{0.1}}{(n+1)!}(0.1)^{n+1} < 0.00001$, and by trial and error we find that $n = 3$ satisfies this inequality since $R_3(0.1) < 0.0000046$. Thus, by adding the four terms of the Maclaurin series for e^x corresponding to $n = 0$, 1, 2, and 3, we can estimate $e^{0.1}$ to within 0.00001. (In fact, this sum is $1.1051\overline{6}$ and $e^{0.1} \approx 1.10517$.)

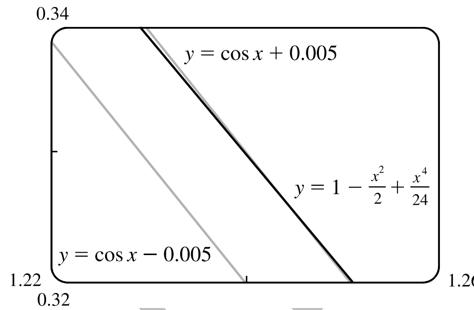
26. From Table 1 in Section 11.10, $\ln(1+x) = \sum\limits_{n=1}^{\infty}(-1)^{n-1}\dfrac{x^n}{n}$ for $|x| < 1$. Thus, $\ln 1.4 = \ln(1 + 0.4) = \sum\limits_{n=1}^{\infty}(-1)^{n-1}\dfrac{(0.4)^n}{n}$. Since this is an alternating series, the error is less than the first neglected term by the Alternating Series Estimation Theorem, and we find that $|a_6| = (0.4)^6/6 \approx 0.0007 < 0.001$. So we need the first five (nonzero) terms of the Maclaurin series for the desired accuracy. (In fact, this sum is approximately 0.33698 and $\ln 1.4 \approx 0.33647$.)

27. $\sin x = x - \dfrac{1}{3!}x^3 + \dfrac{1}{5!}x^5 - \cdots$. By the Alternating Series Estimation Theorem, the error in the approximation $\sin x = x - \dfrac{1}{3!}x^3$ is less than $\left|\dfrac{1}{5!}x^5\right| < 0.01 \quad\Leftrightarrow\quad \left|x^5\right| < 120(0.01) \quad\Leftrightarrow\quad |x| < (1.2)^{1/5} \approx 1.037$. The curves $y = x - \frac{1}{6}x^3$ and $y = \sin x - 0.01$ intersect at $x \approx 1.043$, so the graph confirms our estimate. Since both the sine function

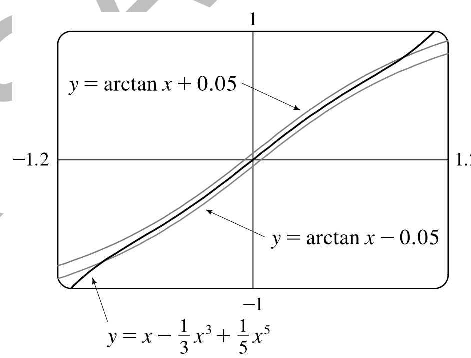


and the given approximation are odd functions, we need to check the estimate only for $x > 0$. Thus, the desired range of values for x is $-1.037 < x < 1.037$.

28. $\cos x = 1 - \frac{1}{2!}x^2 + \frac{1}{4!}x^4 - \frac{1}{6!}x^6 + \cdots$. By the Alternating Series Estimation Theorem, the error is less than $\left|-\frac{1}{6!}x^6\right| < 0.005 \Leftrightarrow x^6 < 720(0.005) \Leftrightarrow |x| < (3.6)^{1/6} \approx 1.238$. The curves $y = 1 - \frac{1}{2}x^2 + \frac{1}{24}x^4$ and $y = \cos x + 0.005$ intersect at $x \approx 1.244$, so the graph confirms our estimate. Since both the cosine function and the given approximation are even functions, we need to check the estimate only for $x > 0$. Thus, the desired range of values for x is $-1.238 < x < 1.238$.



29. $\arctan x = x - \frac{x^3}{3} + \frac{x^5}{5} - \frac{x^7}{7} + \cdots$. By the Alternating Series Estimation Theorem, the error is less than $\left|-\frac{1}{7}x^7\right| < 0.05 \Leftrightarrow \left|x^7\right| < 0.35 \Leftrightarrow |x| < (0.35)^{1/7} \approx 0.8607$. The curves $y = x - \frac{1}{3}x^3 + \frac{1}{5}x^5$ and $y = \arctan x + 0.05$ intersect at $x \approx 0.9245$, so the graph confirms our estimate. Since both the arctangent function and the given approximation are odd functions, we need to check the estimate only for $x > 0$. Thus, the desired range of values for x is $-0.86 < x < 0.86$.



30. $f(x) = \sum_{n=0}^{\infty} \frac{f^{(n)}(4)}{n!}(x-4)^n = \sum_{n=0}^{\infty} \frac{(-1)^n\, n!}{3^n(n+1)\, n!}(x-4)^n = \sum_{n=0}^{\infty} \frac{(-1)^n}{3^n(n+1)}(x-4)^n$. Now

$f(5) = \sum_{n=0}^{\infty} \frac{(-1)^n}{3^n(n+1)} = \sum_{n=0}^{\infty} (-1)^n b_n$ is the sum of an alternating series that satisfies (i) $b_{n+1} \le b_n$ and (ii) $\lim_{n\to\infty} b_n = 0$, so by the Alternating Series Estimation Theorem, $|R_5(5)| = |f(5) - T_5(5)| \le b_6$, and

$b_6 = \frac{1}{3^6(7)} = \frac{1}{5103} \approx 0.000196 < 0.0002$; that is, the fifth-degree Taylor polynomial approximates $f(5)$ with error less than 0.0002.

31. Let $s(t)$ be the position function of the car, and for convenience set $s(0) = 0$. The velocity of the car is $v(t) = s'(t)$ and the acceleration is $a(t) = s''(t)$, so the second degree Taylor polynomial is $T_2(t) = s(0) + v(0)t + \frac{a(0)}{2}t^2 = 20t + t^2$. We estimate the distance traveled during the next second to be $s(1) \approx T_2(1) = 20 + 1 = 21$ m. The function $T_2(t)$ would not be accurate over a full minute, since the car could not possibly maintain an acceleration of 2 m/s^2 for that long (if it did, its final speed would be 140 m/s ≈ 313 mi/h!).

32. (a)

n	$\rho^{(n)}(t)$	$\rho^{(n)}(20)$
0	$\rho_{20}e^{\alpha(t-20)}$	ρ_{20}
1	$\alpha\rho_{20}e^{\alpha(t-20)}$	$\alpha\rho_{20}$
2	$\alpha^2\rho_{20}e^{\alpha(t-20)}$	$\alpha^2\rho_{20}$

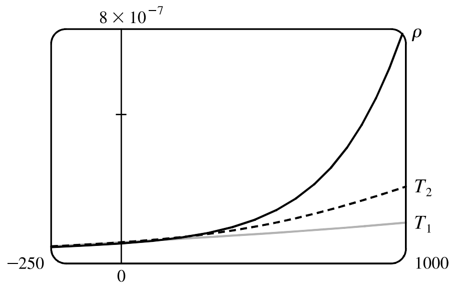
The linear approximation is

$$T_1(t) = \rho(20) + \rho'(20)(t-20) = \rho_{20}[1 + \alpha(t-20)]$$

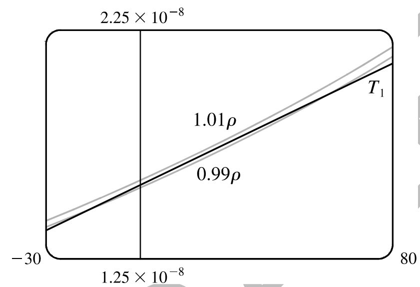
The quadratic approximation is

$$T_2(t) = \rho(20) + \rho'(20)(t-20) + \frac{\rho''(20)}{2}(t-20)^2$$
$$= \rho_{20}\left[1 + \alpha(t-20) + \tfrac{1}{2}\alpha^2(t-20)^2\right]$$

(b)



(c)



From the graph, it seems that $T_1(t)$ is within 1% of $\rho(t)$, that is, $0.99\rho(t) \le T_1(t) \le 1.01\rho(t)$, for $-14^\circ\text{C} \le t \le 58^\circ\text{C}$.

33. $E = \dfrac{q}{D^2} - \dfrac{q}{(D+d)^2} = \dfrac{q}{D^2} - \dfrac{q}{D^2(1+d/D)^2} = \dfrac{q}{D^2}\left[1 - \left(1 + \dfrac{d}{D}\right)^{-2}\right]$.

We use the Binomial Series to expand $(1 + d/D)^{-2}$:

$$E = \frac{q}{D^2}\left[1 - \left(1 - 2\left(\frac{d}{D}\right) + \frac{2\cdot 3}{2!}\left(\frac{d}{D}\right)^2 - \frac{2\cdot 3\cdot 4}{3!}\left(\frac{d}{D}\right)^3 + \cdots\right)\right] = \frac{q}{D^2}\left[2\left(\frac{d}{D}\right) - 3\left(\frac{d}{D}\right)^2 + 4\left(\frac{d}{D}\right)^3 - \cdots\right]$$
$$\approx \frac{q}{D^2}\cdot 2\left(\frac{d}{D}\right) = 2qd\cdot\frac{1}{D^3}$$

when D is much larger than d; that is, when P is far away from the dipole.

34. (a) $\dfrac{n_1}{\ell_o} + \dfrac{n_2}{\ell_i} = \dfrac{1}{R}\left(\dfrac{n_2 s_i}{\ell_i} - \dfrac{n_1 s_o}{\ell_o}\right)$ [Equation 1] where

$$\ell_o = \sqrt{R^2 + (s_o+R)^2 - 2R(s_o+R)\cos\phi} \quad \text{and} \quad \ell_i = \sqrt{R^2 + (s_i-R)^2 + 2R(s_i-R)\cos\phi} \quad \textbf{(2)}$$

Using $\cos\phi \approx 1$ gives

$$\ell_o = \sqrt{R^2 + (s_o+R)^2 - 2R(s_o+R)} = \sqrt{R^2 + s_o^2 + 2Rs_o + R^2 - 2Rs_o - 2R^2} = \sqrt{s_o^2} = s_o$$

and similarly, $\ell_i = s_i$. Thus, Equation 1 becomes $\dfrac{n_1}{s_o} + \dfrac{n_2}{s_i} = \dfrac{1}{R}\left(\dfrac{n_2 s_i}{s_i} - \dfrac{n_1 s_o}{s_o}\right) \;\Rightarrow\; \dfrac{n_1}{s_o} + \dfrac{n_2}{s_i} = \dfrac{n_2 - n_1}{R}$.

(b) Using $\cos\phi \approx 1 - \frac{1}{2}\phi^2$ in **(2)** gives us

$$\ell_o = \sqrt{R^2 + (s_o+R)^2 - 2R(s_o+R)\left(1 - \tfrac{1}{2}\phi^2\right)}$$
$$= \sqrt{R^2 + s_o^2 + 2Rs_o + R^2 - 2Rs_o + Rs_o\phi^2 - 2R^2 + R^2\phi^2} = \sqrt{s_o^2 + Rs_o\phi^2 + R^2\phi^2}$$

Anticipating that we will use the binomial series expansion $(1+x)^k \approx 1+kx$, we can write the last expression for ℓ_o as $s_o\sqrt{1+\phi^2\left(\frac{R}{s_o}+\frac{R^2}{s_o^2}\right)}$ and similarly, $\ell_i = s_i\sqrt{1-\phi^2\left(\frac{R}{s_i}-\frac{R^2}{s_i^2}\right)}$. Thus, from Equation 1,

$$\frac{n_1}{\ell_o}+\frac{n_2}{\ell_i}=\frac{1}{R}\left(\frac{n_2 s_i}{\ell_i}-\frac{n_1 s_o}{\ell_o}\right) \quad\Leftrightarrow\quad n_1\ell_o^{-1}+n_2\ell_i^{-1}=\frac{n_2}{R}\cdot\frac{s_i}{\ell_i}-\frac{n_1}{R}\cdot\frac{s_o}{\ell_o} \quad\Leftrightarrow$$

$$\frac{n_1}{s_o}\left[1+\phi^2\left(\frac{R}{s_o}+\frac{R^2}{s_o^2}\right)\right]^{-1/2}+\frac{n_2}{s_i}\left[1-\phi^2\left(\frac{R}{s_i}-\frac{R^2}{s_i^2}\right)\right]^{-1/2}$$
$$=\frac{n_2}{R}\left[1-\phi^2\left(\frac{R}{s_i}-\frac{R^2}{s_i^2}\right)\right]^{-1/2}-\frac{n_1}{R}\left[1+\phi^2\left(\frac{R}{s_o}+\frac{R^2}{s_o^2}\right)\right]^{-1/2}$$

Approximating the expressions for ℓ_o^{-1} and ℓ_i^{-1} by the first two terms in their binomial series, we get

$$\frac{n_1}{s_o}\left[1-\tfrac{1}{2}\phi^2\left(\frac{R}{s_o}+\frac{R^2}{s_o^2}\right)\right]+\frac{n_2}{s_i}\left[1+\tfrac{1}{2}\phi^2\left(\frac{R}{s_i}-\frac{R^2}{s_i^2}\right)\right]$$
$$=\frac{n_2}{R}\left[1+\tfrac{1}{2}\phi^2\left(\frac{R}{s_i}-\frac{R^2}{s_i^2}\right)\right]-\frac{n_1}{R}\left[1-\tfrac{1}{2}\phi^2\left(\frac{R}{s_o}+\frac{R^2}{s_o^2}\right)\right] \quad\Leftrightarrow$$

$$\frac{n_1}{s_o}-\frac{n_1\phi^2}{2s_o}\left(\frac{R}{s_o}+\frac{R^2}{s_o^2}\right)+\frac{n_2}{s_i}+\frac{n_2\phi^2}{2s_i}\left(\frac{R}{s_i}-\frac{R^2}{s_i^2}\right)=\frac{n_2}{R}+\frac{n_2\phi^2}{2R}\left(\frac{R}{s_i}-\frac{R^2}{s_i^2}\right)-\frac{n_1}{R}+\frac{n_1\phi^2}{2R}\left(\frac{R}{s_o}+\frac{R^2}{s_o^2}\right) \quad\Leftrightarrow$$

$$\frac{n_1}{s_o}+\frac{n_2}{s_i}=\frac{n_2}{R}-\frac{n_1}{R}+\frac{n_1\phi^2}{2s_o}\left(\frac{R}{s_o}+\frac{R^2}{s_o^2}\right)+\frac{n_1\phi^2}{2R}\left(\frac{R}{s_o}+\frac{R^2}{s_o^2}\right)+\frac{n_2\phi^2}{2R}\left(\frac{R}{s_i}-\frac{R^2}{s_i^2}\right)-\frac{n_2\phi^2}{2s_i}\left(\frac{R}{s_i}-\frac{R^2}{s_i^2}\right)$$
$$=\frac{n_2-n_1}{R}+\frac{n_1\phi^2}{2}\left(\frac{R}{s_o}+\frac{R^2}{s_o^2}\right)\left(\frac{1}{s_o}+\frac{1}{R}\right)+\frac{n_2\phi^2}{2}\left(\frac{R}{s_i}-\frac{R^2}{s_i^2}\right)\left(\frac{1}{R}-\frac{1}{s_i}\right)$$
$$=\frac{n_2-n_1}{R}+\frac{n_1\phi^2R^2}{2s_o}\left(\frac{1}{R}+\frac{1}{s_o}\right)\left(\frac{1}{R}+\frac{1}{s_o}\right)+\frac{n_2\phi^2R^2}{2s_i}\left(\frac{1}{R}-\frac{1}{s_i}\right)\left(\frac{1}{R}-\frac{1}{s_i}\right)$$
$$=\frac{n_2-n_1}{R}+\phi^2R^2\left[\frac{n_1}{2s_o}\left(\frac{1}{R}+\frac{1}{s_o}\right)^2+\frac{n_2}{2s_i}\left(\frac{1}{R}-\frac{1}{s_i}\right)^2\right]$$

From Figure 8, we see that $\sin\phi = h/R$. So if we approximate $\sin\phi$ with ϕ, we get $h = R\phi$ and $h^2 = \phi^2R^2$ and hence, Equation 4, as desired.

35. (a) If the water is deep, then $2\pi d/L$ is large, and we know that $\tanh x \to 1$ as $x\to\infty$. So we can approximate $\tanh(2\pi d/L)\approx 1$, and so $v^2 \approx gL/(2\pi) \quad\Leftrightarrow\quad v\approx\sqrt{gL/(2\pi)}$.

(b) From the table, the first term in the Maclaurin series of $\tanh x$ is x, so if the water is shallow, we can approximate $\tanh\frac{2\pi d}{L}\approx\frac{2\pi d}{L}$, and so $v^2\approx\frac{gL}{2\pi}\cdot\frac{2\pi d}{L} \quad\Leftrightarrow\quad v\approx\sqrt{gd}$.

n	$f^{(n)}(x)$	$f^{(n)}(0)$
0	$\tanh x$	0
1	$\operatorname{sech}^2 x$	1
2	$-2\operatorname{sech}^2 x\tanh x$	0
3	$2\operatorname{sech}^2 x\,(3\tanh^2 x-1)$	-2

(c) Since $\tanh x$ is an odd function, its Maclaurin series is alternating, so the error in the approximation

$\tanh \frac{2\pi d}{L} \approx \frac{2\pi d}{L}$ is less than the first neglected term, which is $\frac{|f'''(0)|}{3!}\left(\frac{2\pi d}{L}\right)^3 = \frac{1}{3}\left(\frac{2\pi d}{L}\right)^3$.

If $L > 10d$, then $\frac{1}{3}\left(\frac{2\pi d}{L}\right)^3 < \frac{1}{3}\left(2\pi \cdot \frac{1}{10}\right)^3 = \frac{\pi^3}{375}$, so the error in the approximation $v^2 = gd$ is less

than $\frac{gL}{2\pi} \cdot \frac{\pi^3}{375} \approx 0.0132gL$.

36. First note that

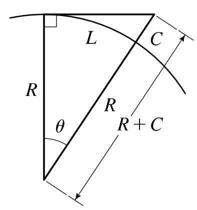
$$\begin{aligned} 2\left(\sqrt{d^2+R^2}-d\right) &= 2\left[\sqrt{d^2}\sqrt{1+\frac{R^2}{d^2}}-d\right] \\ &\approx 2\left[d\left(1+\frac{R^2}{d^2}\cdot\frac{1}{2}+\cdots\right)-d\right] \quad \left[\text{use the binomial series } 1+\tfrac{1}{2}x+\cdots \text{ for } \sqrt{1+x}\right] \\ &= 2\left[\left(d+\frac{R^2}{2d}+\cdots\right)-d\right] \approx \frac{R^2}{d} \end{aligned}$$

since for large d the other terms are comparatively small. Now $V = 2\pi k_e \sigma\left(\sqrt{d^2+R^2}-d\right) \approx \frac{\pi k_e R^2 \sigma}{d}$ by the preceding approximation.

37. (a) L is the length of the arc subtended by the angle θ, so $L = R\theta \Rightarrow$

$\theta = L/R$. Now $\sec\theta = (R+C)/R \Rightarrow R\sec\theta = R+C \Rightarrow$

$C = R\sec\theta - R = R\sec(L/R) - R$.



(b) First we'll find a Taylor polynomial $T_4(x)$ for $f(x) = \sec x$ at $x = 0$.

n	$f^{(n)}(x)$	$f^{(n)}(0)$
0	$\sec x$	1
1	$\sec x \tan x$	0
2	$\sec x(2\tan^2 x+1)$	1
3	$\sec x \tan x(6\tan^2 x+5)$	0
4	$\sec x(24\tan^4 x+28\tan^2 x+5)$	5

Thus, $f(x) = \sec x \approx T_4(x) = 1 + \frac{1}{2!}(x-0)^2 + \frac{5}{4!}(x-0)^4 = 1 + \frac{1}{2}x^2 + \frac{5}{24}x^4$. By part (a),

$$C \approx R\left[1+\frac{1}{2}\left(\frac{L}{R}\right)^2+\frac{5}{24}\left(\frac{L}{R}\right)^4\right]-R = R+\frac{1}{2}R\cdot\frac{L^2}{R^2}+\frac{5}{24}R\cdot\frac{L^4}{R^4}-R = \frac{L^2}{2R}+\frac{5L^4}{24R^3}.$$

(c) Taking $L = 100$ km and $R = 6370$ km, the formula in part (a) says that

$C = R\sec(L/R) - R = 6370 \sec(100/6370) - 6370 \approx 0.785\,009\,965\,44$ km.

The formula in part (b) says that $C \approx \frac{L^2}{2R} + \frac{5L^4}{24R^3} = \frac{100^2}{2\cdot 6370} + \frac{5\cdot 100^4}{24\cdot 6370^3} \approx 0.785\,009\,957\,36$ km.

The difference between these two results is only 0.000 000 008 08 km, or 0.000 008 08 m!

38. (a) $4\sqrt{\frac{L}{g}}\int_0^{\pi/2}\frac{dx}{\sqrt{1-k^2\sin^2 x}} = 4\sqrt{\frac{L}{g}}\int_0^{\pi/2}\left[1+\left(-k^2\sin^2 x\right)\right]^{-1/2}\,dx$

$$= 4\sqrt{\frac{L}{g}}\int_0^{\pi/2}\left[1-\frac{1}{2}\left(-k^2\sin^2 x\right)+\frac{\frac{1}{2}\cdot\frac{3}{2}}{2!}\left(-k^2\sin^2 x\right)^2-\frac{\frac{1}{2}\cdot\frac{3}{2}\cdot\frac{5}{2}}{3!}\left(-k^2\sin^2 x\right)^3+\cdots\right]dx$$

$$= 4\sqrt{\frac{L}{g}}\int_0^{\pi/2}\left[1+\left(\frac{1}{2}\right)k^2\sin^2 x+\left(\frac{1\cdot 3}{2\cdot 4}\right)k^4\sin^4 x+\left(\frac{1\cdot 3\cdot 5}{2\cdot 4\cdot 6}\right)k^6\sin^6 x+\cdots\right]dx$$

$$= 4\sqrt{\frac{L}{g}}\left[\frac{\pi}{2}+\left(\frac{1}{2}\right)\left(\frac{1}{2}\cdot\frac{\pi}{2}\right)k^2+\left(\frac{1\cdot 3}{2\cdot 4}\right)\left(\frac{1\cdot 3}{2\cdot 4}\cdot\frac{\pi}{2}\right)k^4+\left(\frac{1\cdot 3\cdot 5}{2\cdot 4\cdot 6}\right)\left(\frac{1\cdot 3\cdot 5}{2\cdot 4\cdot 6}\cdot\frac{\pi}{2}\right)k^6+\cdots\right]$$

[split up the integral and use the result from Exercise 7.1.50]

$$= 2\pi\sqrt{\frac{L}{g}}\left[1+\frac{1^2}{2^2}k^2+\frac{1^2\cdot 3^2}{2^2\cdot 4^2}k^4+\frac{1^2\cdot 3^2\cdot 5^2}{2^2\cdot 4^2\cdot 6^2}k^6+\cdots\right]$$

(b) The first of the two inequalities is true because all of the terms in the series are positive. For the second,

$$T = 2\pi\sqrt{\frac{L}{g}}\left[1+\frac{1^2}{2^2}k^2+\frac{1^2\cdot 3^2}{2^2\cdot 4^2}k^4+\frac{1^2\cdot 3^2\cdot 5^2}{2^2\cdot 4^2\cdot 6^2}k^6+\frac{1^2\cdot 3^2\cdot 5^2\cdot 7^2}{2^2\cdot 4^2\cdot 6^2\cdot 8^2}k^8+\cdots\right]$$

$$\le 2\pi\sqrt{\frac{L}{g}}\left[1+\tfrac{1}{4}k^2+\tfrac{1}{4}k^4+\tfrac{1}{4}k^6+\tfrac{1}{4}k^8+\cdots\right]$$

The terms in brackets (after the first) form a geometric series with $a=\frac{1}{4}k^2$ and $r=k^2=\sin^2\left(\frac{1}{2}\theta_0\right)<1$.

So $T\le 2\pi\sqrt{\frac{L}{g}}\left[1+\frac{k^2/4}{1-k^2}\right]=2\pi\sqrt{\frac{L}{g}}\,\frac{4-3k^2}{4-4k^2}$.

(c) We substitute $L=1$, $g=9.8$, and $k=\sin(10^\circ/2)\approx 0.08716$, and the inequality from part (b) becomes

$2.01090\le T\le 2.01093$, so $T\approx 2.0109$. The estimate $T\approx 2\pi\sqrt{L/g}\approx 2.0071$ differs by about 0.2%.

If $\theta_0=42^\circ$, then $k\approx 0.35837$ and the inequality becomes $2.07153\le T\le 2.08103$, so $T\approx 2.0763$.

The one-term estimate is the same, and the discrepancy between the two estimates increases to about 3.4%.

39. Using $f(x)=T_n(x)+R_n(x)$ with $n=1$ and $x=r$, we have $f(r)=T_1(r)+R_1(r)$, where T_1 is the first-degree Taylor polynomial of f at a. Because $a=x_n$, $f(r)=f(x_n)+f'(x_n)(r-x_n)+R_1(r)$. But r is a root of f, so $f(r)=0$ and we have $0=f(x_n)+f'(x_n)(r-x_n)+R_1(r)$. Taking the first two terms to the left side gives us

$f'(x_n)(x_n-r)-f(x_n)=R_1(r)$. Dividing by $f'(x_n)$, we get $x_n-r-\dfrac{f(x_n)}{f'(x_n)}=\dfrac{R_1(r)}{f'(x_n)}$. By the formula for Newton's method, the left side of the preceding equation is $x_{n+1}-r$, so $|x_{n+1}-r|=\left|\dfrac{R_1(r)}{f'(x_n)}\right|$. Taylor's Inequality gives us

$|R_1(r)|\le\dfrac{|f''(r)|}{2!}\,|r-x_n|^2$. Combining this inequality with the facts $|f''(x)|\le M$ and $|f'(x)|\ge K$ gives us $|x_{n+1}-r|\le\dfrac{M}{2K}\,|x_n-r|^2$.

APPLIED PROJECT Radiation from the Stars

1. If we write $f(\lambda) = \dfrac{8\pi hc\lambda^{-5}}{e^{hc/(\lambda kT)} - 1} = \dfrac{a\lambda^{-5}}{e^{b/(\lambda T)} - 1}$, then as $\lambda \to 0^+$, it is of the form ∞/∞, and as $\lambda \to \infty$ it is of the form $0/0$, so in either case we can use l'Hospital's Rule. First of all,

$$\lim_{\lambda\to\infty} f(\lambda) \overset{\text{H}}{=} \lim_{\lambda\to\infty} \frac{a\left(-5\lambda^{-6}\right)}{-\dfrac{bT}{(\lambda T)^2} e^{b/(\lambda T)}} = 5\,\frac{aT}{b} \lim_{\lambda\to\infty} \frac{\lambda^2\lambda^{-6}}{e^{b/(\lambda T)}} = 5\,\frac{aT}{b} \lim_{\lambda\to\infty} \frac{\lambda^{-4}}{e^{b/(\lambda T)}} = 0$$

Also, $$\lim_{\lambda\to 0^+} f(\lambda) \overset{\text{H}}{=} 5\,\frac{aT}{b} \lim_{\lambda\to 0^+} \frac{\lambda^{-4}}{e^{b/(\lambda T)}} \overset{\text{H}}{=} 5\,\frac{aT}{b} \lim_{\lambda\to 0^+} \frac{-4\lambda^{-5}}{-\dfrac{bT}{(\lambda T)^2} e^{b/(\lambda T)}} = 20\,\frac{aT^2}{b^2} \lim_{\lambda\to 0^+} \frac{\lambda^{-3}}{e^{b/(\lambda T)}}$$

This is still indeterminate, but note that each time we use l'Hospital's Rule, we gain a factor of λ in the numerator, as well as a constant factor, and the denominator is unchanged. So if we use l'Hospital's Rule three more times, the exponent of λ in the numerator will become 0. That is, for some $\{k_i\}$, all constant,

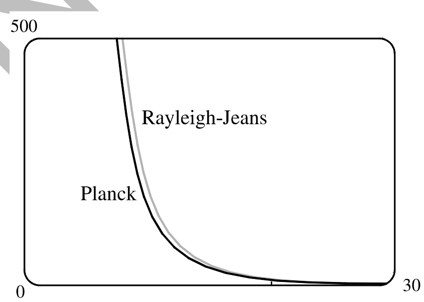
$$\lim_{\lambda\to 0^+} f(\lambda) \overset{\text{H}}{=} k_1 \lim_{\lambda\to 0^+} \frac{\lambda^{-3}}{e^{b/(\lambda T)}} \overset{\text{H}}{=} k_2 \lim_{\lambda\to 0^+} \frac{\lambda^{-2}}{e^{b/(\lambda T)}} \overset{\text{H}}{=} k_3 \lim_{\lambda\to 0^+} \frac{\lambda^{-1}}{e^{b/(\lambda T)}} \overset{\text{H}}{=} k_4 \lim_{\lambda\to 0^+} \frac{1}{e^{b/(\lambda T)}} = 0$$

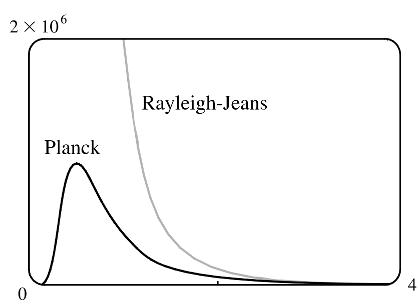
2. We expand the denominator of Planck's Law using the Taylor series $e^x = 1 + x + \dfrac{x^2}{2!} + \dfrac{x^3}{3!} + \cdots$ with $x = \dfrac{hc}{\lambda kT}$, and use the fact that if λ is large, then all subsequent terms in the Taylor expansion are very small compared to the first one, so we can approximate using the Taylor polynomial T_1:

$$f(\lambda) = \frac{8\pi hc\lambda^{-5}}{e^{hc/(\lambda kT)} - 1} = \frac{8\pi hc\lambda^{-5}}{\left[1 + \dfrac{hc}{\lambda kT} + \dfrac{1}{2!}\left(\dfrac{hc}{\lambda kT}\right)^2 + \dfrac{1}{3!}\left(\dfrac{hc}{\lambda kT}\right)^3 + \cdots\right] - 1} \approx \frac{8\pi hc\lambda^{-5}}{\left(1 + \dfrac{hc}{\lambda kT}\right) - 1} = \frac{8\pi kT}{\lambda^4}$$

which is the Rayleigh-Jeans Law.

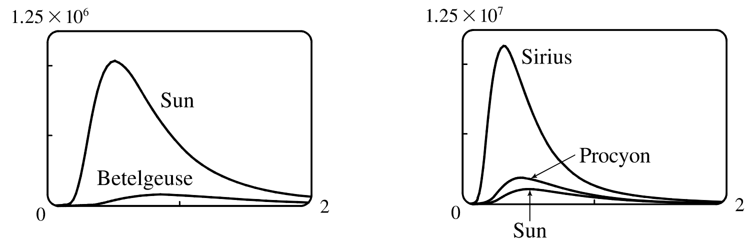
3. To convert to μm, we substitute $\lambda/10^6$ for λ in both laws. The first figure shows that the two laws are similar for large λ. The second figure shows that the two laws are very different for short wavelengths (Planck's Law gives a maximum at $\lambda \approx 0.51\ \mu$m; the Rayleigh-Jeans Law gives no minimum or maximum.).





4. From the graph in Problem 3, $f(\lambda)$ has a maximum under Planck's Law at $\lambda \approx 0.51\ \mu$m.

5.



As T gets larger, the total area under the curve increases, as we would expect: the hotter the star, the more energy it emits. Also, as T increases, the λ-value of the maximum decreases, so the higher the temperature, the shorter the peak wavelength (and consequently the average wavelength) of light emitted. This is why Sirius is a blue star and Betelgeuse is a red star: most of Sirius's light is of a fairly short wavelength; that is, a higher frequency, toward the blue end of the spectrum, whereas most of Betelgeuse's light is of a lower frequency, toward the red end of the spectrum.

11 Review

TRUE-FALSE QUIZ

1. False. See Note 2 after Theorem 11.2.6.

2. False. The series $\sum_{n=1}^{\infty} n^{-\sin 1} = \sum_{n=1}^{\infty} \frac{1}{n^{\sin 1}}$ is a p-series with $p = \sin 1 \approx 0.84 \leq 1$, so the series diverges.

3. True. If $\lim_{n\to\infty} a_n = L$, then as $n \to \infty$, $2n + 1 \to \infty$, so $a_{2n+1} \to L$.

4. True by Theorem 11.8.4.
Or: Use the Comparison Test to show that $\sum c_n(-2)^n$ converges absolutely.

5. False. For example, take $c_n = (-1)^n/(n6^n)$.

6. True by Theorem 11.8.4.

7. False, since $\lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty} \left|\frac{1}{(n+1)^3} \cdot \frac{n^3}{1}\right| = \lim_{n\to\infty} \left|\frac{n^3}{(n+1)^3} \cdot \frac{1/n^3}{1/n^3}\right| = \lim_{n\to\infty} \frac{1}{(1+1/n)^3} = 1$.

8. True, since $\lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty} \left|\frac{1}{(n+1)!} \cdot \frac{n!}{1}\right| = \lim_{n\to\infty} \frac{1}{n+1} = 0 < 1$.

9. False. See the note after Example 11.4.2.

10. True, since $\frac{1}{e} = e^{-1}$ and $e^x = \sum_{n=0}^{\infty} \frac{x^n}{n!}$, so $e^{-1} = \sum_{n=0}^{\infty} \frac{(-1)^n}{n!}$.

11. True. See (9) in Section 11.1.

12. True, because if $\sum |a_n|$ is convergent, then so is $\sum a_n$ by Theorem 11.6.3.

13. True. By Theorem 11.10.5 the coefficient of x^3 is $\frac{f'''(0)}{3!} = \frac{1}{3} \Rightarrow f'''(0) = 2$.
Or: Use Theorem 11.9.2 to differentiate f three times.

14. False. Let $a_n = n$ and $b_n = -n$. Then $\{a_n\}$ and $\{b_n\}$ are divergent, but $a_n + b_n = 0$, so $\{a_n + b_n\}$ is convergent.

15. False. For example, let $a_n = b_n = (-1)^n$. Then $\{a_n\}$ and $\{b_n\}$ are divergent, but $a_n b_n = 1$, so $\{a_n b_n\}$ is convergent.

16. True by the Monotonic Sequence Theorem, since $\{a_n\}$ is decreasing and $0 < a_n \le a_1$ for all $n \Rightarrow \{a_n\}$ is bounded.

17. True by Theorem 11.6.3. $\left[\sum (-1)^n a_n \text{ is absolutely convergent and hence convergent.}\right]$

18. True. $\lim\limits_{n\to\infty} \dfrac{a_{n+1}}{a_n} < 1 \Rightarrow \sum a_n$ converges (Ratio Test) $\Rightarrow \lim\limits_{n\to\infty} a_n = 0$ [Theorem 11.2.6].

19. True. $0.99999\ldots = 0.9 + 0.9(0.1)^1 + 0.9(0.1)^2 + 0.9(0.1)^3 + \cdots = \sum\limits_{n=1}^{\infty} (0.9)(0.1)^{n-1} = \dfrac{0.9}{1-0.1} = 1$ by the formula for the sum of a geometric series $[S = a_1/(1-r)]$ with ratio r satisfying $|r| < 1$.

20. True. Since $\lim\limits_{n\to\infty} a_n = 2$, we know that $\lim\limits_{n\to\infty} a_{n+3} = 2$. Thus, $\lim\limits_{n\to\infty} (a_{n+3} - a_n) = \lim\limits_{n\to\infty} a_{n+3} - \lim\limits_{n\to\infty} a_n = 2 - 2 = 0$.

21. True. A finite number of terms doesn't affect convergence or divergence of a series.

22. False. Let $a_n = (0.1)^n$ and $b_n = (0.2)^n$. Then $\sum\limits_{n=1}^{\infty} a_n = \sum\limits_{n=1}^{\infty} (0.1)^n = \dfrac{0.1}{1-0.1} = \dfrac{1}{9} = A$,

$\sum\limits_{n=1}^{\infty} b_n = \sum\limits_{n=1}^{\infty} (0.2)^n = \dfrac{0.2}{1-0.2} = \dfrac{1}{4} = B$, and $\sum\limits_{n=1}^{\infty} a_n b_n = \sum\limits_{n=1}^{\infty} (0.02)^n = \dfrac{0.02}{1-0.02} = \dfrac{1}{49}$, but

$AB = \frac{1}{9} \cdot \frac{1}{4} = \frac{1}{36}$.

EXERCISES

1. $\left\{\dfrac{2+n^3}{1+2n^3}\right\}$ converges since $\lim\limits_{n\to\infty} \dfrac{2+n^3}{1+2n^3} = \lim\limits_{n\to\infty} \dfrac{2/n^3+1}{1/n^3+2} = \dfrac{1}{2}$.

2. $a_n = \dfrac{9^{n+1}}{10^n} = 9 \cdot \left(\frac{9}{10}\right)^n$, so $\lim\limits_{n\to\infty} a_n = 9 \lim\limits_{n\to\infty} \left(\frac{9}{10}\right)^n = 9 \cdot 0 = 0$ by (11.1.9).

3. $\lim\limits_{n\to\infty} a_n = \lim\limits_{n\to\infty} \dfrac{n^3}{1+n^2} = \lim\limits_{n\to\infty} \dfrac{n}{1/n^2+1} = \infty$, so the sequence diverges.

4. $a_n = \cos(n\pi/2)$, so $a_n = 0$ if n is odd and $a_n = \pm 1$ if n is even. As n increases, a_n keeps cycling through the values 0, 1, 0, -1, so the sequence $\{a_n\}$ is divergent.

5. $|a_n| = \left|\dfrac{n \sin n}{n^2+1}\right| \le \dfrac{n}{n^2+1} < \dfrac{1}{n}$, so $|a_n| \to 0$ as $n \to \infty$. Thus, $\lim\limits_{n\to\infty} a_n = 0$. The sequence $\{a_n\}$ is convergent.

6. $a_n = \dfrac{\ln n}{\sqrt{n}}$. Let $f(x) = \dfrac{\ln x}{\sqrt{x}}$ for $x > 0$. Then $\lim\limits_{x\to\infty} f(x) = \lim\limits_{x\to\infty} \dfrac{\ln x}{\sqrt{x}} \overset{\text{H}}{=} \lim\limits_{x\to\infty} \dfrac{1/x}{1/(2\sqrt{x})} = \lim\limits_{x\to\infty} \dfrac{2}{\sqrt{x}} = 0$.

Thus, by Theorem 11.1.3, $\{a_n\}$ converges and $\lim\limits_{n\to\infty} a_n = 0$.

7. $\left\{\left(1+\dfrac{3}{n}\right)^{4n}\right\}$ is convergent. Let $y=\left(1+\dfrac{3}{x}\right)^{4x}$. Then

$$\lim_{x\to\infty}\ln y=\lim_{x\to\infty}4x\ln(1+3/x)=\lim_{x\to\infty}\frac{\ln(1+3/x)}{1/(4x)}\overset{\text{H}}{=}\lim_{x\to\infty}\frac{\dfrac{1}{1+3/x}\left(-\dfrac{3}{x^2}\right)}{-1/(4x^2)}=\lim_{x\to\infty}\frac{12}{1+3/x}=12,\text{ so}$$

$$\lim_{x\to\infty}y=\lim_{n\to\infty}\left(1+\frac{3}{n}\right)^{4n}=e^{12}.$$

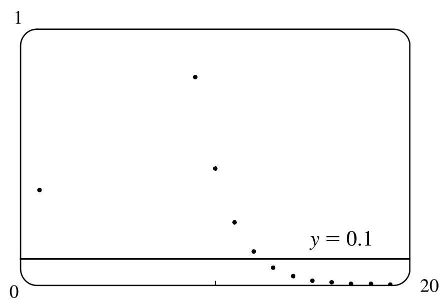
8. $\left\{\dfrac{(-10)^n}{n!}\right\}$ converges, since $\dfrac{10^n}{n!}=\dfrac{10\cdot10\cdot10\cdot\cdots\cdot10}{1\cdot2\cdot3\cdot\cdots\cdot10}\cdot\dfrac{10\cdot10\cdot\cdots\cdot10}{11\cdot12\cdot\cdots\cdot n}\le10^{10}\left(\dfrac{10}{11}\right)^{n-10}\to0$ as $n\to\infty$, so $\lim\limits_{n\to\infty}\dfrac{(-10)^n}{n!}=0$ [Squeeze Theorem]. *Or:* Use (11.10.10).

9. We use induction, hypothesizing that $a_{n-1}<a_n<2$. Note first that $1<a_2=\frac{1}{3}(1+4)=\frac{5}{3}<2$, so the hypothesis holds for $n=2$. Now assume that $a_{k-1}<a_k<2$. Then $a_k=\frac{1}{3}(a_{k-1}+4)<\frac{1}{3}(a_k+4)<\frac{1}{3}(2+4)=2$. So $a_k<a_{k+1}<2$, and the induction is complete. To find the limit of the sequence, we note that $L=\lim\limits_{n\to\infty}a_n=\lim\limits_{n\to\infty}a_{n+1}\Rightarrow$ $L=\frac{1}{3}(L+4)\Rightarrow L=2$.

10. $\lim\limits_{x\to\infty}\dfrac{x^4}{e^x}\overset{\text{H}}{=}\lim\limits_{x\to\infty}\dfrac{4x^3}{e^x}\overset{\text{H}}{=}\lim\limits_{x\to\infty}\dfrac{12x^2}{e^x}\overset{\text{H}}{=}\lim\limits_{x\to\infty}\dfrac{24x}{e^x}\overset{\text{H}}{=}\lim\limits_{x\to\infty}\dfrac{24}{e^x}=0$

Then we conclude from Theorem 11.1.3 that $\lim\limits_{n\to\infty}n^4e^{-n}=0$.

From the graph, it seems that $12^4e^{-12}>0.1$, but $n^4e^{-n}<0.1$ whenever $n>12$. So the smallest value of N corresponding to $\varepsilon=0.1$ in the definition of the limit is $N=12$.



11. $\dfrac{n}{n^3+1}<\dfrac{n}{n^3}=\dfrac{1}{n^2}$, so $\sum\limits_{n=1}^{\infty}\dfrac{n}{n^3+1}$ converges by the Comparison Test with the convergent p-series $\sum\limits_{n=1}^{\infty}\dfrac{1}{n^2}$ $[p=2>1]$.

12. Let $a_n=\dfrac{n^2+1}{n^3+1}$ and $b_n=\dfrac{1}{n}$, so $\lim\limits_{n\to\infty}\dfrac{a_n}{b_n}=\lim\limits_{n\to\infty}\dfrac{n^3+n}{n^3+1}=\lim\limits_{n\to\infty}\dfrac{1+1/n^2}{1+1/n^3}=1>0$.

Since $\sum\limits_{n=1}^{\infty}b_n$ is the divergent harmonic series, $\sum\limits_{n=1}^{\infty}a_n$ also diverges by the Limit Comparison Test.

13. $\lim\limits_{n\to\infty}\left|\dfrac{a_{n+1}}{a_n}\right|=\lim\limits_{n\to\infty}\left[\dfrac{(n+1)^3}{5^{n+1}}\cdot\dfrac{5^n}{n^3}\right]=\lim\limits_{n\to\infty}\left(1+\dfrac{1}{n}\right)^3\cdot\dfrac{1}{5}=\dfrac{1}{5}<1$, so $\sum\limits_{n=1}^{\infty}\dfrac{n^3}{5^n}$ converges by the Ratio Test.

14. Let $b_n=\dfrac{1}{\sqrt{n+1}}$. Then b_n is positive for $n\ge1$, the sequence $\{b_n\}$ is decreasing, and $\lim\limits_{n\to\infty}b_n=0$, so the series $\sum\limits_{n=1}^{\infty}\dfrac{(-1)^n}{\sqrt{n+1}}$ converges by the Alternating Series Test.

15. Let $f(x) = \dfrac{1}{x\sqrt{\ln x}}$. Then f is continuous, positive, and decreasing on $[2, \infty)$, so the Integral Test applies.

$$\int_2^\infty f(x)\,dx = \lim_{t\to\infty}\int_2^t \frac{1}{x\sqrt{\ln x}}\,dx \quad \left[u = \ln x,\, du = \tfrac{1}{x}\,dx\right] \quad = \lim_{t\to\infty}\int_{\ln 2}^{\ln t} u^{-1/2}\,du = \lim_{t\to\infty}\left[2\sqrt{u}\right]_{\ln 2}^{\ln t}$$

$$= \lim_{t\to\infty}\left(2\sqrt{\ln t} - 2\sqrt{\ln 2}\right) = \infty,$$

so the series $\sum\limits_{n=2}^{\infty} \dfrac{1}{n\sqrt{\ln n}}$ diverges.

16. $\lim\limits_{n\to\infty} \dfrac{n}{3n+1} = \dfrac{1}{3}$, so $\lim\limits_{n\to\infty} \ln\left(\dfrac{n}{3n+1}\right) = \ln\frac{1}{3} \neq 0$. Thus, the series $\sum\limits_{n=1}^{\infty} \ln\left(\dfrac{n}{3n+1}\right)$ diverges by the Test for Divergence.

17. $|a_n| = \left|\dfrac{\cos 3n}{1+(1.2)^n}\right| \leq \dfrac{1}{1+(1.2)^n} < \dfrac{1}{(1.2)^n} = \left(\dfrac{5}{6}\right)^n$, so $\sum\limits_{n=1}^{\infty} |a_n|$ converges by comparison with the convergent geometric series $\sum\limits_{n=1}^{\infty} \left(\frac{5}{6}\right)^n$ $\left[r = \frac{5}{6} < 1\right]$. It follows that $\sum\limits_{n=1}^{\infty} a_n$ converges (by Theorem 11.6.3).

18. $\lim\limits_{n\to\infty} \sqrt[n]{|a_n|} = \lim\limits_{n\to\infty} \sqrt[n]{\left|\dfrac{n^{2n}}{(1+2n^2)^n}\right|} = \lim\limits_{n\to\infty} \dfrac{n^2}{1+2n^2} = \lim\limits_{n\to\infty} \dfrac{1}{1/n^2+2} = \dfrac{1}{2} < 1$, so $\sum\limits_{n=1}^{\infty} \dfrac{n^{2n}}{(1+2n^2)^n}$ converges by the Root Test.

19. $\lim\limits_{n\to\infty} \left|\dfrac{a_{n+1}}{a_n}\right| = \lim\limits_{n\to\infty} \dfrac{1\cdot 3\cdot 5\cdot\cdots\cdot(2n-1)(2n+1)}{5^{n+1}\,(n+1)!} \cdot \dfrac{5^n\,n!}{1\cdot 3\cdot 5\cdot\cdots\cdot(2n-1)} = \lim\limits_{n\to\infty} \dfrac{2n+1}{5(n+1)} = \dfrac{2}{5} < 1$, so the series converges by the Ratio Test.

20. $\sum\limits_{n=1}^{\infty} \dfrac{(-5)^{2n}}{n^2\,9^n} = \sum\limits_{n=1}^{\infty} \dfrac{1}{n^2}\left(\dfrac{25}{9}\right)^n$. Now $\lim\limits_{n\to\infty} \left|\dfrac{a_{n+1}}{a_n}\right| = \lim\limits_{n\to\infty} \dfrac{25^{n+1}}{(n+1)^2\cdot 9^{n+1}} \cdot \dfrac{n^2\cdot 9^n}{25^n} = \lim\limits_{n\to\infty} \dfrac{25n^2}{9(n+1)^2} = \dfrac{25}{9} > 1$, so the series diverges by the Ratio Test.

21. $b_n = \dfrac{\sqrt{n}}{n+1} > 0$, $\{b_n\}$ is decreasing, and $\lim\limits_{n\to\infty} b_n = 0$, so the series $\sum\limits_{n=1}^{\infty} (-1)^{n-1}\dfrac{\sqrt{n}}{n+1}$ converges by the Alternating Series Test.

22. Use the Limit Comparison Test with $a_n = \dfrac{\sqrt{n+1}-\sqrt{n-1}}{n} = \dfrac{2}{n\left(\sqrt{n+1}+\sqrt{n-1}\right)}$ (rationalizing the numerator) and $b_n = \dfrac{1}{n^{3/2}}$. $\lim\limits_{n\to\infty} \dfrac{a_n}{b_n} = \lim\limits_{n\to\infty} \dfrac{2\sqrt{n}}{\sqrt{n+1}+\sqrt{n-1}} = 1$, so since $\sum\limits_{n=1}^{\infty} b_n$ converges $\left[p = \frac{3}{2} > 1\right]$, $\sum\limits_{n=1}^{\infty} a_n$ converges also.

23. Consider the series of absolute values: $\sum\limits_{n=1}^{\infty} n^{-1/3}$ is a p-series with $p = \frac{1}{3} \leq 1$ and is therefore divergent. But if we apply the Alternating Series Test, we see that $b_n = \dfrac{1}{\sqrt[3]{n}} > 0$, $\{b_n\}$ is decreasing, and $\lim\limits_{n\to\infty} b_n = 0$, so the series $\sum\limits_{n=1}^{\infty} (-1)^{n-1}\,n^{-1/3}$ converges. Thus, $\sum\limits_{n=1}^{\infty} (-1)^{n-1}\,n^{-1/3}$ is conditionally convergent.

24. $\sum_{n=1}^{\infty} \left|(-1)^{n-1} n^{-3}\right| = \sum_{n=1}^{\infty} n^{-3}$ is a convergent p-series $[p = 3 > 1]$. Therefore, $\sum_{n=1}^{\infty} (-1)^{n-1} n^{-3}$ is absolutely convergent.

25. $\left|\frac{a_{n+1}}{a_n}\right| = \left|\frac{(-1)^{n+1}(n+2)3^{n+1}}{2^{2n+3}} \cdot \frac{2^{2n+1}}{(-1)^n(n+1)3^n}\right| = \frac{n+2}{n+1} \cdot \frac{3}{4} = \frac{1+(2/n)}{1+(1/n)} \cdot \frac{3}{4} \to \frac{3}{4} < 1$ as $n \to \infty$, so by the Ratio Test, $\sum_{n=1}^{\infty} \frac{(-1)^n(n+1)3^n}{2^{2n+1}}$ is absolutely convergent.

26. $\lim_{x\to\infty} \frac{\sqrt{x}}{\ln x} \overset{\text{H}}{=} \lim_{x\to\infty} \frac{1/(2\sqrt{x})}{1/x} = \lim_{x\to\infty} \frac{\sqrt{x}}{2} = \infty$. Therefore, $\lim_{n\to\infty} \frac{(-1)^n \sqrt{n}}{\ln n} \neq 0$, so the given series is divergent by the Test for Divergence.

27.
$$\sum_{n=1}^{\infty} \frac{(-3)^{n-1}}{2^{3n}} = \sum_{n=1}^{\infty} \frac{(-3)^{n-1}}{(2^3)^n} = \sum_{n=1}^{\infty} \frac{(-3)^{n-1}}{8^n} = \frac{1}{8}\sum_{n=1}^{\infty} \frac{(-3)^{n-1}}{8^{n-1}} = \frac{1}{8}\sum_{n=1}^{\infty} \left(-\frac{3}{8}\right)^{n-1} = \frac{1}{8}\left(\frac{1}{1-(-3/8)}\right)$$
$$= \frac{1}{8} \cdot \frac{8}{11} = \frac{1}{11}$$

28. $\sum_{n=1}^{\infty} \frac{1}{n(n+3)} = \sum_{n=1}^{\infty} \left[\frac{1}{3n} - \frac{1}{3(n+3)}\right]$ [partial fractions].

$s_n = \sum_{i=1}^{n} \left[\frac{1}{3i} - \frac{1}{3(i+3)}\right] = \frac{1}{3} + \frac{1}{6} + \frac{1}{9} - \frac{1}{3(n+1)} - \frac{1}{3(n+2)} - \frac{1}{3(n+3)}$ (telescoping sum), so

$\sum_{n=1}^{\infty} \frac{1}{n(n+3)} = \lim_{n\to\infty} s_n = \frac{1}{3} + \frac{1}{6} + \frac{1}{9} = \frac{11}{18}$.

29.
$$\begin{aligned}\sum_{n=1}^{\infty} [\tan^{-1}(n+1) - \tan^{-1} n] &= \lim_{n\to\infty} s_n \\ &= \lim_{n\to\infty} [(\tan^{-1} 2 - \tan^{-1} 1) + (\tan^{-1} 3 - \tan^{-1} 2) + \cdots + (\tan^{-1}(n+1) - \tan^{-1} n)] \\ &= \lim_{n\to\infty} [\tan^{-1}(n+1) - \tan^{-1} 1] = \tfrac{\pi}{2} - \tfrac{\pi}{4} = \tfrac{\pi}{4}\end{aligned}$$

30. $\sum_{n=0}^{\infty} \frac{(-1)^n \pi^n}{3^{2n}(2n)!} = \sum_{n=0}^{\infty} (-1)^n \frac{1}{(2n)!} \cdot \frac{\pi^n}{3^{2n}} = \sum_{n=0}^{\infty} (-1)^n \frac{1}{(2n)!} \cdot \left(\frac{\sqrt{\pi}}{3}\right)^{2n} = \cos\left(\frac{\sqrt{\pi}}{3}\right)$ since $\cos x = \sum_{n=0}^{\infty} (-1)^n \frac{x^{2n}}{(2n)!}$ for all x.

31. $1 - e + \frac{e^2}{2!} - \frac{e^3}{3!} + \frac{e^4}{4!} - \cdots = \sum_{n=0}^{\infty} (-1)^n \frac{e^n}{n!} = \sum_{n=0}^{\infty} \frac{(-e)^n}{n!} = e^{-e}$ since $e^x = \sum_{n=0}^{\infty} \frac{x^n}{n!}$ for all x.

32. $4.17\overline{326} = 4.17 + \frac{326}{10^5} + \frac{326}{10^8} + \cdots = 4.17 + \frac{326/10^5}{1 - 1/10^3} = \frac{417}{100} + \frac{326}{99{,}900} = \frac{416{,}909}{99{,}900}$

33.
$$\begin{aligned}\cosh x &= \frac{1}{2}(e^x + e^{-x}) = \frac{1}{2}\left(\sum_{n=0}^{\infty} \frac{x^n}{n!} + \sum_{n=0}^{\infty} \frac{(-x)^n}{n!}\right) \\ &= \frac{1}{2}\left[\left(1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \frac{x^4}{4!} + \cdots\right) + \left(1 - x + \frac{x^2}{2!} - \frac{x^3}{3!} + \frac{x^4}{4!} - \cdots\right)\right] \\ &= \frac{1}{2}\left(2 + 2 \cdot \frac{x^2}{2!} + 2 \cdot \frac{x^4}{4!} + \cdots\right) = 1 + \frac{1}{2}x^2 + \sum_{n=2}^{\infty} \frac{x^{2n}}{(2n)!} \geq 1 + \frac{1}{2}x^2 \quad \text{for all } x\end{aligned}$$

34. $\sum_{n=1}^{\infty} (\ln x)^n$ is a geometric series which converges whenever $|\ln x| < 1 \Rightarrow -1 < \ln x < 1 \Rightarrow e^{-1} < x < e$.

35. $\sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n^5} = 1 - \frac{1}{32} + \frac{1}{243} - \frac{1}{1024} + \frac{1}{3125} - \frac{1}{7776} + \frac{1}{16{,}807} - \frac{1}{32{,}768} + \cdots$.

Since $b_8 = \frac{1}{8^5} = \frac{1}{32{,}768} < 0.000031$, $\sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n^5} \approx \sum_{n=1}^{7} \frac{(-1)^{n+1}}{n^5} \approx 0.9721$.

36. (a) $s_5 = \sum_{n=1}^{5} \frac{1}{n^6} = 1 + \frac{1}{2^6} + \cdots + \frac{1}{5^6} \approx 1.017305$. The series $\sum_{n=1}^{\infty} \frac{1}{n^6}$ converges by the Integral Test, so we estimate the remainder R_5 with (11.3.2): $R_5 \leq \int_5^{\infty} \frac{dx}{x^6} = \left[-\frac{x^{-5}}{5}\right]_5^{\infty} = \frac{5^{-5}}{5} = 0.000064$. So the error is at most 0.000064.

(b) In general, $R_n \leq \int_n^{\infty} \frac{dx}{x^6} = \frac{1}{5n^5}$. If we take $n = 9$, then $s_9 \approx 1.01734$ and $R_9 \leq \frac{1}{5 \cdot 9^5} \approx 3.4 \times 10^{-6}$.

So to five decimal places, $\sum_{n=1}^{\infty} \frac{1}{n^5} \approx \sum_{n=1}^{9} \frac{1}{n^5} \approx 1.01734$.

Another method: Use (11.3.3) instead of (11.3.2).

37. $\sum_{n=1}^{\infty} \frac{1}{2+5^n} \approx \sum_{n=1}^{8} \frac{1}{2+5^n} \approx 0.18976224$. To estimate the error, note that $\frac{1}{2+5^n} < \frac{1}{5^n}$, so the remainder term is

$R_8 = \sum_{n=9}^{\infty} \frac{1}{2+5^n} < \sum_{n=9}^{\infty} \frac{1}{5^n} = \frac{1/5^9}{1-1/5} = 6.4 \times 10^{-7}$ [geometric series with $a = \frac{1}{5^9}$ and $r = \frac{1}{5}$].

38. (a) $$\lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty} \left|\frac{(n+1)^{n+1}}{[2(n+1)]!} \cdot \frac{(2n)!}{n^n}\right| = \lim_{n\to\infty} \frac{(n+1)^n (n+1)^1}{(2n+2)(2n+1)n^n} = \lim_{n\to\infty} \left(\frac{n+1}{n}\right)^n \frac{1}{2(2n+1)}$$
$$= \lim_{n\to\infty} \left(1 + \frac{1}{n}\right)^n \frac{1}{2(2n+1)} = e \cdot 0 = 0 < 1$$

so the series converges by the Ratio Test.

(b) The series in part (a) is convergent, so $\lim_{n\to\infty} a_n = \lim_{n\to\infty} \frac{n^n}{(2n)!} = 0$ by Theorem 11.2.6.

39. Use the Limit Comparison Test. $\lim_{n\to\infty} \left|\frac{\left(\frac{n+1}{n}\right)a_n}{a_n}\right| = \lim_{n\to\infty} \frac{n+1}{n} = \lim_{n\to\infty} \left(1 + \frac{1}{n}\right) = 1 > 0$.

Since $\sum |a_n|$ is convergent, so is $\sum \left|\left(\frac{n+1}{n}\right)a_n\right|$, by the Limit Comparison Test.

40. $\lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty} \left|\frac{x^{n+1}}{(n+1)^2\, 5^{n+1}} \cdot \frac{n^2 5^n}{x^n}\right| = \lim_{n\to\infty} \frac{1}{(1+1/n)^2} \frac{|x|}{5} = \frac{|x|}{5}$, so by the Ratio Test, $\sum_{n=1}^{\infty} (-1)^n \frac{x^n}{n^2\, 5^n}$ converges when $\frac{|x|}{5} < 1 \Leftrightarrow |x| < 5$, so $R = 5$. When $x = -5$, the series becomes the convergent p-series $\sum_{n=1}^{\infty} \frac{1}{n^2}$ with $p = 2 > 1$. When $x = 5$, the series becomes $\sum_{n=1}^{\infty} \frac{(-1)^n}{n^2}$, which converges by the Alternating Series Test. Thus, $I = [-5, 5]$.

41. $\lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty}\left[\frac{|x+2|^{n+1}}{(n+1)\,4^{n+1}}\cdot\frac{n\,4^n}{|x+2|^n}\right] = \lim_{n\to\infty}\left[\frac{n}{n+1}\frac{|x+2|}{4}\right] = \frac{|x+2|}{4} < 1 \;\Leftrightarrow\; |x+2| < 4$, so $R = 4$.

$|x+2| < 4 \;\Leftrightarrow\; -4 < x+2 < 4 \;\Leftrightarrow\; -6 < x < 2$. If $x = -6$, then the series $\sum_{n=1}^{\infty}\frac{(x+2)^n}{n\,4^n}$ becomes

$\sum_{n=1}^{\infty}\frac{(-4)^n}{n4^n} = \sum_{n=1}^{\infty}\frac{(-1)^n}{n}$, the alternating harmonic series, which converges by the Alternating Series Test. When $x = 2$, the series becomes the harmonic series $\sum_{n=1}^{\infty}\frac{1}{n}$, which diverges. Thus, $I = [-6, 2)$.

42. $\lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty}\left|\frac{2^{n+1}\,(x-2)^{n+1}}{(n+3)!}\cdot\frac{(n+2)!}{2^n(x-2)^n}\right| = \lim_{n\to\infty}\frac{2}{n+3}\,|x-2| = 0 < 1$, so the series $\sum_{n=1}^{\infty}\frac{2^n\,(x-2)^n}{(n+2)!}$ converges for all x. $R = \infty$ and $I = (-\infty, \infty)$.

43. $\lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty}\left|\frac{2^{n+1}(x-3)^{n+1}}{\sqrt{n+4}}\cdot\frac{\sqrt{n+3}}{2^n(x-3)^n}\right| = 2\,|x-3|\lim_{n\to\infty}\sqrt{\frac{n+3}{n+4}} = 2\,|x-3| < 1 \;\Leftrightarrow\; |x-3| < \frac{1}{2}$,

so $R = \frac{1}{2}$. $|x-3| < \frac{1}{2} \;\Leftrightarrow\; -\frac{1}{2} < x-3 < \frac{1}{2} \;\Leftrightarrow\; \frac{5}{2} < x < \frac{7}{2}$. For $x = \frac{7}{2}$, the series $\sum_{n=1}^{\infty}\frac{2^n\,(x-3)^n}{\sqrt{n+3}}$ becomes

$\sum_{n=0}^{\infty}\frac{1}{\sqrt{n+3}} = \sum_{n=3}^{\infty}\frac{1}{n^{1/2}}$, which diverges $\left[p = \frac{1}{2} \le 1\right]$, but for $x = \frac{5}{2}$, we get $\sum_{n=0}^{\infty}\frac{(-1)^n}{\sqrt{n+3}}$, which is a convergent alternating series, so $I = \left[\frac{5}{2}, \frac{7}{2}\right)$.

44. $\lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \lim_{n\to\infty}\left|\frac{(2n+2)!\,x^{n+1}}{[(n+1)!]^2}\cdot\frac{(n!)^2}{(2n)!\,x^n}\right| = \lim_{n\to\infty}\frac{(2n+2)(2n+1)}{(n+1)(n+1)}\,|x| = 4\,|x|$.

To converge, we must have $4\,|x| < 1 \;\Leftrightarrow\; |x| < \frac{1}{4}$, so $R = \frac{1}{4}$.

45.

n	$f^{(n)}(x)$	$f^{(n)}\left(\frac{\pi}{6}\right)$
0	$\sin x$	$\frac{1}{2}$
1	$\cos x$	$\frac{\sqrt{3}}{2}$
2	$-\sin x$	$-\frac{1}{2}$
3	$-\cos x$	$-\frac{\sqrt{3}}{2}$
4	$\sin x$	$\frac{1}{2}$
⋮	⋮	⋮

$$\sin x = f\left(\frac{\pi}{6}\right) + f'\left(\frac{\pi}{6}\right)\left(x-\frac{\pi}{6}\right) + \frac{f''\left(\frac{\pi}{6}\right)}{2!}\left(x-\frac{\pi}{6}\right)^2 + \frac{f^{(3)}\left(\frac{\pi}{6}\right)}{3!}\left(x-\frac{\pi}{6}\right)^3 + \frac{f^{(4)}\left(\frac{\pi}{6}\right)}{4!}\left(x-\frac{\pi}{6}\right)^4 + \cdots$$

$$= \frac{1}{2}\left[1 - \frac{1}{2!}\left(x-\frac{\pi}{6}\right)^2 + \frac{1}{4!}\left(x-\frac{\pi}{6}\right)^4 - \cdots\right] + \frac{\sqrt{3}}{2}\left[\left(x-\frac{\pi}{6}\right) - \frac{1}{3!}\left(x-\frac{\pi}{6}\right)^3 + \cdots\right]$$

$$= \frac{1}{2}\sum_{n=0}^{\infty}(-1)^n\frac{1}{(2n)!}\left(x-\frac{\pi}{6}\right)^{2n} + \frac{\sqrt{3}}{2}\sum_{n=0}^{\infty}(-1)^n\frac{1}{(2n+1)!}\left(x-\frac{\pi}{6}\right)^{2n+1}$$

46.

n	$f^{(n)}(x)$	$f^{(n)}\left(\frac{\pi}{3}\right)$
0	$\cos x$	$\frac{1}{2}$
1	$-\sin x$	$-\frac{\sqrt{3}}{2}$
2	$-\cos x$	$-\frac{1}{2}$
3	$\sin x$	$\frac{\sqrt{3}}{2}$
4	$\cos x$	$\frac{1}{2}$
$\vdots$	$\vdots$	$\vdots$

$$\cos x = f\left(\frac{\pi}{3}\right) + f'\left(\frac{\pi}{3}\right)\left(x-\frac{\pi}{3}\right) + \frac{f''\left(\frac{\pi}{3}\right)}{2!}\left(x-\frac{\pi}{3}\right)^2 + \frac{f^{(3)}\left(\frac{\pi}{3}\right)}{3!}\left(x-\frac{\pi}{3}\right)^3 + \frac{f^{(4)}\left(\frac{\pi}{3}\right)}{4!}\left(x-\frac{\pi}{3}\right)^4 + \cdots$$

$$= \frac{1}{2}\left[1 - \frac{1}{2!}\left(x-\frac{\pi}{3}\right)^2 + \frac{1}{4!}\left(x-\frac{\pi}{3}\right)^4 - \cdots\right] + \frac{\sqrt{3}}{2}\left[-\left(x-\frac{\pi}{3}\right) + \frac{1}{3!}\left(x-\frac{\pi}{3}\right)^3 - \cdots\right]$$

$$= \frac{1}{2}\sum_{n=0}^{\infty}(-1)^n\frac{1}{(2n)!}\left(x-\frac{\pi}{3}\right)^{2n} + \frac{\sqrt{3}}{2}\sum_{n=0}^{\infty}(-1)^{n+1}\frac{1}{(2n+1)!}\left(x-\frac{\pi}{3}\right)^{2n+1}$$

47. $\dfrac{1}{1+x} = \dfrac{1}{1-(-x)} = \sum_{n=0}^{\infty}(-x)^n = \sum_{n=0}^{\infty}(-1)^n x^n$ for $|x|<1 \Rightarrow \dfrac{x^2}{1+x} = \sum_{n=0}^{\infty}(-1)^n x^{n+2}$ with $R=1$.

48. $\tan^{-1} x = \sum_{n=0}^{\infty}(-1)^n \dfrac{x^{2n+1}}{2n+1}$ with interval of convergence $[-1,1]$, so

$\tan^{-1}(x^2) = \sum_{n=0}^{\infty}(-1)^n \dfrac{(x^2)^{2n+1}}{2n+1} = \sum_{n=0}^{\infty}(-1)^n \dfrac{x^{4n+2}}{2n+1}$, which converges when $x^2 \in [-1,1] \Leftrightarrow x \in [-1,1]$.

Therefore, $R=1$.

49. $\displaystyle\int \frac{1}{4-x}\,dx = -\ln(4-x) + C$ and

$$\int \frac{1}{4-x}\,dx = \frac{1}{4}\int \frac{1}{1-x/4}\,dx = \frac{1}{4}\int \sum_{n=0}^{\infty}\left(\frac{x}{4}\right)^n dx = \frac{1}{4}\int \sum_{n=0}^{\infty}\frac{x^n}{4^n}\,dx = \frac{1}{4}\sum_{n=0}^{\infty}\frac{x^{n+1}}{4^n(n+1)} + C.$$ So

$\ln(4-x) = -\dfrac{1}{4}\sum_{n=0}^{\infty}\dfrac{x^{n+1}}{4^n(n+1)} + C = -\sum_{n=0}^{\infty}\dfrac{x^{n+1}}{4^{n+1}(n+1)} + C = -\sum_{n=1}^{\infty}\dfrac{x^n}{n4^n} + C$. Putting $x=0$, we get $C=\ln 4$.

Thus, $f(x) = \ln(4-x) = \ln 4 - \sum_{n=1}^{\infty}\dfrac{x^n}{n4^n}$. The series converges for $|x/4|<1 \Leftrightarrow |x|<4$, so $R=4$.

Another solution:

$$\ln(4-x) = \ln[4(1-x/4)] = \ln 4 + \ln(1-x/4) = \ln 4 + \ln[1+(-x/4)]$$

$$= \ln 4 + \sum_{n=1}^{\infty}(-1)^{n+1}\frac{(-x/4)^n}{n} \text{ [from Table 1] } = \ln 4 + \sum_{n=1}^{\infty}(-1)^{2n+1}\frac{x^n}{n4^n} = \ln 4 - \sum_{n=1}^{\infty}\frac{x^n}{n4^n}.$$

50. $e^x = \sum_{n=0}^{\infty}\dfrac{x^n}{n!} \Rightarrow e^{2x} = \sum_{n=0}^{\infty}\dfrac{(2x)^n}{n!} \Rightarrow xe^{2x} = x\sum_{n=0}^{\infty}\dfrac{2^n x^n}{n!} = \sum_{n=0}^{\infty}\dfrac{2^n x^{n+1}}{n!}$, $R=\infty$

51. $\sin x = \sum_{n=0}^{\infty}\dfrac{(-1)^n x^{2n+1}}{(2n+1)!} \Rightarrow \sin(x^4) = \sum_{n=0}^{\infty}\dfrac{(-1)^n (x^4)^{2n+1}}{(2n+1)!} = \sum_{n=0}^{\infty}\dfrac{(-1)^n x^{8n+4}}{(2n+1)!}$ for all x, so the radius of convergence is ∞.

52. $e^x = \sum_{n=0}^{\infty}\dfrac{x^n}{n!} \Rightarrow 10^x = e^{(\ln 10)x} = \sum_{n=0}^{\infty}\dfrac{[(\ln 10)x]^n}{n!} = \sum_{n=0}^{\infty}\dfrac{(\ln 10)^n x^n}{n!}$, $R=\infty$

53. $f(x) = \dfrac{1}{\sqrt[4]{16-x}} = \dfrac{1}{\sqrt[4]{16(1-x/16)}} = \dfrac{1}{\sqrt[4]{16}\left(1-\frac{1}{16}x\right)^{1/4}} = \frac{1}{2}\left(1-\frac{1}{16}x\right)^{-1/4}$

$$= \frac{1}{2}\left[1 + \left(-\frac{1}{4}\right)\left(-\frac{x}{16}\right) + \frac{\left(-\frac{1}{4}\right)\left(-\frac{5}{4}\right)}{2!}\left(-\frac{x}{16}\right)^2 + \frac{\left(-\frac{1}{4}\right)\left(-\frac{5}{4}\right)\left(-\frac{9}{4}\right)}{3!}\left(-\frac{x}{16}\right)^3 + \cdots\right]$$

$$= \frac{1}{2} + \sum_{n=1}^{\infty} \frac{1\cdot 5\cdot 9\cdot \cdots \cdot (4n-3)}{2\cdot 4^n \cdot n!\cdot 16^n}\, x^n = \frac{1}{2} + \sum_{n=1}^{\infty} \frac{1\cdot 5\cdot 9\cdot \cdots \cdot (4n-3)}{2^{6n+1}\, n!}\, x^n$$

for $\left|-\dfrac{x}{16}\right| < 1 \quad \Leftrightarrow \quad |x| < 16$, so $R = 16$.

54. $(1-3x)^{-5} = \displaystyle\sum_{n=0}^{\infty} \binom{-5}{n} (-3x)^n = 1 + (-5)(-3x) + \frac{(-5)(-6)}{2!}(-3x)^2 + \frac{(-5)(-6)(-7)}{3!}(-3x)^3 + \cdots$

$$= 1 + \sum_{n=1}^{\infty} \frac{5\cdot 6\cdot 7\cdot \cdots \cdot (n+4)\cdot 3^n\, x^n}{n!} \quad \text{for } |-3x| < 1 \quad \Leftrightarrow \quad |x| < \tfrac{1}{3}, \text{ so } R = \tfrac{1}{3}.$$

55. $e^x = \displaystyle\sum_{n=0}^{\infty} \frac{x^n}{n!}$, so $\dfrac{e^x}{x} = \dfrac{1}{x}\displaystyle\sum_{n=0}^{\infty} \frac{x^n}{n!} = \sum_{n=0}^{\infty} \frac{x^{n-1}}{n!} = x^{-1} + \sum_{n=1}^{\infty} \frac{x^{n-1}}{n!} = \frac{1}{x} + \sum_{n=1}^{\infty} \frac{x^{n-1}}{n!}$ and

$\displaystyle\int \frac{e^x}{x}\,dx = C + \ln|x| + \sum_{n=1}^{\infty} \frac{x^n}{n\cdot n!}$.

56. $(1+x^4)^{1/2} = \displaystyle\sum_{n=0}^{\infty} \binom{\frac{1}{2}}{n}(x^4)^n = 1 + \left(\tfrac{1}{2}\right)x^4 + \frac{\left(\frac{1}{2}\right)\left(-\frac{1}{2}\right)}{2!}(x^4)^2 + \frac{\left(\frac{1}{2}\right)\left(-\frac{1}{2}\right)\left(-\frac{3}{2}\right)}{3!}(x^4)^3 + \cdots$

$$= 1 + \tfrac{1}{2}x^4 - \tfrac{1}{8}x^8 + \tfrac{1}{16}x^{12} - \cdots$$

so $\int_0^1 (1+x^4)^{1/2}\,dx = \left[x + \frac{1}{10}x^5 - \frac{1}{72}x^9 + \frac{1}{208}x^{13} - \cdots\right]_0^1 = 1 + \frac{1}{10} - \frac{1}{72} + \frac{1}{208} - \cdots$.

This is an alternating series, so by the Alternating Series Test, the error in the approximation $\int_0^1 (1+x^4)^{1/2}\,dx \approx 1 + \frac{1}{10} - \frac{1}{72} \approx 1.086$ is less than $\frac{1}{208}$, sufficient for the desired accuracy.

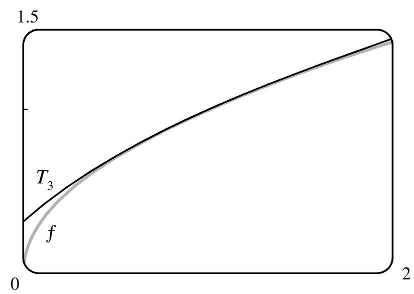
Thus, correct to two decimal places, $\int_0^1 (1+x^4)^{1/2}\,dx \approx 1.09$.

57. (a)

n	$f^{(n)}(x)$	$f^{(n)}(1)$
0	$x^{1/2}$	1
1	$\frac{1}{2}x^{-1/2}$	$\frac{1}{2}$
2	$-\frac{1}{4}x^{-3/2}$	$-\frac{1}{4}$
3	$\frac{3}{8}x^{-5/2}$	$\frac{3}{8}$
4	$-\frac{15}{16}x^{-7/2}$	$-\frac{15}{16}$
⋮	⋮	⋮

$$\sqrt{x} \approx T_3(x) = 1 + \frac{1/2}{1!}(x-1) - \frac{1/4}{2!}(x-1)^2 + \frac{3/8}{3!}(x-1)^3$$
$$= 1 + \tfrac{1}{2}(x-1) - \tfrac{1}{8}(x-1)^2 + \tfrac{1}{16}(x-1)^3$$

(b)

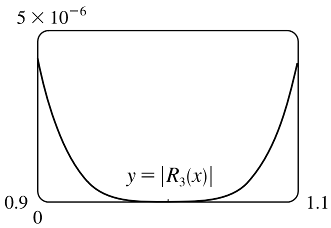


(c) $|R_3(x)| \le \dfrac{M}{4!}|x-1|^4$, where $\left|f^{(4)}(x)\right| \le M$ with $f^{(4)}(x) = -\frac{15}{16}x^{-7/2}$. Now $0.9 \le x \le 1.1 \quad \Rightarrow$

$-0.1 \le x-1 \le 0.1 \quad \Rightarrow \quad (x-1)^4 \le (0.1)^4$, and letting $x = 0.9$ gives $M = \dfrac{15}{16(0.9)^{7/2}}$, so

$|R_3(x)| \le \dfrac{15}{16(0.9)^{7/2}\,4!}(0.1)^4 \approx 0.000\,005\,648 \approx 0.000\,006 = 6\times 10^{-6}$.

(d)



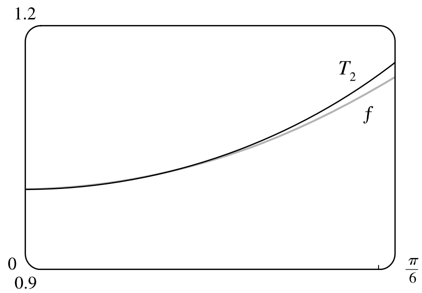
From the graph of $|R_3(x)| = |\sqrt{x} - T_3(x)|$, it appears that the error is less than 5×10^{-6} on $[0.9, 1.1]$.

58. (a)

n	$f^{(n)}(x)$	$f^{(n)}(0)$
0	$\sec x$	1
1	$\sec x \tan x$	0
2	$\sec x \tan^2 x + \sec^3 x$	1
3	$\sec x \tan^3 x + 5\sec^3 x \tan x$	0
$\vdots$	$\vdots$	$\vdots$

$\sec x \approx T_2(x) = 1 + \frac{1}{2}x^2$

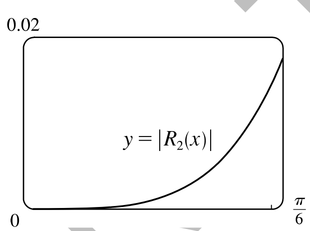
(b)



(c) $|R_2(x)| \leq \dfrac{M}{3!}|x|^3$, where $\left|f^{(3)}(x)\right| \leq M$ with $f^{(3)}(x) = \sec x\, \tan^3 x + 5\sec^3 x\, \tan x$.

Now $0 \leq x \leq \frac{\pi}{6} \quad\Rightarrow\quad x^3 \leq \left(\frac{\pi}{6}\right)^3$, and letting $x = \frac{\pi}{6}$ gives $M = \frac{14}{3}$, so $|R_2(x)| \leq \dfrac{14}{3 \cdot 6}\left(\dfrac{\pi}{6}\right)^3 \approx 0.111648$.

(d)



From the graph of $|R_2(x)| = |\sec x - T_2(x)|$, it appears that the error is less than 0.02 on $\left[0, \frac{\pi}{6}\right]$.

59. $\sin x = \sum\limits_{n=0}^{\infty} (-1)^n \dfrac{x^{2n+1}}{(2n+1)!} = x - \dfrac{x^3}{3!} + \dfrac{x^5}{5!} - \dfrac{x^7}{7!} + \cdots$, so $\sin x - x = -\dfrac{x^3}{3!} + \dfrac{x^5}{5!} - \dfrac{x^7}{7!} + \cdots$ and

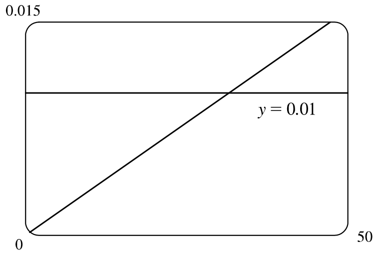
$\dfrac{\sin x - x}{x^3} = -\dfrac{1}{3!} + \dfrac{x^2}{5!} - \dfrac{x^4}{7!} + \cdots$. Thus, $\lim\limits_{x \to 0} \dfrac{\sin x - x}{x^3} = \lim\limits_{x \to 0}\left(-\dfrac{1}{6} + \dfrac{x^2}{120} - \dfrac{x^4}{5040} + \cdots\right) = -\dfrac{1}{6}$.

60. (a) $F = \dfrac{mgR^2}{(R+h)^2} = \dfrac{mg}{(1+h/R)^2} = mg\sum\limits_{n=0}^{\infty}\dbinom{-2}{n}\left(\dfrac{h}{R}\right)^n$ [binomial series]

(b) We expand $F = mg\left[1 - 2\,(h/R) + 3\,(h/R)^2 - \cdots\right]$.

This is an alternating series, so by the Alternating Series Estimation Theorem, the error in the approximation $F = mg$ is less than $2mgh/R$, so for accuracy within 1% we want

$$\left|\frac{2mgh/R}{mgR^2/(R+h)^2}\right| < 0.01 \quad\Leftrightarrow\quad \frac{2h(R+h)^2}{R^3} < 0.01.$$



This inequality would be difficult to solve for h, so we substitute $R = 6{,}400$ km and plot both sides of the inequality. It appears that the approximation is accurate to within 1% for $h < 31$ km.

61. $f(x) = \sum\limits_{n=0}^{\infty} c_n\, x^n \quad\Rightarrow\quad f(-x) = \sum\limits_{n=0}^{\infty} c_n(-x)^n = \sum\limits_{n=0}^{\infty}(-1)^n c_n\, x^n$

(a) If f is an odd function, then $f(-x) = -f(x) \quad\Rightarrow\quad \sum\limits_{n=0}^{\infty}(-1)^n c_n x^n = \sum\limits_{n=0}^{\infty} -c_n x^n$. The coefficients of any power series are uniquely determined (by Theorem 11.10.5), so $(-1)^n\, c_n = -c_n$.

If n is even, then $(-1)^n = 1$, so $c_n = -c_n \quad\Rightarrow\quad 2c_n = 0 \quad\Rightarrow\quad c_n = 0$. Thus, all even coefficients are 0, that is, $c_0 = c_2 = c_4 = \cdots = 0$.

(b) If f is even, then $f(-x) = f(x) \quad\Rightarrow\quad \sum\limits_{n=0}^{\infty}(-1)^n\, c_n\, x^n = \sum\limits_{n=0}^{\infty} c_n\, x^n \quad\Rightarrow\quad (-1)^n\, c_n = c_n$.

If n is odd, then $(-1)^n = -1$, so $-c_n = c_n \quad\Rightarrow\quad 2c_n = 0 \quad\Rightarrow\quad c_n = 0$. Thus, all odd coefficients are 0, that is, $c_1 = c_3 = c_5 = \cdots = 0$.

62. $e^x = \sum\limits_{n=0}^{\infty} \dfrac{x^n}{n!} \quad\Rightarrow\quad f(x) = e^{x^2} = \sum\limits_{n=0}^{\infty} \dfrac{(x^2)^n}{n!} = \sum\limits_{n=0}^{\infty} \dfrac{x^{2n}}{n!} = \sum\limits_{n=0}^{\infty} \dfrac{1}{n!}\, x^{2n}$. By Theorem 11.10.6 with $a = 0$, we also have $f(x) = \sum\limits_{k=0}^{\infty} \dfrac{f^{(k)}(0)}{k!} x^k$. Comparing coefficients for $k = 2n$, we have $\dfrac{f^{(2n)}(0)}{(2n)!} = \dfrac{1}{n!} \quad\Rightarrow\quad f^{(2n)}(0) = \dfrac{(2n)!}{n!}$.

PROBLEMS PLUS

1. It would be far too much work to compute 15 derivatives of f. The key idea is to remember that $f^{(n)}(0)$ occurs in the coefficient of x^n in the Maclaurin series of f. We start with the Maclaurin series for sin: $\sin x = x - \dfrac{x^3}{3!} + \dfrac{x^5}{5!} - \cdots$.

Then $\sin(x^3) = x^3 - \dfrac{x^9}{3!} + \dfrac{x^{15}}{5!} - \cdots$, and so the coefficient of x^{15} is $\dfrac{f^{(15)}(0)}{15!} = \dfrac{1}{5!}$. Therefore,

$f^{(15)}(0) = \dfrac{15!}{5!} = 6 \cdot 7 \cdot 8 \cdot 9 \cdot 10 \cdot 11 \cdot 12 \cdot 13 \cdot 14 \cdot 15 = 10{,}897{,}286{,}400$.

2. We use the problem-solving strategy of taking cases:

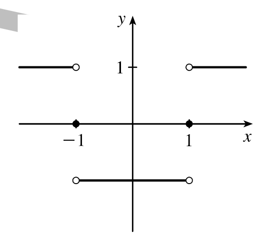
Case (i): If $|x| < 1$, then $0 \le x^2 < 1$, so $\lim\limits_{n\to\infty} x^{2n} = 0$ [see Example 11.1.11]

and $f(x) = \lim\limits_{n\to\infty} \dfrac{x^{2n} - 1}{x^{2n} + 1} = \dfrac{0 - 1}{0 + 1} = -1$.[]

Case (ii): If $|x| = 1$, that is, $x = \pm 1$, then $x^2 = 1$, so $f(x) = \lim\limits_{n\to\infty} \dfrac{x^{2n} - 1}{x^{2n} + 1} = \lim\limits_{n\to\infty} \dfrac{1 - 1}{1 + 1} = 0$.

Case (iii): If $|x| > 1$, then $x^2 > 1$, so $\lim\limits_{n\to\infty} x^{2n} = \infty$ and $f(x) = \lim\limits_{n\to\infty} \dfrac{x^{2n} - 1}{x^{2n} + 1} = \lim\limits_{n\to\infty} \dfrac{1 - (1/x^{2n})}{1 + (1/x^{2n})} = \dfrac{1 - 0}{1 + 0} = 1$.

$$\text{Thus, } f(x) = \begin{cases} 1 & \text{if } x < -1 \\ 0 & \text{if } x = -1 \\ -1 & \text{if } -1 < x < 1 \\ 0 & \text{if } x = 1 \\ 1 & \text{if } x > 1 \end{cases}$$



The graph shows that f is continuous everywhere except at $x = \pm 1$.

3. (a) From Formula 14a in Appendix D, with $x = y = \theta$, we get $\tan 2\theta = \dfrac{2\tan\theta}{1 - \tan^2\theta}$, so $\cot 2\theta = \dfrac{1 - \tan^2\theta}{2\tan\theta} \Rightarrow$

$2\cot 2\theta = \dfrac{1 - \tan^2\theta}{\tan\theta} = \cot\theta - \tan\theta$. Replacing θ by $\frac{1}{2}x$, we get $2\cot x = \cot\frac{1}{2}x - \tan\frac{1}{2}x$, or

$\tan\frac{1}{2}x = \cot\frac{1}{2}x - 2\cot x$.

(b) From part (a) with $\dfrac{x}{2^{n-1}}$ in place of x, $\tan\dfrac{x}{2^n} = \cot\dfrac{x}{2^n} - 2\cot\dfrac{x}{2^{n-1}}$, so the nth partial sum of $\sum\limits_{n=1}^{\infty} \dfrac{1}{2^n}\tan\dfrac{x}{2^n}$ is

$$\begin{aligned} s_n &= \frac{\tan(x/2)}{2} + \frac{\tan(x/4)}{4} + \frac{\tan(x/8)}{8} + \cdots + \frac{\tan(x/2^n)}{2^n} \\ &= \left[\frac{\cot(x/2)}{2} - \cot x\right] + \left[\frac{\cot(x/4)}{4} - \frac{\cot(x/2)}{2}\right] + \left[\frac{\cot(x/8)}{8} - \frac{\cot(x/4)}{4}\right] + \cdots \\ &\qquad + \left[\frac{\cot(x/2^n)}{2^n} - \frac{\cot(x/2^{n-1})}{2^{n-1}}\right] = -\cot x + \frac{\cot(x/2^n)}{2^n} \quad \text{[telescoping sum]} \end{aligned}$$

Now $\dfrac{\cot(x/2^n)}{2^n} = \dfrac{\cos(x/2^n)}{2^n \sin(x/2^n)} = \dfrac{\cos(x/2^n)}{x} \cdot \dfrac{x/2^n}{\sin(x/2^n)} \to \dfrac{1}{x} \cdot 1 = \dfrac{1}{x}$ as $n \to \infty$ since $x/2^n \to 0$

for $x \neq 0$. Therefore, if $x \neq 0$ and $x \neq k\pi$ where k is any integer, then

$$\sum_{n=1}^{\infty} \frac{1}{2^n} \tan \frac{x}{2^n} = \lim_{n\to\infty} s_n = \lim_{n\to\infty} \left(-\cot x + \frac{1}{2^n} \cot \frac{x}{2^n} \right) = -\cot x + \frac{1}{x}$$

If $x = 0$, then all terms in the series are 0, so the sum is 0.

4. $|AP_2|^2 = 2$, $|AP_3|^2 = 2 + 2^2$, $|AP_4|^2 = 2 + 2^2 + (2^2)^2$, $|AP_5|^2 = 2 + 2^2 + (2^2)^2 + (2^3)^2, \ldots,$

$$|AP_n|^2 = 2 + 2^2 + (2^2)^2 + \cdots + (2^{n-2})^2 \quad [\text{for } n \geq 3] \quad = 2 + (4 + 4^2 + 4^3 + \cdots + 4^{n-2})$$

$$= 2 + \frac{4(4^{n-2} - 1)}{4 - 1} \quad [\text{finite geometric sum with } a = 4, r = 4] \quad = \frac{6}{3} + \frac{4^{n-1} - 4}{3} = \frac{2}{3} + \frac{4^{n-1}}{3}$$

So $\tan \angle P_n A P_{n+1} = \dfrac{|P_n P_{n+1}|}{|AP_n|} = \dfrac{2^{n-1}}{\sqrt{\frac{2}{3} + \frac{4^{n-1}}{3}}} = \dfrac{\sqrt{4^{n-1}}}{\sqrt{\frac{2}{3} + \frac{4^{n-1}}{3}}} = \dfrac{1}{\sqrt{\frac{2}{3 \cdot 4^{n-1}} + \frac{1}{3}}} \to \sqrt{3}$ as $n \to \infty$.

Thus, $\angle P_n A P_{n+1} \to \frac{\pi}{3}$ as $n \to \infty$.

5. (a) At each stage, each side is replaced by four shorter sides, each of length $\frac{1}{3}$ of the side length at the preceding stage. Writing s_0 and ℓ_0 for the number of sides and the length of the side of the initial triangle, we generate the table at right. In general, we have $s_n = 3 \cdot 4^n$ and $\ell_n = \left(\frac{1}{3}\right)^n$, so the length of the perimeter at the nth stage of construction is $p_n = s_n \ell_n = 3 \cdot 4^n \cdot \left(\frac{1}{3}\right)^n = 3 \cdot \left(\frac{4}{3}\right)^n$.

$s_0 = 3$	$\ell_0 = 1$
$s_1 = 3 \cdot 4$	$\ell_1 = 1/3$
$s_2 = 3 \cdot 4^2$	$\ell_2 = 1/3^2$
$s_3 = 3 \cdot 4^3$	$\ell_3 = 1/3^3$
$\vdots$	$\vdots$

(b) $p_n = \dfrac{4^n}{3^{n-1}} = 4\left(\dfrac{4}{3}\right)^{n-1}$. Since $\frac{4}{3} > 1$, $p_n \to \infty$ as $n \to \infty$.

(c) The area of each of the small triangles added at a given stage is one-ninth of the area of the triangle added at the preceding stage. Let a be the area of the original triangle. Then the area a_n of each of the small triangles added at stage n is $a_n = a \cdot \dfrac{1}{9^n} = \dfrac{a}{9^n}$. Since a small triangle is added to each side at every stage, it follows that the total area A_n added to the figure at the nth stage is $A_n = s_{n-1} \cdot a_n = 3 \cdot 4^{n-1} \cdot \dfrac{a}{9^n} = a \cdot \dfrac{4^{n-1}}{3^{2n-1}}$. Then the total area enclosed by the snowflake curve is $A = a + A_1 + A_2 + A_3 + \cdots = a + a \cdot \dfrac{1}{3} + a \cdot \dfrac{4}{3^3} + a \cdot \dfrac{4^2}{3^5} + a \cdot \dfrac{4^3}{3^7} + \cdots$. After the first term, this is a geometric series with common ratio $\dfrac{4}{9}$, so $A = a + \dfrac{a/3}{1 - \frac{4}{9}} = a + \dfrac{a}{3} \cdot \dfrac{9}{5} = \dfrac{8a}{5}$. But the area of the original equilateral triangle with side 1 is $a = \dfrac{1}{2} \cdot 1 \cdot \sin \dfrac{\pi}{3} = \dfrac{\sqrt{3}}{4}$. So the area enclosed by the snowflake curve is $\dfrac{8}{5} \cdot \dfrac{\sqrt{3}}{4} = \dfrac{2\sqrt{3}}{5}$.

6. Let the series $S = 1 + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \frac{1}{6} + \frac{1}{8} + \frac{1}{9} + \frac{1}{12} + \cdots$. Then every term in S is of the form $\dfrac{1}{2^m 3^n}$, $m, n \geq 0$, and furthermore each term occurs only once. So we can write

$$S = \sum_{m=0}^{\infty} \sum_{n=0}^{\infty} \frac{1}{2^m 3^n} = \sum_{m=0}^{\infty} \sum_{n=0}^{\infty} \frac{1}{2^m} \frac{1}{3^n} = \sum_{m=0}^{\infty} \frac{1}{2^m} \sum_{n=0}^{\infty} \frac{1}{3^n} = \frac{1}{1 - \frac{1}{2}} \cdot \frac{1}{1 - \frac{1}{3}} = 2 \cdot \tfrac{3}{2} = 3$$

7. (a) Let $a = \arctan x$ and $b = \arctan y$. Then, from Formula 14b in Appendix D,

$$\tan(a-b) = \frac{\tan a - \tan b}{1 + \tan a\ \tan b} = \frac{\tan(\arctan x) - \tan(\arctan y)}{1 + \tan(\arctan x)\tan(\arctan y)} = \frac{x-y}{1+xy}$$

Now $\arctan x - \arctan y = a - b = \arctan(\tan(a-b)) = \arctan\dfrac{x-y}{1+xy}$ since $-\frac{\pi}{2} < a - b < \frac{\pi}{2}$.

(b) From part (a) we have

$$\arctan\tfrac{120}{119} - \arctan\tfrac{1}{239} = \arctan\frac{\frac{120}{119} - \frac{1}{239}}{1 + \frac{120}{119}\cdot\frac{1}{239}} = \arctan\frac{\frac{28{,}561}{28{,}441}}{\frac{28{,}561}{28{,}441}} = \arctan 1 = \tfrac{\pi}{4}$$

(c) Replacing y by $-y$ in the formula of part (a), we get $\arctan x + \arctan y = \arctan\dfrac{x+y}{1-xy}$. So

$$4\arctan\tfrac{1}{5} = 2\left(\arctan\tfrac{1}{5} + \arctan\tfrac{1}{5}\right) = 2\arctan\frac{\frac{1}{5}+\frac{1}{5}}{1 - \frac{1}{5}\cdot\frac{1}{5}} = 2\arctan\tfrac{5}{12} = \arctan\tfrac{5}{12} + \arctan\tfrac{5}{12}$$

$$= \arctan\frac{\frac{5}{12}+\frac{5}{12}}{1 - \frac{5}{12}\cdot\frac{5}{12}} = \arctan\tfrac{120}{119}$$

Thus, from part (b), we have $4\arctan\frac{1}{5} - \arctan\frac{1}{239} = \arctan\frac{120}{119} - \arctan\frac{1}{239} = \frac{\pi}{4}$.

(d) From Example 7 in Section 11.9 we have $\arctan x = x - \dfrac{x^3}{3} + \dfrac{x^5}{5} - \dfrac{x^7}{7} + \dfrac{x^9}{9} - \dfrac{x^{11}}{11} + \cdots$, so

$$\arctan\frac{1}{5} = \frac{1}{5} - \frac{1}{3\cdot 5^3} + \frac{1}{5\cdot 5^5} - \frac{1}{7\cdot 5^7} + \frac{1}{9\cdot 5^9} - \frac{1}{11\cdot 5^{11}} + \cdots$$

This is an alternating series and the size of the terms decreases to 0, so by the Alternating Series Estimation Theorem, the sum lies between s_5 and s_6, that is, $0.197395560 < \arctan\frac{1}{5} < 0.197395562$.

(e) From the series in part (d) we get $\arctan\dfrac{1}{239} = \dfrac{1}{239} - \dfrac{1}{3\cdot 239^3} + \dfrac{1}{5\cdot 239^5} - \cdots$. The third term is less than 2.6×10^{-13}, so by the Alternating Series Estimation Theorem, we have, to nine decimal places, $\arctan\frac{1}{239} \approx s_2 \approx 0.004184076$. Thus, $0.004184075 < \arctan\frac{1}{239} < 0.004184077$.

(f) From part (c) we have $\pi = 16\arctan\frac{1}{5} - 4\arctan\frac{1}{239}$, so from parts (d) and (e) we have $16(0.197395560) - 4(0.004184077) < \pi < 16(0.197395562) - 4(0.004184075) \Rightarrow$ $3.141592652 < \pi < 3.141592692$. So, to 7 decimal places, $\pi \approx 3.1415927$.

8. (a) Let $a = \operatorname{arccot} x$ and $b = \operatorname{arccot} y$ where $0 < a - b < \pi$. Then

$$\cot(a-b) = \frac{1}{\tan(a-b)} = \frac{1 + \tan a\ \tan b}{\tan a - \tan b} = \frac{\frac{1}{\cot a}\cdot\frac{1}{\cot b} + 1}{\frac{1}{\cot a} - \frac{1}{\cot b}}\cdot\frac{\cot a\ \cot b}{\cot a\ \cot b}$$

$$= \frac{1 + \cot a\ \cot b}{\cot b - \cot a} = \frac{1 + \cot(\operatorname{arccot} x)\cot(\operatorname{arccot} y)}{\cot(\operatorname{arccot} y) - \cot(\operatorname{arccot} x)} = \frac{1+xy}{y-x}$$

Now $\operatorname{arccot} x - \operatorname{arccot} y = a - b = \operatorname{arccot}(\cot(a-b)) = \operatorname{arccot}\dfrac{1+xy}{y-x}$ since $0 < a - b < \pi$.

(b) From part (a), we want $\operatorname{arccot}(n^2+n+1)$ to equal $\operatorname{arccot}\dfrac{1+xy}{y-x}$. Note that $1+xy=n^2+n+1 \quad\Leftrightarrow$

$xy=n^2+n=(n+1)n$, so if we let $x=n+1$ and $y=n$, then $y-x=1$. Therefore,

$$\operatorname{arccot}(n^2+n+1)=\operatorname{arccot}(1+n(n+1))=\operatorname{arccot}\frac{1+n(n+1)}{(n+1)-n}=\operatorname{arccot}n-\operatorname{arccot}(n+1)$$

Thus, we have a telescoping series with nth partial sum

$s_n=[\operatorname{arccot}0-\operatorname{arccot}1]+[\operatorname{arccot}1-\operatorname{arccot}2]+\cdots+[\operatorname{arccot}n-\operatorname{arccot}(n+1)]=\operatorname{arccot}0-\operatorname{arccot}(n+1)$.

Thus, $\sum\limits_{n=0}^{\infty}\operatorname{arccot}(n^2+n+1)=\lim\limits_{n\to\infty}s_n=\lim\limits_{n\to\infty}[\operatorname{arccot}0-\operatorname{arccot}(n+1)]=\frac{\pi}{2}-0=\frac{\pi}{2}$.

9. We want $\arctan\left(\dfrac{2}{n^2}\right)$ to equal $\arctan\dfrac{x-y}{1+xy}$. Note that $1+xy=n^2 \quad\Leftrightarrow\quad xy=n^2-1=(n+1)(n-1)$, so if we let $x=n+1$ and $y=n-1$, then $x-y=2$ and $xy\neq-1$. Thus, from Problem 7(a),

$\arctan\left(\dfrac{2}{n^2}\right)=\arctan\dfrac{x-y}{1+xy}=\arctan x-\arctan y=\arctan(n+1)-\arctan(n-1)$. Therefore,

$$\begin{aligned}\sum_{n=1}^{k}\arctan\left(\frac{2}{n^2}\right)&=\sum_{n=1}^{k}[\arctan(n+1)-\arctan(n-1)]\\&=\sum_{n=1}^{k}[\arctan(n+1)-\arctan n+\arctan n-\arctan(n-1)]\\&=\sum_{n=1}^{k}[\arctan(n+1)-\arctan n]+\sum_{n=1}^{k}[\arctan n-\arctan(n-1)]\\&=[\arctan(k+1)-\arctan 1]+[\arctan k-\arctan 0]\quad\text{[since both sums are telescoping]}\\&=\arctan(k+1)-\tfrac{\pi}{4}+\arctan k-0\end{aligned}$$

Now $\sum\limits_{n=1}^{k}\arctan\left(\dfrac{2}{n^2}\right)=\lim\limits_{k\to0}\sum\limits_{n=1}^{k}\arctan\left(\dfrac{2}{n^2}\right)=\lim\limits_{k\to\infty}\left[\arctan(k+1)-\dfrac{\pi}{4}+\arctan k\right]=\dfrac{\pi}{2}-\dfrac{\pi}{4}+\dfrac{\pi}{2}=\dfrac{3\pi}{4}$.

Note: For all $n\geq1$, $0\leq\arctan(n-1)<\arctan(n+1)<\frac{\pi}{2}$, so $-\frac{\pi}{2}<\arctan(n+1)-\arctan(n-1)<\frac{\pi}{2}$, and the identity in Problem 7(a) holds.

10. Let's first try the case $k=1$: $a_0+a_1=0 \quad\Rightarrow\quad a_1=-a_0 \quad\Rightarrow$

$$\begin{aligned}\lim_{n\to\infty}\left(a_0\sqrt{n}+a_1\sqrt{n+1}\right)=\lim_{n\to\infty}\left(a_0\sqrt{n}-a_0\sqrt{n+1}\right)&=a_0\lim_{n\to\infty}\left(\sqrt{n}-\sqrt{n+1}\right)\frac{\sqrt{n}+\sqrt{n+1}}{\sqrt{n}+\sqrt{n+1}}\\&=a_0\lim_{n\to\infty}\frac{-1}{\sqrt{n}+\sqrt{n+1}}=0\end{aligned}$$

In general we have $a_0+a_1+\cdots+a_k=0 \quad\Rightarrow\quad a_k=-a_0-a_1-\cdots-a_{k-1} \quad\Rightarrow$

$$\begin{aligned}&\lim_{n\to\infty}\left(a_0\sqrt{n}+a_1\sqrt{n+1}+a_2\sqrt{n+2}+\cdots+a_k\sqrt{n+k}\right)\\&\quad=\lim_{n\to\infty}\left(a_0\sqrt{n}+a_1\sqrt{n+1}+\cdots+a_{k-1}\sqrt{n+k-1}-a_0\sqrt{n+k}-a_1\sqrt{n+k}-\cdots-a_{k-1}\sqrt{n+k}\right)\\&\quad=a_0\lim_{n\to\infty}\left(\sqrt{n}-\sqrt{n+k}\right)+a_1\lim_{n\to\infty}\left(\sqrt{n+1}-\sqrt{n+k}\right)+\cdots+a_{k-1}\lim_{n\to\infty}\left(\sqrt{n+k-1}-\sqrt{n+k}\right)\end{aligned}$$

Each of these limits is 0 by the same type of simplification as in the case $k=1$. So we have

$$\lim_{n\to\infty}\left(a_0\sqrt{n}+a_1\sqrt{n+1}+a_2\sqrt{n+2}+\cdots+a_k\sqrt{n+k}\right)=a_0(0)+a_1(0)+\cdots+a_{k-1}(0)=0$$

11. We start with the geometric series $\sum\limits_{n=0}^{\infty} x^n = \dfrac{1}{1-x}$, $|x| < 1$, and differentiate:

$$\sum_{n=1}^{\infty} nx^{n-1} = \frac{d}{dx}\left(\sum_{n=0}^{\infty} x^n\right) = \frac{d}{dx}\left(\frac{1}{1-x}\right) = \frac{1}{(1-x)^2} \text{ for } |x| < 1 \quad \Rightarrow \quad \sum_{n=1}^{\infty} nx^n = x\sum_{n=1}^{\infty} nx^{n-1} = \frac{x}{(1-x)^2}$$

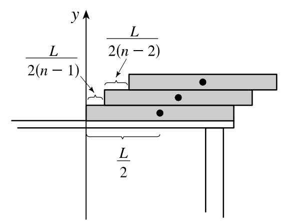
for $|x| < 1$. Differentiate again:

$$\sum_{n=1}^{\infty} n^2 x^{n-1} = \frac{d}{dx}\frac{x}{(1-x)^2} = \frac{(1-x)^2 - x\cdot 2(1-x)(-1)}{(1-x)^4} = \frac{x+1}{(1-x)^3} \quad \Rightarrow \quad \sum_{n=1}^{\infty} n^2 x^n = \frac{x^2+x}{(1-x)^3} \quad \Rightarrow$$

$$\sum_{n=1}^{\infty} n^3 x^{n-1} = \frac{d}{dx}\frac{x^2+x}{(1-x)^3} = \frac{(1-x)^3(2x+1) - (x^2+x)3(1-x)^2(-1)}{(1-x)^6} = \frac{x^2+4x+1}{(1-x)^4} \quad \Rightarrow$$

$\sum\limits_{n=1}^{\infty} n^3 x^n = \dfrac{x^3+4x^2+x}{(1-x)^4}$, $|x| < 1$. The radius of convergence is 1 because that is the radius of convergence for the geometric series we started with. If $x = \pm 1$, the series is $\sum n^3(\pm 1)^n$, which diverges by the Test For Divergence, so the interval of convergence is $(-1, 1)$.

12. Place the y-axis as shown and let the length of each book be L. We want to show that the center of mass of the system of n books lies above the table, that is, $\overline{x} < L$. The x-coordinates of the centers of mass of the books are $x_1 = \dfrac{L}{2}$, $x_2 = \dfrac{L}{2(n-1)} + \dfrac{L}{2}$, $x_3 = \dfrac{L}{2(n-1)} + \dfrac{L}{2(n-2)} + \dfrac{L}{2}$, and so on.



Each book has the same mass m, so if there are n books, then

$$\begin{aligned}
\overline{x} &= \frac{mx_1 + mx_2 + \cdots + mx_n}{mn} = \frac{x_1 + x_2 + \cdots + x_n}{n} \\
&= \frac{1}{n}\left[\frac{L}{2} + \left(\frac{L}{2(n-1)} + \frac{L}{2}\right) + \left(\frac{L}{2(n-1)} + \frac{L}{2(n-2)} + \frac{L}{2}\right) + \cdots \right. \\
&\qquad \left. + \left(\frac{L}{2(n-1)} + \frac{L}{2(n-2)} + \cdots + \frac{L}{4} + \frac{L}{2} + \frac{L}{2}\right)\right] \\
&= \frac{L}{n}\left[\frac{n-1}{2(n-1)} + \frac{n-2}{2(n-2)} + \cdots + \frac{2}{4} + \frac{1}{2} + \frac{n}{2}\right] = \frac{L}{n}\left[(n-1)\frac{1}{2} + \frac{n}{2}\right] = \frac{2n-1}{2n}L < L
\end{aligned}$$

This shows that, no matter how many books are added according to the given scheme, the center of mass lies above the table. It remains to observe that the series $\frac{1}{2} + \frac{1}{4} + \frac{1}{6} + \frac{1}{8} + \cdots = \frac{1}{2}\sum(1/n)$ is divergent (harmonic series), so we can make the top book extend as far as we like beyond the edge of the table if we add enough books.

13.
$$\begin{aligned}
\ln\left(1 - \frac{1}{n^2}\right) &= \ln\left(\frac{n^2-1}{n^2}\right) = \ln\frac{(n+1)(n-1)}{n^2} = \ln[(n+1)(n-1)] - \ln n^2 \\
&= \ln(n+1) + \ln(n-1) - 2\ln n = \ln(n-1) - \ln n - \ln n + \ln(n+1) \\
&= \ln\frac{n-1}{n} - [\ln n - \ln(n+1)] = \ln\frac{n-1}{n} - \ln\frac{n}{n+1}.
\end{aligned}$$

Let $s_k = \sum\limits_{n=2}^{k} \ln\left(1 - \dfrac{1}{n^2}\right) = \sum\limits_{n=2}^{k}\left(\ln\dfrac{n-1}{n} - \ln\dfrac{n}{n+1}\right)$ for $k \geq 2$. Then

$$s_k = \left(\ln\frac{1}{2} - \ln\frac{2}{3}\right) + \left(\ln\frac{2}{3} - \ln\frac{3}{4}\right) + \cdots + \left(\ln\frac{k-1}{k} - \ln\frac{k}{k+1}\right) = \ln\frac{1}{2} - \ln\frac{k}{k+1}, \text{ so}$$

$$\sum_{n=2}^{\infty} \ln\left(1 - \frac{1}{n^2}\right) = \lim_{k\to\infty} s_k = \lim_{k\to\infty}\left(\ln\frac{1}{2} - \ln\frac{k}{k+1}\right) = \ln\frac{1}{2} - \ln 1 = \ln 1 - \ln 2 - \ln 1 = -\ln 2 \text{ (or } \ln\tfrac{1}{2}\text{)}.$$

14. First notice that both series are absolutely convergent (p-series with $p > 1$.) Let the given expression be called x. Then

$$x = \frac{1 + \frac{1}{2^p} + \frac{1}{3^p} + \frac{1}{4^p} + \cdots}{1 - \frac{1}{2^p} + \frac{1}{3^p} - \frac{1}{4^p} + \cdots} = \frac{1 + \left(2\cdot\frac{1}{2^p} - \frac{1}{2^p}\right) + \frac{1}{3^p} + \left(2\cdot\frac{1}{4^p} - \frac{1}{4^p}\right) + \cdots}{1 - \frac{1}{2^p} + \frac{1}{3^p} - \frac{1}{4^p} + \cdots}$$

$$= \frac{\left(1 - \frac{1}{2^p} + \frac{1}{3^p} - \frac{1}{4^p} + \cdots\right) + \left(2\cdot\frac{1}{2^p} + 2\cdot\frac{1}{4^p} + 2\cdot\frac{1}{6^p} + \cdots\right)}{1 - \frac{1}{2^p} + \frac{1}{3^p} - \frac{1}{4^p} + \cdots}$$

$$= 1 + \frac{2\left(\frac{1}{2^p} + \frac{1}{4^p} + \frac{1}{6^p} + \frac{1}{8^p} + \cdots\right)}{1 - \frac{1}{2^p} + \frac{1}{3^p} - \frac{1}{4^p} + \cdots} = 1 + \frac{\frac{1}{2^{p-1}}\left(1 + \frac{1}{2^p} + \frac{1}{3^p} + \frac{1}{4^p} + \cdots\right)}{1 - \frac{1}{2^p} + \frac{1}{3^p} - \frac{1}{4^p} + \cdots} = 1 + 2^{1-p}x$$

Therefore, $x = 1 + 2^{1-p}x \quad\Leftrightarrow\quad x - 2^{1-p}x = 1 \quad\Leftrightarrow\quad x(1 - 2^{1-p}) = 1 \quad\Leftrightarrow\quad x = \dfrac{1}{1 - 2^{1-p}}$.

15. If L is the length of a side of the equilateral triangle, then the area is $A = \frac{1}{2}L\cdot\frac{\sqrt{3}}{2}L = \frac{\sqrt{3}}{4}L^2$ and so $L^2 = \frac{4}{\sqrt{3}}A$.

Let r be the radius of one of the circles. When there are n rows of circles, the figure shows that

$L = \sqrt{3}\,r + r + (n-2)(2r) + r + \sqrt{3}\,r = r\left(2n - 2 + 2\sqrt{3}\right)$, so $r = \dfrac{L}{2\left(n + \sqrt{3} - 1\right)}$.

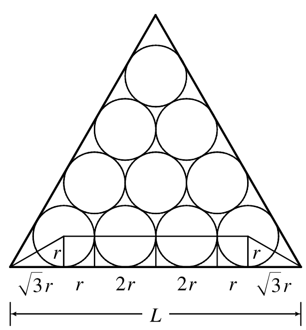
The number of circles is $1 + 2 + \cdots + n = \dfrac{n(n+1)}{2}$, and so the total area of the circles is

$$A_n = \frac{n(n+1)}{2}\pi r^2 = \frac{n(n+1)}{2}\pi\frac{L^2}{4\left(n+\sqrt{3}-1\right)^2}$$

$$= \frac{n(n+1)}{2}\pi\frac{4A/\sqrt{3}}{4\left(n+\sqrt{3}-1\right)^2} = \frac{n(n+1)}{\left(n+\sqrt{3}-1\right)^2}\frac{\pi A}{2\sqrt{3}} \quad\Rightarrow$$

$$\frac{A_n}{A} = \frac{n(n+1)}{\left(n+\sqrt{3}-1\right)^2}\frac{\pi}{2\sqrt{3}}$$

$$= \frac{1 + 1/n}{\left[1 + \left(\sqrt{3}-1\right)/n\right]^2}\frac{\pi}{2\sqrt{3}} \to \frac{\pi}{2\sqrt{3}} \quad \text{as } n \to \infty$$



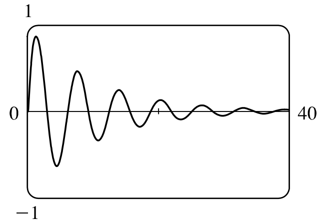
16. Given $a_0 = a_1 = 1$ and $a_n = \dfrac{(n-1)(n-2)a_{n-1} - (n-3)a_{n-2}}{n(n-1)}$, we calculate the next few terms of the sequence:

$a_2 = \dfrac{1\cdot 0\cdot a_1 - (-1)a_0}{2\cdot 1} = \dfrac{1}{2}$, $a_3 = \dfrac{2\cdot 1\cdot a_2 - 0\cdot a_1}{3\cdot 2} = \dfrac{1}{6}$, $a_4 = \dfrac{3\cdot 2\cdot a_3 - 1\cdot a_2}{4\cdot 3} = \dfrac{1}{24}$. It seems that $a_n = \dfrac{1}{n!}$,

so we try to prove this by induction. The first step is done, so assume $a_k = \dfrac{1}{k!}$ and $a_{k-1} = \dfrac{1}{(k-1)!}$. Then

$$a_{k+1} = \frac{k(k-1)a_k - (k-2)a_{k-1}}{(k+1)k} = \frac{\dfrac{k(k-1)}{k!} - \dfrac{k-2}{(k-1)!}}{(k+1)k} = \frac{(k-1)-(k-2)}{[(k+1)(k)](k-1)!} = \frac{1}{(k+1)!}$$ and the induction is complete. Therefore, $\sum\limits_{n=0}^{\infty} a_n = \sum\limits_{n=0}^{\infty} \frac{1}{n!} = e$.

17. (a)



The x-intercepts of the curve occur where $\sin x = 0 \quad \Leftrightarrow \quad x = n\pi$, n an integer. So using the formula for disks (and either a CAS or $\sin^2 x = \frac{1}{2}(1 - \cos 2x)$ and Formula 99 to evaluate the integral), the volume of the nth bead is

$$V_n = \pi \int_{(n-1)\pi}^{n\pi} (e^{-x/10} \sin x)^2\, dx = \pi \int_{(n-1)\pi}^{n\pi} e^{-x/5} \sin^2 x\, dx$$
$$= \tfrac{250\pi}{101}\left(e^{-(n-1)\pi/5} - e^{-n\pi/5}\right)$$

(b) The total volume is

$$\pi \int_0^{\infty} e^{-x/5} \sin^2 x\, dx = \sum_{n=1}^{\infty} V_n = \tfrac{250\pi}{101} \sum_{n=1}^{\infty} \left[e^{-(n-1)\pi/5} - e^{-n\pi/5}\right] = \tfrac{250\pi}{101} \quad \text{[telescoping sum]}.$$

Another method: If the volume in part (a) has been written as $V_n = \frac{250\pi}{101} e^{-n\pi/5}(e^{\pi/5} - 1)$, then we recognize $\sum\limits_{n=1}^{\infty} V_n$ as a geometric series with $a = \frac{250\pi}{101}(1 - e^{-\pi/5})$ and $r = e^{-\pi/5}$.

18. (a) Since P_n is defined as the midpoint of $P_{n-4}P_{n-3}$, $x_n = \frac{1}{2}(x_{n-4} + x_{n-3})$ for $n \geq 5$. So we prove by induction that $\frac{1}{2}x_n + x_{n+1} + x_{n+2} + x_{n+3} = 2$. The case $n = 1$ is immediate, since $\frac{1}{2} \cdot 0 + 1 + 1 + 0 = 2$. Assume that the result holds for $n = k - 1$, that is, $\frac{1}{2}x_{k-1} + x_k + x_{k+1} + x_{k+2} = 2$. Then for $n = k$,

$$\tfrac{1}{2}x_k + x_{k+1} + x_{k+2} + x_{k+3} = \tfrac{1}{2}x_k + x_{k+1} + x_{k+2} + \tfrac{1}{2}(x_{k+3-4} + x_{k+3-3}) \quad \text{[by above]}$$
$$= \tfrac{1}{2}x_{k-1} + x_k + x_{k+1} + x_{k+2} = 2 \quad \text{[by the induction hypothesis]}$$

Similarly, for $n \geq 5$, $y_n = \frac{1}{2}(y_{n-4} + y_{n-3})$, so the same argument as above holds for y, with 2 replaced by $\frac{1}{2}y_1 + y_2 + y_3 + y_4 = \frac{1}{2} \cdot 1 + 1 + 0 + 0 = \frac{3}{2}$. So $\frac{1}{2}y_n + y_{n+1} + y_{n+2} + y_{n+3} = \frac{3}{2}$ for all n.

(b) $\lim\limits_{n\to\infty} \left(\frac{1}{2}x_n + x_{n+1} + x_{n+2} + x_{n+3}\right) = \frac{1}{2} \lim\limits_{n\to\infty} x_n + \lim\limits_{n\to\infty} x_{n+1} + \lim\limits_{n\to\infty} x_{n+2} + \lim\limits_{n\to\infty} x_{n+3} = 2$. Since all the limits on the left hand side are the same, we get $\frac{7}{2} \lim\limits_{n\to\infty} x_n = 2 \quad \Rightarrow \quad \lim\limits_{n\to\infty} x_n = \frac{4}{7}$. In the same way, $\frac{7}{2} \lim\limits_{n\to\infty} y_n = \frac{3}{2} \quad \Rightarrow \quad \lim\limits_{n\to\infty} y_n = \frac{3}{7}$, so $P = \left(\frac{4}{7}, \frac{3}{7}\right)$.

19. By Table 1 in Section 11.10, $\tan^{-1} x = \sum\limits_{n=0}^{\infty} (-1)^n \frac{x^{2n+1}}{2n+1}$ for $|x| < 1$. In particular, for $x = \frac{1}{\sqrt{3}}$, we have $\frac{\pi}{6} = \tan^{-1}\left(\frac{1}{\sqrt{3}}\right) = \sum\limits_{n=0}^{\infty} (-1)^n \frac{(1/\sqrt{3})^{2n+1}}{2n+1} = \sum\limits_{n=0}^{\infty} (-1)^n \left(\frac{1}{3}\right)^n \frac{1}{\sqrt{3}} \frac{1}{2n+1}$, so

$$\pi = \frac{6}{\sqrt{3}} \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n+1)3^n} = 2\sqrt{3} \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n+1)3^n} = 2\sqrt{3}\left(1 + \sum_{n=1}^{\infty} \frac{(-1)^n}{(2n+1)3^n}\right) \quad \Rightarrow \quad \sum_{n=1}^{\infty} \frac{(-1)^n}{(2n+1)3^n} = \frac{\pi}{2\sqrt{3}} - 1.$$

20. (a) Using $s_n = a + ar + ar^2 + \cdots + ar^{n-1} = \dfrac{a(1-r^n)}{1-r}$,

$$1 - x + x^2 - x^3 + \cdots + x^{2n-2} - x^{2n-1} = \frac{1\left[1-(-x)^{2n}\right]}{1-(-x)} = \frac{1-x^{2n}}{1+x}.$$

(b) $\displaystyle\int_0^1 (1 - x + x^2 - x^3 + \cdots + x^{2n-2} - x^{2n-1})\,dx = \int_0^1 \frac{1-x^{2n}}{1+x}\,dx \quad \Rightarrow$

$$\left[x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \cdots + \frac{x^{2n-1}}{2n-1} - \frac{x^{2n}}{2n}\right]_0^1 = \int_0^1 \frac{dx}{1+x} - \int_0^1 \frac{x^{2n}}{1+x}\,dx \quad \Rightarrow$$

$$1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \cdots + \frac{1}{2n-1} - \frac{1}{2n} = \int_0^1 \frac{dx}{1+x} - \int_0^1 \frac{x^{2n}}{1+x}\,dx$$

(c) Since $1 - \frac{1}{2} = \frac{1}{1\cdot 2}, \frac{1}{3} - \frac{1}{4} = \frac{1}{3\cdot 4}, \ldots, \frac{1}{2n-1} - \frac{1}{2n} = \frac{1}{(2n-1)(2n)}$, we see from part (b) that

$$\frac{1}{1\cdot 2} + \frac{1}{3\cdot 4} + \cdots + \frac{1}{(2n-1)(2n)} - \int_0^1 \frac{dx}{1+x} = -\int_0^1 \frac{x^{2n}}{1+x}\,dx. \text{ Thus,}$$

$$\left|\frac{1}{1\cdot 2} + \frac{1}{3\cdot 4} + \cdots + \frac{1}{(2n-1)(2n)} - \int_0^1 \frac{dx}{1+x}\right| = \int_0^1 \frac{x^{2n}}{1+x}\,dx < \int_0^1 x^{2n}\,dx$$

$\left[\text{since } \dfrac{x^{2n}}{1+x} < x^{2n} \text{ for } 0 < x \le 1\right]$.

(d) Note that $\displaystyle\int_0^1 \frac{dx}{1+x} = \Big[\ln(1+x)\Big]_0^1 = \ln 2$ and $\displaystyle\int_0^1 x^{2n}\,dx = \left[\frac{x^{2n+1}}{2n+1}\right]_0^1 = \frac{1}{2n+1}$. So part (c) becomes

$\left|\dfrac{1}{1\cdot 2} + \dfrac{1}{3\cdot 4} + \cdots + \dfrac{1}{(2n-1)(2n)} - \ln 2\right| < \dfrac{1}{2n+1}$. In other words, the nth partial sum s_n of the given series satisfies $|s_n - \ln 2| < \dfrac{1}{2n+1}$. Thus, $\lim\limits_{n\to\infty} s_n = \ln 2$, that is, $\dfrac{1}{1\cdot 2} + \dfrac{1}{3\cdot 4} + \dfrac{1}{5\cdot 6} + \dfrac{1}{7\cdot 8} + \cdots = \ln 2$.

21. Let $f(x)$ denote the left-hand side of the equation $1 + \dfrac{x}{2!} + \dfrac{x^2}{4!} + \dfrac{x^3}{6!} + \dfrac{x^4}{8!} + \cdots = 0$. If $x \ge 0$, then $f(x) \ge 1$ and there are no solutions of the equation. Note that $f(-x^2) = 1 - \dfrac{x^2}{2!} + \dfrac{x^4}{4!} - \dfrac{x^6}{6!} + \dfrac{x^8}{8!} - \cdots = \cos x$. The solutions of $\cos x = 0$ for $x < 0$ are given by $x = \dfrac{\pi}{2} - \pi k$, where k is a positive integer. Thus, the solutions of $f(x) = 0$ are $x = -\left(\dfrac{\pi}{2} - \pi k\right)^2$, where k is a positive integer.

22. Suppose the base of the first right triangle has length a. Then by repeated use of the Pythagorean theorem, we find that the base of the second right triangle has length $\sqrt{1+a^2}$, the base of the third right triangle has length $\sqrt{2+a^2}$, and in general, the nth right triangle has base of length $\sqrt{n-1+a^2}$ and hypotenuse of length $\sqrt{n+a^2}$. Thus, $\theta_n = \tan^{-1}\left(1/\sqrt{n-1+a^2}\right)$ and

$$\sum_{n=1}^{\infty} \theta_n = \sum_{n=1}^{\infty} \tan^{-1}\left(\frac{1}{\sqrt{n-1+a^2}}\right) = \sum_{n=0}^{\infty} \tan^{-1}\left(\frac{1}{\sqrt{n+a^2}}\right). \text{ We wish to show that this series diverges.}$$

First notice that the series $\displaystyle\sum_{n=1}^{\infty} \frac{1}{\sqrt{n+a^2}}$ diverges by the Limit Comparison Test with the divergent p-series $\displaystyle\sum_{n=1}^{\infty} \frac{1}{\sqrt{n}}$

$\left[p = \frac{1}{2} \le 1\right]$ since $\displaystyle\lim_{n\to\infty} \frac{1/\sqrt{n+a^2}}{1/\sqrt{n}} = \lim_{n\to\infty} \frac{\sqrt{n}}{\sqrt{n+a^2}} = \lim_{n\to\infty} \sqrt{\frac{n}{n+a^2}} = \lim_{n\to\infty} \sqrt{\frac{1}{1+a^2/n}} = 1 > 0$. Thus,

$\sum\limits_{n=0}^{\infty} \dfrac{1}{\sqrt{n+a^2}}$ also diverges. Now $\sum\limits_{n=0}^{\infty} \tan^{-1}\left(\dfrac{1}{\sqrt{n+a^2}}\right)$ diverges by the Limit Comparison Test with $\sum\limits_{n=0}^{\infty} \dfrac{1}{\sqrt{n+a^2}}$ since

$$\lim_{n\to\infty} \frac{\tan^{-1}\left(1/\sqrt{n+a^2}\right)}{1/\sqrt{n+a^2}} = \lim_{x\to\infty} \frac{\tan^{-1}\left(1/\sqrt{x+a^2}\right)}{1/\sqrt{x+a^2}} = \lim_{y\to\infty} \frac{\tan^{-1}(1/y)}{1/y} \qquad \left[y=\sqrt{x+a^2}\,\right]$$

$$= \lim_{z\to 0^+} \frac{\tan^{-1} z}{z} \quad \left[z=1/y\right] \quad \overset{\text{H}}{=} \lim_{z\to 0^+} \frac{1/(1+z^2)}{1} = 1 > 0$$

Thus, $\sum\limits_{n=1}^{\infty} \theta_n$ is a divergent series.

23. Call the series S. We group the terms according to the number of digits in their denominators:

$$S = \underbrace{\left(\tfrac{1}{1}+\tfrac{1}{2}+\cdots+\tfrac{1}{8}+\tfrac{1}{9}\right)}_{g_1} + \underbrace{\left(\tfrac{1}{11}+\cdots+\tfrac{1}{99}\right)}_{g_2} + \underbrace{\left(\tfrac{1}{111}+\cdots+\tfrac{1}{999}\right)}_{g_3} + \cdots$$

Now in the group g_n, since we have 9 choices for each of the n digits in the denominator, there are 9^n terms.

Furthermore, each term in g_n is less than $\frac{1}{10^{n-1}}$ [except for the first term in g_1]. So $g_n < 9^n \cdot \frac{1}{10^{n-1}} = 9\left(\frac{9}{10}\right)^{n-1}$.

Now $\sum\limits_{n=1}^{\infty} 9\left(\frac{9}{10}\right)^{n-1}$ is a geometric series with $a=9$ and $r=\frac{9}{10}<1$. Therefore, by the Comparison Test,

$S = \sum\limits_{n=1}^{\infty} g_n < \sum\limits_{n=1}^{\infty} 9\left(\frac{9}{10}\right)^{n-1} = \frac{9}{1-9/10} = 90$.

24. (a) Let $f(x) = \dfrac{x}{1-x-x^2} = \sum\limits_{n=0}^{\infty} c_n x^n = c_0 + c_1x + c_2x^2 + c_3x^3 + \cdots$. Then

$$x = (1-x-x^2)(c_0 + c_1x + c_2x^2 + c_3x^3 + \cdots)$$

$$\begin{aligned} x = c_0 + c_1x &+ c_2x^2 + c_3x^3 + c_4x^4 + c_5x^5 + \cdots \\ - c_0x &- c_1x^2 - c_2x^3 - c_3x^4 - c_4x^5 - \cdots \\ &- c_0x^2 - c_1x^3 - c_2x^4 - c_3x^5 - \cdots \end{aligned}$$

$$x = c_0 + (c_1 - c_0)x + (c_2 - c_1 - c_0)x^2 + (c_3 - c_2 - c_1)x^3 + \cdots$$

Comparing coefficients of powers of x gives us $c_0 = 0$ and

$$\begin{aligned} c_1 - c_0 &= 1 &&\Rightarrow\quad c_1 = c_0 + 1 = 1 \\ c_2 - c_1 - c_0 &= 0 &&\Rightarrow\quad c_2 = c_1 + c_0 = 1 + 0 = 1 \\ c_3 - c_2 - c_1 &= 0 &&\Rightarrow\quad c_3 = c_2 + c_1 = 1 + 1 = 2 \end{aligned}$$

In general, we have $c_n = c_{n-1} + c_{n-2}$ for $n \geq 3$. Each c_n is equal to the nth Fibonacci number, that is,

$$\sum_{n=0}^{\infty} c_n x^n = \sum_{n=1}^{\infty} c_n x^n = \sum_{n=1}^{\infty} f_n x^n$$

(b) Completing the square on $x^2 + x - 1$ gives us

$$\left(x^2 + x + \frac{1}{4}\right) - 1 - \frac{1}{4} = \left(x + \frac{1}{2}\right)^2 - \frac{5}{4} = \left(x + \frac{1}{2}\right)^2 - \left(\frac{\sqrt{5}}{2}\right)^2$$

$$= \left(x + \frac{1}{2} + \frac{\sqrt{5}}{2}\right)\left(x + \frac{1}{2} - \frac{\sqrt{5}}{2}\right) = \left(x + \frac{1+\sqrt{5}}{2}\right)\left(x + \frac{1-\sqrt{5}}{2}\right)$$

[continued]

So $\dfrac{x}{1-x-x^2} = \dfrac{-x}{x^2+x-1} = \dfrac{-x}{\left(x+\frac{1+\sqrt{5}}{2}\right)\left(x+\frac{1-\sqrt{5}}{2}\right)}$. The factors in the denominator are linear,

so the partial fraction decomposition is

$$\frac{-x}{\left(x+\frac{1+\sqrt{5}}{2}\right)\left(x+\frac{1-\sqrt{5}}{2}\right)} = \frac{A}{x+\frac{1+\sqrt{5}}{2}} + \frac{B}{x+\frac{1-\sqrt{5}}{2}} \quad -x = A\left(x+\tfrac{1-\sqrt{5}}{2}\right) + B\left(x+\tfrac{1+\sqrt{5}}{2}\right)$$

If $x = \frac{-1+\sqrt{5}}{2}$, then $-\frac{-1+\sqrt{5}}{2} = B\sqrt{5} \quad \Rightarrow \quad B = \frac{1-\sqrt{5}}{2\sqrt{5}}$.

If $x = \frac{-1-\sqrt{5}}{2}$, then $-\frac{-1-\sqrt{5}}{2} = A\left(-\sqrt{5}\right) \quad \Rightarrow \quad A = \frac{1+\sqrt{5}}{-2\sqrt{5}}$. Thus,

$$\begin{aligned}
\frac{x}{1-x-x^2} &= \frac{\dfrac{1+\sqrt{5}}{-2\sqrt{5}}}{x+\dfrac{1+\sqrt{5}}{2}} + \frac{\dfrac{1-\sqrt{5}}{2\sqrt{5}}}{x+\dfrac{1-\sqrt{5}}{2}} = \frac{\dfrac{1+\sqrt{5}}{-2\sqrt{5}}}{x+\dfrac{1+\sqrt{5}}{2}} \cdot \frac{\dfrac{2}{1+\sqrt{5}}}{\dfrac{2}{1+\sqrt{5}}} + \frac{\dfrac{1-\sqrt{5}}{2\sqrt{5}}}{x+\dfrac{1-\sqrt{5}}{2}} \cdot \frac{\dfrac{2}{1-\sqrt{5}}}{\dfrac{2}{1-\sqrt{5}}} \\
&= \frac{-1/\sqrt{5}}{1+\dfrac{2}{1+\sqrt{5}}\,x} + \frac{1/\sqrt{5}}{1+\dfrac{2}{1-\sqrt{5}}\,x} = -\frac{1}{\sqrt{5}}\sum_{n=0}^{\infty}\left(-\frac{2}{1+\sqrt{5}}\,x\right)^n + \frac{1}{\sqrt{5}}\sum_{n=0}^{\infty}\left(-\frac{2}{1-\sqrt{5}}\,x\right)^n \\
&= \frac{1}{\sqrt{5}}\sum_{n=0}^{\infty}\left[\left(\frac{-2}{1-\sqrt{5}}\right)^n - \left(\frac{-2}{1+\sqrt{5}}\right)^n\right]x^n \\
&= \frac{1}{\sqrt{5}}\sum_{n=1}^{\infty}\left[\frac{(-2)^n\left(1+\sqrt{5}\right)^n - (-2)^n\left(1-\sqrt{5}\right)^n}{\left(1-\sqrt{5}\right)^n\left(1+\sqrt{5}\right)^n}\right]x^n \qquad [\text{the } n=0 \text{ term is } 0] \\
&= \frac{1}{\sqrt{5}}\sum_{n=1}^{\infty}\left[\frac{(-2)^n\left(\left(1+\sqrt{5}\right)^n - \left(1-\sqrt{5}\right)^n\right)}{(1-5)^n}\right]x^n \\
&= \frac{1}{\sqrt{5}}\sum_{n=1}^{\infty}\left[\frac{\left(1+\sqrt{5}\right)^n - \left(1-\sqrt{5}\right)^n}{2^n}\right]x^n \qquad [(-4)^n = (-2)^n \cdot 2^n]
\end{aligned}$$

From part (a), this series must equal $\sum_{n=1}^{\infty} f_n x^n$, so $f_n = \dfrac{\left(1+\sqrt{5}\right)^n - \left(1-\sqrt{5}\right)^n}{2^n\sqrt{5}}$, which is an explicit formula for the nth Fibonacci number.

25. $u = 1 + \dfrac{x^3}{3!} + \dfrac{x^6}{6!} + \dfrac{x^9}{9!} + \cdots$, $v = x + \dfrac{x^4}{4!} + \dfrac{x^7}{7!} + \dfrac{x^{10}}{10!} + \cdots$, $w = \dfrac{x^2}{2!} + \dfrac{x^5}{5!} + \dfrac{x^8}{8!} + \cdots$.

Use the Ratio Test to show that the series for u, v, and w have positive radii of convergence (∞ in each case), so Theorem 11.9.2 applies, and hence, we may differentiate each of these series:

$$\frac{du}{dx} = \frac{3x^2}{3!} + \frac{6x^5}{6!} + \frac{9x^8}{9!} + \cdots = \frac{x^2}{2!} + \frac{x^5}{5!} + \frac{x^8}{8!} + \cdots = w$$

Similarly, $\dfrac{dv}{dx} = 1 + \dfrac{x^3}{3!} + \dfrac{x^6}{6!} + \dfrac{x^9}{9!} + \cdots = u$, and $\dfrac{dw}{dx} = x + \dfrac{x^4}{4!} + \dfrac{x^7}{7!} + \dfrac{x^{10}}{10!} + \cdots = v$.

So $u' = w$, $v' = u$, and $w' = v$. Now differentiate the left-hand side of the desired equation:

$$\begin{aligned}
\frac{d}{dx}(u^3+v^3+w^3-3uvw) &= 3u^2u' + 3v^2v' + 3w^2w' - 3(u'vw + uv'w + uvw') \\
&= 3u^2w + 3v^2u + 3w^2v - 3(vw^2 + u^2w + uv^2) = 0 \quad \Rightarrow
\end{aligned}$$

$u^3 + v^3 + w^3 - 3uvw = C$. To find the value of the constant C, we put $x = 0$ in the last equation and get $1^3 + 0^3 + 0^3 - 3(1 \cdot 0 \cdot 0) = C \quad \Rightarrow \quad C = 1$, so $u^3 + v^3 + w^3 - 3uvw = 1$.

26. To prove: If $n > 1$, then the nth partial sum $s_n = \sum_{i=1}^{n} \frac{1}{i}$ of the harmonic series is not an integer.

Proof: Let 2^k be the largest power of 2 that is less than or equal to n and let M be the product of all the odd positive integers that are less than or equal to n. Suppose that $s_n = m$, an integer. Then $M2^k s_n = M2^k m$. Since $n \geq 2$, we have $k \geq 1$, and hence, $M2^k m$ is an even integer. We will show that $M2^k s_n$ is an odd integer, contradicting the equality $M2^k s_n = M2^k m$ and showing that the supposition that s_n is an integer must have been wrong.

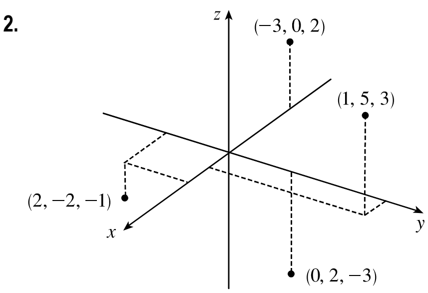
$M2^k s_n = M2^k \sum_{i=1}^{n} \frac{1}{i} = \sum_{i=1}^{n} \frac{M2^k}{i}$. If $1 \leq i \leq n$ and i is odd, then $\frac{M}{i}$ is an odd integer since i is one of the odd integers that were multiplied together to form M. Thus, $\frac{M2^k}{i}$ is an even integer in this case. If $1 \leq i \leq n$ and i is even, then we can write $i = 2^r l$, where 2^r is the largest power of 2 dividing i and l is odd. If $r < k$, then $\frac{M2^k}{i} = \frac{2^k}{2^r} \cdot \frac{M}{l} = 2^{k-r} \frac{M}{l}$, which is an even integer, the product of the even integer 2^{k-r} and the odd integer $\frac{M}{l}$. If $r = k$, then $l = 1$, since $l > 1 = l \geq 2 \quad \Rightarrow$ $i = 2^k l \geq 2^k \cdot 2 = 2^{k+1}$, contrary to the choice of 2^k as the largest power of 2 that is less than or equal to n. This shows that $r = k$ only when $i = 2^k$. In that case, $\frac{M2^k}{i} = M$, an *odd* integer. Since $\frac{M2^k}{i}$ is an even integer for every i except 2^k and $\frac{M2^k}{i}$ is an odd integer when $i = 2^k$, we see that $M2^k s_n$ is an odd integer. This concludes the proof.

12 ☐ VECTORS AND THE GEOMETRY OF SPACE

12.1 Three-Dimensional Coordinate Systems

1. We start at the origin, which has coordinates $(0, 0, 0)$. First we move 4 units along the positive x-axis, affecting only the x-coordinate, bringing us to the point $(4, 0, 0)$. We then move 3 units straight downward, in the negative z-direction. Thus only the z-coordinate is affected, and we arrive at $(4, 0, -3)$.

2.

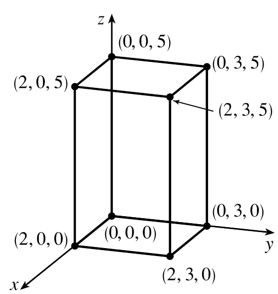


3. The distance from a point to the yz-plane is the absolute value of the x-coordinate of the point. $C(2, 4, 6)$ has the x-coordinate with the smallest absolute value, so C is the point closest to the yz-plane. $A(-4, 0, -1)$ must lie in the xz-plane since the distance from A to the xz-plane, given by the y-coordinate of A, is 0.

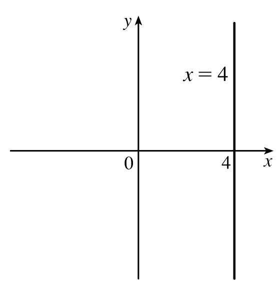
4. The projection of $(2, 3, 5)$ onto the xy-plane is $(2, 3, 0)$; onto the yz-plane, $(0, 3, 5)$; onto the xz-plane, $(2, 0, 5)$.

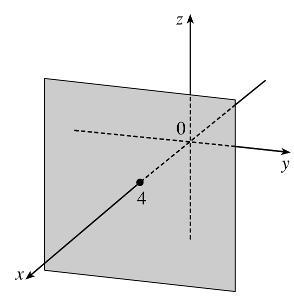
The length of the diagonal of the box is the distance between the origin and $(2, 3, 5)$, given by

$$\sqrt{(2-0)^2 + (3-0)^2 + (5-0)^2} = \sqrt{38} \approx 6.16$$



5. In $\mathbb{R}^2$, the equation $x = 4$ represents a line parallel to the y-axis and 4 units to the right of it. In $\mathbb{R}^3$, the equation $x = 4$ represents the set $\{(x, y, z) \mid x = 4\}$, the set of all points whose x-coordinate is 4. This is the vertical plane that is parallel to the yz-plane and 4 units in front of it.

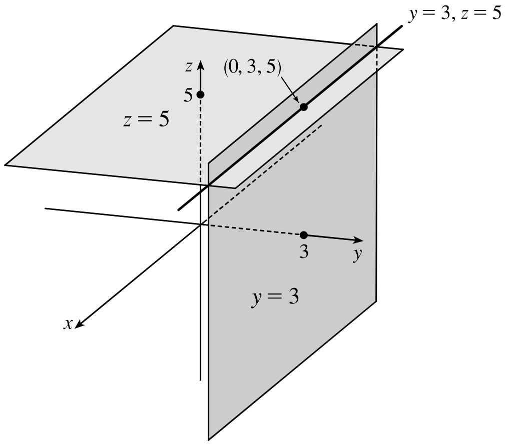




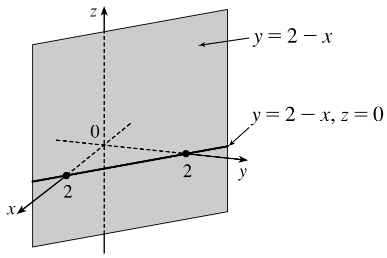
6. In $\mathbb{R}^3$, the equation $y = 3$ represents a vertical plane that is parallel to the xz-plane and 3 units to the right of it. The equation $z = 5$ represents a horizontal plane parallel to the xy-plane and 5 units above it. The pair of equations $y = 3$, $z = 5$ represents the set of points that are simultaneously on both planes, or in other words, the line of intersection of the planes $y = 3$, $z = 5$.

[continued]

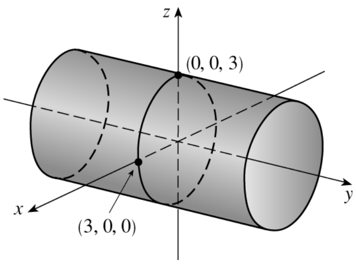
This line can also be described as the set $\{(x, 3, 5) \mid x \in \mathbb{R}\}$, which is the set of all points in $\mathbb{R}^3$ whose x-coordinate may vary but whose y- and z-coordinates are fixed at 3 and 5, respectively. Thus the line is parallel to the x-axis and intersects the yz-plane in the point $(0, 3, 5)$.



7. The equation $x + y = 2$ represents the set of all points in $\mathbb{R}^3$ whose x- and y-coordinates have a sum of 2, or equivalently where $y = 2 - x$. This is the set $\{(x, 2 - x, z) \mid x \in \mathbb{R}, z \in \mathbb{R}\}$ which is a vertical plane that intersects the xy-plane in the line $y = 2 - x$, $z = 0$.



8. The equation $x^2 + z^2 = 9$ has no restrictions on y, and the x- and z-coordinates satisfy the equation for a circle of radius 3 with center the origin. Thus the surface $x^2 + z^2 = 9$ in $\mathbb{R}^3$ consists of all possible vertical circles (parallel to the xz-plane) $x^2 + z^2 = 9$, $y = k$, and is therefore a circular cylinder with radius 3 whose axis is the y-axis.



9. We can find the lengths of the sides of the triangle by using the distance formula between pairs of vertices:

$$|PQ| = \sqrt{(7-3)^2 + [0-(-2)]^2 + [1-(-3)]^2} = \sqrt{16+4+16} = 6$$

$$|QR| = \sqrt{(1-7)^2 + (2-0)^2 + (1-1)^2} = \sqrt{36+4+0} = \sqrt{40} = 2\sqrt{10}$$

$$|RP| = \sqrt{(3-1)^2 + (-2-2)^2 + (-3-1)^2} = \sqrt{4+16+16} = 6$$

The longest side is QR, but the Pythagorean Theorem is not satisfied: $|PQ|^2 + |RP|^2 \neq |QR|^2$. Thus PQR is not a right triangle. PQR is isosceles, as two sides have the same length.

10. Compute the lengths of the sides of the triangle by using the distance formula between pairs of vertices:

$$|PQ| = \sqrt{(4-2)^2 + [1-(-1)]^2 + (1-0)^2} = \sqrt{4+4+1} = 3$$

$$|QR| = \sqrt{(4-4)^2 + (-5-1)^2 + (4-1)^2} = \sqrt{0+36+9} = \sqrt{45} = 3\sqrt{5}$$

$$|RP| = \sqrt{(2-4)^2 + [-1-(-5)]^2 + (0-4)^2} = \sqrt{4+16+16} = 6$$

Since the Pythagorean Theorem is satisfied by $|PQ|^2 + |RP|^2 = |QR|^2$, PQR is a right triangle. PQR is not isosceles, as no two sides have the same length.

11. (a) First we find the distances between points:

$$|AB| = \sqrt{(3-2)^2 + (7-4)^2 + (-2-2)^2} = \sqrt{26}$$
$$|BC| = \sqrt{(1-3)^2 + (3-7)^2 + [3-(-2)]^2} = \sqrt{45} = 3\sqrt{5}$$
$$|AC| = \sqrt{(1-2)^2 + (3-4)^2 + (3-2)^2} = \sqrt{3}$$

In order for the points to lie on a straight line, the sum of the two shortest distances must be equal to the longest distance. Since $\sqrt{26} + \sqrt{3} \neq 3\sqrt{5}$, the three points do not lie on a straight line.

(b) First we find the distances between points:

$$|DE| = \sqrt{(1-0)^2 + [-2-(-5)]^2 + (4-5)^2} = \sqrt{11}$$
$$|EF| = \sqrt{(3-1)^2 + [4-(-2)]^2 + (2-4)^2} = \sqrt{44} = 2\sqrt{11}$$
$$|DF| = \sqrt{(3-0)^2 + [4-(-5)]^2 + (2-5)^2} = \sqrt{99} = 3\sqrt{11}$$

Since $|DE| + |EF| = |DF|$, the three points lie on a straight line.

12. (a) The distance from a point to the xy-plane is the absolute value of the z-coordinate of the point. Thus, the distance is $|6| = 6$.

(b) Similarly, the distance to the yz-plane is the absolute value of the x-coordinate of the point: $|4| = 4$.

(c) The distance to the xz-plane is the absolute value of the y-coordinate of the point: $|-2| = 2$.

(d) The point on the x-axis closest to $(4,-2,6)$ is the point $(4,0,0)$. (Approach the x-axis perpendicularly.) The distance from $(4,-2,6)$ to the x-axis is the distance between these two points: $\sqrt{(4-4)^2 + (-2-0)^2 + (6-0)^2} = \sqrt{40} = 2\sqrt{10} \approx 6.32$.

(e) The point on the y-axis closest to $(4,-2,6)$ is $(0,-2,0)$. The distance between these points is $\sqrt{(4-0)^2 + [-2-(-2)]^2 + (6-0)^2} = \sqrt{52} = 2\sqrt{13} \approx 7.21$.

(f) The point on the z-axis closest to $(4,-2,6)$ is $(0,0,6)$. The distance between these points is $\sqrt{(4-0)^2 + (-2-0)^2 + (6-6)^2} = \sqrt{20} = 2\sqrt{5} \approx 4.47$.

13. An equation of the sphere with center $(-3,2,5)$ and radius 4 is $[x-(-3)]^2 + (y-2)^2 + (z-5)^2 = 4^2$ or $(x+3)^2 + (y-2)^2 + (z-5)^2 = 16$. The intersection of this sphere with the yz-plane is the set of points on the sphere whose x-coordinate is 0. Putting $x = 0$ into the equation, we have $9 + (y-2)^2 + (z-5)^2 = 16$, $x = 0$ or $(y-2)^2 + (z-5)^2 = 7$, $x = 0$, which represents a circle in the yz-plane with center $(0,2,5)$ and radius $\sqrt{7}$.

14. An equation of the sphere with center $(2,-6,4)$ and radius 5 is $(x-2)^2 + [y-(-6)]^2 + (z-4)^2 = 5^2$ or $(x-2)^2 + (y+6)^2 + (z-4)^2 = 25$. The intersection of this sphere with the xy-plane is the set of points on the sphere whose z-coordinate is 0. Putting $z = 0$ into the equation, we have $(x-2)^2 + (y+6)^2 = 9$, $z = 0$ which represents a circle in the xy-plane with center $(2,-6,0)$ and radius 3. To find the intersection with the xz-plane, we set $y = 0$: $(x-2)^2 + (z-4)^2 = -11$. Since no points satisfy this equation, the sphere does not intersect the xz-plane. (Also note that the distance from the center of the sphere to the xz-plane is greater than the radius of the sphere.) To find the intersection with the yz-plane, we set $x = 0$: $(y+6)^2 + (z-4)^2 = 21$, $x = 0$, a circle in the yz-plane with center $(0,-6,4)$ and radius $\sqrt{21}$.

15. The radius of the sphere is the distance between $(4,3,-1)$ and $(3,8,1)$: $r = \sqrt{(3-4)^2+(8-3)^2+[1-(-1)]^2} = \sqrt{30}$. Thus, an equation of the sphere is $(x-3)^2+(y-8)^2+(z-1)^2 = 30$.

16. If the sphere passes through the origin, the radius of the sphere must be the distance from the origin to the point $(1,2,3)$: $r = \sqrt{(1-0)^2+(2-0)^2+(3-0)^2} = \sqrt{14}$. Then an equation of the sphere is $(x-1)^2+(y-2)^2+(z-3)^2 = 14$.

17. Completing squares in the equation $x^2+y^2+z^2-2x-4y+8z=15$ gives $(x^2-2x+1)+(y^2-4y+4)+(z^2+8z+16) = 15+1+4+16 \quad\Rightarrow\quad (x-1)^2+(y-2)^2+(z+4)^2 = 36$, which we recognize as an equation of a sphere with center $(1,2,-4)$ and radius 6.

18. Completing squares in the equation gives $(x^2+8x+16)+(y^2-6y+9)+(z^2+2z+1) = -17+16+9+1 \quad\Rightarrow$ $(x+4)^2+(y-3)^2+(z+1)^2 = 9$, which we recognize as an equation of a sphere with center $(-4,3,-1)$ and radius 3.

19. Completing squares in the equation $2x^2-8x+2y^2+2z^2+24z=1$ gives $2(x^2-4x+4)+2y^2+2(z^2+12z+36) = 1+8+72 \quad\Rightarrow\quad 2(x-2)^2+2y^2+2(z+6)^2 = 81 \quad\Rightarrow$ $(x-2)^2+y^2+(z+6)^2 = \frac{81}{2}$, which we recognize as an equation of a sphere with center $(2,0,-6)$ and radius $\sqrt{\frac{81}{2}} = 9/\sqrt{2}$.

20. Completing squares in the equation $3x^2+3y^2-6y+3z^2-12z=10$ gives $3x^2+3(y^2-2y+1)+3(z^2-4z+4) = 10+3+12 \quad\Rightarrow\quad 3x^2+3(y-1)^2+3(z-2)^2 = 25 \quad\Rightarrow$ $x^2+(y-1)^2+(z-2)^2 = \frac{25}{3}$, which we recognize as an equation of a sphere with center $(0,1,2)$ and radius $\sqrt{\frac{25}{3}} = 5/\sqrt{3}$.

21. (a) If the midpoint of the line segment from $P_1(x_1,y_1,z_1)$ to $P_2(x_2,y_2,z_2)$ is $Q = \left(\frac{x_1+x_2}{2}, \frac{y_1+y_2}{2}, \frac{z_1+z_2}{2}\right)$, then the distances $|P_1Q|$ and $|QP_2|$ are equal, and each is half of $|P_1P_2|$. We verify that this is the case:

$$|P_1P_2| = \sqrt{(x_2-x_1)^2+(y_2-y_1)^2+(z_2-z_1)^2}$$

$$\begin{aligned}
|P_1Q| &= \sqrt{\left[\tfrac{1}{2}(x_1+x_2)-x_1\right]^2+\left[\tfrac{1}{2}(y_1+y_2)-y_1\right]^2+\left[\tfrac{1}{2}(z_1+z_2)-z_1\right]^2} \\
&= \sqrt{\left(\tfrac{1}{2}x_2-\tfrac{1}{2}x_1\right)^2+\left(\tfrac{1}{2}y_2-\tfrac{1}{2}y_1\right)^2+\left(\tfrac{1}{2}z_2-\tfrac{1}{2}z_1\right)^2} \\
&= \sqrt{\left(\tfrac{1}{2}\right)^2\left[(x_2-x_1)^2+(y_2-y_1)^2+(z_2-z_1)^2\right]} = \tfrac{1}{2}\sqrt{(x_2-x_1)^2+(y_2-y_1)^2+(z_2-z_1)^2} \\
&= \tfrac{1}{2}\,|P_1P_2|
\end{aligned}$$

$$\begin{aligned}
|QP_2| &= \sqrt{\left[x_2-\tfrac{1}{2}(x_1+x_2)\right]^2+\left[y_2-\tfrac{1}{2}(y_1+y_2)\right]^2+\left[z_2-\tfrac{1}{2}(z_1+z_2)\right]^2} \\
&= \sqrt{\left(\tfrac{1}{2}x_2-\tfrac{1}{2}x_1\right)^2+\left(\tfrac{1}{2}y_2-\tfrac{1}{2}y_1\right)^2+\left(\tfrac{1}{2}z_2-\tfrac{1}{2}z_1\right)^2} = \sqrt{\left(\tfrac{1}{2}\right)^2\left[(x_2-x_1)^2+(y_2-y_1)^2+(z_2-z_1)^2\right]} \\
&= \tfrac{1}{2}\sqrt{(x_2-x_1)^2+(y_2-y_1)^2+(z_2-z_1)^2} = \tfrac{1}{2}\,|P_1P_2|
\end{aligned}$$

So Q is indeed the midpoint of P_1P_2.

(b) By part (a), the midpoints of sides AB, BC and CA are $P_1\left(-\frac{1}{2},1,4\right)$, $P_2\left(1,\frac{1}{2},5\right)$ and $P_3\left(\frac{5}{2},\frac{3}{2},4\right)$. Then the lengths of the medians are:

$$|AP_2| = \sqrt{0^2 + \left(\tfrac{1}{2}-2\right)^2 + (5-3)^2} = \sqrt{\tfrac{9}{4}+4} = \sqrt{\tfrac{25}{4}} = \tfrac{5}{2}$$

$$|BP_3| = \sqrt{\left(\tfrac{5}{2}+2\right)^2 + \left(\tfrac{3}{2}\right)^2 + (4-5)^2} = \sqrt{\tfrac{81}{4}+\tfrac{9}{4}+1} = \sqrt{\tfrac{94}{4}} = \tfrac{1}{2}\sqrt{94}$$

$$|CP_1| = \sqrt{\left(-\tfrac{1}{2}-4\right)^2 + (1-1)^2 + (4-5)^2} = \sqrt{\tfrac{81}{4}+1} = \tfrac{1}{2}\sqrt{85}$$

22. By Exercise 21(a), the midpoint of the diameter (and thus the center of the sphere) is $\left(\frac{5+1}{2},\frac{4+6}{2},\frac{3+(-9)}{2}\right) = (3,5,-3)$. The radius is half the diameter, so $r = \frac{1}{2}\sqrt{(1-5)^2+(6-4)^2+(-9-3)^2} = \frac{1}{2}\sqrt{164} = \sqrt{41}$. Therefore an equation of the sphere is $(x-3)^2+(y-5)^2+(z+3)^2 = 41$.

23. (a) Since the sphere touches the xy-plane, its radius is the distance from its center, $(2,-3,6)$, to the xy-plane, namely 6. Therefore $r=6$ and an equation of the sphere is $(x-2)^2+(y+3)^2+(z-6)^2 = 6^2 = 36$.

(b) The radius of this sphere is the distance from its center $(2,-3,6)$ to the yz-plane, which is 2. Therefore, an equation is $(x-2)^2+(y+3)^2+(z-6)^2 = 4$.

(c) Here the radius is the distance from the center $(2,-3,6)$ to the xz-plane, which is 3. Therefore, an equation is $(x-2)^2+(y+3)^2+(z-6)^2 = 9$.

24. The largest sphere contained in the first octant must have a radius equal to the minimum distance from the center $(5,4,9)$ to any of the three coordinate planes. The shortest such distance is to the xz-plane, a distance of 4. Thus an equation of the sphere is $(x-5)^2+(y-4)^2+(z-9)^2 = 16$.

25. The equation $x=5$ represents a plane parallel to the yz-plane and 5 units in front of it.

26. The equation $y=-2$ represents a plane parallel to the xz-plane and 2 units to the left of it.

27. The inequality $y<8$ represents a half-space consisting of all points to the left of the plane $y=8$.

28. The inequality $z \geq -1$ represents a half-space consisting of all points on or above the plane $z=-1$.

29. The inequality $0 \leq z \leq 6$ represents all points on or between the horizontal planes $z=0$ (the xy-plane) and $z=6$.

30. The equation $y^2 = 4 \quad \Leftrightarrow \quad y = \pm 2$ represents two vertical planes; $y=2$ is parallel to the xz-plane, two units to the right of it, and $y=-2$ is two units to the left of it.

31. Because $z=-1$, all points in the region must lie in the horizontal plane $z=-1$. In addition, $x^2+y^2=4$, so the region consists of all points that lie on a circle with radius 2 and center on the z-axis that is contained in the plane $z=-1$.

32. Here $x^2+y^2=4$ with no restrictions on z, so a point in the region must lie on a circle of radius 2, center on the z-axis, but it could be in any horizontal plane $z=k$ (parallel to the xy-plane). Thus the region consists of all possible circles $x^2+y^2=4$, $z=k$ and is therefore a circular cylinder with radius 2 whose axis is the z-axis.

33. The equation $x^2 + y^2 + z^2 = 4$ is equivalent to $\sqrt{x^2 + y^2 + z^2} = 2$, so the region consists of those points whose distance from the origin is 2. This is the set of all points on a sphere with radius 2 and center $(0, 0, 0)$.

34. The inequality $x^2 + y^2 + z^2 \le 4$ is equivalent to $\sqrt{x^2 + y^2 + z^2} \le 2$, so the region consists of those points whose distance from the origin is at most 2. This is the set of all points on or inside a sphere with radius 2 and center $(0, 0, 0)$.

35. The inequalities $1 \le x^2 + y^2 + z^2 \le 5$ are equivalent to $1 \le \sqrt{x^2 + y^2 + z^2} \le \sqrt{5}$, so the region consists of those points whose distance from the origin is at least 1 and at most $\sqrt{5}$. This is the set of all points on or between spheres with radii 1 and $\sqrt{5}$ and centers $(0, 0, 0)$.

36. The equation $x = z$ represents a plane perpendicular to the xz-plane and intersecting the xz-plane in the line $x = z$, $y = 0$.

37. Here $x^2 + z^2 \le 9$ or equivalently $\sqrt{x^2 + z^2} \le 3$ which describes the set of all points in $\mathbb{R}^3$ whose distance from the y-axis is at most 3. Thus the inequality represents the region consisting of all points on or inside a circular cylinder of radius 3 with axis the y-axis.

38. The inequality $x^2 + y^2 + z^2 > 2z \quad \Leftrightarrow \quad x^2 + y^2 + (z-1)^2 > 1$ is equivalent to $\sqrt{x^2 + y^2 + (z-1)^2} > 1$, so the region consists of those points whose distance from the point $(0, 0, 1)$ is greater than 1. This is the set of all points outside the sphere with radius 1 and center $(0, 0, 1)$.

39. This describes all points whose x-coordinate is between 0 and 5, that is, $0 < x < 5$.

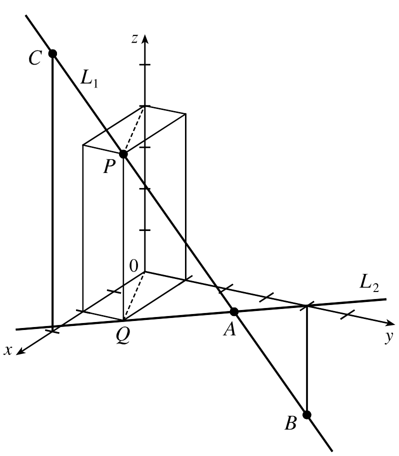
40. For any point on or above the disk in the xy-plane with center the origin and radius 2 we have $x^2 + y^2 \le 4$. Also each point lies on or between the planes $z = 0$ and $z = 8$, so the region is described by $x^2 + y^2 \le 4$, $0 \le z \le 8$.

41. This describes a region all of whose points have a distance to the origin which is greater than r, but smaller than R. So inequalities describing the region are $r < \sqrt{x^2 + y^2 + z^2} < R$, or $r^2 < x^2 + y^2 + z^2 < R^2$.

42. The solid sphere itself is represented by $\sqrt{x^2 + y^2 + z^2} \le 2$. Since we want only the upper hemisphere, we restrict the z-coordinate to nonnegative values. Then inequalities describing the region are $\sqrt{x^2 + y^2 + z^2} \le 2$, $z \ge 0$, or $x^2 + y^2 + z^2 \le 4$, $z \ge 0$.

43. (a) To find the x- and y-coordinates of the point P, we project it onto L_2 and project the resulting point Q onto the x- and y-axes. To find the z-coordinate, we project P onto either the xz-plane or the yz-plane (using our knowledge of its x- or y-coordinate) and then project the resulting point onto the z-axis. (Or, we could draw a line parallel to QO from P to the z-axis.) The coordinates of P are $(2, 1, 4)$.

(b) A is the intersection of L_1 and L_2, B is directly below the y-intercept of L_2, and C is directly above the x-intercept of L_2.



44. Let $P = (x, y, z)$. Then $2\,|PB| = |PA| \iff 4\,|PB|^2 = |PA|^2 \iff$

$4\big((x-6)^2 + (y-2)^2 + (z+2)^2\big) = (x+1)^2 + (y-5)^2 + (z-3)^2 \iff$

$4(x^2 - 12x + 36) - x^2 - 2x + 4(y^2 - 4y + 4) - y^2 + 10y + 4(z^2 + 4z + 4) - z^2 + 6z = 35 \iff$

$3x^2 - 50x + 3y^2 - 6y + 3z^2 + 22z = 35 - 144 - 16 - 16 \iff x^2 - \frac{50}{3}x + y^2 - 2y + z^2 + \frac{22}{3}z = -\frac{141}{3}$.

By completing the square three times we get $\left(x - \frac{25}{3}\right)^2 + (y-1)^2 + \left(z + \frac{11}{3}\right)^2 = \frac{332}{9}$, which is an equation of a sphere with center $\left(\frac{25}{3}, 1, -\frac{11}{3}\right)$ and radius $\frac{\sqrt{332}}{3}$.

45. We need to find a set of points $\{P(x, y, z) \mid |AP| = |BP|\}$.

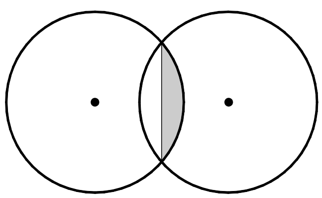
$\sqrt{(x+1)^2 + (y-5)^2 + (z-3)^2} = \sqrt{(x-6)^2 + (y-2)^2 + (z+2)^2} \Rightarrow$

$(x+1)^2 + (y-5) + (z-3)^2 = (x-6)^2 + (y-2)^2 + (z+2)^2 \Rightarrow$

$x^2 + 2x + 1 + y^2 - 10y + 25 + z^2 - 6z + 9 = x^2 - 12x + 36 + y^2 - 4y + 4 + z^2 + 4z + 4 \Rightarrow 14x - 6y - 10z = 9$.

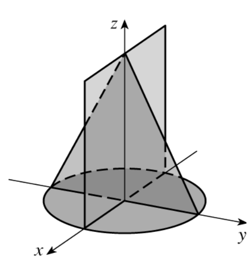
Thus the set of points is a plane perpendicular to the line segment joining A and B (since this plane must contain the perpendicular bisector of the line segment AB).

46. Completing the square three times in the first equation gives $(x+2)^2 + (y-1)^2 + (z+2)^2 = 2^2$, a sphere with center $(-2, 1, 2)$ and radius 2. The second equation is that of a sphere with center $(0, 0, 0)$ and radius 2. The distance between the centers of the spheres is $\sqrt{(-2-0)^2 + (1-0)^2 + (-2-0)^2} = \sqrt{4+1+4} = 3$. Since the spheres have the same radius, the volume inside both spheres is symmetrical about the plane containing the circle of intersection of the spheres. The distance from this plane to the center of the circles is $\frac{3}{2}$. So the region inside both spheres consists of two caps of spheres of height $h = 2 - \frac{3}{2} = \frac{1}{2}$. From Exercise 5.2.49 [ET 6.2.49], the volume of a cap of a sphere is $V = \pi h^2\left(r - \frac{1}{3}h\right) = \pi\left(\frac{1}{2}\right)^2\left(2 - \frac{1}{3}\cdot\frac{1}{2}\right) = \frac{11\pi}{24}$. So the total volume is $2 \cdot \frac{11\pi}{24} = \frac{11\pi}{12}$.



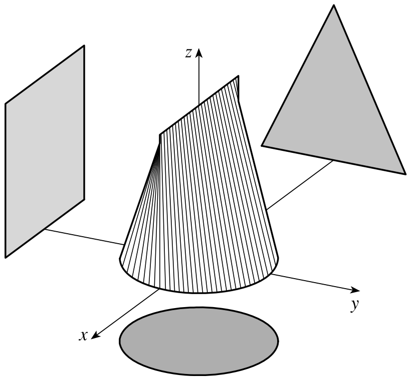
47. The sphere $x^2 + y^2 + z^2 = 4$ has center $(0, 0, 0)$ and radius 2. Completing squares in $x^2 - 4x + y^2 - 4y + z^2 - 4z = -11$ gives $(x^2 - 4x + 4) + (y^2 - 4y + 4) + (z^2 - 4z + 4) = -11 + 4 + 4 + 4 \Rightarrow (x-2)^2 + (y-2)^2 + (z-2)^2 = 1$, so this is the sphere with center $(2, 2, 2)$ and radius 1. The (shortest) distance between the spheres is measured along the line segment connecting their centers. The distance between $(0, 0, 0)$ and $(2, 2, 2)$ is $\sqrt{(2-0)^2 + (2-0)^2 + (2-0)^2} = \sqrt{12} = 2\sqrt{3}$, and subtracting the radius of each circle, the distance between the spheres is $2\sqrt{3} - 2 - 1 = 2\sqrt{3} - 3$.

48. There are many different solids that fit the given description. However, any possible solid must have a circular horizontal cross-section at its top or at its base. Here we illustrate a solid with a circular base in the xy-plane. (A circular cross-section at the top results in an inverted version of the solid described below.) The vertical cross-section through the center of the base that is parallel to the xz-plane must be a square, and the vertical cross-section parallel to the yz-plane (perpendicular to the square) through the center of the base must be a triangle with two vertices on the circle and the third vertex at the center of the top side of the square. (See the figure.)



[continued]

The solid can include any additional points that do not extend beyond these three "silhouettes" when viewed from directions parallel to the coordinate axes. One possibility shown here is to draw the circular base and the vertical square first. Then draw a surface formed by line segments parallel to the yz-plane that connect the top of the square to the circle.



Problem 8 in the Problems Plus section at the end of the chapter illustrates another possible solid.

12.2 Vectors

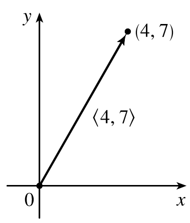
1. (a) The cost of a theater ticket is a scalar, because it has only magnitude.

(b) The current in a river is a vector, because it has both magnitude (the speed of the current) and direction at any given location.

(c) If we assume that the initial path is linear, the initial flight path from Houston to Dallas is a vector, because it has both magnitude (distance) and direction.

(d) The population of the world is a scalar, because it has only magnitude.

2. If the initial point of the vector $\langle 4, 7\rangle$ is placed at the origin, then $\langle 4, 7\rangle$ is the position vector of the point $(4, 7)$.



3. Vectors are equal when they share the same length and direction (but not necessarily location). Using the symmetry of the parallelogram as a guide, we see that $\overrightarrow{AB} = \overrightarrow{DC}$, $\overrightarrow{DA} = \overrightarrow{CB}$, $\overrightarrow{DE} = \overrightarrow{EB}$, and $\overrightarrow{EA} = \overrightarrow{CE}$.

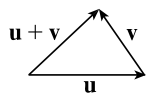
4. (a) The initial point of $\overrightarrow{BC}$ is positioned at the terminal point of $\overrightarrow{AB}$, so by the Triangle Law the sum $\overrightarrow{AB} + \overrightarrow{BC}$ is the vector with initial point A and terminal point C, namely $\overrightarrow{AC}$.

(b) By the Triangle Law, $\overrightarrow{CD} + \overrightarrow{DB}$ is the vector with initial point C and terminal point B, namely $\overrightarrow{CB}$.

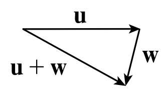
(c) First we consider $\overrightarrow{DB} - \overrightarrow{AB}$ as $\overrightarrow{DB} + \left(-\overrightarrow{AB}\right)$. Then since $-\overrightarrow{AB}$ has the same length as $\overrightarrow{AB}$ but points in the opposite direction, we have $-\overrightarrow{AB} = \overrightarrow{BA}$ and so $\overrightarrow{DB} - \overrightarrow{AB} = \overrightarrow{DB} + \overrightarrow{BA} = \overrightarrow{DA}$.

(d) We use the Triangle Law twice: $\overrightarrow{DC} + \overrightarrow{CA} + \overrightarrow{AB} = \left(\overrightarrow{DC} + \overrightarrow{CA}\right) + \overrightarrow{AB} = \overrightarrow{DA} + \overrightarrow{AB} = \overrightarrow{DB}$.

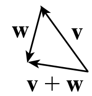
5. (a)



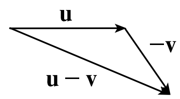
(b)



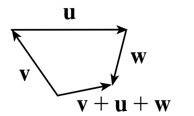
(c)



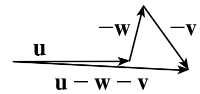
(d)



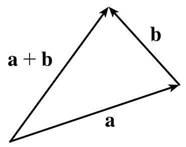
(e)



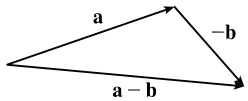
(f)



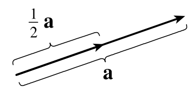
6. (a)



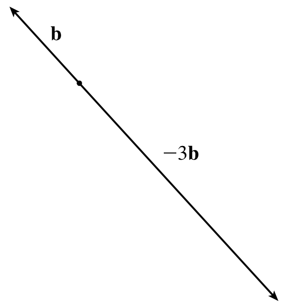
(b)



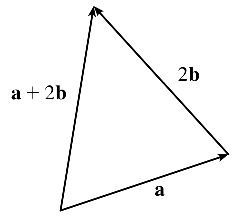
(c)



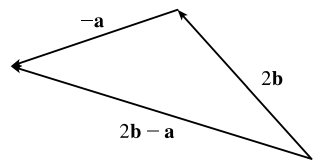
(d)



(e)

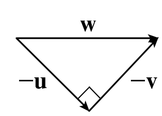


(f)



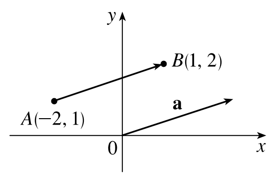
7. Because the tail of $\mathbf{d}$ is the midpoint of QR we have $\overrightarrow{QR} = 2\mathbf{d}$, and by the Triangle Law, $\mathbf{a} + 2\mathbf{d} = \mathbf{b} \quad \Rightarrow \quad 2\mathbf{d} = \mathbf{b} - \mathbf{a} \quad \Rightarrow \quad \mathbf{d} = \frac{1}{2}(\mathbf{b} - \mathbf{a}) = \frac{1}{2}\mathbf{b} - \frac{1}{2}\mathbf{a}$. Again by the Triangle Law we have $\mathbf{c} + \mathbf{d} = \mathbf{b}$ so $\mathbf{c} = \mathbf{b} - \mathbf{d} = \mathbf{b} - \left(\frac{1}{2}\mathbf{b} - \frac{1}{2}\mathbf{a}\right) = \frac{1}{2}\mathbf{a} + \frac{1}{2}\mathbf{b}$.

8. We are given $\mathbf{u} + \mathbf{v} + \mathbf{w} = \mathbf{0}$, so $\mathbf{w} = (-\mathbf{u}) + (-\mathbf{v})$. (See the figure.)

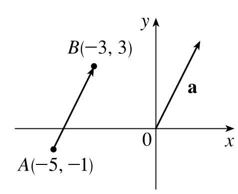


Vectors $-\mathbf{u}$, $-\mathbf{v}$, and $\mathbf{w}$ form a right triangle, so from the Pythagorean Theorem we have $|-\mathbf{u}|^2 + |-\mathbf{v}|^2 = |\mathbf{w}|^2$. But $|-\mathbf{u}| = |\mathbf{u}| = 1$ and $|-\mathbf{v}| = |\mathbf{v}| = 1$ so $|\mathbf{w}| = \sqrt{|-\mathbf{u}|^2 + |-\mathbf{v}|^2} = \sqrt{2}$.

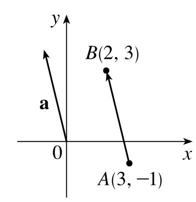
9. $\mathbf{a} = \langle 1 - (-2), 2 - 1 \rangle = \langle 3, 1 \rangle$



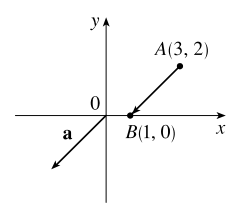
10. $\mathbf{a} = \langle -3 - (-5), 3 - (-1) \rangle = \langle 2, 4 \rangle$



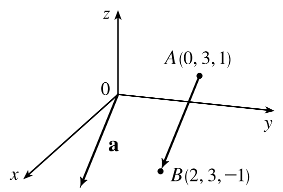
11. $\mathbf{a} = \langle 2 - 3, 3 - (-1) \rangle = \langle -1, 4 \rangle$



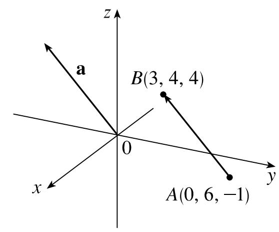
12. $\mathbf{a} = \langle 1 - 3, 0 - 2 \rangle = \langle -2, -2 \rangle$



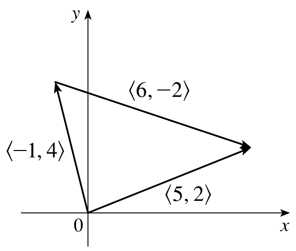
13. $\mathbf{a} = \langle 2-0, 3-3, -1-1\rangle = \langle 2, 0, -2\rangle$



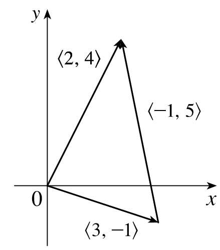
14. $\mathbf{a} = \langle 3-0, 4-6, 4-(-1)\rangle = \langle 3, -2, 5\rangle$



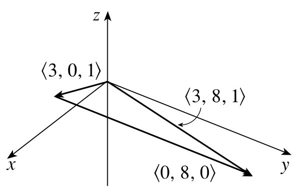
15. $\langle -1, 4\rangle + \langle 6, -2\rangle = \langle -1+6, 4+(-2)\rangle = \langle 5, 2\rangle$



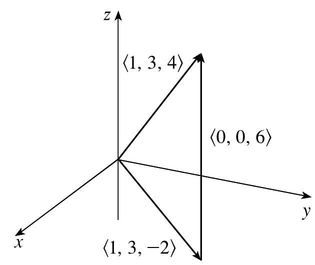
16. $\langle 3, -1\rangle + \langle -1, 5\rangle = \langle 3+(-1), -1+5\rangle = \langle 2, 4\rangle$



17. $\langle 3, 0, 1\rangle + \langle 0, 8, 0\rangle = \langle 3+0, 0+8, 1+0\rangle$
$= \langle 3, 8, 1\rangle$



18. $\langle 1, 3, -2\rangle + \langle 0, 0, 6\rangle = \langle 1+0, 3+0, -2+6\rangle$
$= \langle 1, 3, 4\rangle$



19. $\mathbf{a}+\mathbf{b} = \langle -3, 4\rangle + \langle 9, -1\rangle = \langle -3+9, 4+(-1)\rangle = \langle 6, 3\rangle$

$4\,\mathbf{a}+2\,\mathbf{b} = 4\,\langle -3, 4\rangle + 2\,\langle 9, -1\rangle = \langle -12, 16\rangle + \langle 18, -2\rangle = \langle 6, 14\rangle$

$|\mathbf{a}| = \sqrt{(-3)^2+4^2} = \sqrt{25} = 5$

$|\mathbf{a}-\mathbf{b}| = |\langle -3-9, 4-(-1)\rangle| = |\langle -12, 5\rangle| = \sqrt{(-12)^2+5^2} = \sqrt{169} = 13$

20. $\mathbf{a}+\mathbf{b} = (5\,\mathbf{i}+3\,\mathbf{j}) + (-\mathbf{i}-2\,\mathbf{j}) = 4\,\mathbf{i}+\mathbf{j}$

$4\,\mathbf{a}+2\,\mathbf{b} = 4\,(5\,\mathbf{i}+3\,\mathbf{j}) + 2\,(-\mathbf{i}-2\,\mathbf{j}) = 20\,\mathbf{i}+12\,\mathbf{j}-2\,\mathbf{i}-4\,\mathbf{j} = 18\,\mathbf{i}+8\,\mathbf{j}$

$|\mathbf{a}| = \sqrt{5^2+3^2} = \sqrt{34}$

$|\mathbf{a}-\mathbf{b}| = |(5\,\mathbf{i}+3\,\mathbf{j}) - (-\mathbf{i}-2\,\mathbf{j})| = |6\,\mathbf{i}+5\,\mathbf{j}| = \sqrt{6^2+5^2} = \sqrt{61}$

21. $\mathbf{a}+\mathbf{b} = (4\,\mathbf{i}-3\,\mathbf{j}+2\,\mathbf{k}) + (2\,\mathbf{i}-4\,\mathbf{k}) = 6\,\mathbf{i}-3\,\mathbf{j}-2\mathbf{k}$

$4\,\mathbf{a}+2\,\mathbf{b} = 4\,(4\,\mathbf{i}-3\,\mathbf{j}+2\,\mathbf{k}) + 2\,(2\,\mathbf{i}-4\,\mathbf{k}) = 16\,\mathbf{i}-12\,\mathbf{j}+8\,\mathbf{k}+4\,\mathbf{i}-8\,\mathbf{k} = 20\,\mathbf{i}-12\,\mathbf{j}$

$|\mathbf{a}| = \sqrt{4^2+(-3)^2+2^2} = \sqrt{29}$

$|\mathbf{a}-\mathbf{b}| = |(4\,\mathbf{i}-3\,\mathbf{j}+2\,\mathbf{k}) - (2\,\mathbf{i}-4\,\mathbf{k})| = |2\,\mathbf{i}-3\,\mathbf{j}+6\,\mathbf{k}| = \sqrt{2^2+(-3)^2+6^2} = \sqrt{49} = 7$

22. $\mathbf{a}+\mathbf{b}=\langle 8+5, 1+(-2), -4+1\rangle=\langle 13,-1,-3\rangle$

$4\,\mathbf{a}+2\,\mathbf{b}=4\,\langle 8,1,-4\rangle+2\,\langle 5,-2,1\rangle=\langle 32,4,-16\rangle+\langle 10,-4,2\rangle=\langle 42,0,-14\rangle$

$|\mathbf{a}|=\sqrt{8^2+1^2+(-4)^2}=\sqrt{81}=9$

$|\mathbf{a}-\mathbf{b}|=|\langle 8-5,1-(-2),-4-1\rangle|=|\langle 3,3,-5\rangle|=\sqrt{3^2+3^2+(-5)^2}=\sqrt{43}$

23. The vector $\langle 6,-2\rangle$ has length $|\langle 6,-2\rangle|=\sqrt{6^2+(-2)^2}=\sqrt{40}=2\sqrt{10}$, so by Equation 4 the unit vector with the same direction is $\dfrac{1}{2\sqrt{10}}\,\langle 6,-2\rangle=\left\langle\dfrac{3}{\sqrt{10}},-\dfrac{1}{\sqrt{10}}\right\rangle$.

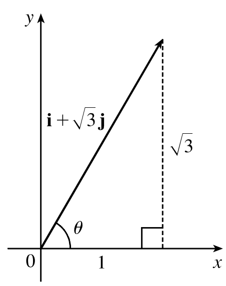
24. The vector $-5\,\mathbf{i}+3\,\mathbf{j}-\mathbf{k}$ has length $|-5\,\mathbf{i}+3\,\mathbf{j}-\mathbf{k}|=\sqrt{(-5)^2+3^2+(-1)^2}=\sqrt{35}$, so by Equation 4 the unit vector with the same direction is $\dfrac{1}{\sqrt{35}}(-5\,\mathbf{i}+3\,\mathbf{j}-\mathbf{k})=-\dfrac{5}{\sqrt{35}}\,\mathbf{i}+\dfrac{3}{\sqrt{35}}\,\mathbf{j}-\dfrac{1}{\sqrt{35}}\,\mathbf{k}$.

25. The vector $8\,\mathbf{i}-\mathbf{j}+4\,\mathbf{k}$ has length $|8\,\mathbf{i}-\mathbf{j}+4\,\mathbf{k}|=\sqrt{8^2+(-1)^2+4^2}=\sqrt{81}=9$, so by Equation 4 the unit vector with the same direction is $\frac{1}{9}(8\,\mathbf{i}-\mathbf{j}+4\,\mathbf{k})=\frac{8}{9}\,\mathbf{i}-\frac{1}{9}\,\mathbf{j}+\frac{4}{9}\,\mathbf{k}$.

26. $|\langle 6,2,-3\rangle|=\sqrt{6^2+2^2+(-3)^2}=\sqrt{49}=7$, so a unit vector in the direction of $\langle 6,2,-3\rangle$ is $\mathbf{u}=\frac{1}{7}\,\langle 6,2,-3\rangle$.

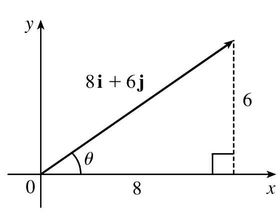
A vector in the same direction but with length 4 is $4\mathbf{u}=4\cdot\frac{1}{7}\,\langle 6,2,-3\rangle=\left\langle\frac{24}{7},\frac{8}{7},-\frac{12}{7}\right\rangle$.

27.



From the figure, we see that $\tan\theta=\dfrac{\sqrt{3}}{1}=\sqrt{3}\quad\Rightarrow\quad\theta=60^\circ$.

28.



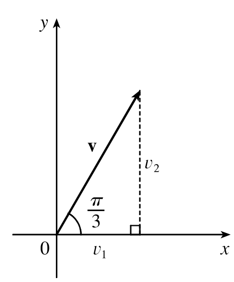
From the figure we see that $\tan\theta=\frac{6}{8}=\frac{3}{4}$, so $\theta=\tan^{-1}\left(\frac{3}{4}\right)\approx 36.9^\circ$.

29. From the figure, we see that the x-component of $\mathbf{v}$ is

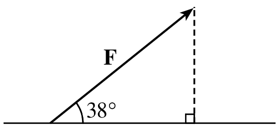
$v_1=|\mathbf{v}|\cos(\pi/3)=4\cdot\frac{1}{2}=2$ and the y-component is

$v_2=|\mathbf{v}|\sin(\pi/3)=4\cdot\frac{\sqrt{3}}{2}=2\sqrt{3}$. Thus

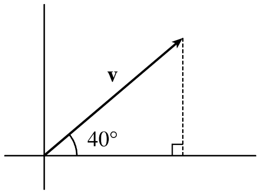
$\mathbf{v}=\langle v_1,v_2\rangle=\left\langle 2,2\sqrt{3}\right\rangle$.



30. From the figure, we see that the horizontal component of the force $\mathbf{F}$ is $|\mathbf{F}|\cos 38° = 50\cos 38° \approx 39.4$ N, and the vertical component is $|\mathbf{F}|\sin 38° = 50\sin 38° \approx 30.8$ N.



31. The velocity vector $\mathbf{v}$ makes an angle of $40°$ with the horizontal and has magnitude equal to the speed at which the football was thrown. From the figure, we see that the horizontal component of $\mathbf{v}$ is $|\mathbf{v}|\cos 40° = 60\cos 40° \approx 45.96$ ft/s and the vertical component is $|\mathbf{v}|\sin 40° = 60\sin 40° \approx 38.57$ ft/s.



32. The given force vectors can be expressed in terms of their horizontal and vertical components as $20\cos 45°\,\mathbf{i} + 20\sin 45°\,\mathbf{j} = 10\sqrt{2}\,\mathbf{i} + 10\sqrt{2}\,\mathbf{j}$ and $16\cos 30°\,\mathbf{i} - 16\sin 30°\,\mathbf{j} = 8\sqrt{3}\,\mathbf{i} - 8\,\mathbf{j}$. The resultant force $\mathbf{F}$ is the sum of these two vectors: $\mathbf{F} = \left(10\sqrt{2} + 8\sqrt{3}\right)\mathbf{i} + \left(10\sqrt{2} - 8\right)\mathbf{j} \approx 28.00\,\mathbf{i} + 6.14\,\mathbf{j}$. Then we have $|\mathbf{F}| \approx \sqrt{(28.00)^2 + (6.14)^2} \approx 28.7$ lb and, letting θ be the angle $\mathbf{F}$ makes with the positive x-axis,

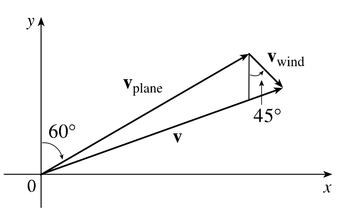
$$\tan\theta = \frac{10\sqrt{2} - 8}{10\sqrt{2} + 8\sqrt{3}} \quad\Rightarrow\quad \theta = \tan^{-1}\left(\frac{10\sqrt{2} - 8}{10\sqrt{2} + 8\sqrt{3}}\right) \approx 12.4°.$$

33. The given force vectors can be expressed in terms of their horizontal and vertical components as $-300\,\mathbf{i}$ and $200\cos 60°\,\mathbf{i} + 200\sin 60°\,\mathbf{j} = 200\left(\frac{1}{2}\right)\,\mathbf{i} + 200\left(\frac{\sqrt{3}}{2}\right)\,\mathbf{j} = 100\,\mathbf{i} + 100\sqrt{3}\,\mathbf{j}$. The resultant force $\mathbf{F}$ is the sum of these two vectors: $\mathbf{F} = (-300 + 100)\,\mathbf{i} + \left(0 + 100\sqrt{3}\right)\mathbf{j} = -200\,\mathbf{i} + 100\sqrt{3}\,\mathbf{j}$. Then we have $|\mathbf{F}| \approx \sqrt{(-200)^2 + \left(100\sqrt{3}\right)^2} = \sqrt{70{,}000} = 100\sqrt{7} \approx 264.6$ N. Let θ be the angle $\mathbf{F}$ makes with the positive x-axis. Then $\tan\theta = \dfrac{100\sqrt{3}}{-200} = -\dfrac{\sqrt{3}}{2}$ and the terminal point of $\mathbf{F}$ lies in the second quadrant, so

$$\theta = \tan^{-1}\left(-\frac{\sqrt{3}}{2}\right) + 180° \approx -40.9° + 180° = 139.1°.$$

34. Set up the coordinate axes so that north is the positive y-direction, and east is the positive x-direction. The wind is blowing at 50 km/h from the direction N45°W, so that its velocity vector is 50 km/h S45°E, which can be written as $\mathbf{v}_{\text{wind}} = 50(\cos 45°\mathbf{i} - \sin 45°\mathbf{j})$. With respect to the still air, the velocity vector of the plane is 250 km/h N 60°E, or equivalently $\mathbf{v}_{\text{plane}} = 250(\cos 30°\mathbf{i} + \sin 30°\mathbf{j})$. The velocity of the plane relative to the ground is

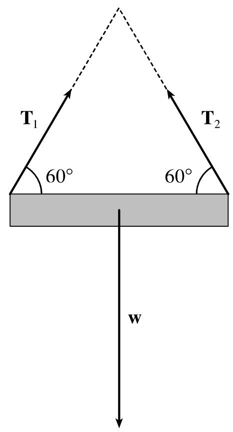
$$\begin{aligned}
\mathbf{v} &= \mathbf{v}_{\text{plane}} + \mathbf{v}_{\text{wind}} \\
&= (250\cos 30° + 50\cos 45°)\,\mathbf{i} + (250\sin 30° - 50\sin 45°)\,\mathbf{j} \\
&= \left(125\sqrt{3} + 25\sqrt{2}\right)\mathbf{i} + \left(125 - 25\sqrt{2}\right)\mathbf{j} \\
&\approx 251.9\,\mathbf{i} + 89.6\,\mathbf{j}
\end{aligned}$$



(See the figure.) The ground speed is $|\mathbf{v}| \approx \sqrt{(251.9)^2 + (89.6)^2} \approx 267$ km/h. The angle the velocity vector makes with the x-axis is $\theta \approx \tan^{-1}\left(\frac{89.6}{251.9}\right) \approx 20°$. Therefore, the true course of the plane is about N$(90 - 20)°$E = N 70°E.

35. With respect to the water's surface, the woman's velocity is the vector sum of the velocity of the ship with respect to the water, and the woman's velocity with respect to the ship. If we let north be the positive y-direction, then $\mathbf{v} = \langle 0, 22 \rangle + \langle -3, 0 \rangle = \langle -3, 22 \rangle$. The woman's speed is $|\mathbf{v}| = \sqrt{9 + 484} \approx 22.2$ mi/h. The vector $\mathbf{v}$ makes an angle θ with the east, where $\theta = \tan^{-1}\left(\frac{22}{-3}\right) \approx 98°$. Therefore, the woman's direction is about $\text{N}(98 - 90)°\text{W} = \text{N}8°\text{W}$.

36. Let $\mathbf{T}_1$ and $\mathbf{T}_2$ be the tension vectors corresponding to the support cables as shown in the figure. In terms of vertical and horizontal components,



$$\mathbf{T}_1 = |\mathbf{T}_1| \cos 60° \mathbf{i} + |\mathbf{T}_1| \sin 60° \mathbf{j} = \frac{1}{2} |\mathbf{T}_1| \mathbf{i} + \frac{\sqrt{3}}{2} |\mathbf{T}_1| \mathbf{j}$$

$$\mathbf{T}_2 = -|\mathbf{T}_2| \cos 60° \mathbf{i} + |\mathbf{T}_2| \sin 60° \mathbf{j} = -\frac{1}{2} |\mathbf{T}_2| \mathbf{i} + \frac{\sqrt{3}}{2} |\mathbf{T}_2| \mathbf{j}$$

The resultant of these tensions, $\mathbf{T}_1 + \mathbf{T}_2$, counterbalances the weight $\mathbf{w} = -500\,\mathbf{j}$. So $\mathbf{T}_1 + \mathbf{T}_2 = -\mathbf{w} = 500\,\mathbf{j} \quad \Rightarrow$

$$\left(\frac{1}{2} |\mathbf{T}_1| \mathbf{i} + \frac{\sqrt{3}}{2} |\mathbf{T}_1| \mathbf{j}\right) + \left(-\frac{1}{2} |\mathbf{T}_2| \mathbf{i} + \frac{\sqrt{3}}{2} |\mathbf{T}_2| \mathbf{j}\right) = 500\,\mathbf{j}.$$

Equating x-components gives $\frac{1}{2} |\mathbf{T}_1| \mathbf{i} - \frac{1}{2} |\mathbf{T}_2| \mathbf{i} = 0$, so $|\mathbf{T}_1| = |\mathbf{T}_2|$ (as we would expect from the symmetry of the problem). Equating y-components, we have $\frac{\sqrt{3}}{2} |\mathbf{T}_1| \mathbf{j} + \frac{\sqrt{3}}{2} |\mathbf{T}_2| \mathbf{j} = \sqrt{3}\,|\mathbf{T}_1| \mathbf{j} = 500\,\mathbf{j} \quad \Rightarrow \quad |\mathbf{T}_1| = \frac{500}{\sqrt{3}}$. Thus the magnitude of each tension is $|\mathbf{T}_1| = |\mathbf{T}_2| = \frac{500}{\sqrt{3}} \approx 288.68$ lb. The tension vectors are

$$\mathbf{T}_1 = \frac{1}{2} |\mathbf{T}_1| \mathbf{i} + \frac{\sqrt{3}}{2} |\mathbf{T}_1| \mathbf{j} = \frac{250}{\sqrt{3}} \mathbf{i} + 250\,\mathbf{j} \approx 144.34\,\mathbf{i} + 250\,\mathbf{j} \text{ and } \mathbf{T}_2 = -\frac{250}{\sqrt{3}} \mathbf{i} + 250\,\mathbf{j} \approx -144.34\,\mathbf{i} + 250\,\mathbf{j}.$$

37. Call the two tension vectors $\mathbf{T}_2$ and $\mathbf{T}_3$, corresponding to the ropes of length 2 m and 3 m. In terms of vertical and horizontal components,

$$\mathbf{T}_2 = -|\mathbf{T}_2| \cos 50° \mathbf{i} + |\mathbf{T}_2| \sin 50° \mathbf{j} \quad (\mathbf{1}) \qquad \text{and} \qquad \mathbf{T}_3 = |\mathbf{T}_3| \cos 38° \mathbf{i} + |\mathbf{T}_3| \sin 38° \mathbf{j} \quad (\mathbf{2})$$

The resultant of these forces, $\mathbf{T}_2 + \mathbf{T}_3$, counterbalances the weight of the hoist (which is $-350\,\mathbf{j}$), so $\mathbf{T}_2 + \mathbf{T}_3 = 350\,\mathbf{j} \quad \Rightarrow$

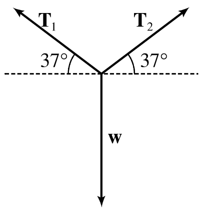
$(-|\mathbf{T}_2| \cos 50° + |\mathbf{T}_3| \cos 38°)\,\mathbf{i} + (|\mathbf{T}_2| \sin 50° + |\mathbf{T}_3| \sin 38°)\,\mathbf{j} = 350\,\mathbf{j}$. Equating components, we have

$-|\mathbf{T}_2| \cos 50° + |\mathbf{T}_3| \cos 38° = 0 \quad \Rightarrow \quad |\mathbf{T}_2| = |\mathbf{T}_3| \dfrac{\cos 38°}{\cos 50°}$ and

$|\mathbf{T}_2| \sin 50° + |\mathbf{T}_3| \sin 38° = 350$. Substituting the first equation into the second gives

$|\mathbf{T}_3| \dfrac{\cos 38°}{\cos 50°} \sin 50° + |\mathbf{T}_3| \sin 38° = 350 \quad \Rightarrow \quad |\mathbf{T}_3| (\cos 38° \tan 50° + \sin 38°) = 350$, so the magnitudes of the tensions are $|\mathbf{T}_3| = \dfrac{350}{\cos 38° \tan 50° + \sin 38°} \approx 225.11$ N and $|\mathbf{T}_2| = |\mathbf{T}_3| \dfrac{\cos 38°}{\cos 50°} \approx 275.97$ N. Finally, from (**1**) and (**2**), the tension vectors are $\mathbf{T}_2 \approx -177.39\,\mathbf{i} + 211.41\,\mathbf{j}$ and $\mathbf{T}_3 \approx 177.39\,\mathbf{i} + 138.59\,\mathbf{j}$.

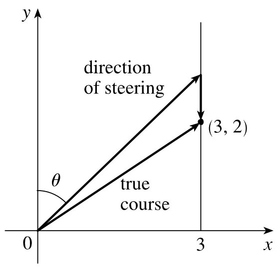
38. We can consider the weight of the chain to be concentrated at its midpoint. The forces acting on the chain then are the tension vectors $\mathbf{T}_1$, $\mathbf{T}_2$ in each end of the chain and the weight $\mathbf{w}$, as shown in the figure. We know $|\mathbf{T}_1| = |\mathbf{T}_2| = 25$ N so, in terms of vertical and horizontal components, we have



$$\mathbf{T}_1 = -25\cos 37°\,\mathbf{i} + 25\sin 37°\,\mathbf{j} \qquad \mathbf{T}_2 = 25\cos 37°\,\mathbf{i} + 25\sin 37°\,\mathbf{j}$$

The resultant vector $\mathbf{T}_1 + \mathbf{T}_2$ of the tensions counterbalances the weight $\mathbf{w}$, giving $\mathbf{T}_1 + \mathbf{T}_2 = -\mathbf{w}$. Since $\mathbf{w} = -|\mathbf{w}|\,\mathbf{j}$, we have $(-25\cos 37°\,\mathbf{i} + 25\sin 37°\,\mathbf{j}) + (25\cos 37°\,\mathbf{i} + 25\sin 37°\,\mathbf{j}) = |\mathbf{w}|\,\mathbf{j} \Rightarrow 50\sin 37°\,\mathbf{j} = |\mathbf{w}|\,\mathbf{j} \Rightarrow$ $|\mathbf{w}| = 50\sin 37° \approx 30.1$. So the weight is 30.1 N, and since $w = mg$, the mass is $\frac{30.1}{9.8} \approx 3.07$ kg.

39. (a) Set up coordinate axes so that the boatman is at the origin, the canal is bordered by the y-axis and the line $x = 3$, and the current flows in the negative y-direction. The boatman wants to reach the point $(3, 2)$. Let θ be the angle, measured from the positive y-axis, in the direction he should steer. (See the figure.)



In still water, the boat has velocity $\mathbf{v}_b = \langle 13\sin\theta, 13\cos\theta\rangle$ and the velocity of the current is $\mathbf{v}_c\ \langle 0, -3.5\rangle$, so the true path of the boat is determined by the velocity vector $\mathbf{v} = \mathbf{v}_b + \mathbf{v}_c = \langle 13\sin\theta, 13\cos\theta - 3.5\rangle$. Let t be the time (in hours) after the boat departs; then the position of the boat at time t is given by $t\mathbf{v}$ and the boat crosses the canal when $t\mathbf{v} = \langle 13\sin\theta, 13\cos\theta - 3.5\rangle\, t = \langle 3, 2\rangle$. Thus $13(\sin\theta)t = 3 \quad\Rightarrow\quad t = \dfrac{3}{13\sin\theta}$ and $(13\cos\theta - 3.5)\,t = 2$.

Substituting gives $(13\cos\theta - 3.5)\,\dfrac{3}{13\sin\theta} = 2 \quad\Rightarrow\quad 39\cos\theta - 10.5 = 26\sin\theta$ (**1**). Squaring both sides, we have

$$1521\cos^2\theta - 819\cos\theta + 110.25 = 676\sin^2\theta = 676\left(1 - \cos^2\theta\right)$$

$$2197\cos^2\theta - 819\cos\theta - 565.75 = 0$$

The quadratic formula gives

$$\cos\theta = \frac{819 \pm \sqrt{(-819)^2 - 4(2197)(-565.75)}}{2(2197)}$$

$$= \frac{819 \pm \sqrt{5{,}642{,}572}}{4394} \approx 0.72699 \text{ or } -0.35421$$

The acute value for θ is approximately $\cos^{-1}(0.72699) \approx 43.4°$. Thus the boatman should steer in the direction that is $43.4°$ from the bank, toward upstream.

Alternate solution: We could solve (**1**) graphically by plotting $y = 39\cos\theta - 10.5$ and $y = 26\sin\theta$ on a graphing device and finding the appoximate intersection point $(0.757, 17.85)$. Thus $\theta \approx 0.757$ radians or equivalently $43.4°$.

(b) From part (a) we know the trip is completed when $t = \dfrac{3}{13\sin\theta}$. But $\theta \approx 43.4°$, so the time required is approximately $\dfrac{3}{13\sin 43.4°} \approx 0.336$ hours or 20.2 minutes.

40. Let $\mathbf{v}_1$, $\mathbf{v}_2$, and $\mathbf{v}_3$ be the force vectors where $|\mathbf{v}_1| = 25$, $|\mathbf{v}_2| = 12$, and $|\mathbf{v}_3| = 4$. Set up coordinate axes so that the object is at the origin and $\mathbf{v}_1$, $\mathbf{v}_2$ lie in the xy-plane. We can position the vectors so that $\mathbf{v}_1 = 25\,\mathbf{i}$, $\mathbf{v}_2 = 12\cos 100^\circ\,\mathbf{i} + 12\sin 100^\circ\,\mathbf{j}$, and $\mathbf{v}_3 = 4\,\mathbf{k}$. The magnitude of a force that counterbalances the three given forces must match the magnitude of the resultant force. We have $\mathbf{v}_1 + \mathbf{v}_2 + \mathbf{v}_3 = (25 + 12\cos 100^\circ)\,\mathbf{i} + 12\sin 100^\circ\,\mathbf{j} + 4\,\mathbf{k}$, so the counterbalancing force must have magnitude $|\mathbf{v}_1 + \mathbf{v}_2 + \mathbf{v}_3| = \sqrt{(25 + 12\cos 100^\circ)^2 + (12\sin 100^\circ)^2 + 4^2} \approx 26.1$ N.

41. The slope of the tangent line to the graph of $y = x^2$ at the point $(2, 4)$ is

$$\left.\frac{dy}{dx}\right|_{x=2} = \left. 2x\right|_{x=2} = 4$$

and a parallel vector is $\mathbf{i} + 4\,\mathbf{j}$ which has length $|\mathbf{i} + 4\,\mathbf{j}| = \sqrt{1^2 + 4^2} = \sqrt{17}$, so unit vectors parallel to the tangent line are $\pm\frac{1}{\sqrt{17}}\,(\mathbf{i} + 4\,\mathbf{j})$.

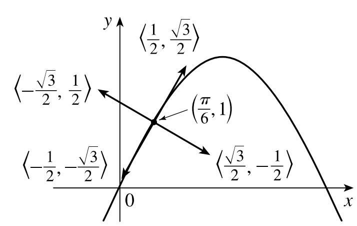
42. (a) The slope of the tangent line to the graph of $y = 2\sin x$ at the point $(\pi/6, 1)$ is

$$\left.\frac{dy}{dx}\right|_{x=\pi/6} = \left. 2\cos x\right|_{x=\pi/6} = 2 \cdot \frac{\sqrt{3}}{2} = \sqrt{3}$$

and a parallel vector is $\mathbf{i} + \sqrt{3}\,\mathbf{j}$ which has length $\left|\mathbf{i} + \sqrt{3}\,\mathbf{j}\right| = \sqrt{1^2 + \left(\sqrt{3}\right)^2} = \sqrt{4} = 2$, so unit vectors parallel to the tangent line are $\pm\frac{1}{2}\left(\mathbf{i} + \sqrt{3}\,\mathbf{j}\right)$.

(b) The slope of the tangent line is $\sqrt{3}$, so the slope of a line perpendicular to the tangent line is $-\frac{1}{\sqrt{3}}$ and a vector in this direction is $\sqrt{3}\,\mathbf{i} - \mathbf{j}$. Since $\left|\sqrt{3}\,\mathbf{i} - \mathbf{j}\right| = \sqrt{\left(\sqrt{3}\right)^2 + (-1)^2} = 2$, unit vectors perpendicular to the tangent line are $\pm\frac{1}{2}\left(\sqrt{3}\,\mathbf{i} - \mathbf{j}\right)$.

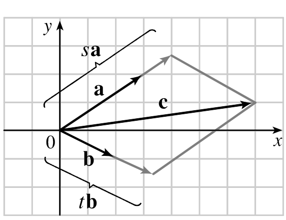
(c)



43. By the Triangle Law, $\overrightarrow{AB} + \overrightarrow{BC} = \overrightarrow{AC}$. Then $\overrightarrow{AB} + \overrightarrow{BC} + \overrightarrow{CA} = \overrightarrow{AC} + \overrightarrow{CA}$, but $\overrightarrow{AC} + \overrightarrow{CA} = \overrightarrow{AC} + \left(-\overrightarrow{AC}\right) = \mathbf{0}$. So $\overrightarrow{AB} + \overrightarrow{BC} + \overrightarrow{CA} = \mathbf{0}$.

44. $\overrightarrow{AC} = \frac{1}{3}\overrightarrow{AB}$ and $\overrightarrow{BC} = \frac{2}{3}\overrightarrow{BA}$. $\mathbf{c} = \overrightarrow{OA} + \overrightarrow{AC} = \mathbf{a} + \frac{1}{3}\overrightarrow{AB} \;\Rightarrow\; \overrightarrow{AB} = 3\,\mathbf{c} - 3\,\mathbf{a}$. $\mathbf{c} = \overrightarrow{OB} + \overrightarrow{BC} = \overrightarrow{OA} + \frac{2}{3}\overrightarrow{BA} \;\Rightarrow\; \overrightarrow{BA} = \frac{3}{2}\,\mathbf{c} - \frac{3}{2}\,\mathbf{b}$. $\overrightarrow{BA} = -\overrightarrow{AB}$, so $\frac{3}{2}\,\mathbf{c} - \frac{3}{2}\,\mathbf{b} = 3\,\mathbf{a} - 3\,\mathbf{c} \;\Leftrightarrow\; \mathbf{c} + 2\,\mathbf{c} = 2\,\mathbf{a} + \mathbf{b} \;\Leftrightarrow\; \mathbf{c} = \frac{2}{3}\,\mathbf{a} + \frac{1}{3}\,\mathbf{b}$.

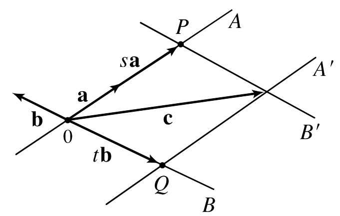
45. (a), (b)



(c) From the sketch, we estimate that $s \approx 1.3$ and $t \approx 1.6$.

(d) $\mathbf{c} = s\,\mathbf{a} + t\,\mathbf{b} \;\Leftrightarrow\; 7 = 3s + 2t$ and $1 = 2s - t$.
Solving these equations gives $s = \frac{9}{7}$ and $t = \frac{11}{7}$.

46. Draw $\mathbf{a}$, $\mathbf{b}$, and $\mathbf{c}$ emanating from the origin. Extend $\mathbf{a}$ and $\mathbf{b}$ to form lines A and B, and draw lines A' and B' parallel to these two lines through the terminal point of $\mathbf{c}$. Since $\mathbf{a}$ and $\mathbf{b}$ are not parallel, A and B' must meet (at P), and A' and B must also meet (at Q). Now we see that $\overrightarrow{OP} + \overrightarrow{OQ} = \mathbf{c}$, so if



$s = \dfrac{|\overrightarrow{OP}|}{|\mathbf{a}|}$ (or its negative, if $\mathbf{a}$ points in the direction opposite $\overrightarrow{OP}$) and $t = \dfrac{|\overrightarrow{OQ}|}{|\mathbf{b}|}$ (or its negative, as in the diagram), then $\mathbf{c} = s\mathbf{a} + t\mathbf{b}$, as required.

Argument using components: Since $\mathbf{a}$, $\mathbf{b}$, and $\mathbf{c}$ all lie in the same plane, we can consider them to be vectors in two dimensions. Let $\mathbf{a} = \langle a_1, a_2 \rangle$, $\mathbf{b} = \langle b_1, b_2 \rangle$, and $\mathbf{c} = \langle c_1, c_2 \rangle$. We need $sa_1 + tb_1 = c_1$ and $sa_2 + tb_2 = c_2$. Multiplying the first equation by a_2 and the second by a_1 and subtracting, we get $t = \dfrac{c_2 a_1 - c_1 a_2}{b_2 a_1 - b_1 a_2}$. Similarly $s = \dfrac{b_2 c_1 - b_1 c_2}{b_2 a_1 - b_1 a_2}$. Since $\mathbf{a} \neq \mathbf{0}$ and $\mathbf{b} \neq \mathbf{0}$ and $\mathbf{a}$ is not a scalar multiple of $\mathbf{b}$, the denominator is not zero.

47. $|\mathbf{r} - \mathbf{r}_0|$ is the distance between the points (x, y, z) and (x_0, y_0, z_0), so the set of points is a sphere with radius 1 and center (x_0, y_0, z_0).

Alternate method: $|\mathbf{r} - \mathbf{r}_0| = 1 \quad \Leftrightarrow \quad \sqrt{(x - x_0)^2 + (y - y_0)^2 + (z - z_0)^2} = 1 \quad \Leftrightarrow$ $(x - x_0)^2 + (y - y_0)^2 + (z - z_0)^2 = 1$, which is the equation of a sphere with radius 1 and center (x_0, y_0, z_0).

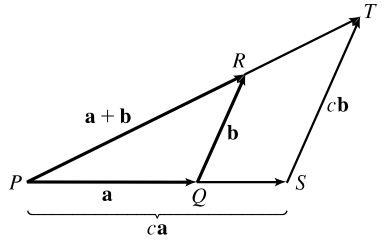
48. Let P_1 and P_2 be the points with position vectors $\mathbf{r}_1$ and $\mathbf{r}_2$ respectively. Then $|\mathbf{r} - \mathbf{r}_1| + |\mathbf{r} - \mathbf{r}_2|$ is the sum of the distances from (x, y) to P_1 and P_2. Since this sum is constant, the set of points (x, y) represents an ellipse with foci P_1 and P_2. The condition $k > |\mathbf{r}_1 - \mathbf{r}_2|$ assures us that the ellipse is not degenerate.

49.
$$\begin{aligned}\mathbf{a} + (\mathbf{b} + \mathbf{c}) &= \langle a_1, a_2 \rangle + (\langle b_1, b_2 \rangle + \langle c_1, c_2 \rangle) = \langle a_1, a_2 \rangle + \langle b_1 + c_1, b_2 + c_2 \rangle \\ &= \langle a_1 + b_1 + c_1, a_2 + b_2 + c_2 \rangle = \langle (a_1 + b_1) + c_1, (a_2 + b_2) + c_2 \rangle \\ &= \langle a_1 + b_1, a_2 + b_2 \rangle + \langle c_1, c_2 \rangle = (\langle a_1, a_2 \rangle + \langle b_1, b_2 \rangle) + \langle c_1, c_2 \rangle \\ &= (\mathbf{a} + \mathbf{b}) + \mathbf{c}\end{aligned}$$

50. *Algebraically:*
$$\begin{aligned}c(\mathbf{a} + \mathbf{b}) &= c\,(\langle a_1, a_2, a_3 \rangle + \langle b_1, b_2, b_3 \rangle) = c\,\langle a_1 + b_1, a_2 + b_2, a_3 + b_3 \rangle \\ &= \langle c\,(a_1 + b_1), c\,(a_2 + b_2), c\,(a_3 + b_3) \rangle = \langle ca_1 + cb_1, ca_2 + cb_2, ca_3 + cb_3 \rangle \\ &= \langle ca_1, ca_2, ca_3 \rangle + \langle cb_1, cb_2, cb_3 \rangle = c\,\mathbf{a} + c\,\mathbf{b}\end{aligned}$$

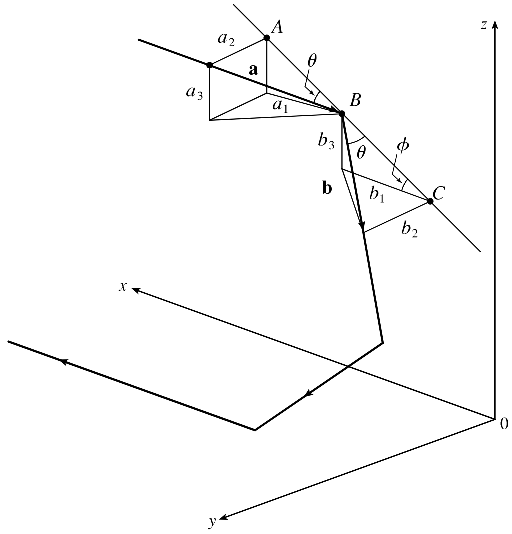
Geometrically:

According to the Triangle Law, if $\mathbf{a} = \overrightarrow{PQ}$ and $\mathbf{b} = \overrightarrow{QR}$, then $\mathbf{a} + \mathbf{b} = \overrightarrow{PR}$. Construct triangle PST as shown so that $\overrightarrow{PS} = c\,\mathbf{a}$ and $\overrightarrow{ST} = c\,\mathbf{b}$. (We have drawn the case where $c > 1$.) By the Triangle Law, $\overrightarrow{PT} = c\,\mathbf{a} + c\,\mathbf{b}$. But triangle PQR and triangle PST are similar triangles because $c\,\mathbf{b}$ is parallel to $\mathbf{b}$. Therefore, $\overrightarrow{PR}$ and $\overrightarrow{PT}$ are parallel and, in fact, $\overrightarrow{PT} = c\overrightarrow{PR}$. Thus, $c\,\mathbf{a} + c\,\mathbf{b} = c(\mathbf{a} + \mathbf{b})$.



51. Consider triangle ABC, where D and E are the midpoints of AB and BC. We know that $\overrightarrow{AB} + \overrightarrow{BC} = \overrightarrow{AC}$ **(1)** and $\overrightarrow{DB} + \overrightarrow{BE} = \overrightarrow{DE}$ **(2)**. However, $\overrightarrow{DB} = \frac{1}{2}\overrightarrow{AB}$, and $\overrightarrow{BE} = \frac{1}{2}\overrightarrow{BC}$. Substituting these expressions for $\overrightarrow{DB}$ and $\overrightarrow{BE}$ into **(2)** gives $\frac{1}{2}\overrightarrow{AB} + \frac{1}{2}\overrightarrow{BC} = \overrightarrow{DE}$. Comparing this with **(1)** gives $\overrightarrow{DE} = \frac{1}{2}\overrightarrow{AC}$. Therefore $\overrightarrow{AC}$ and $\overrightarrow{DE}$ are parallel and $\left|\overrightarrow{DE}\right| = \frac{1}{2}\left|\overrightarrow{AC}\right|$.

52. The question states that the light ray strikes all three mirrors, so it is not parallel to any of them and $a_1 \neq 0$, $a_2 \neq 0$ and $a_3 \neq 0$. Let $\mathbf{b} = \langle b_1, b_2, b_3 \rangle$, as in the diagram. We can let $|\mathbf{b}| = |\mathbf{a}|$, since only its direction is important. Then $\dfrac{|b_2|}{|\mathbf{b}|} = \sin\theta = \dfrac{|a_2|}{|\mathbf{a}|} \quad \Rightarrow \quad |b_2| = |a_2|$.



From the diagram $b_2\,\mathbf{j}$ and $a_2\,\mathbf{j}$ point in opposite directions, so $b_2 = -a_2$. $|AB| = |BC|$, so $|b_3| = \sin\phi\,|BC| = \sin\phi\,|AB| = |a_3|$, and $|b_1| = \cos\phi\,|BC| = \cos\phi\,|AB| = |a_1|$. $b_3\,\mathbf{k}$ and $a_3\,\mathbf{k}$ have the same direction, as do $b_1\,\mathbf{i}$ and $a_1\,\mathbf{i}$, so $\mathbf{b} = \langle a_1, -a_2, a_3 \rangle$. When the ray hits the other mirrors, similar arguments show that these reflections will reverse the signs of the other two coordinates, so the final reflected ray will be $\langle -a_1, -a_2, -a_3 \rangle = -\mathbf{a}$, which is parallel to $\mathbf{a}$.

12.3 The Dot Product

1. (a) $\mathbf{a} \cdot \mathbf{b}$ is a scalar, and the dot product is defined only for vectors, so $(\mathbf{a} \cdot \mathbf{b}) \cdot \mathbf{c}$ has no meaning.

(b) $(\mathbf{a} \cdot \mathbf{b})\,\mathbf{c}$ is a scalar multiple of a vector, so it does have meaning.

(c) Both $|\mathbf{a}|$ and $\mathbf{b} \cdot \mathbf{c}$ are scalars, so $|\mathbf{a}|\,(\mathbf{b} \cdot \mathbf{c})$ is an ordinary product of real numbers, and has meaning.

(d) Both $\mathbf{a}$ and $\mathbf{b} + \mathbf{c}$ are vectors, so the dot product $\mathbf{a} \cdot (\mathbf{b} + \mathbf{c})$ has meaning.

(e) $\mathbf{a} \cdot \mathbf{b}$ is a scalar, but $\mathbf{c}$ is a vector, and so the two quantities cannot be added and $\mathbf{a} \cdot \mathbf{b} + \mathbf{c}$ has no meaning.

(f) $|\mathbf{a}|$ is a scalar, and the dot product is defined only for vectors, so $|\mathbf{a}| \cdot (\mathbf{b} + \mathbf{c})$ has no meaning.

2. $\mathbf{a} \cdot \mathbf{b} = \langle 5, -2 \rangle \cdot \langle 3, 4 \rangle = (5)(3) + (-2)(4) = 15 - 8 = 7$

3. $\mathbf{a} \cdot \mathbf{b} = \langle 1.5, 0.4 \rangle \cdot \langle -4, 6 \rangle = (1.5)(-4) + (0.4)(6) = -6 + 2.4 = -3.6$

4. $\mathbf{a} \cdot \mathbf{b} = \langle 6, -2, 3 \rangle \cdot \langle 2, 5, -1 \rangle = (6)(2) + (-2)\,(5) + (3)(-1) = 12 - 10 - 3 = -1$

5. $\mathbf{a} \cdot \mathbf{b} = \left\langle 4, 1, \frac{1}{4} \right\rangle \cdot \langle 6, -3, -8 \rangle = (4)(6) + (1)(-3) + \left(\frac{1}{4}\right)(-8) = 19$

6. $\mathbf{a} \cdot \mathbf{b} = \langle p, -p, 2p \rangle \cdot \langle 2q, q, -q \rangle = (p)(2q) + (-p)(q) + (2p)(-q) = 2pq - pq - 2pq = -pq$

7. $\mathbf{a}\cdot\mathbf{b} = (2\,\mathbf{i}+\mathbf{j})\cdot(\mathbf{i}-\mathbf{j}+\mathbf{k}) = (2)(1)+(1)(-1)+(0)(1) = 1$

8. $\mathbf{a}\cdot\mathbf{b} = (3\,\mathbf{i}+2\,\mathbf{j}-\mathbf{k})\cdot(4\,\mathbf{i}+5\,\mathbf{k}) = (3)(4)+(2)(0)+(-1)(5) = 7$

9. By Theorem 3, $\mathbf{a}\cdot\mathbf{b} = |\mathbf{a}|\,|\mathbf{b}|\cos\theta = (7)(4)\cos 30^\circ = 28\left(\frac{\sqrt{3}}{2}\right) = 14\sqrt{3} \approx 24.25$.

10. By Theorem 3, $\mathbf{a}\cdot\mathbf{b} = |\mathbf{a}|\,|\mathbf{b}|\cos\theta = (80)(50)\cos\frac{3\pi}{4} = 4000\left(-\frac{\sqrt{2}}{2}\right) = -2000\sqrt{2} \approx -2828.43$.

11. $\mathbf{u}$, $\mathbf{v}$, and $\mathbf{w}$ are all unit vectors, so the triangle is an equilateral triangle. Thus the angle between $\mathbf{u}$ and $\mathbf{v}$ is 60° and $\mathbf{u}\cdot\mathbf{v} = |\mathbf{u}|\,|\mathbf{v}|\cos 60^\circ = (1)(1)\left(\frac{1}{2}\right) = \frac{1}{2}$. If $\mathbf{w}$ is moved so it has the same initial point as $\mathbf{u}$, we can see that the angle between them is 120° and we have $\mathbf{u}\cdot\mathbf{w} = |\mathbf{u}|\,|\mathbf{w}|\cos 120^\circ = (1)(1)\left(-\frac{1}{2}\right) = -\frac{1}{2}$.

12. $\mathbf{u}$ is a unit vector, so $\mathbf{w}$ is also a unit vector, and $|\mathbf{v}|$ can be determined by examining the right triangle formed by $\mathbf{u}$ and $\mathbf{v}$. Since the angle between $\mathbf{u}$ and $\mathbf{v}$ is 45°, we have $|\mathbf{v}| = |\mathbf{u}|\cos 45^\circ = \frac{\sqrt{2}}{2}$. Then $\mathbf{u}\cdot\mathbf{v} = |\mathbf{u}|\,|\mathbf{v}|\cos 45^\circ = (1)\left(\frac{\sqrt{2}}{2}\right)\frac{\sqrt{2}}{2} = \frac{1}{2}$. Since $\mathbf{u}$ and $\mathbf{w}$ are orthogonal, $\mathbf{u}\cdot\mathbf{w} = 0$.

13. (a) $\mathbf{i}\cdot\mathbf{j} = \langle 1,0,0\rangle\cdot\langle 0,1,0\rangle = (1)(0)+(0)(1)+(0)(0) = 0$. Similarly, $\mathbf{j}\cdot\mathbf{k} = (0)(0)+(1)(0)+(0)(1) = 0$ and $\mathbf{k}\cdot\mathbf{i} = (0)(1)+(0)(0)+(1)(0) = 0$.

Another method: Because $\mathbf{i}$, $\mathbf{j}$, and $\mathbf{k}$ are mutually perpendicular, the cosine factor in each dot product (see Theorem 3) is $\cos\frac{\pi}{2} = 0$.

(b) By Property 1 of the dot product, $\mathbf{i}\cdot\mathbf{i} = |\mathbf{i}|^2 = 1^2 = 1$ since $\mathbf{i}$ is a unit vector. Similarly, $\mathbf{j}\cdot\mathbf{j} = |\mathbf{j}|^2 = 1$ and $\mathbf{k}\cdot\mathbf{k} = |\mathbf{k}|^2 = 1$.

14. The dot product $\mathbf{A}\cdot\mathbf{P}$ is

$$\begin{aligned}\langle a,b,c\rangle\cdot\langle 4,2.5,1\rangle &= a(4)+b(2.5)+c(1)\\ &= \text{(number of hamburgers sold)(price per hamburger)}\\ &\quad + \text{(number of hot dogs sold)(price per hot dog)}\\ &\quad + \text{(number of soft drinks sold)(price per soft drink)}\end{aligned}$$

so it is equal to the vendor's total revenue for that day.

15. $|\mathbf{a}| = \sqrt{4^2+3^2} = 5$, $|\mathbf{b}| = \sqrt{2^2+(-1)^2} = \sqrt{5}$, and $\mathbf{a}\cdot\mathbf{b} = (4)(2)+(3)(-1) = 5$. From Corollary 6, we have $\cos\theta = \dfrac{\mathbf{a}\cdot\mathbf{b}}{|\mathbf{a}|\,|\mathbf{b}|} = \dfrac{5}{5\cdot\sqrt{5}} = \dfrac{1}{\sqrt{5}}$. So the angle between $\mathbf{a}$ and $\mathbf{b}$ is $\theta = \cos^{-1}\left(\dfrac{1}{\sqrt{5}}\right) \approx 63^\circ$.

16. $|\mathbf{a}| = \sqrt{(-2)^2+5^2} = \sqrt{29}$, $|\mathbf{b}| = \sqrt{5^2+12^2} = 13$, and $\mathbf{a}\cdot\mathbf{b} = (-2)(5)+(5)(12) = 50$. Using Corollary 6, we have $\cos\theta = \dfrac{\mathbf{a}\cdot\mathbf{b}}{|\mathbf{a}|\,|\mathbf{b}|} = \dfrac{50}{\sqrt{29}\cdot 13} = \dfrac{50}{13\sqrt{29}}$ and the angle between $\mathbf{a}$ and $\mathbf{b}$ is $\theta = \cos^{-1}\left(\dfrac{50}{13\sqrt{29}}\right) \approx 44^\circ$.

17. $|\mathbf{a}| = \sqrt{1^2+(-4)^2+1^2} = \sqrt{18} = 3\sqrt{2}$, $|\mathbf{b}| = \sqrt{0^2+2^2+(-2)^2} = \sqrt{8} = 2\sqrt{2}$, and $\mathbf{a}\cdot\mathbf{b} = (1)(0)+(-4)(2)+(1)(-2) = -10$. From Corollary 6, we have $\cos\theta = \dfrac{\mathbf{a}\cdot\mathbf{b}}{|\mathbf{a}|\,|\mathbf{b}|} = \dfrac{-10}{3\sqrt{2}\cdot 2\sqrt{2}} = -\dfrac{10}{12} = -\dfrac{5}{6}$ and the angle between $\mathbf{a}$ and $\mathbf{b}$ is $\theta = \cos^{-1}\left(-\frac{5}{6}\right) \approx 146^\circ$.

18. $|\mathbf{a}| = \sqrt{(-1)^2 + 3^2 + 4^2} = \sqrt{26}$, $|\mathbf{b}| = \sqrt{5^2 + 2^2 + 1^2} = \sqrt{30}$, and $\mathbf{a} \cdot \mathbf{b} = (-1)(5) + (3)(2) + (4)(1) = 5$.

Then $\cos\theta = \dfrac{\mathbf{a} \cdot \mathbf{b}}{|\mathbf{a}|\,|\mathbf{b}|} = \dfrac{5}{\sqrt{26} \cdot \sqrt{30}} = \dfrac{5}{\sqrt{780}} = \dfrac{5}{2\sqrt{195}}$ and $\theta = \cos^{-1}\left(\dfrac{5}{2\sqrt{195}}\right) \approx 80^\circ$.

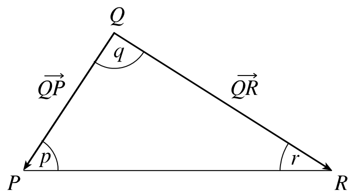
19. $|\mathbf{a}| = \sqrt{4^2 + (-3)^2 + 1^2} = \sqrt{26}$, $|\mathbf{b}| = \sqrt{2^2 + 0^2 + (-1)^2} = \sqrt{5}$, and $\mathbf{a} \cdot \mathbf{b} = (4)(2) + (-3)(0) + (1)(-1) = 7$.

Then $\cos\theta = \dfrac{\mathbf{a} \cdot \mathbf{b}}{|\mathbf{a}|\,|\mathbf{b}|} = \dfrac{7}{\sqrt{26} \cdot \sqrt{5}} = \dfrac{7}{\sqrt{130}}$ and $\theta = \cos^{-1}\left(\dfrac{7}{\sqrt{130}}\right) \approx 52^\circ$.

20. $|\mathbf{a}| = \sqrt{8^2 + (-1)^2 + 4^2} = \sqrt{81} = 9$, $|\mathbf{b}| = \sqrt{0^2 + 4^2 + 2^2} = \sqrt{20} = 2\sqrt{5}$, and $\mathbf{a} \cdot \mathbf{b} = (8)(0) + (-1)(4) + (4)(2) = 4$.

Then $\cos\theta = \dfrac{\mathbf{a} \cdot \mathbf{b}}{|\mathbf{a}|\,|\mathbf{b}|} = \dfrac{4}{9 \cdot 2\sqrt{5}} = \dfrac{2}{9\sqrt{5}}$ and $\theta = \cos^{-1}\left(\dfrac{2}{9\sqrt{5}}\right) \approx 84^\circ$.

21. Let p, q, and r be the angles at vertices P, Q, and R respectively. Then p is the angle between vectors $\overrightarrow{PQ}$ and $\overrightarrow{PR}$, q is the angle between vectors $\overrightarrow{QP}$ and $\overrightarrow{QR}$, and r is the angle between vectors $\overrightarrow{RP}$ and $\overrightarrow{RQ}$.



Thus $\cos p = \dfrac{\overrightarrow{PQ} \cdot \overrightarrow{PR}}{\left|\overrightarrow{PQ}\right|\,\left|\overrightarrow{PR}\right|} = \dfrac{\langle -2, 3\rangle \cdot \langle 1, 4\rangle}{\sqrt{(-2)^2 + 3^2}\,\sqrt{1^2 + 4^2}} = \dfrac{-2 + 12}{\sqrt{13}\,\sqrt{17}} = \dfrac{10}{\sqrt{221}}$ and $p = \cos^{-1}\left(\dfrac{10}{\sqrt{221}}\right) \approx 48^\circ$. Similarly,

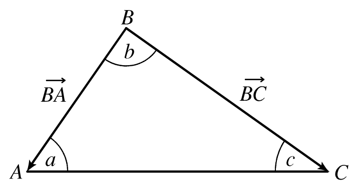
$\cos q = \dfrac{\overrightarrow{QP} \cdot \overrightarrow{QR}}{\left|\overrightarrow{QP}\right|\,\left|\overrightarrow{QR}\right|} = \dfrac{\langle 2, -3\rangle \cdot \langle 3, 1\rangle}{\sqrt{4 + 9}\,\sqrt{9 + 1}} = \dfrac{6 - 3}{\sqrt{13}\,\sqrt{10}} = \dfrac{3}{\sqrt{130}}$ so $q = \cos^{-1}\left(\dfrac{3}{\sqrt{130}}\right) \approx 75^\circ$ and

$r \approx 180^\circ - (48^\circ + 75^\circ) = 57^\circ$.

Alternate solution: Apply the Law of Cosines three times as follows: $\cos p = \dfrac{\left|\overrightarrow{QR}\right|^2 - \left|\overrightarrow{PQ}\right|^2 - \left|\overrightarrow{PR}\right|^2}{2\left|\overrightarrow{PQ}\right|\,\left|\overrightarrow{PR}\right|}$,

$\cos q = \dfrac{\left|\overrightarrow{PR}\right|^2 - \left|\overrightarrow{PQ}\right|^2 - \left|\overrightarrow{QR}\right|^2}{2\left|\overrightarrow{PQ}\right|\,\left|\overrightarrow{QR}\right|}$, and $\cos r = \dfrac{\left|\overrightarrow{PQ}\right|^2 - \left|\overrightarrow{PR}\right|^2 - \left|\overrightarrow{QR}\right|^2}{2\left|\overrightarrow{PR}\right|\,\left|\overrightarrow{QR}\right|}$.

22. Let a, b, and c be the angles at vertices A, B, and C. Then a is the angle between vectors $\overrightarrow{AB}$ and $\overrightarrow{AC}$, b is the angle between vectors $\overrightarrow{BA}$ and $\overrightarrow{BC}$, and c is the angle between vectors $\overrightarrow{CA}$ and $\overrightarrow{CB}$.



Thus $\cos a = \dfrac{\overrightarrow{AB} \cdot \overrightarrow{AC}}{\left|\overrightarrow{AB}\right|\,\left|\overrightarrow{AC}\right|} = \dfrac{\langle 2, -2, 1\rangle \cdot \langle 0, 3, 4\rangle}{\sqrt{2^2 + (-2)^2 + 1^2}\,\sqrt{0^2 + 3^2 + 4^2}} = \dfrac{0 - 6 + 4}{3 \cdot 5} = -\dfrac{2}{15}$ and $a = \cos^{-1}\left(-\frac{2}{15}\right) \approx 98^\circ$.

Similarly, $\cos b = \dfrac{\overrightarrow{BA} \cdot \overrightarrow{BC}}{\left|\overrightarrow{BA}\right|\,\left|\overrightarrow{BC}\right|} = \dfrac{\langle -2, 2, -1\rangle \cdot \langle -2, 5, 3\rangle}{\sqrt{4 + 4 + 1}\,\sqrt{4 + 25 + 9}} = \dfrac{4 + 10 - 3}{3 \cdot \sqrt{38}} = \dfrac{11}{3\sqrt{38}}$ so $b = \cos^{-1}\left(\dfrac{11}{3\sqrt{38}}\right) \approx 54^\circ$ and

$c \approx 180^\circ - (98^\circ + 54^\circ) = 28^\circ$.

[continued]

Alternate solution: Apply the Law of Cosines three times as follows:

$$\cos a = \frac{\left|\overrightarrow{BC}\right|^2 - \left|\overrightarrow{AB}\right|^2 - \left|\overrightarrow{AC}\right|^2}{2\left|\overrightarrow{AB}\right|\left|\overrightarrow{AC}\right|} \qquad \cos b = \frac{\left|\overrightarrow{AC}\right|^2 - \left|\overrightarrow{AB}\right|^2 - \left|\overrightarrow{BC}\right|^2}{2\left|\overrightarrow{AB}\right|\left|\overrightarrow{BC}\right|} \qquad \cos c = \frac{\left|\overrightarrow{AB}\right|^2 - \left|\overrightarrow{AC}\right|^2 - \left|\overrightarrow{BC}\right|^2}{2\left|\overrightarrow{AC}\right|\left|\overrightarrow{BC}\right|}$$

23. (a) $\mathbf{a}\cdot\mathbf{b} = (9)(-2) + (3)(6) = 0$, so $\mathbf{a}$ and $\mathbf{b}$ are orthogonal (and not parallel).

(b) $\mathbf{a}\cdot\mathbf{b} = (4)(3) + (5)(-1) + (-2)(5) = -3 \neq 0$, so $\mathbf{a}$ and $\mathbf{b}$ are not orthogonal. Also, since $\mathbf{a}$ is not a scalar multiple of $\mathbf{b}$, $\mathbf{a}$ and $\mathbf{b}$ are not parallel.

(c) $\mathbf{a}\cdot\mathbf{b} = (-8)(6) + (12)(-9) + (4)(-3) = -168 \neq 0$, so $\mathbf{a}$ and $\mathbf{b}$ are not orthogonal. Because $\mathbf{a} = -\frac{4}{3}\,\mathbf{b}$, $\mathbf{a}$ and $\mathbf{b}$ are parallel.

(d) $\mathbf{a}\cdot\mathbf{b} = (3)(5) + (-1)(9) + (3)(-2) = 0$, so $\mathbf{a}$ and $\mathbf{b}$ are orthogonal (and not parallel).

24. (a) $\mathbf{u}\cdot\mathbf{v} = (-5)(3) + (4)(4) + (-2)(-1) = 3 \neq 0$, so $\mathbf{u}$ and $\mathbf{v}$ are not orthogonal. Also, $\mathbf{u}$ is not a scalar multiple of $\mathbf{v}$, so $\mathbf{u}$ and $\mathbf{v}$ are not parallel.

(b) $\mathbf{u}\cdot\mathbf{v} = (9)(-6) + (-6)(4) + (3)(-2) = -84 \neq 0$, so $\mathbf{u}$ and $\mathbf{v}$ are not orthogonal. Because $\mathbf{u} = -\frac{3}{2}\,\mathbf{v}$, $\mathbf{u}$ and $\mathbf{v}$ are parallel.

(c) $\mathbf{u}\cdot\mathbf{v} = (c)(c) + (c)(0) + (c)(-c) = c^2 + 0 - c^2 = 0$, so $\mathbf{u}$ and $\mathbf{v}$ are orthogonal (and not parallel). (Note that if $c = 0$ then $\mathbf{u} = \mathbf{v} = \mathbf{0}$, and the zero vector is considered orthogonal to all vectors. Although in this case $\mathbf{u}$ and $\mathbf{v}$ are identical, they are not considered parallel, as only nonzero vectors can be parallel.)

25. $\overrightarrow{QP} = \langle -1, -3, 2\rangle$, $\overrightarrow{QR} = \langle 4, -2, -1\rangle$, and $\overrightarrow{QP}\cdot\overrightarrow{QR} = -4 + 6 - 2 = 0$. Thus $\overrightarrow{QP}$ and $\overrightarrow{QR}$ are orthogonal, so the angle of the triangle at vertex Q is a right angle.

26. By Theorem 3, vectors $\langle 2, 1, -1\rangle$ and $\langle 1, x, 0\rangle$ meet at an angle of 45° when $\langle 2, 1, -1\rangle\cdot\langle 1, x, 0\rangle = \sqrt{4+1+1}\,\sqrt{1+x^2+0}\,\cos 45^\circ$ or $2 + x - 0 = \sqrt{6}\,\sqrt{1+x^2}\cdot\frac{\sqrt{2}}{2} \iff 2 + x = \sqrt{3}\sqrt{1+x^2}$. Squaring both sides gives $4 + 4x + x^2 = 3 + 3x^2 \iff 2x^2 - 4x - 1 = 0$. By the quadratic formula,

$$x = \frac{-(-4) \pm \sqrt{(-4)^2 - 4(2)(-1)}}{2(2)} = \frac{4 \pm \sqrt{24}}{4} = \frac{4 \pm 2\sqrt{6}}{4} = 1 \pm \frac{\sqrt{6}}{2}.$$ (You can verify that both values are valid.)

27. Let $\mathbf{a} = a_1\,\mathbf{i} + a_2\,\mathbf{j} + a_3\,\mathbf{k}$ be a vector orthogonal to both $\mathbf{i}+\mathbf{j}$ and $\mathbf{i}+\mathbf{k}$. Then $\mathbf{a}\cdot(\mathbf{i}+\mathbf{j}) = 0 \iff a_1 + a_2 = 0$ and $\mathbf{a}\cdot(\mathbf{i}+\mathbf{k}) = 0 \iff a_1 + a_3 = 0$, so $a_1 = -a_2 = -a_3$. Furthermore $\mathbf{a}$ is to be a unit vector, so $1 = a_1^2 + a_2^2 + a_3^2 = 3a_1^2$ implies $a_1 = \pm\frac{1}{\sqrt{3}}$. Thus $\mathbf{a} = \frac{1}{\sqrt{3}}\,\mathbf{i} - \frac{1}{\sqrt{3}}\,\mathbf{j} - \frac{1}{\sqrt{3}}\,\mathbf{k}$ and $\mathbf{a} = -\frac{1}{\sqrt{3}}\,\mathbf{i} + \frac{1}{\sqrt{3}}\,\mathbf{j} + \frac{1}{\sqrt{3}}\,\mathbf{k}$ are two such unit vectors.

28. Let $\mathbf{u} = \langle a, b\rangle$ be a unit vector. By Theorem 3 we need $\mathbf{u}\cdot\mathbf{v} = |\mathbf{u}|\;|\mathbf{v}|\cos 60^\circ \iff 3a + 4b = (1)(5)\frac{1}{2} \iff b = \frac{5}{8} - \frac{3}{4}a$. Since $\mathbf{u}$ is a unit vector, $|\mathbf{u}| = \sqrt{a^2+b^2} = 1 \iff a^2 + b^2 = 1 \iff a^2 + \left(\frac{5}{8} - \frac{3}{4}a\right)^2 = 1 \iff \frac{25}{16}a^2 - \frac{15}{16}a + \frac{25}{64} = 1 \iff 100a^2 - 60a - 39 = 0$. By the quadratic formula,

$$a = \frac{-(-60) \pm \sqrt{(-60)^2 - 4(100)(-39)}}{2(100)} = \frac{60 \pm \sqrt{19{,}200}}{200} = \frac{3 \pm 4\sqrt{3}}{10}.$$ If $a = \frac{3 + 4\sqrt{3}}{10}$ then

$b = \frac{5}{8} - \frac{3}{4}\left(\frac{3+4\sqrt{3}}{10}\right) = \frac{4-3\sqrt{3}}{10}$, and if $a = \frac{3-4\sqrt{3}}{10}$ then $b = \frac{5}{8} - \frac{3}{4}\left(\frac{3-4\sqrt{3}}{10}\right) = \frac{4+3\sqrt{3}}{10}$. Thus the two unit vectors are $\left\langle \frac{3+4\sqrt{3}}{10}, \frac{4-3\sqrt{3}}{10} \right\rangle \approx \langle 0.9928, -0.1196 \rangle$ and $\left\langle \frac{3-4\sqrt{3}}{10}, \frac{4+3\sqrt{3}}{10} \right\rangle \approx \langle -0.3928, 0.9196 \rangle$.

29. The line $2x - y = 3 \quad \Leftrightarrow \quad y = 2x - 3$ has slope 2, so a vector parallel to the line is $\mathbf{a} = \langle 1, 2 \rangle$. The line $3x + y = 7 \quad \Leftrightarrow$ $y = -3x + 7$ has slope -3, so a vector parallel to the line is $\mathbf{b} = \langle 1, -3 \rangle$. The angle between the lines is the same as the angle θ between the vectors. Here we have $\mathbf{a} \cdot \mathbf{b} = (1)(1) + (2)(-3) = -5$, $|\mathbf{a}| = \sqrt{1^2 + 2^2} = \sqrt{5}$, and $|\mathbf{b}| = \sqrt{1^2 + (-3)^2} = \sqrt{10}$, so $\cos\theta = \frac{\mathbf{a} \cdot \mathbf{b}}{|\mathbf{a}|\,|\mathbf{b}|} = \frac{-5}{\sqrt{5} \cdot \sqrt{10}} = \frac{-5}{5\sqrt{2}} = -\frac{1}{\sqrt{2}}$ or $-\frac{\sqrt{2}}{2}$. Thus $\theta = 135^\circ$, and the acute angle between the lines is $180^\circ - 135^\circ = 45^\circ$.

30. The line $x + 2y = 7 \quad \Leftrightarrow \quad y = -\frac{1}{2}x + \frac{7}{2}$ has slope $-\frac{1}{2}$, so a vector parallel to the line is $\mathbf{a} = \langle 2, -1 \rangle$. The line $5x - y = 2 \quad \Leftrightarrow \quad y = 5x - 2$ has slope 5, so a vector parallel to the line is $\mathbf{b} = \langle 1, 5 \rangle$. The lines meet at the same angle θ that the vectors meet at. Here we have $\mathbf{a} \cdot \mathbf{b} = (2)(1) + (-1)(5) = -3$, $|\mathbf{a}| = \sqrt{2^2 + (-1)^2} = \sqrt{5}$, and $|\mathbf{b}| = \sqrt{1^2 + 5^2} = \sqrt{26}$, so $\cos\theta = \frac{\mathbf{a} \cdot \mathbf{b}}{|\mathbf{a}|\,|\mathbf{b}|} = \frac{-3}{\sqrt{5} \cdot \sqrt{26}} = \frac{-3}{\sqrt{130}}$ and $\theta = \cos^{-1}\left(\frac{-3}{\sqrt{130}}\right) \approx 105.3^\circ$. The acute angle between the lines is approximately $180^\circ - 105.3^\circ = 74.7^\circ$.

31. The curves $y = x^2$ and $y = x^3$ meet when $x^2 = x^3 \quad \Leftrightarrow \quad x^3 - x^2 = 0 \quad \Leftrightarrow \quad x^2(x - 1) = 0 \quad \Leftrightarrow \quad x = 0, x = 1$. We have $\frac{d}{dx}x^2 = 2x$ and $\frac{d}{dx}x^3 = 3x^2$, so the tangent lines of both curves have slope 0 at $x = 0$. Thus the angle between the curves is 0° at the point $(0, 0)$. For $x = 1$, $\frac{d}{dx}\left.x^2\right|_{x=1} = 2$ and $\frac{d}{dx}\left.x^3\right|_{x=1} = 3$ so the tangent lines at the point $(1, 1)$ have slopes 2 and 3. Vectors parallel to the tangent lines are $\langle 1, 2 \rangle$ and $\langle 1, 3 \rangle$, and the angle θ between them is given by

$$\cos\theta = \frac{\langle 1, 2 \rangle \cdot \langle 1, 3 \rangle}{|\langle 1, 2 \rangle|\,|\langle 1, 3 \rangle|} = \frac{1 + 6}{\sqrt{5}\sqrt{10}} = \frac{7}{5\sqrt{2}}$$

Thus $\theta = \cos^{-1}\left(\frac{7}{5\sqrt{2}}\right) \approx 8.1^\circ$.

32. The curves $y = \sin x$ and $y = \cos x$ meet when $\sin x = \cos x \quad \Leftrightarrow \quad \tan x = 1 \quad \Leftrightarrow \quad x = \pi/4 \;\; [0 \le x \le \pi/2]$. Thus the point of intersection is $\left(\pi/4, \sqrt{2}/2\right)$. We have $\frac{d}{dx}\left.\sin x\right|_{x=\pi/4} = \left.\cos x\right|_{x=\pi/4} = \frac{\sqrt{2}}{2}$ and $\frac{d}{dx}\left.\cos x\right|_{x=\pi/4} = \left.-\sin x\right|_{x=\pi/4} = -\frac{\sqrt{2}}{2}$, so the tangent lines at that point have slopes $\frac{\sqrt{2}}{2}$ and $-\frac{\sqrt{2}}{2}$. Vectors parallel to the tangent lines are $\left\langle 1, \frac{\sqrt{2}}{2} \right\rangle$ and $\left\langle 1, -\frac{\sqrt{2}}{2} \right\rangle$, and the angle θ between them is given by

$$\cos\theta = \frac{\langle 1, \sqrt{2}/2 \rangle \cdot \langle 1, -\sqrt{2}/2 \rangle}{|\langle 1, \sqrt{2}/2 \rangle|\,|\langle 1, -\sqrt{2}/2 \rangle|} = \frac{1 - \frac{1}{2}}{\sqrt{\frac{3}{2}}\sqrt{\frac{3}{2}}} = \frac{1/2}{3/2} = \frac{1}{3}$$

Thus $\theta = \cos^{-1}\left(\frac{1}{3}\right) \approx 70.5^\circ$.

33. Since $|\langle 2,1,2\rangle| = \sqrt{4+1+4} = \sqrt{9} = 3$, using Equations 8 and 9 we have $\cos\alpha = \frac{2}{3}$, $\cos\beta = \frac{1}{3}$, and $\cos\gamma = \frac{2}{3}$. The direction angles are given by $\alpha = \cos^{-1}\left(\frac{2}{3}\right) \approx 48^\circ$, $\beta = \cos^{-1}\left(\frac{1}{3}\right) \approx 71^\circ$, and $\gamma = \cos^{-1}\left(\frac{2}{3}\right) = 48^\circ$.

34. Since $|\langle 6,3,-2\rangle| = \sqrt{36+9+4} = \sqrt{49} = 7$, using Equations 8 and 9 we have $\cos\alpha = \frac{6}{7}$, $\cos\beta = \frac{3}{7}$, and $\cos\gamma = \frac{-2}{7}$. The direction angles are given by $\alpha = \cos^{-1}\left(\frac{6}{7}\right) \approx 31^\circ$, $\beta = \cos^{-1}\left(\frac{3}{7}\right) \approx 65^\circ$, and $\gamma = \cos^{-1}\left(-\frac{2}{7}\right) = 107^\circ$.

35. Since $|\mathbf{i} - 2\mathbf{j} - 3\mathbf{k}| = \sqrt{1+4+9} = \sqrt{14}$, Equations 8 and 9 give $\cos\alpha = \frac{1}{\sqrt{14}}$, $\cos\beta = \frac{-2}{\sqrt{14}}$, and $\cos\gamma = \frac{-3}{\sqrt{14}}$, while $\alpha = \cos^{-1}\left(\frac{1}{\sqrt{14}}\right) \approx 74^\circ$, $\beta = \cos^{-1}\left(-\frac{2}{\sqrt{14}}\right) \approx 122^\circ$, and $\gamma = \cos^{-1}\left(-\frac{3}{\sqrt{14}}\right) \approx 143^\circ$.

36. Since $\left|\frac{1}{2}\mathbf{i} + \mathbf{j} + \mathbf{k}\right| = \sqrt{\frac{1}{4}+1+1} = \sqrt{\frac{9}{4}} = \frac{3}{2}$, Equations 8 and 9 give $\cos\alpha = \frac{1/2}{3/2} = \frac{1}{3}$, $\cos\beta = \cos\gamma = \frac{1}{3/2} = \frac{2}{3}$, while $\alpha = \cos^{-1}\left(\frac{1}{3}\right) \approx 71^\circ$ and $\beta = \gamma = \cos^{-1}\left(\frac{2}{3}\right) \approx 48^\circ$.

37. $|\langle c,c,c\rangle| = \sqrt{c^2+c^2+c^2} = \sqrt{3}c$ [since $c > 0$], so $\cos\alpha = \cos\beta = \cos\gamma = \dfrac{c}{\sqrt{3}c} = \dfrac{1}{\sqrt{3}}$ and

$\alpha = \beta = \gamma = \cos^{-1}\left(\frac{1}{\sqrt{3}}\right) \approx 55^\circ$.

38. Since $\cos^2\alpha + \cos^2\beta + \cos^2\gamma = 1$, $\cos^2\gamma = 1 - \cos^2\alpha - \cos^2\beta = 1 - \cos^2\left(\frac{\pi}{4}\right) - \cos^2\left(\frac{\pi}{3}\right) = 1 - \left(\frac{\sqrt{2}}{2}\right)^2 - \left(\frac{1}{2}\right)^2 = \frac{1}{4}$. Thus $\cos\gamma = \pm\frac{1}{2}$ and $\gamma = \frac{\pi}{3}$ or $\gamma = \frac{2\pi}{3}$.

39. $|\mathbf{a}| = \sqrt{(-5)^2 + 12^2} = \sqrt{169} = 13$. The scalar projection of $\mathbf{b}$ onto $\mathbf{a}$ is $\text{comp}_{\mathbf{a}}\,\mathbf{b} = \dfrac{\mathbf{a}\cdot\mathbf{b}}{|\mathbf{a}|} = \dfrac{-5\cdot 4 + 12\cdot 6}{13} = 4$ and the vector projection of $\mathbf{b}$ onto $\mathbf{a}$ is $\text{proj}_{\mathbf{a}}\,\mathbf{b} = \left(\dfrac{\mathbf{a}\cdot\mathbf{b}}{|\mathbf{a}|}\right)\dfrac{\mathbf{a}}{|\mathbf{a}|} = 4\cdot\frac{1}{13}\langle -5,12\rangle = \left\langle -\frac{20}{13}, \frac{48}{13}\right\rangle$.

40. $|\mathbf{a}| = \sqrt{1^2 + 4^2} = \sqrt{17}$. The scalar projection of $\mathbf{b}$ onto $\mathbf{a}$ is $\text{comp}_{\mathbf{a}}\,\mathbf{b} = \dfrac{\mathbf{a}\cdot\mathbf{b}}{|\mathbf{a}|} = \dfrac{1\cdot 2 + 4\cdot 3}{\sqrt{17}} = \dfrac{14}{\sqrt{17}}$ and the vector projection of $\mathbf{b}$ onto $\mathbf{a}$ is $\text{proj}_{\mathbf{a}}\,\mathbf{b} = \left(\dfrac{\mathbf{a}\cdot\mathbf{b}}{|\mathbf{a}|}\right)\dfrac{\mathbf{a}}{|\mathbf{a}|} = \frac{14}{\sqrt{17}}\cdot\frac{1}{\sqrt{17}}\langle 1,4\rangle = \left\langle \frac{14}{17}, \frac{56}{17}\right\rangle$.

41. $|\mathbf{a}| = \sqrt{4^2 + 7^2 + (-4)^2} = \sqrt{81} = 9$ so the scalar projection of $\mathbf{b}$ onto $\mathbf{a}$ is

$\text{comp}_{\mathbf{a}}\mathbf{b} = \dfrac{\mathbf{a}\cdot\mathbf{b}}{|\mathbf{a}|} = \dfrac{(4)(3) + (7)(-1) + (-4)(1)}{9} = \dfrac{1}{9}$. The vector projection of $\mathbf{b}$ onto $\mathbf{a}$ is

$\text{proj}_{\mathbf{a}}\mathbf{b} = \left(\dfrac{\mathbf{a}\cdot\mathbf{b}}{|\mathbf{a}|}\right)\dfrac{\mathbf{a}}{|\mathbf{a}|} = \frac{1}{9}\cdot\frac{1}{9}\langle 4,7,-4\rangle = \frac{1}{81}\langle 4,7,-4\rangle = \left\langle \frac{4}{81}, \frac{7}{81}, -\frac{4}{81}\right\rangle$.

42. $|\mathbf{a}| = \sqrt{1+16+64} = \sqrt{81} = 9$ so the scalar projection of $\mathbf{b}$ onto $\mathbf{a}$ is $\text{comp}_{\mathbf{a}}\,\mathbf{b} = \dfrac{\mathbf{a}\cdot\mathbf{b}}{|\mathbf{a}|} = \frac{1}{9}(-12+4+16) = \frac{8}{9}$, while the vector projection of $\mathbf{b}$ onto $\mathbf{a}$ is $\text{proj}_{\mathbf{a}}\,\mathbf{b} = \left(\dfrac{\mathbf{a}\cdot\mathbf{b}}{|\mathbf{a}|}\right)\dfrac{\mathbf{a}}{|\mathbf{a}|} = \frac{8}{9}\cdot\frac{1}{9}\langle -1,4,8\rangle = \frac{8}{81}\langle -1,4,8\rangle = \left\langle -\frac{8}{81}, \frac{32}{81}, \frac{64}{81}\right\rangle$.

43. $|\mathbf{a}| = \sqrt{9+9+1} = \sqrt{19}$ so the scalar projection of $\mathbf{b}$ onto $\mathbf{a}$ is $\text{comp}_{\mathbf{a}}\,\mathbf{b} = \dfrac{\mathbf{a}\cdot\mathbf{b}}{|\mathbf{a}|} = \dfrac{6-12-1}{\sqrt{19}} = -\dfrac{7}{\sqrt{19}}$ while the vector projection of $\mathbf{b}$ onto $\mathbf{a}$ is $\text{proj}_{\mathbf{a}}\,\mathbf{b} = -\dfrac{7}{\sqrt{19}}\dfrac{\mathbf{a}}{|\mathbf{a}|} = -\frac{7}{\sqrt{19}}\cdot\frac{1}{\sqrt{19}}(3\,\mathbf{i} - 3\,\mathbf{j} + \mathbf{k}) = -\frac{7}{19}(3\,\mathbf{i} - 3\,\mathbf{j} + \mathbf{k}) = -\frac{21}{19}\,\mathbf{i} + \frac{21}{19}\,\mathbf{j} - \frac{7}{19}\,\mathbf{k}$.

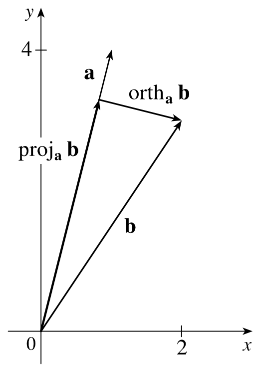
44. $|\mathbf{a}| = \sqrt{1+4+9} = \sqrt{14}$ so the scalar projection of $\mathbf{b}$ onto $\mathbf{a}$ is $\text{comp}_\mathbf{a}\,\mathbf{b} = \dfrac{\mathbf{a}\cdot\mathbf{b}}{|\mathbf{a}|} = \dfrac{5+0-3}{\sqrt{14}} = \dfrac{2}{\sqrt{14}}$ while the vector projection of $\mathbf{b}$ onto $\mathbf{a}$ is $\text{proj}_\mathbf{a}\,\mathbf{b} = \dfrac{2}{\sqrt{14}}\dfrac{\mathbf{a}}{|\mathbf{a}|} = \frac{2}{\sqrt{14}}\cdot\frac{1}{\sqrt{14}}\,(\mathbf{i}+2\,\mathbf{j}+3\,\mathbf{k}) = \frac{1}{7}(\mathbf{i}+2\,\mathbf{j}+3\,\mathbf{k}) = \frac{1}{7}\,\mathbf{i}+\frac{2}{7}\,\mathbf{j}+\frac{3}{7}\,\mathbf{k}$.

45. $(\text{orth}_\mathbf{a}\,\mathbf{b})\cdot\mathbf{a} = (\mathbf{b}-\text{proj}_\mathbf{a}\,\mathbf{b})\cdot\mathbf{a} = \mathbf{b}\cdot\mathbf{a} - (\text{proj}_\mathbf{a}\,\mathbf{b})\cdot\mathbf{a} = \mathbf{b}\cdot\mathbf{a} - \dfrac{\mathbf{a}\cdot\mathbf{b}}{|\mathbf{a}|^2}\,\mathbf{a}\cdot\mathbf{a} = \mathbf{b}\cdot\mathbf{a} - \dfrac{\mathbf{a}\cdot\mathbf{b}}{|\mathbf{a}|^2}\,|\mathbf{a}|^2 = \mathbf{b}\cdot\mathbf{a} - \mathbf{a}\cdot\mathbf{b} = 0$.

So they are orthogonal by (7).

46. Using the formula in Exercise 45 and the result of Exercise 40, we have

$\text{orth}_\mathbf{a}\,\mathbf{b} = \mathbf{b} - \text{proj}_\mathbf{a}\,\mathbf{b} = \langle 2,3\rangle - \left\langle \frac{14}{17}, \frac{56}{17}\right\rangle = \left\langle \frac{20}{17}, -\frac{5}{17}\right\rangle$.



47. $\text{comp}_\mathbf{a}\,\mathbf{b} = \dfrac{\mathbf{a}\cdot\mathbf{b}}{|\mathbf{a}|} = 2 \quad\Leftrightarrow\quad \mathbf{a}\cdot\mathbf{b} = 2\,|\mathbf{a}| = 2\sqrt{10}$. If $\mathbf{b} = \langle b_1, b_2, b_3\rangle$, then we need $3b_1 + 0b_2 - 1b_3 = 2\sqrt{10}$.

One possible solution is obtained by taking $b_1 = 0$, $b_2 = 0$, $b_3 = -2\sqrt{10}$. In general, $\mathbf{b} = \left\langle s, t, 3s - 2\sqrt{10}\right\rangle$, $s, t \in \mathbb{R}$.

48. (a) $\text{comp}_\mathbf{a}\,\mathbf{b} = \text{comp}_\mathbf{b}\,\mathbf{a} \quad\Leftrightarrow\quad \dfrac{\mathbf{a}\cdot\mathbf{b}}{|\mathbf{a}|} = \dfrac{\mathbf{b}\cdot\mathbf{a}}{|\mathbf{b}|} \quad\Leftrightarrow\quad \dfrac{1}{|\mathbf{a}|} = \dfrac{1}{|\mathbf{b}|}$ or $\mathbf{a}\cdot\mathbf{b} = 0 \quad\Leftrightarrow\quad |\mathbf{b}| = |\mathbf{a}|$ or $\mathbf{a}\cdot\mathbf{b} = 0$.

That is, if $\mathbf{a}$ and $\mathbf{b}$ are orthogonal or if they have the same length.

(b) $\text{proj}_\mathbf{a}\,\mathbf{b} = \text{proj}_\mathbf{b}\,\mathbf{a} \quad\Leftrightarrow\quad \dfrac{\mathbf{a}\cdot\mathbf{b}}{|\mathbf{a}|^2}\,\mathbf{a} = \dfrac{\mathbf{b}\cdot\mathbf{a}}{|\mathbf{b}|^2}\,\mathbf{b} \quad\Leftrightarrow\quad \mathbf{a}\cdot\mathbf{b} = 0$ or $\dfrac{\mathbf{a}}{|\mathbf{a}|^2} = \dfrac{\mathbf{b}}{|\mathbf{b}|^2}$.

But $\dfrac{\mathbf{a}}{|\mathbf{a}|^2} = \dfrac{\mathbf{b}}{|\mathbf{b}|^2} \quad\Rightarrow\quad \dfrac{|\mathbf{a}|}{|\mathbf{a}|^2} = \dfrac{|\mathbf{b}|}{|\mathbf{b}|^2} \quad\Rightarrow\quad |\mathbf{a}| = |\mathbf{b}|$. Substituting this into the previous equation gives $\mathbf{a} = \mathbf{b}$.

So $\text{proj}_\mathbf{a}\,\mathbf{b} = \text{proj}_\mathbf{b}\,\mathbf{a} \quad\Leftrightarrow\quad \mathbf{a}$ and $\mathbf{b}$ are orthogonal, or they are equal.

49. The displacement vector is $\mathbf{D} = (6-0)\,\mathbf{i} + (12-10)\,\mathbf{j} + (20-8)\,\mathbf{k} = 6\,\mathbf{i} + 2\,\mathbf{j} + 12\,\mathbf{k}$ so, by Equation 12, the work done is $W = \mathbf{F}\cdot\mathbf{D} = (8\,\mathbf{i} - 6\,\mathbf{j} + 9\,\mathbf{k})\cdot(6\,\mathbf{i} + 2\,\mathbf{j} + 12\,\mathbf{k}) = 48 - 12 + 108 = 144$ joules.

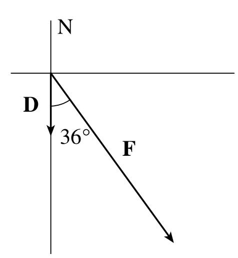
50. Here $|\mathbf{D}| = 1000$ m, $|\mathbf{F}| = 1500$ N, and $\theta = 30^\circ$. Thus

$W = \mathbf{F}\cdot\mathbf{D} = |\mathbf{F}|\,|\mathbf{D}|\cos\theta = (1500)(1000)\left(\frac{\sqrt{3}}{2}\right) = 750{,}000\sqrt{3}$ joules.

51. Here $|\mathbf{D}| = 80$ ft, $|\mathbf{F}| = 30$ lb, and $\theta = 40^\circ$. Thus

$W = \mathbf{F}\cdot\mathbf{D} = |\mathbf{F}|\,|\mathbf{D}|\cos\theta = (30)(80)\cos 40^\circ = 2400\cos 40^\circ \approx 1839$ ft-lb.

52. $W = \mathbf{F}\cdot\mathbf{D} = |\mathbf{F}|\,|\mathbf{D}|\cos\theta = (400)(120)\cos 36^\circ \approx 38{,}833$ ft-lb

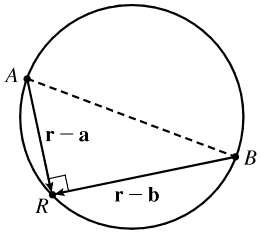


53. First note that $\mathbf{n} = \langle a, b \rangle$ is perpendicular to the line, because if $Q_1 = (a_1, b_1)$ and $Q_2 = (a_2, b_2)$ lie on the line, then $\mathbf{n} \cdot \overrightarrow{Q_1 Q_2} = aa_2 - aa_1 + bb_2 - bb_1 = 0$, since $aa_2 + bb_2 = -c = aa_1 + bb_1$ from the equation of the line.

Let $P_2 = (x_2, y_2)$ lie on the line. Then the distance from P_1 to the line is the absolute value of the scalar projection of $\overrightarrow{P_1 P_2}$ onto $\mathbf{n}$. $\quad \text{comp}_{\mathbf{n}}\left(\overrightarrow{P_1 P_2}\right) = \dfrac{|\mathbf{n} \cdot \langle x_2 - x_1, y_2 - y_1 \rangle|}{|\mathbf{n}|} = \dfrac{|ax_2 - ax_1 + by_2 - by_1|}{\sqrt{a^2 + b^2}} = \dfrac{|ax_1 + by_1 + c|}{\sqrt{a^2 + b^2}}$

since $ax_2 + by_2 = -c$. The required distance is $\dfrac{|(3)(-2) + (-4)(3) + 5|}{\sqrt{3^2 + (-4)^2}} = \dfrac{13}{5}$.

54. $(\mathbf{r} - \mathbf{a}) \cdot (\mathbf{r} - \mathbf{b}) = 0$ implies that the vectors $\mathbf{r} - \mathbf{a}$ and $\mathbf{r} - \mathbf{b}$ are orthogonal. From the diagram (in which A, B and R are the terminal points of the vectors), we see that this implies that R lies on a sphere whose diameter is the line from A to B. The center of this circle is the midpoint of AB, that is, $\frac{1}{2}(\mathbf{a} + \mathbf{b}) = \left\langle \frac{1}{2}(a_1 + b_1), \frac{1}{2}(a_2 + b_2), \frac{1}{2}(a_3 + b_3) \right\rangle$, and its radius is $\frac{1}{2}|\mathbf{a} - \mathbf{b}| = \frac{1}{2}\sqrt{(a_1 - b_1)^2 + (a_2 - b_2)^2 + (a_3 - b_3)^2}$.



Or: Expand the given equation, substitute $\mathbf{r} \cdot \mathbf{r} = x^2 + y^2 + z^2$ and complete the squares.

55. For convenience, consider the unit cube positioned so that its back left corner is at the origin, and its edges lie along the coordinate axes. The diagonal of the cube that begins at the origin and ends at $(1, 1, 1)$ has vector representation $\langle 1, 1, 1 \rangle$. The angle θ between this vector and the vector of the edge which also begins at the origin and runs along the x-axis [that is, $\langle 1, 0, 0 \rangle$] is given by $\cos\theta = \dfrac{\langle 1, 1, 1 \rangle \cdot \langle 1, 0, 0 \rangle}{|\langle 1, 1, 1 \rangle|\,|\langle 1, 0, 0 \rangle|} = \dfrac{1}{\sqrt{3}} \quad \Rightarrow \quad \theta = \cos^{-1}\left(\frac{1}{\sqrt{3}}\right) \approx 55^\circ$.

56. Consider a cube with sides of unit length, wholly within the first octant and with edges along each of the three coordinate axes. $\mathbf{i} + \mathbf{j} + \mathbf{k}$ and $\mathbf{i} + \mathbf{j}$ are vector representations of a diagonal of the cube and a diagonal of one of its faces. If θ is the angle between these diagonals, then $\cos\theta = \dfrac{(\mathbf{i} + \mathbf{j} + \mathbf{k}) \cdot (\mathbf{i} + \mathbf{j})}{|\mathbf{i} + \mathbf{j} + \mathbf{k}|\,|\mathbf{i} + \mathbf{j}|} = \dfrac{1 + 1}{\sqrt{3}\sqrt{2}} = \sqrt{\dfrac{2}{3}} \quad \Rightarrow \quad \theta = \cos^{-1}\sqrt{\frac{2}{3}} \approx 35^\circ$.

57. Consider the H—C—H combination consisting of the sole carbon atom and the two hydrogen atoms that are at $(1, 0, 0)$ and $(0, 1, 0)$ (or any H—C—H combination, for that matter). Vector representations of the line segments emanating from the carbon atom and extending to these two hydrogen atoms are $\left\langle 1 - \frac{1}{2}, 0 - \frac{1}{2}, 0 - \frac{1}{2} \right\rangle = \left\langle \frac{1}{2}, -\frac{1}{2}, -\frac{1}{2} \right\rangle$ and $\left\langle 0 - \frac{1}{2}, 1 - \frac{1}{2}, 0 - \frac{1}{2} \right\rangle = \left\langle -\frac{1}{2}, \frac{1}{2}, -\frac{1}{2} \right\rangle$. The bond angle, θ, is therefore given by

$$\cos\theta = \frac{\left\langle \frac{1}{2}, -\frac{1}{2}, -\frac{1}{2} \right\rangle \cdot \left\langle -\frac{1}{2}, \frac{1}{2}, -\frac{1}{2} \right\rangle}{\left|\left\langle \frac{1}{2}, -\frac{1}{2}, -\frac{1}{2} \right\rangle\right|\left|\left\langle -\frac{1}{2}, \frac{1}{2}, -\frac{1}{2} \right\rangle\right|} = \frac{-\frac{1}{4} - \frac{1}{4} + \frac{1}{4}}{\sqrt{\frac{3}{4}}\sqrt{\frac{3}{4}}} = -\frac{1}{3} \quad \Rightarrow \quad \theta = \cos^{-1}\left(-\frac{1}{3}\right) \approx 109.5^\circ.$$

58. Let α be the angle between $\mathbf{a}$ and $\mathbf{c}$ and β be the angle between $\mathbf{c}$ and $\mathbf{b}$. We need to show that $\alpha = \beta$. Now

$\cos\alpha = \dfrac{\mathbf{a} \cdot \mathbf{c}}{|\mathbf{a}|\,|\mathbf{c}|} = \dfrac{\mathbf{a} \cdot |\mathbf{a}|\,\mathbf{b} + \mathbf{a} \cdot |\mathbf{b}|\,\mathbf{a}}{|\mathbf{a}|\,|\mathbf{c}|} = \dfrac{|\mathbf{a}|\,\mathbf{a} \cdot \mathbf{b} + |\mathbf{a}|^2\,|\mathbf{b}|}{|\mathbf{a}|\,|\mathbf{c}|} = \dfrac{\mathbf{a} \cdot \mathbf{b} + |\mathbf{a}|\,|\mathbf{b}|}{|\mathbf{c}|}$. Similarly,

$\cos\beta = \dfrac{\mathbf{b}\cdot\mathbf{c}}{|\mathbf{b}|\,|\mathbf{c}|} = \dfrac{|\mathbf{a}|\,|\mathbf{b}| + \mathbf{b}\cdot\mathbf{a}}{|\mathbf{c}|}$. Thus $\cos\alpha = \cos\beta$. However $0^\circ \le \alpha \le 180^\circ$ and $0^\circ \le \beta \le 180^\circ$, so $\alpha = \beta$ and $\mathbf{c}$ bisects the angle between $\mathbf{a}$ and $\mathbf{b}$.

59. Let $\mathbf{a} = \langle a_1, a_2, a_3\rangle$ and $= \langle b_1, b_2, b_3\rangle$.

Property 2: $\mathbf{a}\cdot\mathbf{b} = \langle a_1, a_2, a_3\rangle \cdot \langle b_1, b_2, b_3\rangle = a_1b_1 + a_2b_2 + a_3b_3$

$$= b_1a_1 + b_2a_2 + b_3a_3 = \langle b_1, b_2, b_3\rangle \cdot \langle a_1, a_2, a_3\rangle = \mathbf{b}\cdot\mathbf{a}$$

Property 4: $(c\,\mathbf{a})\cdot\mathbf{b} = \langle ca_1, ca_2, ca_3\rangle \cdot \langle b_1, b_2, b_3\rangle = (ca_1)b_1 + (ca_2)b_2 + (ca_3)b_3$

$$= c\,(a_1b_1 + a_2b_2 + a_3b_3) = c\,(\mathbf{a}\cdot\mathbf{b}) = a_1(cb_1) + a_2(cb_2) + a_3(cb_3)$$

$$= \langle a_1, a_2, a_3\rangle \cdot \langle cb_1, cb_2, cb_3\rangle = \mathbf{a}\cdot(c\,\mathbf{b})$$

Property 5: $\mathbf{0}\cdot\mathbf{a} = \langle 0, 0, 0\rangle \cdot \langle a_1, a_2, a_3\rangle = (0)(a_1) + (0)(a_2) + (0)(a_3) = 0$

60. Let the figure be called quadrilateral $ABCD$. The diagonals can be represented by $\overrightarrow{AC}$ and $\overrightarrow{BD}$. $\overrightarrow{AC} = \overrightarrow{AB} + \overrightarrow{BC}$ and $\overrightarrow{BD} = \overrightarrow{BC} + \overrightarrow{CD} = \overrightarrow{BC} - \overrightarrow{DC} = \overrightarrow{BC} - \overrightarrow{AB}$ (Since opposite sides of the object are of the same length and parallel, $\overrightarrow{AB} = \overrightarrow{DC}$.) Thus

$$\overrightarrow{AC}\cdot\overrightarrow{BD} = \left(\overrightarrow{AB} + \overrightarrow{BC}\right)\cdot\left(\overrightarrow{BC} - \overrightarrow{AB}\right) = \overrightarrow{AB}\cdot\left(\overrightarrow{BC} - \overrightarrow{AB}\right) + \overrightarrow{BC}\cdot\left(\overrightarrow{BC} - \overrightarrow{AB}\right)$$

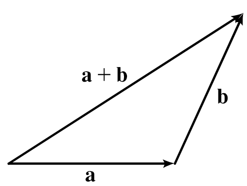
$$= \overrightarrow{AB}\cdot\overrightarrow{BC} - \left|\overrightarrow{AB}\right|^2 + \left|\overrightarrow{BC}\right|^2 - \overrightarrow{AB}\cdot\overrightarrow{BC} = \left|\overrightarrow{BC}\right|^2 - \left|\overrightarrow{AB}\right|^2$$

But $\left|\overrightarrow{AB}\right|^2 = \left|\overrightarrow{BC}\right|^2$ because all sides of the quadrilateral are equal in length. Therefore $\overrightarrow{AC}\cdot\overrightarrow{BD} = 0$, and since both of these vectors are nonzero this tells us that the diagonals of the quadrilateral are perpendicular.

61. $|\mathbf{a}\cdot\mathbf{b}| = \big|\,|\mathbf{a}|\,|\mathbf{b}|\cos\theta\big| = |\mathbf{a}|\,|\mathbf{b}|\,|\cos\theta|$. Since $|\cos\theta| \le 1$, $|\mathbf{a}\cdot\mathbf{b}| = |\mathbf{a}|\,|\mathbf{b}|\,|\cos\,\theta| \le |\mathbf{a}|\,|\mathbf{b}|$.

Note: We have equality in the case of $\cos\theta = \pm 1$, so $\theta = 0$ or $\theta = \pi$, thus equality when $\mathbf{a}$ and $\mathbf{b}$ are parallel.

62. (a)



The Triangle Inequality states that the length of the longest side of a triangle is less than or equal to the sum of the lengths of the two shortest sides.

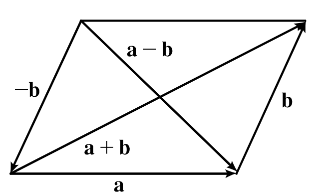
(b) $|\mathbf{a}+\mathbf{b}|^2 = (\mathbf{a}+\mathbf{b})\cdot(\mathbf{a}+\mathbf{b}) = (\mathbf{a}\cdot\mathbf{a}) + 2(\mathbf{a}\cdot\mathbf{b}) + (\mathbf{b}\cdot\mathbf{b}) = |\mathbf{a}|^2 + 2(\mathbf{a}\cdot\mathbf{b}) + |\mathbf{b}|^2$

$$\le |\mathbf{a}|^2 + 2\,|\mathbf{a}|\,|\mathbf{b}| + |\mathbf{b}|^2 \qquad \text{[by the Cauchy-Schwartz Inequality]}$$

$$= (|\mathbf{a}| + |\mathbf{b}|)^2$$

Thus, taking the square root of both sides, $|\mathbf{a}+\mathbf{b}| \le |\mathbf{a}| + |\mathbf{b}|$.

63. (a)



The Parallelogram Law states that the sum of the squares of the lengths of the diagonals of a parallelogram equals the sum of the squares of its (four) sides.

(b) $|\mathbf{a}+\mathbf{b}|^2 = (\mathbf{a}+\mathbf{b})\cdot(\mathbf{a}+\mathbf{b}) = |\mathbf{a}|^2 + 2(\mathbf{a}\cdot\mathbf{b}) + |\mathbf{b}|^2$ and $|\mathbf{a}-\mathbf{b}|^2 = (\mathbf{a}-\mathbf{b})\cdot(\mathbf{a}-\mathbf{b}) = |\mathbf{a}|^2 - 2(\mathbf{a}\cdot\mathbf{b}) + |\mathbf{b}|^2$.

Adding these two equations gives $|\mathbf{a}+\mathbf{b}|^2 + |\mathbf{a}-\mathbf{b}|^2 = 2\,|\mathbf{a}|^2 + 2\,|\mathbf{b}|^2$.

64. If the vectors $\mathbf{u}+\mathbf{v}$ and $\mathbf{u}-\mathbf{v}$ are orthogonal then $(\mathbf{u}+\mathbf{v})\cdot(\mathbf{u}-\mathbf{v}) = 0$. But

$$\begin{aligned}
(\mathbf{u}+\mathbf{v})\cdot(\mathbf{u}-\mathbf{v}) &= (\mathbf{u}+\mathbf{v})\cdot\mathbf{u} - (\mathbf{u}+\mathbf{v})\cdot\mathbf{v} && \text{by Property 3 of the dot product}\\
&= \mathbf{u}\cdot\mathbf{u} + \mathbf{v}\cdot\mathbf{u} - \mathbf{u}\cdot\mathbf{v} - \mathbf{v}\cdot\mathbf{v} && \text{by Property 3}\\
&= |\mathbf{u}|^2 + \mathbf{u}\cdot\mathbf{v} - \mathbf{u}\cdot\mathbf{v} - |\mathbf{v}|^2 && \text{by Properties 1 and 2}\\
&= |\mathbf{u}|^2 - |\mathbf{v}|^2
\end{aligned}$$

Thus $|\mathbf{u}|^2 - |\mathbf{v}|^2 = 0 \;\Rightarrow\; |\mathbf{u}|^2 = |\mathbf{v}|^2 \;\Rightarrow\; |\mathbf{u}| = |\mathbf{v}|$ [since $|\mathbf{u}|, |\mathbf{v}| \geq 0$].

65.

$$\begin{aligned}
\operatorname{proj}_{\mathbf{a}}\mathbf{b}\cdot\operatorname{proj}_{\mathbf{b}}\mathbf{a} &= \frac{\mathbf{a}\cdot\mathbf{b}}{|\mathbf{a}|^2}\mathbf{a}\cdot\frac{\mathbf{b}\cdot\mathbf{a}}{|\mathbf{b}|^2}\mathbf{b} = \frac{\mathbf{a}\cdot\mathbf{b}}{|\mathbf{a}|^2}\cdot\frac{\mathbf{b}\cdot\mathbf{a}}{|\mathbf{b}|^2}\,(\mathbf{a}\cdot\mathbf{b}) && \text{by Property 4 of the dot product}\\
&= \frac{(\mathbf{a}\cdot\mathbf{b})^2}{|\mathbf{a}|^2\,|\mathbf{b}|^2}\,(\mathbf{a}\cdot\mathbf{b}) = \left(\frac{\mathbf{a}\cdot\mathbf{b}}{|\mathbf{a}|\,|\mathbf{b}|}\right)^2(\mathbf{a}\cdot\mathbf{b}) && \text{by Property 2}\\
&= (\cos\theta)^2\,(\mathbf{a}\cdot\mathbf{b}) = (\mathbf{a}\cdot\mathbf{b})\cos^2\theta && \text{by Corollary 6}
\end{aligned}$$

12.4 The Cross Product

1. $\mathbf{a}\times\mathbf{b} = \begin{vmatrix}\mathbf{i} & \mathbf{j} & \mathbf{k}\\ 2 & 3 & 0\\ 1 & 0 & 5\end{vmatrix} = \begin{vmatrix}3 & 0\\ 0 & 5\end{vmatrix}\mathbf{i} - \begin{vmatrix}2 & 0\\ 1 & 5\end{vmatrix}\mathbf{j} + \begin{vmatrix}2 & 3\\ 1 & 0\end{vmatrix}\mathbf{k}$

$= (15-0)\,\mathbf{i} - (10-0)\,\mathbf{j} + (0-3)\,\mathbf{k} = 15\,\mathbf{i} - 10\,\mathbf{j} - 3\,\mathbf{k}$

Now $(\mathbf{a}\times\mathbf{b})\cdot\mathbf{a} = \langle 15, -10, -3\rangle\cdot\langle 2, 3, 0\rangle = 30 - 30 + 0 = 0$ and

$(\mathbf{a}\times\mathbf{b})\cdot\mathbf{b} = \langle 15, -10, -3\rangle\cdot\langle 1, 0, 5\rangle = 15 + 0 - 15 = 0$, so $\mathbf{a}\times\mathbf{b}$ is orthogonal to both $\mathbf{a}$ and $\mathbf{b}$.

2. $\mathbf{a}\times\mathbf{b} = \begin{vmatrix}\mathbf{i} & \mathbf{j} & \mathbf{k}\\ 4 & 3 & -2\\ 2 & -1 & 1\end{vmatrix} = \begin{vmatrix}3 & -2\\ -1 & 1\end{vmatrix}\mathbf{i} - \begin{vmatrix}4 & -2\\ 2 & 1\end{vmatrix}\mathbf{j} + \begin{vmatrix}4 & 3\\ 2 & -1\end{vmatrix}\mathbf{k}$

$= (3-2)\,\mathbf{i} - [4-(-4)]\,\mathbf{j} + (-4-6)\,\mathbf{k} = \mathbf{i} - 8\,\mathbf{j} - 10\,\mathbf{k}$

Now $(\mathbf{a}\times\mathbf{b})\cdot\mathbf{a} = \langle 1, -8, -10\rangle\cdot\langle 4, 3, -2\rangle = 4 - 24 + 20 = 0$ and

$(\mathbf{a}\times\mathbf{b})\cdot\mathbf{b} = \langle 1, -8, -10\rangle\cdot\langle 2, -1, 1\rangle = 2 + 8 - 10 = 0$, so $\mathbf{a}\times\mathbf{b}$ is orthogonal to both $\mathbf{a}$ and $\mathbf{b}$.

3. $\mathbf{a}\times\mathbf{b} = \begin{vmatrix}\mathbf{i} & \mathbf{j} & \mathbf{k}\\ 0 & 2 & -4\\ -1 & 3 & 1\end{vmatrix} = \begin{vmatrix}2 & -4\\ 3 & 1\end{vmatrix}\mathbf{i} - \begin{vmatrix}0 & -4\\ -1 & 1\end{vmatrix}\mathbf{j} + \begin{vmatrix}0 & 2\\ -1 & 3\end{vmatrix}\mathbf{k}$

$= [2-(-12)]\,\mathbf{i} - (0-4)\,\mathbf{j} + [0-(-2)]\,\mathbf{k} = 14\,\mathbf{i} + 4\,\mathbf{j} + 2\,\mathbf{k}$

Since $(\mathbf{a}\times\mathbf{b})\cdot\mathbf{a} = (14\,\mathbf{i} + 4\,\mathbf{j} + 2\,\mathbf{k})\cdot(2\,\mathbf{j} - 4\,\mathbf{k}) = 0 + 8 - 8 = 0$, $\mathbf{a}\times\mathbf{b}$ is orthogonal to $\mathbf{a}$.

Since $(\mathbf{a}\times\mathbf{b})\cdot\mathbf{b} = (14\,\mathbf{i} + 4\,\mathbf{j} + 2\,\mathbf{k})\cdot(-\mathbf{i} + 3\,\mathbf{j} + \mathbf{k}) = -14 + 12 + 2 = 0$, $\mathbf{a}\times\mathbf{b}$ is orthogonal to $\mathbf{b}$.

4. $\mathbf{a}\times\mathbf{b} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 3 & 3 & -3 \\ 3 & -3 & 3 \end{vmatrix} = \begin{vmatrix} 3 & -3 \\ -3 & 3 \end{vmatrix}\mathbf{i} - \begin{vmatrix} 3 & -3 \\ 3 & 3 \end{vmatrix}\mathbf{j} + \begin{vmatrix} 3 & 3 \\ 3 & -3 \end{vmatrix}\mathbf{k}$

$= (9-9)\,\mathbf{i} - [9-(-9)]\,\mathbf{j} + (-9-9)\,\mathbf{k} = -18\,\mathbf{j} - 18\,\mathbf{k}$

Since $(\mathbf{a}\times\mathbf{b})\cdot\mathbf{a} = (-18\,\mathbf{j} - 18\,\mathbf{k})\cdot(3\,\mathbf{i} + 3\,\mathbf{j} - 3\,\mathbf{k}) = 0 - 54 + 54 = 0$, $\mathbf{a}\times\mathbf{b}$ is orthogonal to $\mathbf{a}$.

Since $(\mathbf{a}\times\mathbf{b})\cdot\mathbf{b} = (-18\,\mathbf{j} - 18\,\mathbf{k})\cdot(3\,\mathbf{i} - 3\,\mathbf{j} + 3\,\mathbf{k}) = 0 + 54 - 54 = 0$, $\mathbf{a}\times\mathbf{b}$ is orthogonal to $\mathbf{b}$.

5. $\mathbf{a}\times\mathbf{b} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{1}{2} & \frac{1}{3} & \frac{1}{4} \\ 1 & 2 & -3 \end{vmatrix} = \begin{vmatrix} \frac{1}{3} & \frac{1}{4} \\ 2 & -3 \end{vmatrix}\mathbf{i} - \begin{vmatrix} \frac{1}{2} & \frac{1}{4} \\ 1 & -3 \end{vmatrix}\mathbf{j} + \begin{vmatrix} \frac{1}{2} & \frac{1}{3} \\ 1 & 2 \end{vmatrix}\mathbf{k}$

$= \left(-1 - \frac{1}{2}\right)\mathbf{i} - \left(-\frac{3}{2} - \frac{1}{4}\right)\mathbf{j} + \left(1 - \frac{1}{3}\right)\mathbf{k} = -\frac{3}{2}\,\mathbf{i} + \frac{7}{4}\,\mathbf{j} + \frac{2}{3}\,\mathbf{k}$

Since $(\mathbf{a}\times\mathbf{b})\cdot\mathbf{a} = \left(-\frac{3}{2}\,\mathbf{i} + \frac{7}{4}\,\mathbf{j} + \frac{2}{3}\,\mathbf{k}\right)\cdot\left(\frac{1}{2}\,\mathbf{i} + \frac{1}{3}\,\mathbf{j} + \frac{1}{4}\,\mathbf{k}\right) = -\frac{3}{4} + \frac{7}{12} + \frac{1}{6} = 0$, $\mathbf{a}\times\mathbf{b}$ is orthogonal to $\mathbf{a}$.

Since $(\mathbf{a}\times\mathbf{b})\cdot\mathbf{b} = \left(-\frac{3}{2}\,\mathbf{i} + \frac{7}{4}\,\mathbf{j} + \frac{2}{3}\,\mathbf{k}\right)\cdot(\mathbf{i} + 2\,\mathbf{j} - 3\,\mathbf{k}) = -\frac{3}{2} + \frac{7}{2} - 2 = 0$, $\mathbf{a}\times\mathbf{b}$ is orthogonal to $\mathbf{b}$.

6. $\mathbf{a}\times\mathbf{b} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ t & \cos t & \sin t \\ 1 & -\sin t & \cos t \end{vmatrix} = \begin{vmatrix} \cos t & \sin t \\ -\sin t & \cos t \end{vmatrix}\mathbf{i} - \begin{vmatrix} t & \sin t \\ 1 & \cos t \end{vmatrix}\mathbf{j} + \begin{vmatrix} t & \cos t \\ 1 & -\sin t \end{vmatrix}\mathbf{k}$

$= [\cos^2 t - (-\sin^2 t)]\,\mathbf{i} - (t\cos t - \sin t)\,\mathbf{j} + (-t\sin t - \cos t)\,\mathbf{k} = \mathbf{i} + (\sin t - t\cos t)\,\mathbf{j} + (-t\sin t - \cos t)\,\mathbf{k}$

Since

$$\begin{aligned}(\mathbf{a}\times\mathbf{b})\cdot\mathbf{a} &= [\,\mathbf{i} + (\sin t - t\cos t)\,\mathbf{j} + (-t\sin t - \cos t)\,\mathbf{k}\,]\cdot(t\,\mathbf{i} + \cos t\,\mathbf{j} + \sin t\,\mathbf{k}) \\ &= t + \sin t\cos t - t\cos^2 t - t\sin^2 t - \sin t\cos t \\ &= t - t\left(\cos^2 t + \sin^2 t\right) = 0\end{aligned}$$

$\mathbf{a}\times\mathbf{b}$ is orthogonal to $\mathbf{a}$.

Since

$$\begin{aligned}(\mathbf{a}\times\mathbf{b})\cdot\mathbf{b} &= [\,\mathbf{i} + (\sin t - t\cos t)\,\mathbf{j} + (-t\sin t - \cos t)\,\mathbf{k}\,]\cdot(\mathbf{i} - \sin t\,\mathbf{j} + \cos t\,\mathbf{k}) \\ &= 1 - \sin^2 t + t\sin t\cos t - t\sin t\cos t - \cos^2 t \\ &= 1 - \left(\sin^2 t + \cos^2 t\right) = 0\end{aligned}$$

$\mathbf{a}\times\mathbf{b}$ is orthogonal to $\mathbf{b}$.

7. $\mathbf{a}\times\mathbf{b} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ t & 1 & 1/t \\ t^2 & t^2 & 1 \end{vmatrix} = \begin{vmatrix} 1 & 1/t \\ t^2 & 1 \end{vmatrix}\mathbf{i} - \begin{vmatrix} t & 1/t \\ t^2 & 1 \end{vmatrix}\mathbf{j} + \begin{vmatrix} t & 1 \\ t^2 & t^2 \end{vmatrix}\mathbf{k}$

$= (1-t)\,\mathbf{i} - (t-t)\,\mathbf{j} + (t^3 - t^2)\,\mathbf{k} = (1-t)\,\mathbf{i} + (t^3 - t^2)\,\mathbf{k}$

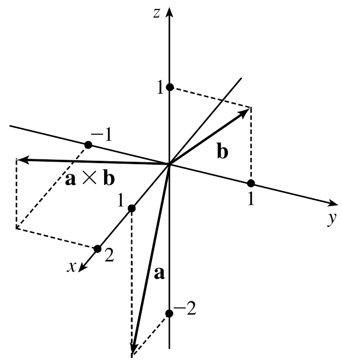
Since $(\mathbf{a}\times\mathbf{b})\cdot\mathbf{a} = \langle 1-t, 0, t^3 - t^2\rangle\cdot\langle t, 1, 1/t\rangle = t - t^2 + 0 + t^2 - t = 0$, $\mathbf{a}\times\mathbf{b}$ is orthogonal to $\mathbf{a}$.

Since $(\mathbf{a}\times\mathbf{b})\cdot\mathbf{b} = \langle 1-t, 0, t^3 - t^2\rangle\cdot\langle t^2, t^2, 1\rangle = t^2 - t^3 + 0 + t^3 - t^2 = 0$, $\mathbf{a}\times\mathbf{b}$ is orthogonal to $\mathbf{b}$.

8. $\mathbf{a}\times\mathbf{b} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 0 & -2 \\ 0 & 1 & 1 \end{vmatrix}$

$$= \begin{vmatrix} 0 & -2 \\ 1 & 1 \end{vmatrix}\mathbf{i} - \begin{vmatrix} 1 & -2 \\ 0 & 1 \end{vmatrix}\mathbf{j} + \begin{vmatrix} 1 & 0 \\ 0 & 1 \end{vmatrix}\mathbf{k}$$

$$= 2\,\mathbf{i} - \mathbf{j} + \mathbf{k}$$



9. According to the discussion following Example 4, $\mathbf{i}\times\mathbf{j}=\mathbf{k}$, so $(\mathbf{i}\times\mathbf{j})\times\mathbf{k}=\mathbf{k}\times\mathbf{k}=\mathbf{0}$ [by Example 2].

10. $\mathbf{k}\times(\mathbf{i}-2\,\mathbf{j}) = \mathbf{k}\times\mathbf{i}+\mathbf{k}\times(-2\,\mathbf{j})$ by Property 3 of the cross product

$= \mathbf{k}\times\mathbf{i}+(-2)\,(\mathbf{k}\times\mathbf{j})$ by Property 2

$= \mathbf{j}+(-2)(-\mathbf{i}) = 2\,\mathbf{i}+\mathbf{j}$ by the discussion following Example 4

11. $(\mathbf{j}-\mathbf{k})\times(\mathbf{k}-\mathbf{i}) = (\mathbf{j}-\mathbf{k})\times\mathbf{k}+(\mathbf{j}-\mathbf{k})\times(-\mathbf{i})$ by Property 3 of the cross product

$= \mathbf{j}\times\mathbf{k}+(-\mathbf{k})\times\mathbf{k}+\mathbf{j}\times(-\mathbf{i})+(-\mathbf{k})\times(-\mathbf{i})$ by Property 4

$= (\mathbf{j}\times\mathbf{k})+(-1)(\mathbf{k}\times\mathbf{k})+(-1)(\mathbf{j}\times\mathbf{i})+(-1)^2(\mathbf{k}\times\mathbf{i})$ by Property 2

$= \mathbf{i}+(-1)\,\mathbf{0}+(-1)(-\mathbf{k})+\mathbf{j} = \mathbf{i}+\mathbf{j}+\mathbf{k}$ by Example 2 and the discussion following Example 4

12. $(\mathbf{i}+\mathbf{j})\times(\mathbf{i}-\mathbf{j}) = (\mathbf{i}+\mathbf{j})\times\mathbf{i}+(\mathbf{i}+\mathbf{j})\times(-\mathbf{j})$ by Property 3 of the cross product

$= \mathbf{i}\times\mathbf{i}+\mathbf{j}\times\mathbf{i}+\mathbf{i}\times(-\mathbf{j})+\mathbf{j}\times(-\mathbf{j})$ by Property 4

$= (\mathbf{i}\times\mathbf{i})+(\mathbf{j}\times\mathbf{i})+(-1)(\mathbf{i}\times\mathbf{j})+(-1)(\mathbf{j}\times\mathbf{j})$ by Property 2

$= \mathbf{0}+(-\mathbf{k})+(-1)\,\mathbf{k}+(-1)\,\mathbf{0} = -2\,\mathbf{k}$ by Example 2 and the discussion following Example 4

13. (a) Since $\mathbf{b}\times\mathbf{c}$ is a vector, the dot product $\mathbf{a}\cdot(\mathbf{b}\times\mathbf{c})$ is meaningful and is a scalar.

(b) $\mathbf{b}\cdot\mathbf{c}$ is a scalar, so $\mathbf{a}\times(\mathbf{b}\cdot\mathbf{c})$ is meaningless, as the cross product is defined only for two *vectors*.

(c) Since $\mathbf{b}\times\mathbf{c}$ is a vector, the cross product $\mathbf{a}\times(\mathbf{b}\times\mathbf{c})$ is meaningful and results in another vector.

(d) $\mathbf{b}\cdot\mathbf{c}$ is a scalar, so the dot product $\mathbf{a}\cdot(\mathbf{b}\cdot\mathbf{c})$ is meaningless, as the dot product is defined only for two vectors.

(e) Since $(\mathbf{a}\cdot\mathbf{b})$ and $(\mathbf{c}\cdot\mathbf{d})$ are both scalars, the cross product $(\mathbf{a}\cdot\mathbf{b})\times(\mathbf{c}\cdot\mathbf{d})$ is meaningless.

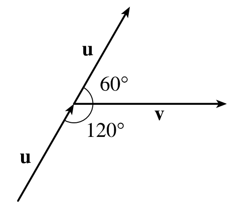
(f) $\mathbf{a}\times\mathbf{b}$ and $\mathbf{c}\times\mathbf{d}$ are both vectors, so the dot product $(\mathbf{a}\times\mathbf{b})\cdot(\mathbf{c}\times\mathbf{d})$ is meaningful and is a scalar.

14. Using Theorem 9, we have $|\mathbf{u}\times\mathbf{v}| = |\mathbf{u}|\,|\mathbf{v}|\sin\theta = (4)(5)\sin 45^\circ = 20\cdot\frac{\sqrt{2}}{2} = 10\sqrt{2}$. By the right-hand rule, $\mathbf{u}\times\mathbf{v}$ is directed out of the page.

15. If we sketch $\mathbf{u}$ and $\mathbf{v}$ starting from the same initial point, we see that the angle between them is 60°. Using Theorem 9, we have

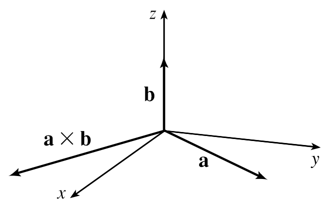
$|\mathbf{u}\times\mathbf{v}| = |\mathbf{u}|\,|\mathbf{v}|\sin\theta = (12)(16)\sin 60^\circ = 192\cdot\dfrac{\sqrt{3}}{2} = 96\sqrt{3}.$

By the right-hand rule, $\mathbf{u}\times\mathbf{v}$ is directed into the page.



16. (a) $|\mathbf{a}\times\mathbf{b}| = |\mathbf{a}|\,|\mathbf{b}|\sin\theta = 3\cdot 2\cdot\sin\frac{\pi}{2} = 6$

(b) $\mathbf{a}\times\mathbf{b}$ is orthogonal to $\mathbf{k}$, so it lies in the xy-plane, and its z-coordinate is 0. By the right-hand rule, its y-component is negative and its x-component is positive.



17. $$\mathbf{a}\times\mathbf{b} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 2 & -1 & 3 \\ 4 & 2 & 1 \end{vmatrix} = \begin{vmatrix} -1 & 3 \\ 2 & 1 \end{vmatrix}\mathbf{i} - \begin{vmatrix} 2 & 3 \\ 4 & 1 \end{vmatrix}\mathbf{j} + \begin{vmatrix} 2 & -1 \\ 4 & 2 \end{vmatrix}\mathbf{k} = (-1-6)\,\mathbf{i} - (2-12)\,\mathbf{j} + [4-(-4)]\,\mathbf{k} = -7\,\mathbf{i} + 10\,\mathbf{j} + 8\,\mathbf{k}$$

$$\mathbf{b}\times\mathbf{a} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 4 & 2 & 1 \\ 2 & -1 & 3 \end{vmatrix} = \begin{vmatrix} 2 & 1 \\ -1 & 3 \end{vmatrix}\mathbf{i} - \begin{vmatrix} 4 & 1 \\ 2 & 3 \end{vmatrix}\mathbf{j} + \begin{vmatrix} 4 & 2 \\ 2 & -1 \end{vmatrix}\mathbf{k} = [6-(-1)]\,\mathbf{i} - (12-2)\,\mathbf{j} + (-4-4)\,\mathbf{k} = 7\,\mathbf{i} - 10\,\mathbf{j} - 8\,\mathbf{k}$$

Notice $\mathbf{a}\times\mathbf{b} = -\mathbf{b}\times\mathbf{a}$ here, as we know is always true by Property 1 of the cross product.

18. $$\mathbf{b}\times\mathbf{c} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 2 & 1 & -1 \\ 0 & 1 & 3 \end{vmatrix} = \begin{vmatrix} 1 & -1 \\ 1 & 3 \end{vmatrix}\mathbf{i} - \begin{vmatrix} 2 & -1 \\ 0 & 3 \end{vmatrix}\mathbf{j} + \begin{vmatrix} 2 & 1 \\ 0 & 1 \end{vmatrix}\mathbf{k} = 4\,\mathbf{i} - 6\,\mathbf{j} + 2\,\mathbf{k} \text{ so}$$

$$\mathbf{a}\times(\mathbf{b}\times\mathbf{c}) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 0 & 1 \\ 4 & -6 & 2 \end{vmatrix} = \begin{vmatrix} 0 & 1 \\ -6 & 2 \end{vmatrix}\mathbf{i} - \begin{vmatrix} 1 & 1 \\ 4 & 2 \end{vmatrix}\mathbf{j} + \begin{vmatrix} 1 & 0 \\ 4 & -6 \end{vmatrix}\mathbf{k} = 6\,\mathbf{i} + 2\,\mathbf{j} - 6\,\mathbf{k}.$$

$$\mathbf{a}\times\mathbf{b} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 0 & 1 \\ 2 & 1 & -1 \end{vmatrix} = \begin{vmatrix} 0 & 1 \\ 1 & -1 \end{vmatrix}\mathbf{i} - \begin{vmatrix} 1 & 1 \\ 2 & -1 \end{vmatrix}\mathbf{j} + \begin{vmatrix} 1 & 0 \\ 2 & 1 \end{vmatrix}\mathbf{k} = -\,\mathbf{i} + 3\,\mathbf{j} + \mathbf{k} \text{ so}$$

$$(\mathbf{a}\times\mathbf{b})\times\mathbf{c} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -1 & 3 & 1 \\ 0 & 1 & 3 \end{vmatrix} = \begin{vmatrix} 3 & 1 \\ 1 & 3 \end{vmatrix}\mathbf{i} - \begin{vmatrix} -1 & 1 \\ 0 & 3 \end{vmatrix}\mathbf{j} + \begin{vmatrix} -1 & 3 \\ 0 & 1 \end{vmatrix}\mathbf{k} = 8\,\mathbf{i} + 3\,\mathbf{j} - \mathbf{k}.$$

Thus $\mathbf{a}\times(\mathbf{b}\times\mathbf{c}) \neq (\mathbf{a}\times\mathbf{b})\times\mathbf{c}$.

19. By Theorem 8, the cross product of two vectors is orthogonal to both vectors. So we calculate

$$\langle 3,2,1\rangle \times \langle -1,1,0\rangle = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 3 & 2 & 1 \\ -1 & 1 & 0 \end{vmatrix} = \begin{vmatrix} 2 & 1 \\ 1 & 0 \end{vmatrix}\mathbf{i} - \begin{vmatrix} 3 & 1 \\ -1 & 0 \end{vmatrix}\mathbf{j} + \begin{vmatrix} 3 & 2 \\ -1 & 1 \end{vmatrix}\mathbf{k} = -\mathbf{i} - \mathbf{j} + 5\,\mathbf{k}.$$

So two unit vectors orthogonal to both given vectors are $\pm\dfrac{\langle -1,-1,5\rangle}{\sqrt{1+1+25}} = \pm\dfrac{\langle -1,-1,5\rangle}{3\sqrt{3}}$, that is, $\left\langle -\frac{1}{3\sqrt{3}}, -\frac{1}{3\sqrt{3}}, \frac{5}{3\sqrt{3}} \right\rangle$ and $\left\langle \frac{1}{3\sqrt{3}}, \frac{1}{3\sqrt{3}}, -\frac{5}{3\sqrt{3}} \right\rangle$.

20. By Theorem 8, the cross product of two vectors is orthogonal to both vectors. So we calculate

$$(\mathbf{j}-\mathbf{k})\times(\mathbf{i}+\mathbf{j})=\begin{vmatrix}\mathbf{i}&\mathbf{j}&\mathbf{k}\\0&1&-1\\1&1&0\end{vmatrix}=\begin{vmatrix}1&-1\\1&0\end{vmatrix}\mathbf{i}-\begin{vmatrix}0&-1\\1&0\end{vmatrix}\mathbf{j}+\begin{vmatrix}0&1\\1&1\end{vmatrix}\mathbf{k}=\mathbf{i}-\mathbf{j}-\mathbf{k}$$

Thus two unit vectors orthogonal to both given vectors are $\pm\frac{1}{\sqrt{3}}(\mathbf{i}-\mathbf{j}-\mathbf{k})$, that is, $\frac{1}{\sqrt{3}}\mathbf{i}-\frac{1}{\sqrt{3}}\mathbf{j}-\frac{1}{\sqrt{3}}\mathbf{k}$ and $-\frac{1}{\sqrt{3}}\mathbf{i}+\frac{1}{\sqrt{3}}\mathbf{j}+\frac{1}{\sqrt{3}}\mathbf{k}$.

21. Let $\mathbf{a}=\langle a_1,a_2,a_3\rangle$. Then

$$\mathbf{0}\times\mathbf{a}=\begin{vmatrix}\mathbf{i}&\mathbf{j}&\mathbf{k}\\0&0&0\\a_1&a_2&a_3\end{vmatrix}=\begin{vmatrix}0&0\\a_2&a_3\end{vmatrix}\mathbf{i}-\begin{vmatrix}0&0\\a_1&a_3\end{vmatrix}\mathbf{j}+\begin{vmatrix}0&0\\a_1&a_2\end{vmatrix}\mathbf{k}=\mathbf{0},$$

$$\mathbf{a}\times\mathbf{0}=\begin{vmatrix}\mathbf{i}&\mathbf{j}&\mathbf{k}\\a_1&a_2&a_3\\0&0&0\end{vmatrix}=\begin{vmatrix}a_2&a_3\\0&0\end{vmatrix}\mathbf{i}-\begin{vmatrix}a_1&a_3\\0&0\end{vmatrix}\mathbf{j}+\begin{vmatrix}a_1&a_2\\0&0\end{vmatrix}\mathbf{k}=\mathbf{0}.$$

22. Let $\mathbf{a}=\langle a_1,a_2,a_3\rangle$ and $\mathbf{b}=\langle b_1,b_2,b_3\rangle$.

$$(\mathbf{a}\times\mathbf{b})\cdot\mathbf{b}=\left\langle\begin{vmatrix}a_2&a_3\\b_2&b_3\end{vmatrix},\begin{vmatrix}a_1&a_3\\b_1&b_3\end{vmatrix},\begin{vmatrix}a_1&a_2\\b_1&b_2\end{vmatrix}\right\rangle\cdot\langle b_1,b_2,b_3\rangle=\begin{vmatrix}a_2&a_3\\b_2&b_3\end{vmatrix}b_1-\begin{vmatrix}a_1&a_3\\b_1&b_3\end{vmatrix}b_2+\begin{vmatrix}a_1&a_2\\b_1&b_2\end{vmatrix}b_3$$

$$=(a_2b_3b_1-a_3b_2b_1)-(a_1b_3b_2-a_3b_1b_2)+(a_1b_2b_3-a_2b_1b_3)=0$$

23. $\mathbf{a}\times\mathbf{b}=\langle a_2b_3-a_3b_2,a_3b_1-a_1b_3,a_1b_2-a_2b_1\rangle$

$$=\langle(-1)(b_2a_3-b_3a_2),(-1)(b_3a_1-b_1a_3),(-1)(b_1a_2-b_2a_1)\rangle$$

$$=-\langle b_2a_3-b_3a_2,b_3a_1-b_1a_3,b_1a_2-b_2a_1\rangle=-\mathbf{b}\times\mathbf{a}$$

24. $c\mathbf{a}=\langle ca_1,ca_2,ca_3\rangle$, so

$$(c\,\mathbf{a})\times\mathbf{b}=\langle ca_2b_3-ca_3b_2,ca_3b_1-ca_1b_3,ca_1b_2-ca_2b_1\rangle$$

$$=c\langle a_2b_3-a_3b_2,a_3b_1-a_1b_3,a_1b_2-a_2b_1\rangle=c(\mathbf{a}\times\mathbf{b})$$

$$=\langle ca_2b_3-ca_3b_2,ca_3b_1-ca_1b_3,ca_1b_2-ca_2b_1\rangle$$

$$=\langle a_2(cb_3)-a_3(cb_2),a_3(cb_1)-a_1(cb_3),a_1(cb_2)-a_2(cb_1)\rangle$$

$$=\mathbf{a}\times c\,\mathbf{b}$$

25. $\mathbf{a}\times(\mathbf{b}+\mathbf{c})=\mathbf{a}\times\langle b_1+c_1,b_2+c_2,b_3+c_3\rangle$

$$=\langle a_2(b_3+c_3)-a_3(b_2+c_2),a_3(b_1+c_1)-a_1(b_3+c_3),a_1(b_2+c_2)-a_2(b_1+c_1)\rangle$$

$$=\langle a_2b_3+a_2c_3-a_3b_2-a_3c_2,a_3b_1+a_3c_1-a_1b_3-a_1c_3,a_1b_2+a_1c_2-a_2b_1-a_2c_1\rangle$$

$$=\langle(a_2b_3-a_3b_2)+(a_2c_3-a_3c_2),\ (a_3b_1-a_1b_3)+(a_3c_1-a_1c_3),\ (a_1b_2-a_2b_1)+(a_1c_2-a_2c_1)\rangle$$

$$=\langle a_2b_3-a_3b_2,a_3b_1-a_1b_3,a_1b_2-a_2b_1\rangle+\langle a_2c_3-a_3c_2,a_3c_1-a_1c_3,a_1c_2-a_2c_1\rangle$$

$$=(\mathbf{a}\times\mathbf{b})+(\mathbf{a}\times\mathbf{c})$$

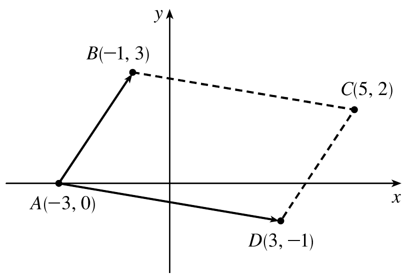
26. $(\mathbf{a}+\mathbf{b})\times\mathbf{c} = -\mathbf{c}\times(\mathbf{a}+\mathbf{b})$ by Property 1 of the cross product

$= -(\mathbf{c}\times\mathbf{a}+\mathbf{c}\times\mathbf{b})$ by Property 3

$= -(-\mathbf{a}\times\mathbf{c}+(-\mathbf{b}\times\mathbf{c}))$ by Property 1

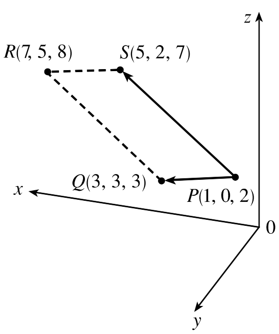
$= \mathbf{a}\times\mathbf{c}+\mathbf{b}\times\mathbf{c}$ by Property 2

27. By plotting the vertices, we can see that the parallelogram is determined by the vectors $\overrightarrow{AB} = \langle 2, 3\rangle$ and $\overrightarrow{AD} = \langle 6, -1\rangle$. We know that the area of the parallelogram determined by two vectors is equal to the length of the cross product of these vectors. In order to compute the cross product, we consider the vector $\overrightarrow{AB}$ as the three-dimensional vector $\langle 2, 3, 0\rangle$ (and similarly for $\overrightarrow{AD}$), and then the area of parallelogram $ABCD$ is



$$\left|\overrightarrow{AB}\times\overrightarrow{AD}\right| = \left\|\begin{matrix}\mathbf{i} & \mathbf{j} & \mathbf{k}\\ 2 & 3 & 0\\ 6 & -1 & 0\end{matrix}\right\| = |(0-0)\,\mathbf{i}-(0-0)\,\mathbf{j}+(-2-18)\,\mathbf{k}| = |-20\,\mathbf{k}| = 20$$

28. By plotting the vertices, we can see that the parallelogram is determined by the vectors $\overrightarrow{PQ} = \langle 2, 3, 1\rangle$ and $\overrightarrow{PS} = \langle 4, 2, 5\rangle$. Thus the area of parallelogram $PQRS$ is



$$\left|\overrightarrow{PQ}\times\overrightarrow{PS}\right| = \left\|\begin{matrix}\mathbf{i} & \mathbf{j} & \mathbf{k}\\ 2 & 3 & 1\\ 4 & 2 & 5\end{matrix}\right\| = |(15-2)\,\mathbf{i}-(10-4)\,\mathbf{j}+(4-12)\,\mathbf{k}|$$

$$= |13\,\mathbf{i}-6\,\mathbf{j}-8\,\mathbf{k}| = \sqrt{169+36+64} = \sqrt{269}\approx 16.40$$

29. (a) Because the plane through P, Q, and R contains the vectors $\overrightarrow{PQ}$ and $\overrightarrow{PR}$, a vector orthogonal to both of these vectors (such as their cross product) is also orthogonal to the plane. Here $\overrightarrow{PQ} = \langle -3, 1, 2\rangle$ and $\overrightarrow{PR} = \langle 3, 2, 4\rangle$, so

$$\overrightarrow{PQ}\times\overrightarrow{PR} = \langle (1)(4)-(2)(2), (2)(3)-(-3)(4), (-3)(2)-(1)(3)\rangle = \langle 0, 18, -9\rangle$$

Therefore, $\langle 0, 18, -9\rangle$ (or any nonzero scalar multiple thereof, such as $\langle 0, 2, -1\rangle$) is orthogonal to the plane through P, Q, and R.

(b) Note that the area of the triangle determined by P, Q, and R is equal to half of the area of the parallelogram determined by the three points. From part (a), the area of the parallelogram is $\left|\overrightarrow{PQ}\times\overrightarrow{PR}\right| = |\langle 0, 18, -9\rangle| = \sqrt{0+324+81} = \sqrt{405} = 9\sqrt{5}$, so the area of the triangle is $\frac{1}{2}\cdot 9\sqrt{5} = \frac{9}{2}\sqrt{5}$.

30. (a) $\overrightarrow{PQ} = \langle 4, 2, 3\rangle$ and $\overrightarrow{PR} = \langle 3, 3, 4\rangle$, so a vector orthogonal to the plane through P, Q, and R is $\overrightarrow{PQ}\times\overrightarrow{PR} = \langle (2)(4)-(3)(3), (3)(3)-(4)(4), (4)(3)-(2)(3)\rangle = \langle -1, -7, 6\rangle$ (or any nonzero scalar mutiple thereof).

(b) The area of the parallelogram determined by $\overrightarrow{PQ}$ and $\overrightarrow{PR}$ is $\left|\overrightarrow{PQ}\times\overrightarrow{PR}\right| = |\langle -1,-7,6\rangle| = \sqrt{1+49+36} = \sqrt{86}$, so the area of triangle PQR is $\frac{1}{2}\sqrt{86}$.

31. (a) $\overrightarrow{PQ} = \langle 4,3,-2\rangle$ and $\overrightarrow{PR} = \langle 5,5,1\rangle$, so a vector orthogonal to the plane through P, Q, and R is $\overrightarrow{PQ}\times\overrightarrow{PR} = \langle (3)(1)-(-2)(5),(-2)(5)-(4)(1),(4)(5)-(3)(5)\rangle = \langle 13,-14,5\rangle$ [or any scalar mutiple thereof].

(b) The area of the parallelogram determined by $\overrightarrow{PQ}$ and $\overrightarrow{PR}$ is $\left|\overrightarrow{PQ}\times\overrightarrow{PR}\right| = |\langle 13,-14,5\rangle| = \sqrt{13^2+(-14)^2+5^2} = \sqrt{390}$, so the area of triangle PQR is $\frac{1}{2}\sqrt{390}$.

32. (a) $\overrightarrow{PQ} = \langle -3,1,-2\rangle$ and $\overrightarrow{PR} = \langle 1,4,-7\rangle$, so a vector orthogonal to the plane through P, Q, and R is $\overrightarrow{PQ}\times\overrightarrow{PR} = \langle (1)(-7)-(-2)(4),(-2)(1)-(-3)(-7),(-3)\,(4)-(1)(1)\rangle = \langle 1,-23,-13\rangle$ [or any scalar multiple thereof].

(b) The area of the parallelogram determined by $\overrightarrow{PQ}$ and $\overrightarrow{PR}$ is $\left|\overrightarrow{PQ}\times\overrightarrow{PR}\right| = |\langle 1,-23,-13\rangle| = \sqrt{1+529+169} = \sqrt{699}$, so the area of triangle PQR is $\frac{1}{2}\sqrt{699}$.

33. By Equation 14, the volume of the parallelepiped determined by $\mathbf{a}$, $\mathbf{b}$, and $\mathbf{c}$ is the magnitude of their scalar triple product, which is $\mathbf{a}\cdot(\mathbf{b}\times\mathbf{c}) = \begin{vmatrix} 1 & 2 & 3 \\ -1 & 1 & 2 \\ 2 & 1 & 4 \end{vmatrix} = 1\begin{vmatrix} 1 & 2 \\ 1 & 4 \end{vmatrix} - 2\begin{vmatrix} -1 & 2 \\ 2 & 4 \end{vmatrix} + 3\begin{vmatrix} -1 & 1 \\ 2 & 1 \end{vmatrix} = 1(4-2)-2(-4-4)+3(-1-2) = 9.$

Thus the volume of the parallelepiped is 9 cubic units.

34. $\mathbf{a}\cdot(\mathbf{b}\times\mathbf{c}) = \begin{vmatrix} 1 & 1 & 0 \\ 0 & 1 & 1 \\ 1 & 1 & 1 \end{vmatrix} = 1\begin{vmatrix} 1 & 1 \\ 1 & 1 \end{vmatrix} - 1\begin{vmatrix} 0 & 1 \\ 1 & 1 \end{vmatrix} + 0\begin{vmatrix} 0 & 1 \\ 1 & 1 \end{vmatrix} = 0+1+0 = 1.$

So the volume of the parallelepiped determined by $\mathbf{a}$, $\mathbf{b}$, and $\mathbf{c}$ is 1 cubic unit.

35. $\mathbf{a} = \overrightarrow{PQ} = \langle 4,2,2\rangle$, $\mathbf{b} = \overrightarrow{PR} = \langle 3,3,-1\rangle$, and $\mathbf{c} = \overrightarrow{PS} = \langle 5,5,1\rangle$.

$\mathbf{a}\cdot(\mathbf{b}\times\mathbf{c}) = \begin{vmatrix} 4 & 2 & 2 \\ 3 & 3 & -1 \\ 5 & 5 & 1 \end{vmatrix} = 4\begin{vmatrix} 3 & -1 \\ 5 & 1 \end{vmatrix} - 2\begin{vmatrix} 3 & -1 \\ 5 & 1 \end{vmatrix} + 2\begin{vmatrix} 3 & 3 \\ 5 & 5 \end{vmatrix} = 32-16+0 = 16,$

so the volume of the parallelepiped is 16 cubic units.

36. $\mathbf{a} = \overrightarrow{PQ} = \langle -4,2,4\rangle$, $\mathbf{b} = \overrightarrow{PR} = \langle 2,1,-2\rangle$ and $\mathbf{c} = \overrightarrow{PS} = \langle -3,4,1\rangle$.

$\mathbf{a}\cdot(\mathbf{b}\times\mathbf{c}) = \begin{vmatrix} -4 & 2 & 4 \\ 2 & 1 & -2 \\ -3 & 4 & 1 \end{vmatrix} = -4\begin{vmatrix} 1 & -2 \\ 4 & 1 \end{vmatrix} - 2\begin{vmatrix} 2 & -2 \\ -3 & 1 \end{vmatrix} + 4\begin{vmatrix} 2 & 1 \\ -3 & 4 \end{vmatrix} = -36+8+44 = 16$, so the volume of the parallelepiped is 16 cubic units.

37. $\mathbf{u}\cdot(\mathbf{v}\times\mathbf{w}) = \begin{vmatrix} 1 & 5 & -2 \\ 3 & -1 & 0 \\ 5 & 9 & -4 \end{vmatrix} = 1\begin{vmatrix} -1 & 0 \\ 9 & -4 \end{vmatrix} - 5\begin{vmatrix} 3 & 0 \\ 5 & -4 \end{vmatrix} + (-2)\begin{vmatrix} 3 & -1 \\ 5 & 9 \end{vmatrix} = 4 + 60 - 64 = 0$, which says that the volume of the parallelepiped determined by $\mathbf{u}$, $\mathbf{v}$ and $\mathbf{w}$ is 0, and thus these three vectors are coplanar.

38. $\mathbf{u} = \overrightarrow{AB} = \langle 2, -4, 4\rangle$, $\mathbf{v} = \overrightarrow{AC} = \langle 4, -1, -2\rangle$ and $\mathbf{w} = \overrightarrow{AD} = \langle 2, 3, -6\rangle$.

$\mathbf{u}\cdot(\mathbf{v}\times\mathbf{w}) = \begin{vmatrix} 2 & -4 & 4 \\ 4 & -1 & -2 \\ 2 & 3 & -6 \end{vmatrix} = 2\begin{vmatrix} -1 & -2 \\ 3 & -6 \end{vmatrix} - (-4)\begin{vmatrix} 4 & -2 \\ 2 & -6 \end{vmatrix} + 4\begin{vmatrix} 4 & -1 \\ 2 & 3 \end{vmatrix} = 24 - 80 + 56 = 0$, so the volume of the parallelepiped determined by $\mathbf{u}$, $\mathbf{v}$ and $\mathbf{w}$ is 0, which says these vectors lie in the same plane. Therefore, their initial and terminal points A, B, C and D also lie in the same plane.

39. Using the notation of the text, $|\mathbf{r}| = 0.18$ m, $|\mathbf{F}| = 60$ N, and the angle between $\mathbf{r}$ and $\mathbf{F}$ is $\theta = 70^\circ + 10^\circ = 80^\circ$. (Move $\mathbf{F}$ so that both vectors start from the same point.) Then the magnitude of the torque is $|\boldsymbol{\tau}| = |\mathbf{r}\times\mathbf{F}| = |\mathbf{r}|\,|\mathbf{F}|\sin\theta = (0.18)(60)\sin 80^\circ = 10.8\sin 80^\circ \approx 10.6$ N·m.

40. (a) The position vector from the point P to the handle is $\mathbf{r} = \langle 1, 2\rangle$ and has magnitude $|\mathbf{r}| = \sqrt{1^2 + 2^2} = \sqrt{5}$ ft. Since the force vector $\mathbf{F}$ is parallel to the x-axis, the angle between $\mathbf{r}$ and $\mathbf{F}$ is $\theta = \tan^{-1}\left(\frac{2}{1}\right) \approx 63.43^\circ$ and the magnitude of the torque is $|\boldsymbol{\tau}| = |\mathbf{r}\times\mathbf{F}| = |\mathbf{r}|\,|\mathbf{F}|\sin\theta \approx \left(\sqrt{5}\right)(20)\sin 63.43^\circ \approx 40.0$ ft-lb. (Alternatively, we can observe that $\sin\theta = \frac{2}{\sqrt{5}}$, so $|\mathbf{r}|\,|\mathbf{F}|\sin\theta = \sqrt{5}\cdot 20\cdot\frac{2}{\sqrt{5}} = 40$.)

(b) In this case $\mathbf{r} = \overrightarrow{PQ} = \langle 0.6, 0.6\rangle$, so $|\mathbf{r}| = \sqrt{(0.6)^2 + (0.6)^2} = \sqrt{0.72}$ and $\theta = 45^\circ$. The magnitude of the torque is $|\boldsymbol{\tau}| = |\mathbf{r}|\,|\mathbf{F}|\sin\theta = \left(\sqrt{0.72}\right)(20)\sin 45^\circ = \left(\sqrt{0.72}\right)(20)\cdot\frac{\sqrt{2}}{2} = 10\sqrt{1.44} = 12$ ft-lb.

41. Using the notation of the text, $\mathbf{r} = \langle 0, 0.3, 0\rangle$ (measuring in meters) and $\mathbf{F}$ has direction $\langle 0, 3, -4\rangle$. The angle θ between them can be determined by $\cos\theta = \dfrac{\langle 0, 0.3, 0\rangle\cdot\langle 0, 3, -4\rangle}{|\langle 0, 0.3, 0\rangle|\,|\langle 0, 3, -4\rangle|} \Rightarrow \cos\theta = \dfrac{0.9}{(0.3)(5)} \Rightarrow \cos\theta = 0.6 \Rightarrow$ $\theta = \cos^{-1}(0.6) \approx 53.1^\circ$. Then $|\boldsymbol{\tau}| = |\mathbf{r}|\,|\mathbf{F}|\sin\theta \Rightarrow 100 \approx 0.3\,|\mathbf{F}|\sin 53.1^\circ \Rightarrow |\mathbf{F}| \approx \dfrac{100}{0.3\sin 53.1^\circ} \approx 417$ N.

42. Since $|\mathbf{u}\times\mathbf{v}| = |\mathbf{u}|\,|\mathbf{v}|\sin\theta$, $0 \le \theta \le \pi$, $|\mathbf{u}\times\mathbf{v}|$ achieves its maximum value for $\sin\theta = 1 \Rightarrow \theta = \frac{\pi}{2}$, in which case $|\mathbf{u}\times\mathbf{v}| = |\mathbf{u}|\,|\mathbf{v}| = 15$. The minimum value is zero, which occurs when $\sin\theta = 0 \Rightarrow \theta = 0$ or π, so when $\mathbf{u}$, $\mathbf{v}$ are parallel. Thus, when $\mathbf{u}$ points in the same direction as $\mathbf{v}$, so $\mathbf{u} = 3\,\mathbf{j}$, $|\mathbf{u}\times\mathbf{v}| = 0$. As $\mathbf{u}$ rotates counterclockwise, $\mathbf{u}\times\mathbf{v}$ is directed in the negative z-direction (by the right-hand rule) and the length increases until $\theta = \frac{\pi}{2}$, in which case $\mathbf{u} = -3\,\mathbf{i}$ and $|\mathbf{u}\times\mathbf{v}| = 15$. As $\mathbf{u}$ rotates to the negative y-axis, $\mathbf{u}\times\mathbf{v}$ remains pointed in the negative z-direction and the length of $\mathbf{u}\times\mathbf{v}$ decreases to 0, after which the direction of $\mathbf{u}\times\mathbf{v}$ reverses to point in the positive z-direction and $|\mathbf{u}\times\mathbf{v}|$ increases. When $\mathbf{u} = 3\,\mathbf{i}$ (so $\theta = \frac{\pi}{2}$), $|\mathbf{u}\times\mathbf{v}|$ again reaches its maximum of 15, after which $|\mathbf{u}\times\mathbf{v}|$ decreases to 0 as $\mathbf{u}$ rotates to the positive y-axis.

43. From Theorem 9 we have $|\mathbf{a}\times\mathbf{b}| = |\mathbf{a}|\,|\mathbf{b}|\sin\theta$, where θ is the angle between $\mathbf{a}$ and $\mathbf{b}$, and from Theorem 12.3.3 we have

$\mathbf{a}\cdot\mathbf{b} = |\mathbf{a}|\,|\mathbf{b}|\cos\theta \quad\Rightarrow\quad |\mathbf{a}|\,|\mathbf{b}| = \dfrac{\mathbf{a}\cdot\mathbf{b}}{\cos\theta}$. Substituting the second equation into the first gives $|\mathbf{a}\times\mathbf{b}| = \dfrac{\mathbf{a}\cdot\mathbf{b}}{\cos\theta}\sin\theta$, so

$\dfrac{|\mathbf{a}\times\mathbf{b}|}{\mathbf{a}\cdot\mathbf{b}} = \tan\theta$. Here $|\mathbf{a}\times\mathbf{b}| = |\langle 1,2,2\rangle| = \sqrt{1+4+4} = 3$, so $\tan\theta = \dfrac{|\mathbf{a}\times\mathbf{b}|}{\mathbf{a}\cdot\mathbf{b}} = \dfrac{3}{\sqrt{3}} = \sqrt{3} \quad\Rightarrow\quad \theta = 60^\circ$.

44. (a) Let $\mathbf{v} = \langle v_1, v_2, v_3\rangle$. Then

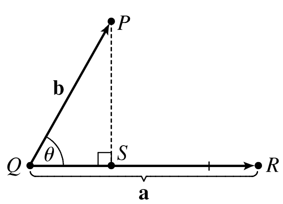
$$\langle 1,2,1\rangle\times\mathbf{v} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 2 & 1 \\ v_1 & v_2 & v_3 \end{vmatrix} = \begin{vmatrix} 2 & 1 \\ v_2 & v_3 \end{vmatrix}\mathbf{i} - \begin{vmatrix} 1 & 1 \\ v_1 & v_3 \end{vmatrix}\mathbf{j} + \begin{vmatrix} 1 & 2 \\ v_1 & v_2 \end{vmatrix}\mathbf{k} = (2v_3 - v_2)\,\mathbf{i} - (v_3 - v_1)\,\mathbf{j} + (v_2 - 2v_1)\,\mathbf{k}.$$

If $\langle 1,2,1\rangle\times\mathbf{v} = \langle 3,1,-5\rangle$ then $\langle 2v_3 - v_2, v_1 - v_3, v_2 - 2v_1\rangle = \langle 3,1,-5\rangle \quad\Leftrightarrow\quad 2v_3 - v_2 = 3$ **(1)**, $v_1 - v_3 = 1$ **(2)**, and $v_2 - 2v_1 = -5$ **(3)**. From **(3)** we have $v_2 = 2v_1 - 5$ and from **(2)** we have $v_3 = v_1 - 1$; substitution into **(1)** gives $2(v_1 - 1) - (2v_1 - 5) = 3 \quad\Rightarrow\quad 3 = 3$, so this is a dependent system. If we let $v_1 = a$ then $v_2 = 2a - 5$ and $v_3 = a - 1$, so $\mathbf{v}$ is any vector of the form $\langle a, 2a-5, a-1\rangle$.

(b) If $\langle 1,2,1\rangle\times\mathbf{v} = \langle 3,1,5\rangle$ then $2v_3 - v_2 = 3$ **(1)**, $v_1 - v_3 = 1$ **(2)**, and $v_2 - 2v_1 = 5$ **(3)**. From **(3)** we have $v_2 = 2v_1 + 5$ and from **(2)** we have $v_3 = v_1 - 1$; substitution into **(1)** gives $2(v_1 - 1) - (2v_1 + 5) = 3 \quad\Rightarrow\quad -7 = 3$, so this is an inconsistent system and has no solution.

Alternatively, if we use matrices to solve the system we could show that the determinant is 0 (and hence the system has no solution).

45. (a)



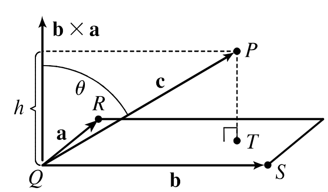
The distance between a point and a line is the length of the perpendicular from the point to the line, here $\left|\overrightarrow{PS}\right| = d$. But referring to triangle PQS, $d = \left|\overrightarrow{PS}\right| = \left|\overrightarrow{QP}\right|\sin\theta = |\mathbf{b}|\sin\theta$. But θ is the angle between $\overrightarrow{QP} = \mathbf{b}$ and $\overrightarrow{QR} = \mathbf{a}$. Thus by Theorem 9, $\sin\theta = \dfrac{|\mathbf{a}\times\mathbf{b}|}{|\mathbf{a}|\,|\mathbf{b}|}$ and so $d = |\mathbf{b}|\sin\theta = \dfrac{|\mathbf{b}|\,|\mathbf{a}\times\mathbf{b}|}{|\mathbf{a}|\,|\mathbf{b}|} = \dfrac{|\mathbf{a}\times\mathbf{b}|}{|\mathbf{a}|}$.

(b) $\mathbf{a} = \overrightarrow{QR} = \langle -1,-2,-1\rangle$ and $\mathbf{b} = \overrightarrow{QP} = \langle 1,-5,-7\rangle$. Then

$\mathbf{a}\times\mathbf{b} = \langle (-2)(-7) - (-1)(-5), (-1)(1) - (-1)(-7), (-1)(-5) - (-2)(1)\rangle = \langle 9,-8,7\rangle$.

Thus the distance is $d = \dfrac{|\mathbf{a}\times\mathbf{b}|}{|\mathbf{a}|} = \frac{1}{\sqrt{6}}\sqrt{81+64+49} = \sqrt{\frac{194}{6}} = \sqrt{\frac{97}{3}}$.

46. (a) The distance between a point and a plane is the length of the perpendicular from the point to the plane, here $\left|\overrightarrow{TP}\right| = d$. But $\overrightarrow{TP}$ is parallel to $\mathbf{b}\times\mathbf{a}$ (because $\mathbf{b}\times\mathbf{a}$ is perpendicular to $\mathbf{b}$ and $\mathbf{a}$) and $d = \left|\overrightarrow{TP}\right| =$ the absolute value of the scalar projection of $\mathbf{c}$ along $\mathbf{b}\times\mathbf{a}$, which is $|\mathbf{c}|\,|\cos\theta|$. (Notice that this is the same



setup as the development of the volume of a parallelepiped with $h = |\mathbf{c}|\,|\cos\theta|$). Thus $d = |\mathbf{c}|\,|\cos\theta| = h = V/A$ where $A = |\mathbf{a}\times\mathbf{b}|$, the area of the base. So finally $d = \dfrac{V}{A} = \dfrac{|\mathbf{a}\cdot(\mathbf{b}\times\mathbf{c})|}{|\mathbf{a}\times\mathbf{b}|}$.

(b) $\mathbf{a} = \overrightarrow{QR} = \langle -1, 2, 0\rangle$, $\mathbf{b} = \overrightarrow{QS} = \langle -1, 0, 3\rangle$ and $\mathbf{c} = \overrightarrow{QP} = \langle 1, 1, 4\rangle$. Then

$$\mathbf{a}\cdot(\mathbf{b}\times\mathbf{c}) = \begin{vmatrix} -1 & 2 & 0 \\ -1 & 0 & 3 \\ 1 & 1 & 4 \end{vmatrix} = (-1)\begin{vmatrix} 0 & 3 \\ 1 & 4 \end{vmatrix} - 2\begin{vmatrix} -1 & 3 \\ 1 & 4 \end{vmatrix} + 0 = 17$$

and

$$\mathbf{a}\times\mathbf{b} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -1 & 2 & 0 \\ -1 & 0 & 3 \end{vmatrix} = \begin{vmatrix} 2 & 0 \\ 0 & 3 \end{vmatrix}\mathbf{i} - \begin{vmatrix} -1 & 0 \\ -1 & 3 \end{vmatrix}\mathbf{j} + \begin{vmatrix} -1 & 2 \\ -1 & 0 \end{vmatrix}\mathbf{k} = 6\,\mathbf{i} + 3\,\mathbf{j} + 2\,\mathbf{k}$$

Thus $d = \dfrac{|\mathbf{a}\cdot(\mathbf{b}\times\mathbf{c})|}{|\mathbf{a}\times\mathbf{b}|} = \dfrac{17}{\sqrt{36+9+4}} = \dfrac{17}{7}$.

47. From Theorem 9 we have $|\mathbf{a}\times\mathbf{b}| = |\mathbf{a}|\,|\mathbf{b}|\sin\theta$ so

$$\begin{aligned} |\mathbf{a}\times\mathbf{b}|^2 &= |\mathbf{a}|^2\,|\mathbf{b}|^2\sin^2\theta = |\mathbf{a}|^2\,|\mathbf{b}|^2\left(1-\cos^2\theta\right) \\ &= |\mathbf{a}|^2\,|\mathbf{b}|^2 - (|\mathbf{a}|\,|\mathbf{b}|\cos\theta)^2 = |\mathbf{a}|^2\,|\mathbf{b}|^2 - (\mathbf{a}\cdot\mathbf{b})^2 \end{aligned}$$

by Theorem 12.3.3.

48. If $\mathbf{a}+\mathbf{b}+\mathbf{c} = \mathbf{0}$ then $\mathbf{b} = -(\mathbf{a}+\mathbf{c})$, so

$$\begin{aligned} \mathbf{a}\times\mathbf{b} &= \mathbf{a}\times[-(\mathbf{a}+\mathbf{c})] = -[\mathbf{a}\times(\mathbf{a}+\mathbf{c})] && \text{by Property 2 of the cross product (with } c=-1) \\ &= -[(\mathbf{a}\times\mathbf{a}) + (\mathbf{a}\times\mathbf{c})] && \text{by Property 3} \\ &= -[\mathbf{0} + (\mathbf{a}\times\mathbf{c})] = -\mathbf{a}\times\mathbf{c} && \text{by Example 2} \\ &= \mathbf{c}\times\mathbf{a} && \text{by Property 1} \end{aligned}$$

Similarly, $\mathbf{a} = -(\mathbf{b}+\mathbf{c})$ so

$$\begin{aligned} \mathbf{c}\times\mathbf{a} &= \mathbf{c}\times[-(\mathbf{b}+\mathbf{c})] = -[\mathbf{c}\times(\mathbf{b}+\mathbf{c})] \\ &= -[(\mathbf{c}\times\mathbf{b}) + (\mathbf{c}\times\mathbf{c})] = -[(\mathbf{c}\times\mathbf{b}) + \mathbf{0}] \\ &= -\mathbf{c}\times\mathbf{b} = \mathbf{b}\times\mathbf{c} \end{aligned}$$

Thus $\mathbf{a}\times\mathbf{b} = \mathbf{b}\times\mathbf{c} = \mathbf{c}\times\mathbf{a}$.

49.
$$\begin{aligned} (\mathbf{a}-\mathbf{b})\times(\mathbf{a}+\mathbf{b}) &= (\mathbf{a}-\mathbf{b})\times\mathbf{a} + (\mathbf{a}-\mathbf{b})\times\mathbf{b} && \text{by Property 3 of the cross product} \\ &= \mathbf{a}\times\mathbf{a} + (-\mathbf{b})\times\mathbf{a} + \mathbf{a}\times\mathbf{b} + (-\mathbf{b})\times\mathbf{b} && \text{by Property 4} \\ &= (\mathbf{a}\times\mathbf{a}) - (\mathbf{b}\times\mathbf{a}) + (\mathbf{a}\times\mathbf{b}) - (\mathbf{b}\times\mathbf{b}) && \text{by Property 2 (with } c=-1) \\ &= \mathbf{0} - (\mathbf{b}\times\mathbf{a}) + (\mathbf{a}\times\mathbf{b}) - \mathbf{0} && \text{by Example 2} \\ &= (\mathbf{a}\times\mathbf{b}) + (\mathbf{a}\times\mathbf{b}) && \text{by Property 1} \\ &= 2(\mathbf{a}\times\mathbf{b}) \end{aligned}$$

50. Let $\mathbf{a} = \langle a_1, a_2, a_3 \rangle$, $\mathbf{b} = \langle b_1, b_2, b_3 \rangle$ and $\mathbf{c} = \langle c_1, c_2, c_3 \rangle$, so $\mathbf{b} \times \mathbf{c} = \langle b_2c_3 - b_3c_2, b_3c_1 - b_1c_3, b_1c_2 - b_2c_1 \rangle$ and

$$\begin{aligned}
\mathbf{a} \times (\mathbf{b} \times \mathbf{c}) &= \langle a_2(b_1c_2 - b_2c_1) - a_3(b_3c_1 - b_1c_3), a_3(b_2c_3 - b_3c_2) - a_1(b_1c_2 - b_2c_1), \\
&\qquad a_1(b_3c_1 - b_1c_3) - a_2(b_2c_3 - b_3c_2) \rangle \\
&= \langle a_2b_1c_2 - a_2b_2c_1 - a_3b_3c_1 + a_3b_1c_3, a_3b_2c_3 - a_3b_3c_2 - a_1b_1c_2 + a_1b_2c_1, \\
&\qquad a_1b_3c_1 - a_1b_1c_3 - a_2b_2c_3 + a_2b_3c_2 \rangle \\
&= \langle (a_2c_2 + a_3c_3)b_1 - (a_2b_2 + a_3b_3)c_1, (a_1c_1 + a_3c_3)b_2 - (a_1b_1 + a_3b_3)c_2, \\
&\qquad (a_1c_1 + a_2c_2)b_3 - (a_1b_1 + a_2b_2)c_3 \rangle \\
(\star) \quad &= \langle (a_2c_2 + a_3c_3)b_1 - (a_2b_2 + a_3b_3)c_1 + a_1b_1c_1 - a_1b_1c_1, \\
&\qquad (a_1c_1 + a_3c_3)b_2 - (a_1b_1 + a_3b_3)c_2 + a_2b_2c_2 - a_2b_2c_2, \\
&\qquad (a_1c_1 + a_2c_2)b_3 - (a_1b_1 + a_2b_2)c_3 + a_3b_3c_3 - a_3b_3c_3 \rangle \\
&= \langle (a_1c_1 + a_2c_2 + a_3c_3)b_1 - (a_1b_1 + a_2b_2 + a_3b_3)c_1, \\
&\qquad (a_1c_1 + a_2c_2 + a_3c_3)b_2 - (a_1b_1 + a_2b_2 + a_3b_3)c_2, \\
&\qquad (a_1c_1 + a_2c_2 + a_3c_3)b_3 - (a_1b_1 + a_2b_2 + a_3b_3)c_3 \rangle \\
&= (a_1c_1 + a_2c_2 + a_3c_3) \langle b_1, b_2, b_3 \rangle - (a_1b_1 + a_2b_2 + a_3b_3) \langle c_1, c_2, c_3 \rangle \\
&= (\mathbf{a} \cdot \mathbf{c})\mathbf{b} - (\mathbf{a} \cdot \mathbf{b})\mathbf{c}
\end{aligned}$$

($\star$) Here we look ahead to see what terms are still needed to arrive at the desired equation. By adding and subtracting the same terms, we don't change the value of the component.

51. $\mathbf{a} \times (\mathbf{b} \times \mathbf{c}) + \mathbf{b} \times (\mathbf{c} \times \mathbf{a}) + \mathbf{c} \times (\mathbf{a} \times \mathbf{b})$

$$\begin{aligned}
&= [(\mathbf{a} \cdot \mathbf{c})\mathbf{b} - (\mathbf{a} \cdot \mathbf{b})\mathbf{c}] + [(\mathbf{b} \cdot \mathbf{a})\mathbf{c} - (\mathbf{b} \cdot \mathbf{c})\mathbf{a}] + [(\mathbf{c} \cdot \mathbf{b})\mathbf{a} - (\mathbf{c} \cdot \mathbf{a})\mathbf{b}] \qquad \text{by Exercise 50} \\
&= (\mathbf{a} \cdot \mathbf{c})\mathbf{b} - (\mathbf{a} \cdot \mathbf{b})\mathbf{c} + (\mathbf{a} \cdot \mathbf{b})\mathbf{c} - (\mathbf{b} \cdot \mathbf{c})\mathbf{a} + (\mathbf{b} \cdot \mathbf{c})\mathbf{a} - (\mathbf{a} \cdot \mathbf{c})\mathbf{b} = \mathbf{0}
\end{aligned}$$

52. Let $\mathbf{c} \times \mathbf{d} = \mathbf{v}$. Then

$$\begin{aligned}
(\mathbf{a} \times \mathbf{b}) \cdot (\mathbf{c} \times \mathbf{d}) &= (\mathbf{a} \times \mathbf{b}) \cdot \mathbf{v} = \mathbf{a} \cdot (\mathbf{b} \times \mathbf{v}) && \text{by Property 5 of the cross product} \\
&= \mathbf{a} \cdot [\mathbf{b} \times (\mathbf{c} \times \mathbf{d})] = \mathbf{a} \cdot [(\mathbf{b} \cdot \mathbf{d})\mathbf{c} - (\mathbf{b} \cdot \mathbf{c})\mathbf{d}] && \text{by Exercise 50} \\
&= (\mathbf{b} \cdot \mathbf{d})(\mathbf{a} \cdot \mathbf{c}) - (\mathbf{b} \cdot \mathbf{c})(\mathbf{a} \cdot \mathbf{d}) && \text{by Properties 3 and 4 of the dot product} \\
&= \begin{vmatrix} \mathbf{a} \cdot \mathbf{c} & \mathbf{b} \cdot \mathbf{c} \\ \mathbf{a} \cdot \mathbf{d} & \mathbf{b} \cdot \mathbf{d} \end{vmatrix}
\end{aligned}$$

53. (a) No. If $\mathbf{a} \cdot \mathbf{b} = \mathbf{a} \cdot \mathbf{c}$, then $\mathbf{a} \cdot (\mathbf{b} - \mathbf{c}) = 0$, so $\mathbf{a}$ is perpendicular to $\mathbf{b} - \mathbf{c}$, which can happen if $\mathbf{b} \neq \mathbf{c}$. For example, let $\mathbf{a} = \langle 1, 1, 1 \rangle$, $\mathbf{b} = \langle 1, 0, 0 \rangle$ and $\mathbf{c} = \langle 0, 1, 0 \rangle$.

(b) No. If $\mathbf{a} \times \mathbf{b} = \mathbf{a} \times \mathbf{c}$ then $\mathbf{a} \times (\mathbf{b} - \mathbf{c}) = \mathbf{0}$, which implies that $\mathbf{a}$ is parallel to $\mathbf{b} - \mathbf{c}$, which of course can happen if $\mathbf{b} \neq \mathbf{c}$.

(c) Yes. Since $\mathbf{a} \cdot \mathbf{c} = \mathbf{a} \cdot \mathbf{b}$, $\mathbf{a}$ is perpendicular to $\mathbf{b} - \mathbf{c}$, by part (a). From part (b), $\mathbf{a}$ is also parallel to $\mathbf{b} - \mathbf{c}$. Thus since $\mathbf{a} \neq \mathbf{0}$ but is both parallel and perpendicular to $\mathbf{b} - \mathbf{c}$, we have $\mathbf{b} - \mathbf{c} = \mathbf{0}$, so $\mathbf{b} = \mathbf{c}$.

54. (a) $\mathbf{k}_i$ is perpendicular to $\mathbf{v}_i$ if $i \neq j$ by the definition of $\mathbf{k}_i$ and Theorem 8.

(b) $\mathbf{k}_1 \cdot \mathbf{v}_1 = \dfrac{\mathbf{v}_2 \times \mathbf{v}_3}{\mathbf{v}_1 \cdot (\mathbf{v}_2 \times \mathbf{v}_3)} \cdot \mathbf{v}_1 = \dfrac{\mathbf{v}_1 \cdot (\mathbf{v}_2 \times \mathbf{v}_3)}{\mathbf{v}_1 \cdot (\mathbf{v}_2 \times \mathbf{v}_3)} = 1$

$\mathbf{k}_2 \cdot \mathbf{v}_2 = \dfrac{\mathbf{v}_3 \times \mathbf{v}_1}{\mathbf{v}_1 \cdot (\mathbf{v}_2 \times \mathbf{v}_3)} \cdot \mathbf{v}_2 = \dfrac{\mathbf{v}_2 \cdot (\mathbf{v}_3 \times \mathbf{v}_1)}{\mathbf{v}_1 \cdot (\mathbf{v}_2 \times \mathbf{v}_3)} = \dfrac{(\mathbf{v}_2 \times \mathbf{v}_3) \cdot \mathbf{v}_1}{\mathbf{v}_1 \cdot (\mathbf{v}_2 \times \mathbf{v}_3)} = 1$ [by Property 5 of the cross product]

$\mathbf{k}_3 \cdot \mathbf{v}_3 = \dfrac{(\mathbf{v}_1 \times \mathbf{v}_2) \cdot \mathbf{v}_3}{\mathbf{v}_1 \cdot (\mathbf{v}_2 \times \mathbf{v}_3)} = \dfrac{\mathbf{v}_1 \cdot (\mathbf{v}_2 \times \mathbf{v}_3)}{\mathbf{v}_1 \cdot (\mathbf{v}_2 \times \mathbf{v}_3)} = 1$ [by Property 5]

(c) $\mathbf{k}_1 \cdot (\mathbf{k}_2 \times \mathbf{k}_3) = \mathbf{k}_1 \cdot \left(\dfrac{\mathbf{v}_3 \times \mathbf{v}_1}{\mathbf{v}_1 \cdot (\mathbf{v}_2 \times \mathbf{v}_3)} \times \dfrac{\mathbf{v}_1 \times \mathbf{v}_2}{\mathbf{v}_1 \cdot (\mathbf{v}_2 \times \mathbf{v}_3)} \right) = \dfrac{\mathbf{k}_1}{[\mathbf{v}_1 \cdot (\mathbf{v}_2 \times \mathbf{v}_3)]^2} \cdot [(\mathbf{v}_3 \times \mathbf{v}_1) \times (\mathbf{v}_1 \times \mathbf{v}_2)]$

$= \dfrac{\mathbf{k}_1}{[\mathbf{v}_1 \cdot (\mathbf{v}_2 \times \mathbf{v}_3)]^2} \cdot ([(\mathbf{v}_3 \times \mathbf{v}_1) \cdot \mathbf{v}_2]\, \mathbf{v}_1 - [(\mathbf{v}_3 \times \mathbf{v}_1) \cdot \mathbf{v}_1]\, \mathbf{v}_2)$ [by Exercise 50]

But $(\mathbf{v}_3 \times \mathbf{v}_1) \cdot \mathbf{v}_1 = 0$ since $\mathbf{v}_3 \times \mathbf{v}_1$ is orthogonal to $\mathbf{v}_1$, and

$(\mathbf{v}_3 \times \mathbf{v}_1) \cdot \mathbf{v}_2 = \mathbf{v}_2 \cdot (\mathbf{v}_3 \times \mathbf{v}_1) = (\mathbf{v}_2 \times \mathbf{v}_3) \cdot \mathbf{v}_1 = \mathbf{v}_1 \cdot (\mathbf{v}_2 \times \mathbf{v}_3)$. Thus

$$\mathbf{k}_1 \cdot (\mathbf{k}_2 \times \mathbf{k}_3) = \frac{\mathbf{k}_1}{[\mathbf{v}_1 \cdot (\mathbf{v}_2 \times \mathbf{v}_3)]^2} \cdot [\mathbf{v}_1 \cdot (\mathbf{v}_2 \times \mathbf{v}_3)]\, \mathbf{v}_1 = \frac{\mathbf{k}_1 \cdot \mathbf{v}_1}{\mathbf{v}_1 \cdot (\mathbf{v}_2 \times \mathbf{v}_3)} = \frac{1}{\mathbf{v}_1 \cdot (\mathbf{v}_2 \times \mathbf{v}_3)} \quad \text{[by part (b)]}$$

DISCOVERY PROJECT The Geometry of a Tetrahedron

1. Set up a coordinate system so that vertex S is at the origin, $R = (0, y_1, 0)$, $Q = (x_2, y_2, 0)$, $P = (x_3, y_3, z_3)$.

Then $\overrightarrow{SR} = \langle 0, y_1, 0 \rangle$, $\overrightarrow{SQ} = \langle x_2, y_2, 0 \rangle$, $\overrightarrow{SP} = \langle x_3, y_3, z_3 \rangle$, $\overrightarrow{QR} = \langle -x_2, y_1 - y_2, 0 \rangle$, and $\overrightarrow{QP} = \langle x_3 - x_2, y_3 - y_2, z_3 \rangle$.

Let

$$\mathbf{v}_S = \overrightarrow{QR} \times \overrightarrow{QP} = (y_1 z_3 - y_2 z_3)\, \mathbf{i} + x_2 z_3\, \mathbf{j} + (-x_2 y_3 - x_3 y_1 + x_3 y_2 + x_2 y_1)\, \mathbf{k}$$

Then $\mathbf{v}_S$ is an outward normal to the face opposite vertex S. Similarly,

$\mathbf{v}_R = \overrightarrow{SQ} \times \overrightarrow{SP} = y_2 z_3\, \mathbf{i} - x_2 z_3\, \mathbf{j} + (x_2 y_3 - x_3 y_2)\, \mathbf{k}$, $\mathbf{v}_Q = \overrightarrow{SP} \times \overrightarrow{SR} = -y_1 z_3\, \mathbf{i} + x_3 y_1\, \mathbf{k}$, and

$\mathbf{v}_P = \overrightarrow{SR} \times \overrightarrow{SQ} = -x_2 y_1\, \mathbf{k} \quad \Rightarrow \quad \mathbf{v}_S + \mathbf{v}_R + \mathbf{v}_Q + \mathbf{v}_P = \mathbf{0}$. Now

$$\begin{aligned} |\mathbf{v}_S| &= \text{area of the parallelogram determined by } \overrightarrow{QR} \text{ and } \overrightarrow{QP} \\ &= 2\,(\text{area of triangle } RQP) = 2|\mathbf{v}_1| \end{aligned}$$

So $\mathbf{v}_S = 2\mathbf{v}_1$, and similarly $\mathbf{v}_R = 2\mathbf{v}_2$, $\mathbf{v}_Q = 2\mathbf{v}_3$, $\mathbf{v}_P = 2\mathbf{v}_4$. Thus $\mathbf{v}_1 + \mathbf{v}_2 + \mathbf{v}_3 + \mathbf{v}_4 = \mathbf{0}$.

2. (a) Let $S = (x_0, y_0, z_0)$, $R = (x_1, y_1, z_1)$, $Q = (x_2, y_2, z_2)$, $P = (x_3, y_3, z_3)$ be the four vertices. Then

$$\begin{aligned} \text{Volume} &= \tfrac{1}{3}(\text{distance from } S \text{ to plane } RQP) \times (\text{area of triangle } RQP) \\ &= \tfrac{1}{3} \frac{\left|\mathbf{N} \cdot \overrightarrow{SR}\right|}{|\mathbf{N}|} \cdot \tfrac{1}{2} \left| \overrightarrow{RQ} \times \overrightarrow{RP} \right| \end{aligned}$$

where $\mathbf{N}$ is a vector which is normal to the face RQP. Thus $\mathbf{N} = \overrightarrow{RQ} \times \overrightarrow{RP}$. Therefore

$$V = \left|\tfrac{1}{6}\left(\overrightarrow{RQ} \times \overrightarrow{RP}\right) \cdot \overrightarrow{SR}\right| = \frac{1}{6}\left|\begin{vmatrix} x_0 - x & y_0 - y_1 & z_0 - z_1 \\ x_2 - x_1 & y_2 - y_1 & z_2 - z_1 \\ x_3 - x_1 & y_3 - y_1 & z_3 - z_1 \end{vmatrix}\right|$$

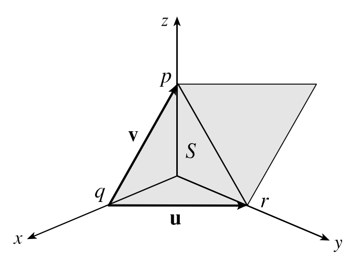
(b) Using the formula from part (a), $V = \dfrac{1}{6}\left|\begin{vmatrix} 1-1 & 1-2 & 1-3 \\ 1-1 & 1-2 & 2-3 \\ 3-1 & -1-2 & 2-3 \end{vmatrix}\right| = \dfrac{1}{6}\left|2(1-2)\right| = \dfrac{1}{3}$.

3. We define a vector $\mathbf{v}_1$ to have length equal to the area of the face opposite vertex P, so we can say $|\mathbf{v}_1| = A$, and direction perpendicular to the face and pointing outward, as in Problem 1. Similarly, we define $\mathbf{v}_2$, $\mathbf{v}_3$, and $\mathbf{v}_4$ so that $|\mathbf{v}_2| = B$, $|\mathbf{v}_3| = C$, and $|\mathbf{v}_4| = D$ and with the analogous directions. From Problem 1, we know $\mathbf{v}_1 + \mathbf{v}_2 + \mathbf{v}_3 + \mathbf{v}_4 = \mathbf{0} \Rightarrow$ $\mathbf{v}_4 = -(\mathbf{v}_1 + \mathbf{v}_2 + \mathbf{v}_3) \Rightarrow |\mathbf{v}_4| = |-(\mathbf{v}_1 + \mathbf{v}_2 + \mathbf{v}_3)| = |\mathbf{v}_1 + \mathbf{v}_2 + \mathbf{v}_3| \Rightarrow |\mathbf{v}_4|^2 = |\mathbf{v}_1 + \mathbf{v}_2 + \mathbf{v}_3|^2 \Rightarrow$

$$\begin{aligned} \mathbf{v}_4 \cdot \mathbf{v}_4 &= (\mathbf{v}_1 + \mathbf{v}_2 + \mathbf{v}_3) \cdot (\mathbf{v}_1 + \mathbf{v}_2 + \mathbf{v}_3) \\ &= \mathbf{v}_1 \cdot \mathbf{v}_1 + \mathbf{v}_1 \cdot \mathbf{v}_2 + \mathbf{v}_1 \cdot \mathbf{v}_3 + \mathbf{v}_2 \cdot \mathbf{v}_1 + \mathbf{v}_2 \cdot \mathbf{v}_2 + \mathbf{v}_2 \cdot \mathbf{v}_3 + \mathbf{v}_3 \cdot \mathbf{v}_1 + \mathbf{v}_3 \cdot \mathbf{v}_2 + \mathbf{v}_3 \cdot \mathbf{v}_3 \end{aligned}$$

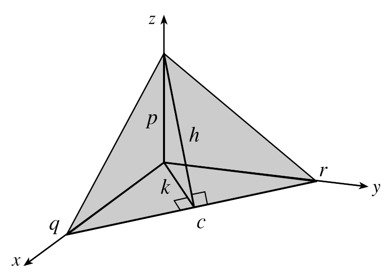
Since the vertex S is trirectangular, we know the three faces meeting at S are mutually perpendicular, so the vectors $\mathbf{v}_1$, $\mathbf{v}_2$, $\mathbf{v}_3$ are also mutually perpendicular. Therefore, $\mathbf{v}_i \cdot \mathbf{v}_j = 0$ for $i \neq j$ and $i, j \in \{1, 2, 3\}$. Thus we have $\mathbf{v}_4 \cdot \mathbf{v}_4 = \mathbf{v}_1 \cdot \mathbf{v}_1 + \mathbf{v}_2 \cdot \mathbf{v}_2 + \mathbf{v}_3 \cdot \mathbf{v}_3 \Rightarrow |\mathbf{v}_4|^2 = |\mathbf{v}_1|^2 + |\mathbf{v}_2|^2 + |\mathbf{v}_3|^2 \Rightarrow D^2 = A^2 + B^2 + C^2$.

Another method: We introduce a coordinate system, as shown. Recall that the area of the parallelogram spanned by two vectors is equal to the length of their cross product, so since $\mathbf{u} \times \mathbf{v} = \langle -q, r, 0\rangle \times \langle -q, 0, p\rangle = \langle pr, pq, qr\rangle$, we have $|\mathbf{u} \times \mathbf{v}| = \sqrt{(pr)^2 + (pq)^2 + (qr)^2}$, and therefore



$$\begin{aligned} D^2 &= \left(\tfrac{1}{2}|\mathbf{u} \times \mathbf{v}|\right)^2 = \tfrac{1}{4}[(pr)^2 + (pq)^2 + (qr)^2] \\ &= \left(\tfrac{1}{2}pr\right)^2 + \left(\tfrac{1}{2}pq\right)^2 + \left(\tfrac{1}{2}qr\right)^2 = A^2 + B^2 + C^2. \end{aligned}$$

A third method: We draw a line from S perpendicular to QR, as shown. Now $D = \frac{1}{2}ch$, so $D^2 = \frac{1}{4}c^2h^2$. Substituting $h^2 = p^2 + k^2$, we get $D^2 = \frac{1}{4}c^2\left(p^2 + k^2\right) = \frac{1}{4}c^2p^2 + \frac{1}{4}c^2k^2$. But $C = \frac{1}{2}ck$, so $D^2 = \frac{1}{4}c^2p^2 + C^2$. Now substituting $c^2 = q^2 + r^2$ gives $D^2 = \frac{1}{4}p^2q^2 + \frac{1}{4}q^2r^2 + C^2 = A^2 + B^2 + C^2$.



12.5 Equations of Lines and Planes

1. (a) True; each of the first two lines has a direction vector parallel to the direction vector of the third line, so these vectors are each scalar multiples of the third direction vector. Then the first two direction vectors are also scalar multiples of each other, so these vectors, and hence the two lines, are parallel.

(b) False; for example, the x- and y-axes are both perpendicular to the z-axis, yet the x- and y-axes are not parallel.

(c) True; each of the first two planes has a normal vector parallel to the normal vector of the third plane, so these two normal vectors are parallel to each other and the planes are parallel.

(d) False; for example, the xy- and yz-planes are not parallel, yet they are both perpendicular to the xz-plane.

(e) False; the x- and y-axes are not parallel, yet they are both parallel to the plane $z = 1$.

(f) True; if each line is perpendicular to a plane, then the lines' direction vectors are both parallel to a normal vector for the plane. Thus, the direction vectors are parallel to each other and the lines are parallel.

(g) False; the planes $y = 1$ and $z = 1$ are not parallel, yet they are both parallel to the x-axis.

(h) True; if each plane is perpendicular to a line, then any normal vector for each plane is parallel to a direction vector for the line. Thus, the normal vectors are parallel to each other and the planes are parallel.

(i) True; see Figure 9 and the accompanying discussion.

(j) False; they can be skew, as in Example 3.

(k) True. Consider any normal vector for the plane and any direction vector for the line. If the normal vector is perpendicular to the direction vector, the line and plane are parallel. Otherwise, the vectors meet at an angle θ, $0^\circ \leq \theta < 90^\circ$, and the line will intersect the plane at an angle $90^\circ - \theta$.

2. For this line, we have $\mathbf{r}_0 = 6\,\mathbf{i} - 5\,\mathbf{j} + 2\,\mathbf{k}$ and $\mathbf{v} = \mathbf{i} + 3\,\mathbf{j} - \frac{2}{3}\,\mathbf{k}$, so a vector equation is $\mathbf{r} = \mathbf{r}_0 + t\,\mathbf{v} = (6\,\mathbf{i} - 5\,\mathbf{j} + 2\,\mathbf{k}) + t\big(\mathbf{i} + 3\,\mathbf{j} - \frac{2}{3}\,\mathbf{k}\big) = (6 + t)\,\mathbf{i} + (-5 + 3t)\,\mathbf{j} + \big(2 - \frac{2}{3}t\big)\,\mathbf{k}$ and parametric equations are $x = 6 + t$, $y = -5 + 3t$, $z = 2 - \frac{2}{3}t$.

3. For this line, we have $\mathbf{r}_0 = 2\,\mathbf{i} + 2.4\,\mathbf{j} + 3.5\,\mathbf{k}$ and $\mathbf{v} = 3\,\mathbf{i} + 2\,\mathbf{j} - \mathbf{k}$, so a vector equation is $\mathbf{r} = \mathbf{r}_0 + t\,\mathbf{v} = (2\,\mathbf{i} + 2.4\,\mathbf{j} + 3.5\,\mathbf{k}) + t(3\,\mathbf{i} + 2\,\mathbf{j} - \mathbf{k}) = (2 + 3t)\,\mathbf{i} + (2.4 + 2t)\,\mathbf{j} + (3.5 - t)\,\mathbf{k}$ and parametric equations are $x = 2 + 3t$, $y = 2.4 + 2t$, $z = 3.5 - t$.

4. This line has the same direction as the given line, $\mathbf{v} = 2\,\mathbf{i} - 3\,\mathbf{j} + 9\,\mathbf{k}$. Here $\mathbf{r}_0 = 14\,\mathbf{j} - 10\,\mathbf{k}$, so a vector equation is $\mathbf{r} = (14\,\mathbf{j} - 10\,\mathbf{k}) + t(2\,\mathbf{i} - 3\,\mathbf{j} + 9\,\mathbf{k}) = 2t\,\mathbf{i} + (14 - 3t)\,\mathbf{j} + (-10 + 9t)\,\mathbf{k}$ and parametric equations are $x = 2t$, $y = 14 - 3t$, $z = -10 + 9t$.

5. A line perpendicular to the given plane has the same direction as a normal vector to the plane, such as $\mathbf{n} = \langle 1, 3, 1 \rangle$. So $\mathbf{r}_0 = \mathbf{i} + 6\,\mathbf{k}$, and we can take $\mathbf{v} = \mathbf{i} + 3\,\mathbf{j} + \mathbf{k}$. Then a vector equation is $\mathbf{r} = (\mathbf{i} + 6\,\mathbf{k}) + t(\mathbf{i} + 3\,\mathbf{j} + \mathbf{k}) = (1 + t)\,\mathbf{i} + 3t\,\mathbf{j} + (6 + t)\,\mathbf{k}$, and parametric equations are $x = 1 + t$, $y = 3t$, $z = 6 + t$.

6. The vector $\mathbf{v} = \langle 4-0, 3-0, -1-0 \rangle = \langle 4, 3, -1 \rangle$ is parallel to the line. Letting $P_0 = (0, 0, 0)$, parametric equations are $x = 0 + 4 \cdot t = 4t$, $y = 0 + 3 \cdot t = 3t$, $z = 0 + (-1) \cdot t = -t$, while symmetric equations are $\dfrac{x}{4} = \dfrac{y}{3} = \dfrac{z}{-1}$ or $\dfrac{x}{4} = \dfrac{y}{3} = -z$.

7. The vector $\mathbf{v} = \left\langle 2-0, 1-\frac{1}{2}, -3-1 \right\rangle = \left\langle 2, \frac{1}{2}, -4 \right\rangle$ is parallel to the line. Letting $P_0 = (2, 1, -3)$, parametric equations are $x = 2 + 2t$, $y = 1 + \frac{1}{2}t$, $z = -3 - 4t$, while symmetric equations are $\dfrac{x-2}{2} = \dfrac{y-1}{1/2} = \dfrac{z+3}{-4}$ or $\dfrac{x-2}{2} = 2y - 2 = \dfrac{z+3}{-4}$.

8. $\mathbf{v} = \langle 2.6-1, 1.2-2.4, 0.3-4.6 \rangle = \langle 1.6, -1.2, -4.3 \rangle$, and letting $P_0 = (1, 2.4, 4.6)$, parametric equations are $x = 1 + 1.6t$, $y = 2.4 - 1.2t$, $z = 4.6 - 4.3t$, while symmetric equations are $\dfrac{x-1}{1.6} = \dfrac{y-2.4}{-1.2} = \dfrac{z-4.6}{-4.3}$.

9. $\mathbf{v} = \langle 3-(-8), -2-1, 4-4 \rangle = \langle 11, -3, 0 \rangle$, and letting $P_0 = (-8, 1, 4)$, parametric equations are $x = -8 + 11t$, $y = 1 - 3t$, $z = 4 + 0t = 4$, while symmetric equations are $\dfrac{x+8}{11} = \dfrac{y-1}{-3}$, $z = 4$. Notice here that the direction number $c = 0$, so rather than writing $\dfrac{z-4}{0}$ in the symmetric equation we must write the equation $z = 4$ separately.

10. $\mathbf{v} = (\mathbf{i} + \mathbf{j}) \times (\mathbf{j} + \mathbf{k}) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 1 & 0 \\ 0 & 1 & 1 \end{vmatrix} = \mathbf{i} - \mathbf{j} + \mathbf{k}$ is the direction of the line perpendicular to both $\mathbf{i} + \mathbf{j}$ and $\mathbf{j} + \mathbf{k}$.

With $P_0 = (2, 1, 0)$, parametric equations are $x = 2 + t$, $y = 1 - t$, $z = t$ and symmetric equations are $x - 2 = \dfrac{y-1}{-1} = z$ or $x - 2 = 1 - y = z$.

11. The given line $\dfrac{x}{2} = \dfrac{y}{3} = \dfrac{z+1}{1}$ has direction $\mathbf{v} = \langle 2, 3, 1 \rangle$. Taking $(-6, 2, 3)$ as P_0, parametric equations are $x = -6 + 2t$, $y = 2 + 3t$, $z = 3 + t$ and symmetric equations are $\dfrac{x+6}{2} = \dfrac{y-2}{3} = z - 3$.

12. Setting $z = 0$ we see that $(1, 0, 0)$ satisfies the equations of both planes, so they do in fact have a line of intersection. The line is perpendicular to the normal vectors of both planes, so a direction vector for the line is $\mathbf{v} = \mathbf{n}_1 \times \mathbf{n}_2 = \langle 1, 2, 3 \rangle \times \langle 1, -1, 1 \rangle = \langle 5, 2, -3 \rangle$. Taking the point $(1, 0, 0)$ as P_0, parametric equations are $x = 1 + 5t$, $y = 2t$, $z = -3t$, and symmetric equations are $\dfrac{x-1}{5} = \dfrac{y}{2} = \dfrac{z}{-3}$.

13. Direction vectors of the lines are $\mathbf{v}_1 = \langle -2-(-4), 0-(-6), -3-1 \rangle = \langle 2, 6, -4 \rangle$ and $\mathbf{v}_2 = \langle 5-10, 3-18, 14-4 \rangle = \langle -5, -15, 10 \rangle$, and since $\mathbf{v}_2 = -\frac{5}{2}\mathbf{v}_1$, the direction vectors and thus the lines are parallel.

14. Direction vectors of the lines are $\mathbf{v}_1 = \langle 3, -3, 1 \rangle$ and $\mathbf{v}_2 = \langle 1, -4, -12 \rangle$. Since $\mathbf{v}_1 \cdot \mathbf{v}_2 = 3 + 12 - 12 \neq 0$, the vectors and thus the lines are not perpendicular.

15. (a) The line passes through the point $(1,-5,6)$ and a direction vector for the line is $\langle -1,2,-3\rangle$, so symmetric equations for the line are $\dfrac{x-1}{-1}=\dfrac{y+5}{2}=\dfrac{z-6}{-3}$.

(b) The line intersects the xy-plane when $z=0$, so we need $\dfrac{x-1}{-1}=\dfrac{y+5}{2}=\dfrac{0-6}{-3}$ or $\dfrac{x-1}{-1}=2 \;\Rightarrow\; x=-1$, $\dfrac{y+5}{2}=2 \;\Rightarrow\; y=-1$. Thus the point of intersection with the xy-plane is $(-1,-1,0)$. Similarly for the yz-plane, we need $x=0 \;\Rightarrow\; 1=\dfrac{y+5}{2}=\dfrac{z-6}{-3} \;\Rightarrow\; y=-3$, $z=3$. Thus the line intersects the yz-plane at $(0,-3,3)$. For the xz-plane, we need $y=0 \;\Rightarrow\; \dfrac{x-1}{-1}=\dfrac{5}{2}=\dfrac{z-6}{-3} \;\Rightarrow\; x=-\frac{3}{2}$, $z=-\frac{3}{2}$. So the line intersects the xz-plane at $\left(-\frac{3}{2},0,-\frac{3}{2}\right)$.

16. (a) A vector normal to the plane $x-y+3z=7$ is $\mathbf{n}=\langle 1,-1,3\rangle$, and since the line is to be perpendicular to the plane, $\mathbf{n}$ is also a direction vector for the line. Thus parametric equations of the line are $x=2+t$, $y=4-t$, $z=6+3t$.

(b) On the xy-plane, $z=0$. So $z=6+3t=0 \;\Rightarrow\; t=-2$ in the parametric equations of the line, and therefore $x=0$ and $y=6$, giving the point of intersection $(0,6,0)$. For the yz-plane, $x=0$ so we get the same point of interesection: $(0,6,0)$. For the xz-plane, $y=0$ which implies $t=4$, so $x=6$ and $z=18$ and the point of intersection is $(6,0,18)$.

17. From Equation 4, the line segment from $\mathbf{r}_0=6\,\mathbf{i}-\mathbf{j}+9\,\mathbf{k}$ to $\mathbf{r}_1=7\,\mathbf{i}+6\,\mathbf{j}$ has vector equation

$$\begin{aligned}\mathbf{r}(t)&=(1-t)\,\mathbf{r}_0+t\,\mathbf{r}_1=(1-t)(6\,\mathbf{i}-\mathbf{j}+9\,\mathbf{k})+t(7\,\mathbf{i}+6\,\mathbf{j})\\&=(6\,\mathbf{i}-\mathbf{j}+9\,\mathbf{k})-t(6\,\mathbf{i}-\mathbf{j}+9\,\mathbf{k})+t(7\,\mathbf{i}+6\,\mathbf{j})\\&=(6\,\mathbf{i}-\mathbf{j}+9\,\mathbf{k})+t(\,\mathbf{i}+7\,\mathbf{j}-9\,\mathbf{k}),\quad 0\le t\le 1.\end{aligned}$$

18. From Equation 4, the line segment from $\mathbf{r}_0=-2\,\mathbf{i}+18\,\mathbf{j}+31\,\mathbf{k}$ to $\mathbf{r}_1=11\,\mathbf{i}-4\,\mathbf{j}+48\,\mathbf{k}$ has vector equation

$$\begin{aligned}\mathbf{r}(t)&=(1-t)\,\mathbf{r}_0+t\,\mathbf{r}_1=(1-t)(-2\,\mathbf{i}+18\,\mathbf{j}+31\,\mathbf{k})+t(11\,\mathbf{i}-4\,\mathbf{j}+48\,\mathbf{k})\\&=(-2\,\mathbf{i}+18\,\mathbf{j}+31\,\mathbf{k})+t(13\,\mathbf{i}-22\,\mathbf{j}+17\,\mathbf{k}),\quad 0\le t\le 1.\end{aligned}$$

The corresponding parametric equations are $x=-2+13t$, $y=18-22t$, $z=31+17t$, $0\le t\le 1$.

19. Since the direction vectors $\langle 2,-1,3\rangle$ and $\langle 4,-2,5\rangle$ are not scalar multiples of each other, the lines aren't parallel. For the lines to intersect, we must be able to find one value of t and one value of s that produce the same point from the respective parametric equations. Thus we need to satisfy the following three equations: $3+2t=1+4s$, $4-t=3-2s$, $1+3t=4+5s$. Solving the last two equations we get $t=1$, $s=0$ and checking, we see that these values don't satisfy the first equation. Thus the lines aren't parallel and don't intersect, so they must be skew lines.

20. Since the direction vectors are $\mathbf{v}_1=\langle -12,9,-3\rangle$ and $\mathbf{v}_2=\langle 8,-6,2\rangle$, we have $\mathbf{v}_1=-\frac{3}{2}\mathbf{v}_2$ so the lines are parallel.

21. Since the direction vectors $\langle 1,-2,-3\rangle$ and $\langle 1,3,-7\rangle$ aren't scalar multiples of each other, the lines aren't parallel. Parametric equations of the lines are L_1: $x=2+t$, $y=3-2t$, $z=1-3t$ and L_2: $x=3+s$, $y=-4+3s$, $z=2-7s$. Thus, for the lines to intersect, the three equations $2+t=3+s$, $3-2t=-4+3s$, and $1-3t=2-7s$ must be satisfied simultaneously. Solving the first two equations gives $t=2$, $s=1$ and checking, we see that these values do satisfy the third equation, so the lines intersect when $t=2$ and $s=1$, that is, at the point $(4,-1,-5)$.

22. The direction vectors $\langle 1, -1, 3\rangle$ and $\langle 2, -2, 7\rangle$ are not parallel, so neither are the lines. Parametric equations for the lines are L_1: $x = t$, $y = 1 - t$, $z = 2 + 3t$ and L_2: $x = 2 + 2s$, $y = 3 - 2s$, $z = 7s$. Thus, for the lines to interesect, the three equations $t = 2 + 2s$, $1 - t = 3 - 2s$, and $2 + 3t = 7s$ must be satisfied simultaneously. Solving the last two equations gives $t = -10$, $s = -4$ and checking, we see that these values don't satisfy the first equation. Thus the lines aren't parallel and don't intersect, so they must be skew.

23. Since the plane is perpendicular to the vector $\langle 1, -2, 5\rangle$, we can take $\langle 1, -2, 5\rangle$ as a normal vector to the plane. $(0, 0, 0)$ is a point on the plane, so setting $a = 1$, $b = -2$, $c = 5$ and $x_0 = 0$, $y_0 = 0$, $z_0 = 0$ in Equation 7 gives $1(x - 0) + (-2)(y - 0) + 5(z - 0) = 0$ or $x - 2y + 5z = 0$ as an equation of the plane.

24. $2\,\mathbf{i} + \mathbf{j} - \mathbf{k} = \langle 2, 1, -1\rangle$ is a normal vector to the plane and $(5, 3, 5)$ is a point on the plane, so setting $a = 2$, $b = 1$, $c = -1$, $x_0 = 5$, $y_0 = 3$, $z_0 = 5$ in Equation 7 gives $2(x - 5) + 1(y - 3) + (-1)(z - 5) = 0$ or $2x + y - z = 8$ as an equation of the plane.

25. $\mathbf{i} + 4\,\mathbf{j} + \mathbf{k} = \langle 1, 4, 1\rangle$ is a normal vector to the plane and $\left(-1, \frac{1}{2}, 3\right)$ is a point on the plane, so setting $a = 1$, $b = 4$, $c = 1$, $x_0 = -1$, $y_0 = \frac{1}{2}$, $z_0 = 3$ in Equation 7 gives $1[x - (-1)] + 4\left(y - \frac{1}{2}\right) + 1(z - 3) = 0$ or $x + 4y + z = 4$ as an equation of the plane.

26. Since the line is perpendicular to the plane, its direction vector $\langle 3, -1, 4\rangle$ is a normal vector to the plane. The point $(2, 0, 1)$ is on the plane, so an equation of the plane is $3(x - 2) + (-1)(y - 0) + 4(z - 1) = 0$ or $3x - y + 4z = 10$.

27. Since the two planes are parallel, they will have the same normal vectors. So we can take $\mathbf{n} = \langle 5, -1, -1\rangle$, and an equation of the plane is $5(x - 1) - 1[y - (-1)] - 1[z - (-1)] = 0$ or $5x - y - z = 7$.

28. Since the two planes are parallel, they will have the same normal vectors. A normal vector for the plane $z = x + y$ or $x + y - z = 0$ is $\mathbf{n} = \langle 1, 1, -1\rangle$, and an equation of the desired plane is $1(x - 3) + 1[y - (-2)] - 1(z - 8) = 0$ or $x + y - z = -7$.

29. Since the two planes are parallel, they will have the same normal vectors. So we can take $\mathbf{n} = \langle 1, 1, 1\rangle$, and an equation of the plane is $1(x - 1) + 1\left(y - \frac{1}{2}\right) + 1\left(z - \frac{1}{3}\right) = 0$ or $x + y + z = \frac{11}{6}$ or $6x + 6y + 6z = 11$.

30. First, a normal vector for the plane $5x + 2y + z = 1$ is $\mathbf{n} = \langle 5, 2, 1\rangle$. A direction vector for the line is $\mathbf{v} = \langle 1, -1, -3\rangle$, and since $\mathbf{n} \cdot \mathbf{v} = 0$ we know the line is perpendicular to $\mathbf{n}$ and hence parallel to the plane. Thus, there is a parallel plane which contains the line. By putting $t = 0$, we know that the point $(1, 2, 4)$ is on the line and hence the new plane. We can use the same normal vector $\mathbf{n} = \langle 5, 2, 1\rangle$, so an equation of the plane is $5(x - 1) + 2(y - 2) + 1(z - 4) = 0$ or $5x + 2y + z = 13$.

31. The vector from $(0, 1, 1)$ to $(1, 0, 1)$, namely $\mathbf{a} = \langle 1 - 0, 0 - 1, 1 - 1\rangle = \langle 1, -1, 0\rangle$, and the vector from $(0, 1, 1)$ to $(1, 1, 0)$, $\mathbf{b} = \langle 1 - 0, 1 - 1, 0 - 1\rangle = \langle 1, 0, -1\rangle$, both lie in the plane, so $\mathbf{a} \times \mathbf{b}$ is a normal vector to the plane. Thus, we can take $\mathbf{n} = \mathbf{a} \times \mathbf{b} = \langle (-1)((-1) - (0)(0), (0)(1) - (1)(-1), (1)(0) - (-1)(1)\rangle = \langle 1, 1, 1\rangle$. If P_0 is the point $(0, 1, 1)$, an equation of the plane is $1(x - 0) + 1(y - 1) + 1(z - 1) = 0$ or $x + y + z = 2$.

32. Here the vectors $\mathbf{a} = \langle 3, -2, 1\rangle$ and $\mathbf{b} = \langle 1, 1, 1\rangle$ lie in the plane, so $\mathbf{n} = \mathbf{a} \times \mathbf{b} = \langle (-2)(1) - (1)(1), (1)(1) - (3)(1), (3)(1) - (-2)(1)\rangle = \langle -3, -2, 5\rangle$ is a normal vector to the plane. We can take the origin as P_0, so an equation of the plane is $-3(x - 0) - 2(y - 0) + 5(z - 0) = 0$ or $-3x - 2y + 5z = 0$ or $3x + 2y - 5z = 0$.

33. Here the vectors $\mathbf{a} = \langle 3 - 2, -8 - 1, 6 - 2\rangle = \langle 1, -9, 4\rangle$ and $\mathbf{b} = \langle -2 - 2, -3 - 1, 1 - 2\rangle = \langle -4, -4, -1\rangle$ lie in the plane, so a normal vector to the plane is $\mathbf{n} = \mathbf{a} \times \mathbf{b} = \langle 9 + 16, -16 + 1, -4 - 36\rangle = \langle 25, -15, -40\rangle$ and an equation of the plane is $25(x - 2) - 15(y - 1) - 40(z - 2) = 0$ or $25x - 15y - 40z = -45$ or $5x - 3y - 8z = -9$.

34. The vectors $\mathbf{a} = \langle -2 - 3, -2 - 0, 3 - (-1)\rangle = \langle -5, -2, 4\rangle$ and $\mathbf{b} = \langle 7 - 3, 1 - 0, -4 - (-1)\rangle = \langle 4, 1, -3\rangle$ lie in the plane, so a normal vector to the plane is $\mathbf{n} = \mathbf{a} \times \mathbf{b} = \langle 6 - 4, 16 - 15, -5 + 8\rangle = \langle 2, 1, 3\rangle$ and an equation of the plane is $2(x - 3) + 1(y - 0) + 3[z - (-1)] = 0$ or $2x + y + 3z = 3$.

35. If we first find two nonparallel vectors in the plane, their cross product will be a normal vector to the plane. Since the given line lies in the plane, its direction vector $\mathbf{a} = \langle -1, 2, -3\rangle$ is one vector in the plane. We can verify that the given point $(3, 5, -1)$ does not lie on this line, so to find another nonparallel vector $\mathbf{b}$ which lies in the plane, we can pick any point on the line and find a vector connecting the points. If we put $t = 0$, we see that $(4, -1, 0)$ is on the line, so $\mathbf{b} = \langle 4 - 3, -1 - 5, 0 - (-1)\rangle = \langle 1, -6, 1\rangle$ and $\mathbf{n} = \mathbf{a} \times \mathbf{b} = \langle 2 - 18, -3 + 1, 6 - 2\rangle = \langle -16, -2, 4\rangle$. Thus, an equation of the plane is $-16(x - 3) - 2(y - 5) + 4[z - (-1)] = 0$ or $-16x - 2y + 4z = -62$ or $8x + y - 2z = 31$.

36. Since the line $\dfrac{x}{3} = \dfrac{y + 4}{1} = \dfrac{z}{2}$ lies in the plane, its direction vector $\mathbf{a} = \langle 3, 1, 2\rangle$ is parallel to the plane. The point $(0, -4, 0)$ is on the line (put $t = 0$ in the corresponding parametric equations), and we can verify that the given point $(6, -1, 3)$ in the plane is not on the line. The vector connecting these two points, $\mathbf{b} = \langle 6, 3, 3\rangle$, is therefore parallel to the plane, but not parallel to $\mathbf{a}$. Then $\mathbf{a} \times \mathbf{b} = \langle 3 - 6, 12 - 9, 9 - 6\rangle = \langle -3, 3, 3\rangle$ is a normal vector to the plane, and an equation of the plane is $-3(x - 0) + 3[y - (-4)] + 3(z - 0) = 0$ or $-3x + 3y + 3z = -12$ or $x - y - z = 4$.

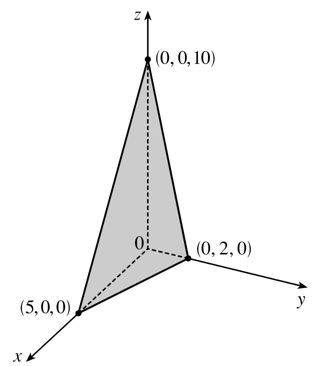
37. Normal vectors for the given planes are $\mathbf{n}_1 = \langle 1, 2, 3\rangle$ and $\mathbf{n}_2 = \langle 2, -1, 1\rangle$. A direction vector, then, for the line of intersection is $\mathbf{a} = \mathbf{n}_1 \times \mathbf{n}_2 = \langle 2 + 3, 6 - 1, -1 - 4\rangle = \langle 5, 5, -5\rangle$, and $\mathbf{a}$ is parallel to the desired plane. Another vector parallel to the plane is the vector connecting any point on the line of intersection to the given point $(3, 1, 4)$ in the plane. Setting $z = 0$, the equations of the planes reduce to $x + 2y = 1$ and $2x - y = -3$ with simultaneous solution $x = -1$ and $y = 1$. So a point on the line is $(-1, 1, 0)$ and another vector parallel to the plane is $\mathbf{b} = \langle 3 - (-1), 1 - 1, 4 - 0\rangle = \langle 4, 0, 4\rangle$. Then a normal vector to the plane is $\mathbf{n} = \mathbf{a} \times \mathbf{b} = \langle 20 - 0, -20 - 20, 0 - 20\rangle = \langle 20, -40, -20\rangle$. Equivalently, we can take $\langle 1, -2, -1\rangle$ as a normal vector, and an equation of the plane is $1(x - 3) - 2(y - 1) - 1(z - 4) = 0$ or $x - 2y - z = -3$.

38. The points $(0, -2, 5)$ and $(-1, 3, 1)$ lie in the desired plane, so the vector $\mathbf{v}_1 = \langle -1, 5, -4\rangle$ connecting them is parallel to the plane. The desired plane is perpendicular to the plane $2z = 5x + 4y$ or $5x + 4y - 2z = 0$ and for perpendicular planes, a normal vector for one plane is parallel to the other plane, so $\mathbf{v}_2 = \langle 5, 4, -2\rangle$ is also parallel to the desired plane. A normal vector to the desired plane is $\mathbf{n} = \mathbf{v}_1 \times \mathbf{v}_2 = \langle -10 + 16, -20 - 2, -4 - 25\rangle = \langle 6, -22, -29\rangle$. Taking $(x_0, y_0, z_0) = (0, -2, 5)$, the equation we are looking for is $6(x - 0) - 22(y + 2) - 29(z - 5) = 0$ or $6x - 22y - 29z = -101$.

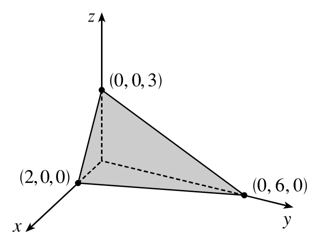
39. If a plane is perpendicular to two other planes, its normal vector is perpendicular to the normal vectors of the other two planes. Thus $\langle 2, 1, -2\rangle \times \langle 1, 0, 3\rangle = \langle 3 - 0, -2 - 6, 0 - 1\rangle = \langle 3, -8, -1\rangle$ is a normal vector to the desired plane. The point $(1, 5, 1)$ lies on the plane, so an equation is $3(x - 1) - 8(y - 5) - (z - 1) = 0$ or $3x - 8y - z = -38$.

40. $\mathbf{n}_1 = \langle 1, 0, -1\rangle$ and $\mathbf{n}_2 = \langle 0, 1, 2\rangle$. Setting $z = 0$, it is easy to see that $(1, 3, 0)$ is a point on the line of intersection of $x - z = 1$ and $y + 2z = 3$. The direction of this line is $\mathbf{v}_1 = \mathbf{n}_1 \times \mathbf{n}_2 = \langle 1, -2, 1\rangle$. A second vector parallel to the desired plane is $\mathbf{v}_2 = \langle 1, 1, -2\rangle$, since it is perpendicular to $x + y - 2z = 1$. Therefore, a normal of the plane in question is $\mathbf{n} = \mathbf{v}_1 \times \mathbf{v}_2 = \langle 4 - 1, 1 + 2, 1 + 2\rangle = \langle 3, 3, 3\rangle$, or we can use $\langle 1, 1, 1\rangle$. Taking $(x_0, y_0, z_0) = (1, 3, 0)$, the equation we are looking for is $(x - 1) + (y - 3) + z = 0 \quad\Leftrightarrow\quad x + y + z = 4$.

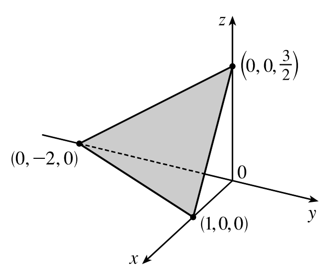
41. To find the x-intercept we set $y = z = 0$ in the equation $2x + 5y + z = 10$ and obtain $2x = 10 \quad\Rightarrow\quad x = 5$ so the x-intercept is $(5, 0, 0)$. When $x = z = 0$ we get $5y = 10 \quad\Rightarrow\quad y = 2$, so the y-intercept is $(0, 2, 0)$. Setting $x = y = 0$ gives $z = 10$, so the z-intercept is $(0, 0, 10)$ and we graph the portion of the plane that lies in the first octant.



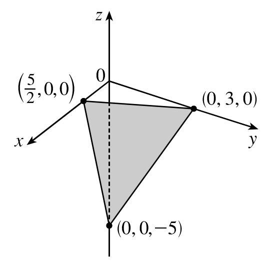
42. To find the x-intercept we set $y = z = 0$ in the equation $3x + y + 2z = 6$ and obtain $3x = 6 \quad\Rightarrow\quad x = 2$ so the x-intercept is $(2, 0, 0)$. When $x = z = 0$ we get $y = 6$ so the y-intercept is $(0, 6, 0)$. Setting $x = y = 0$ gives $2z = 6 \quad\Rightarrow\quad z = 3$, so the z-intercept is $(0, 0, 3)$. The figure shows the portion of the plane that lies in the first octant.



43. Setting $y = z = 0$ in the equation $6x - 3y + 4z = 6$ gives $6x = 6 \quad\Rightarrow\quad x = 1$, when $x = z = 0$ we have $-3y = 6 \quad\Rightarrow\quad y = -2$, and $x = y = 0$ implies $4z = 6 \quad\Rightarrow\quad z = \frac{3}{2}$, so the intercepts are $(1, 0, 0)$, $(0, -2, 0)$, and $(0, 0, \frac{3}{2})$. The figure shows the portion of the plane cut off by the coordinate planes.



44. Setting $y = z = 0$ in the equation $6x + 5y - 3z = 15$ gives $6x = 15 \Rightarrow x = \frac{5}{2}$, when $x = z = 0$ we have $5y = 15 \Rightarrow y = 3$, and $x = y = 0$ implies $-3z = 15 \Rightarrow z = -5$, so the intercepts are $(\frac{5}{2}, 0, 0)$, $(0, 3, 0)$, and $(0, 0, -5)$. The figure shows the portion of the plane cut off by the coordinate planes.



45. Substitute the parametric equations of the line into the equation of the plane: $x + 2y - z = 7 \Rightarrow (2 - 2t) + 2(3t) - (1 + t) = 7 \Rightarrow 3t + 1 = 7 \Rightarrow t = 2$. Therefore, the point of intersection of the line and the plane is given by $x = 2 - 2(2) = -2$, $y = 3(2) = 6$, and $z = 1 + 2 = 3$, that is, the point $(-2, 6, 3)$.

46. Substitute the parametric equations of the line into the equation of the plane: $3(t - 1) - (1 + 2t) + 2(3 - t) = 5 \Rightarrow -t + 2 = 5 \Rightarrow t = -3$. Therefore, the point of intersection of the line and the plane is given by $x = -3 - 1 = -4$, $y = 1 + 2(-3) = -5$, and $z = 3 - (-3) = 6$, that is, the point $(-4, -5, 6)$.

47. Parametric equations for the line are $x = \frac{1}{5}t$, $y = 2t$, $z = t - 2$ and substitution into the equation of the plane gives $10\left(\frac{1}{5}t\right) - 7(2t) + 3(t - 2) + 24 = 0 \Rightarrow -9t + 18 = 0 \Rightarrow t = 2$. Thus $x = \frac{1}{5}(2) = \frac{2}{5}$, $y = 2(2) = 4$, $z = 2 - 2 = 0$ and the point of intersection is $\left(\frac{2}{5}, 4, 0\right)$.

48. A direction vector for the line through $(-3, 1, 0)$ and $(-1, 5, 6)$ is $\mathbf{v} = \langle 2, 4, 6 \rangle$ and, taking $P_0 = (-3, 1, 0)$, parametric equations for the line are $x = -3 + 2t$, $y = 1 + 4t$, $z = 6t$. Substitution of the parametric equations into the equation of the plane gives $2(-3 + 2t) + (1 + 4t) - (6t) = -2 \Rightarrow 2t - 5 = -2 \Rightarrow t = \frac{3}{2}$. Then $x = -3 + 2\left(\frac{3}{2}\right) = 0$, $y = 1 + 4\left(\frac{3}{2}\right) = 7$, and $z = 6\left(\frac{3}{2}\right) = 9$, and the point of intersection is $(0, 7, 9)$.

49. Setting $x = 0$, we see that $(0, 1, 0)$ satisfies the equations of both planes, so that they do in fact have a line of intersection. $\mathbf{v} = \mathbf{n}_1 \times \mathbf{n}_2 = \langle 1, 1, 1 \rangle \times \langle 1, 0, 1 \rangle = \langle 1, 0, -1 \rangle$ is the direction of this line. Therefore, direction numbers of the intersecting line are $1, 0, -1$.

50. The angle between the two planes is the same as the angle between their normal vectors. The normal vectors of the two planes are $\langle 1, 1, 1 \rangle$ and $\langle 1, 2, 3 \rangle$. The cosine of the angle θ between these two planes is

$$\cos\theta = \frac{\langle 1, 1, 1 \rangle \cdot \langle 1, 2, 3 \rangle}{|\langle 1, 1, 1 \rangle|\,|\langle 1, 2, 3 \rangle|} = \frac{1 + 2 + 3}{\sqrt{1 + 1 + 1}\,\sqrt{1 + 4 + 9}} = \frac{6}{\sqrt{42}} = \sqrt{\frac{6}{7}}.$$

51. Normal vectors for the planes are $\mathbf{n}_1 = \langle 1, 4, -3 \rangle$ and $\mathbf{n}_2 = \langle -3, 6, 7 \rangle$. The normals aren't parallel (they are not scalar multiples of each other), so neither are the planes. But $\mathbf{n}_1 \cdot \mathbf{n}_2 = -3 + 24 - 21 = 0$, so the normals, and thus the planes, are perpendicular.

52. Normal vectors for the planes are $\mathbf{n}_1 = \langle 9, -3, 6 \rangle$ and $\mathbf{n}_2 = \langle 6, -2, 4 \rangle$ (the plane's equation is $6x - 2y + 4z = 0$). Since $\mathbf{n}_1 = \frac{3}{2}\mathbf{n}_2$, the normals, and thus the planes, are parallel.

53. Normal vectors for the planes are $\mathbf{n}_1 = \langle 1, 2, -1 \rangle$ and $\mathbf{n}_2 = \langle 2, -2, 1 \rangle$. The normals are not parallel (they are not scalar multiples of each other), so neither are the planes. Furthermore, $\mathbf{n}_1 \cdot \mathbf{n}_2 = 2 - 4 - 1 = -3 \neq 0$, so the planes aren't perpendicular. The angle between the planes is the same as the angle between the normals, given by

$$\cos\theta = \frac{\mathbf{n}_1 \cdot \mathbf{n}_2}{|\mathbf{n}_1|\,|\mathbf{n}_2|} = \frac{-3}{\sqrt{6}\sqrt{9}} = -\frac{1}{\sqrt{6}} \quad\Rightarrow\quad \theta = \cos^{-1}\left(-\frac{1}{\sqrt{6}}\right) \approx 114.1^\circ.$$

54. Normal vectors for the planes are $\mathbf{n}_1 = \langle 1, -1, 3\rangle$ and $\mathbf{n}_2 = \langle 3, 1, -1\rangle$. The normals are not parallel, so neither are the planes. Since $\mathbf{n}_1 \cdot \mathbf{n}_2 = 3 - 1 - 3 = -1 \neq 0$, the planes aren't perpendicular. The angle between the planes is given by

$$\cos\theta = \frac{\mathbf{n}_1 \cdot \mathbf{n}_2}{|\mathbf{n}_1|\,|\mathbf{n}_2|} = \frac{-1}{\sqrt{11}\sqrt{11}} = -\frac{1}{11} \quad\Rightarrow\quad \theta = \cos^{-1}\left(-\tfrac{1}{11}\right) \approx 95.2^\circ.$$

55. The planes are $2x - 3y - z = 0$ and $4x - 6y - 2z = 3$ with normal vectors $\mathbf{n}_1 = \langle 2, -3, -1\rangle$ and $\mathbf{n}_2 = \langle 4, -6, -2\rangle$. Since $\mathbf{n}_2 = 2\mathbf{n}_1$, the normals, and thus the planes, are parallel.

56. The normals are $\mathbf{n}_1 = \langle 5, 2, 3\rangle$ and $\mathbf{n}_2 = \langle 4, -1, -6\rangle$ which are not scalar multiples of each other, so the planes aren't parallel. Since $\mathbf{n}_1 \cdot \mathbf{n}_2 = 20 - 2 - 18 = 0$, the normals, and thus the planes, are perpendicular.

57. (a) To find a point on the line of intersection, set one of the variables equal to a constant, say $z = 0$. (This will fail if the line of intersection does not cross the xy-plane; in that case, try setting x or y equal to 0.) The equations of the two planes reduce to $x + y = 1$ and $x + 2y = 1$. Solving these two equations gives $x = 1$, $y = 0$. Thus a point on the line is $(1, 0, 0)$. A vector $\mathbf{v}$ in the direction of this intersecting line is perpendicular to the normal vectors of both planes, so we can take $\mathbf{v} = \mathbf{n}_1 \times \mathbf{n}_2 = \langle 1, 1, 1\rangle \times \langle 1, 2, 2\rangle = \langle 2 - 2, 1 - 2, 2 - 1\rangle = \langle 0, -1, 1\rangle$. By Equations 2, parametric equations for the line are $x = 1$, $y = -t$, $z = t$.

(b) The angle between the planes satisfies $\cos\theta = \dfrac{\mathbf{n}_1 \cdot \mathbf{n}_2}{|\mathbf{n}_1|\,|\mathbf{n}_2|} = \dfrac{1 + 2 + 2}{\sqrt{3}\sqrt{9}} = \dfrac{5}{3\sqrt{3}}$. Therefore $\theta = \cos^{-1}\left(\dfrac{5}{3\sqrt{3}}\right) \approx 15.8^\circ$.

58. (a) If we set $z = 0$ then the equations of the planes reduce to $3x - 2y = 1$ and $2x + y = 3$ and solving these two equations gives $x = 1$, $y = 1$. Thus a point on the line of intersection is $(1, 1, 0)$. A vector $\mathbf{v}$ in the direction of this intersecting line is perpendicular to the normal vectors of both planes, so let $\mathbf{v} = \mathbf{n}_1 \times \mathbf{n}_2 = \langle 3, -2, 1\rangle \times \langle 2, 1, -3\rangle = \langle 5, 11, 7\rangle$. By Equations 2, parametric equations for the line are $x = 1 + 5t$, $y = 1 + 11t$, $z = 7t$.

(b) $\cos\theta = \dfrac{\mathbf{n}_1 \cdot \mathbf{n}_2}{|\mathbf{n}_1|\,|\mathbf{n}_2|} = \dfrac{6 - 2 - 3}{\sqrt{14}\sqrt{14}} = \dfrac{1}{14} \quad\Rightarrow\quad \theta = \cos^{-1}\left(\tfrac{1}{14}\right) \approx 85.9^\circ$.

59. Setting $z = 0$, the equations of the two planes become $5x - 2y = 1$ and $4x + y = 6$. Solving these two equations gives $x = 1$, $y = 2$ so a point on the line of intersection is $(1, 2, 0)$. A vector $\mathbf{v}$ in the direction of this intersecting line is perpendicular to the normal vectors of both planes. So we can use $\mathbf{v} = \mathbf{n}_1 \times \mathbf{n}_2 = \langle 5, -2, -2\rangle \times \langle 4, 1, 1\rangle = \langle 0, -13, 13\rangle$ or equivalently we can take $\mathbf{v} = \langle 0, -1, 1\rangle$, and symmetric equations for the line are $x = 1$, $\dfrac{y - 2}{-1} = \dfrac{z}{1}$ or $x = 1$, $y - 2 = -z$.

60. If we set $z = 0$ then the equations of the planes reduce to $2x - y - 5 = 0$ and $4x + 3y - 5 = 0$ and solving these two equations gives $x = 2$, $y = -1$. Thus a point on the line of intersection is $(2, -1, 0)$. A vector $\mathbf{v}$ in the direction of this intersecting line is perpendicular to the normal vectors of both planes, so take $\mathbf{v} = \mathbf{n}_1 \times \mathbf{n}_2 = \langle 2, -1, -1\rangle \times \langle 4, 3, -1\rangle = \langle 4, -2, 10\rangle$ or equivalently we can take $\mathbf{v} = \langle 2, -1, 5\rangle$. Symmetric equations for the line are $\dfrac{x - 2}{2} = \dfrac{y + 1}{-1} = \dfrac{z}{5}$.

61. The distance from a point (x, y, z) to $(1, 0, -2)$ is $d_1 = \sqrt{(x-1)^2 + y^2 + (z+2)^2}$ and the distance from (x, y, z) to $(3, 4, 0)$ is $d_2 = \sqrt{(x-3)^2 + (y-4)^2 + z^2}$. The plane consists of all points (x, y, z) where $d_1 = d_2 \;\Rightarrow\; d_1^2 = d_2^2 \;\Leftrightarrow$
$(x-1)^2 + y^2 + (z+2)^2 = (x-3)^2 + (y-4)^2 + z^2 \;\Leftrightarrow$
$x^2 - 2x + y^2 + z^2 + 4z + 5 = x^2 - 6x + y^2 - 8y + z^2 + 25 \;\Leftrightarrow\; 4x + 8y + 4z = 20$ so an equation for the plane is $4x + 8y + 4z = 20$ or equivalently $x + 2y + z = 5$.

Alternatively, you can argue that the segment joining points $(1, 0, -2)$ and $(3, 4, 0)$ is perpendicular to the plane and the plane includes the midpoint of the segment.

62. The distance from a point (x, y, z) to $(2, 5, 5)$ is $d_1 = \sqrt{(x-2)^2 + (y-5)^2 + (z-5)^2}$ and the distance from (x, y, z) to $(-6, 3, 1)$ is $d_2 = \sqrt{(x+6)^2 + (y-3)^2 + (z-1)^2}$. The plane consists of all points (x, y, z) where $d_1 = d_2 \;\Rightarrow$
$d_1^2 = d_2^2 \;\Leftrightarrow\; (x-2)^2 + (y-5)^2 + (z-5)^2 = (x+6)^2 + (y-3)^2 + (z-1)^2 \;\Leftrightarrow$
$x^2 - 4x + y^2 - 10y + z^2 - 10z + 54 = x^2 + 12x + y^2 - 6y + z^2 - 2z + 46 \;\Leftrightarrow\; 16x + 4y + 8z = 8$ so an equation for the plane is $16x + 4y + 8z = 8$ or equivalently $4x + y + 2z = 2$.

63. The plane contains the points $(a, 0, 0)$, $(0, b, 0)$ and $(0, 0, c)$. Thus the vectors $\mathbf{a} = \langle -a, b, 0 \rangle$ and $\mathbf{b} = \langle -a, 0, c \rangle$ lie in the plane, and $\mathbf{n} = \mathbf{a} \times \mathbf{b} = \langle bc - 0, 0 + ac, 0 + ab \rangle = \langle bc, ac, ab \rangle$ is a normal vector to the plane. The equation of the plane is therefore $bcx + acy + abz = abc + 0 + 0$ or $bcx + acy + abz = abc$. Notice that if $a \neq 0$, $b \neq 0$ and $c \neq 0$ then we can rewrite the equation as $\dfrac{x}{a} + \dfrac{y}{b} + \dfrac{z}{c} = 1$. This is a good equation to remember!

64. (a) For the lines to intersect, we must be able to find one value of t and one value of s satisfying the three equations $1 + t = 2 - s$, $1 - t = s$ and $2t = 2$. From the third we get $t = 1$, and putting this in the second gives $s = 0$. These values of s and t do satisfy the first equation, so the lines intersect at the point $P_0 = (1 + 1, 1 - 1, 2(1)) = (2, 0, 2)$.

(b) The direction vectors of the lines are $\langle 1, -1, 2 \rangle$ and $\langle -1, 1, 0 \rangle$, so a normal vector for the plane is $\langle -1, 1, 0 \rangle \times \langle 1, -1, 2 \rangle = \langle 2, 2, 0 \rangle$ and it contains the point $(2, 0, 2)$. Then an equation of the plane is
$2(x-2) + 2(y-0) + 0(z-2) = 0 \;\Leftrightarrow\; x + y = 2$.

65. Two vectors which are perpendicular to the required line are the normal of the given plane, $\langle 1, 1, 1 \rangle$, and a direction vector for the given line, $\langle 1, -1, 2 \rangle$. So a direction vector for the required line is $\langle 1, 1, 1 \rangle \times \langle 1, -1, 2 \rangle = \langle 3, -1, -2 \rangle$. Thus L is given by $\langle x, y, z \rangle = \langle 0, 1, 2 \rangle + t\langle 3, -1, -2 \rangle$, or in parametric form, $x = 3t$, $y = 1 - t$, $z = 2 - 2t$.

66. Let L be the given line. Then $(1, 1, 0)$ is the point on L corresponding to $t = 0$. L is in the direction of $\mathbf{a} = \langle 1, -1, 2 \rangle$ and $\mathbf{b} = \langle -1, 0, 2 \rangle$ is the vector joining $(1, 1, 0)$ and $(0, 1, 2)$. Then
$\mathbf{b} - \operatorname{proj}_{\mathbf{a}} \mathbf{b} = \langle -1, 0, 2 \rangle - \dfrac{\langle 1, -1, 2 \rangle \cdot \langle -1, 0, 2 \rangle}{1^2 + (-1)^2 + 2^2} \langle 1, -1, 2 \rangle = \langle -1, 0, 2 \rangle - \frac{1}{2}\langle 1, -1, 2 \rangle = \left\langle -\frac{3}{2}, \frac{1}{2}, 1 \right\rangle$ is a direction vector for the required line. Thus $2\left\langle -\frac{3}{2}, \frac{1}{2}, 1 \right\rangle = \langle -3, 1, 2 \rangle$ is also a direction vector, and the line has parametric equations $x = -3t$, $y = 1 + t$, $z = 2 + 2t$. (Notice that this is the same line as in Exercise 65.)

67. Let P_i have normal vector $\mathbf{n}_i$. Then $\mathbf{n}_1 = \langle 3, 6, -3\rangle$, $\mathbf{n}_2 = \langle 4, -12, 8\rangle$, $\mathbf{n}_3 = \langle 3, -9, 6\rangle$, $\mathbf{n}_4 = \langle 1, 2, -1\rangle$. Now $\mathbf{n}_1 = 3\mathbf{n}_4$, so $\mathbf{n}_1$ and $\mathbf{n}_4$ are parallel, and hence P_1 and P_4 are parallel; similarly P_2 and P_3 are parallel because $\mathbf{n}_2 = \frac{4}{3}\mathbf{n}_3$. However, $\mathbf{n}_1$ and $\mathbf{n}_2$ are not parallel (so not all four planes are parallel). Notice that the point $(2, 0, 0)$ lies on both P_1 and P_4, so these two planes are identical. The point $\left(\frac{5}{4}, 0, 0\right)$ lies on P_2 but not on P_3, so these are different planes.

68. Let L_i have direction vector $\mathbf{v}_i$. Rewrite the symmetric equations for L_3 as $\dfrac{x-1}{1/2} = \dfrac{y-1}{-1/4} = \dfrac{z+1}{1}$; then $\mathbf{v}_1 = \langle 6, -3, 12\rangle$, $\mathbf{v}_2 = \langle 2, 1, 4\rangle$, $\mathbf{v}_3 = \left\langle \frac{1}{2}, -\frac{1}{4}, 1\right\rangle$, and $\mathbf{v}_4 = \langle 4, 2, 8\rangle$. $\mathbf{v}_1 = 12\mathbf{v}_3$, so L_1 and L_3 are parallel. $\mathbf{v}_4 = 2\mathbf{v}_2$, so L_2 and L_4 are parallel. (Note that L_1 and L_2 are not parallel.) L_1 contains the point $(1, 1, 5)$, but this point does not lie on L_3, so they're not identical. $(3, 1, 5)$ lies on L_4 and also on L_2 (for $t = 1$), so L_2 and L_4 are the same line.

69. Let $Q = (1, 3, 4)$ and $R = (2, 1, 1)$, points on the line corresponding to $t = 0$ and $t = 1$. Let $P = (4, 1, -2)$. Then $\mathbf{a} = \overrightarrow{QR} = \langle 1, -2, -3\rangle$, $\mathbf{b} = \overrightarrow{QP} = \langle 3, -2, -6\rangle$. The distance is

$$d = \frac{|\mathbf{a} \times \mathbf{b}|}{|\mathbf{a}|} = \frac{|\langle 1, -2, -3\rangle \times \langle 3, -2, -6\rangle|}{|\langle 1, -2, -3\rangle|} = \frac{|\langle 6, -3, 4\rangle|}{|\langle 1, -2, -3\rangle|} = \frac{\sqrt{6^2 + (-3)^2 + 4^2}}{\sqrt{1^2 + (-2)^2 + (-3)^2}} = \frac{\sqrt{61}}{\sqrt{14}} = \sqrt{\frac{61}{14}}.$$

70. Let $Q = (0, 6, 3)$ and $R = (2, 4, 4)$, points on the line corresponding to $t = 0$ and $t = 1$. Let $P = (0, 1, 3)$. Then $\mathbf{a} = \overrightarrow{QR} = \langle 2, -2, 1\rangle$ and $\mathbf{b} = \overrightarrow{QP} = \langle 0, -5, 0\rangle$. The distance is

$$d = \frac{|\mathbf{a} \times \mathbf{b}|}{|\mathbf{a}|} = \frac{|\langle 2, -2, 1\rangle \times \langle 0, -5, 0\rangle|}{|\langle 2, -2, 1\rangle|} = \frac{|\langle 5, 0, -10\rangle|}{|\langle 2, -2, 1\rangle|} = \frac{\sqrt{5^2 + 0^2 + (-10)^2}}{\sqrt{2^2 + (-2)^2 + 1^2}} = \frac{\sqrt{125}}{\sqrt{9}} = \frac{5\sqrt{5}}{3}.$$

71. By Equation 9, the distance is $D = \dfrac{|ax_1 + by_1 + cz_1 + d|}{\sqrt{a^2 + b^2 + c^2}} = \dfrac{|3(1) + 2(-2) + 6(4) - 5|}{\sqrt{3^2 + 2^2 + 6^2}} = \dfrac{|18|}{\sqrt{49}} = \dfrac{18}{7}.$

72. By Equation 9, the distance is $D = \dfrac{|1(-6) - 2(3) - 4(5) - 8|}{\sqrt{1^2 + (-2)^2 + (-4)^2}} = \dfrac{|-40|}{\sqrt{21}} = \dfrac{40}{\sqrt{21}}.$

73. Put $y = z = 0$ in the equation of the first plane to get the point $(2, 0, 0)$ on the plane. Because the planes are parallel, the distance D between them is the distance from $(2, 0, 0)$ to the second plane. By Equation 9,

$$D = \frac{|4(2) - 6(0) + 2(0) - 3|}{\sqrt{4^2 + (-6)^2 + (2)^2}} = \frac{5}{\sqrt{56}} = \frac{5}{2\sqrt{14}} \text{ or } \frac{5\sqrt{14}}{28}.$$

74. Put $x = y = 0$ in the equation of the first plane to get the point $(0, 0, 0)$ on the plane. Because the planes are parallel the distance D between them is the distance from $(0, 0, 0)$ to the second plane $3x - 6y + 9z - 1 = 0$. By Equation 9,

$$D = \frac{|3(0) - 6(0) + 9(0) - 1|}{\sqrt{3^2 + (-6)^2 + 9^2}} = \frac{1}{\sqrt{126}} = \frac{1}{3\sqrt{14}}.$$

75. The distance between two parallel planes is the same as the distance between a point on one of the planes and the other plane. Let $P_0 = (x_0, y_0, z_0)$ be a point on the plane given by $ax + by + cz + d_1 = 0$. Then $ax_0 + by_0 + cz_0 + d_1 = 0$ and the distance between P_0 and the plane given by $ax + by + cz + d_2 = 0$ is, from Equation 9,

$$D = \frac{|ax_0 + by_0 + cz_0 + d_2|}{\sqrt{a^2 + b^2 + c^2}} = \frac{|-d_1 + d_2|}{\sqrt{a^2 + b^2 + c^2}} = \frac{|d_1 - d_2|}{\sqrt{a^2 + b^2 + c^2}}.$$

76. The planes must have parallel normal vectors, so if $ax + by + cz + d = 0$ is such a plane, then for some $t \neq 0$, $\langle a, b, c\rangle = t\langle 1, 2, -2\rangle = \langle t, 2t, -2t\rangle$. So this plane is given by the equation $x + 2y - 2z + k = 0$, where $k = d/t$. By Exercise 75, the distance between the planes is $2 = \dfrac{|1-k|}{\sqrt{1^2 + 2^2 + (-2)^2}} \Leftrightarrow 6 = |1 - k| \Leftrightarrow k = 7$ or -5. So the desired planes have equations $x + 2y - 2z = 7$ and $x + 2y - 2z = -5$.

77. L_1: $x = y = z \Rightarrow x = y$ (**1**). L_2: $x + 1 = y/2 = z/3 \Rightarrow x + 1 = y/2$ (**2**). The solution of (**1**) and (**2**) is $x = y = -2$. However, when $x = -2$, $x = z \Rightarrow z = -2$, but $x + 1 = z/3 \Rightarrow z = -3$, a contradiction. Hence the lines do not intersect. For L_1, $\mathbf{v}_1 = \langle 1, 1, 1\rangle$, and for L_2, $\mathbf{v}_2 = \langle 1, 2, 3\rangle$, so the lines are not parallel. Thus the lines are skew lines. If two lines are skew, they can be viewed as lying in two parallel planes and so the distance between the skew lines would be the same as the distance between these parallel planes. The common normal vector to the planes must be perpendicular to both $\langle 1, 1, 1\rangle$ and $\langle 1, 2, 3\rangle$, the direction vectors of the two lines. So set $\mathbf{n} = \langle 1, 1, 1\rangle \times \langle 1, 2, 3\rangle = \langle 3 - 2, -3 + 1, 2 - 1\rangle = \langle 1, -2, 1\rangle$. From above, we know that $(-2, -2, -2)$ and $(-2, -2, -3)$ are points of L_1 and L_2 respectively. So in the notation of Equation 8, $1(-2) - 2(-2) + 1(-2) + d_1 = 0 \Rightarrow d_1 = 0$ and $1(-2) - 2(-2) + 1(-3) + d_2 = 0 \Rightarrow d_2 = 1$.

By Exercise 75, the distance between these two skew lines is $D = \dfrac{|0-1|}{\sqrt{1+4+1}} = \dfrac{1}{\sqrt{6}}$.

Alternate solution (without reference to planes): A vector which is perpendicular to both of the lines is $\mathbf{n} = \langle 1, 1, 1\rangle \times \langle 1, 2, 3\rangle = \langle 1, -2, 1\rangle$. Pick any point on each of the lines, say $(-2, -2, -2)$ and $(-2, -2, -3)$, and form the vector $\mathbf{b} = \langle 0, 0, 1\rangle$ connecting the two points. The distance between the two skew lines is the absolute value of the scalar projection of $\mathbf{b}$ along $\mathbf{n}$, that is, $D = \dfrac{|\mathbf{n} \cdot \mathbf{b}|}{|\mathbf{n}|} = \dfrac{|1 \cdot 0 - 2 \cdot 0 + 1 \cdot 1|}{\sqrt{1+4+1}} = \dfrac{1}{\sqrt{6}}$.

78. First notice that if two lines are skew, they can be viewed as lying in two parallel planes and so the distance between the skew lines would be the same as the distance between these parallel planes. The common normal vector to the planes must be perpendicular to both $\mathbf{v}_1 = \langle 1, 6, 2\rangle$ and $\mathbf{v}_2 = \langle 2, 15, 6\rangle$, the direction vectors of the two lines respectively. Thus set $\mathbf{n} = \mathbf{v}_1 \times \mathbf{v}_2 = \langle 36 - 30, 4 - 6, 15 - 12\rangle = \langle 6, -2, 3\rangle$. Setting $t = 0$ and $s = 0$ gives the points $(1, 1, 0)$ and $(1, 5, -2)$. So in the notation of Equation 8, $6 - 2 + 0 + d_1 = 0 \Rightarrow d_1 = -4$ and $6 - 10 - 6 + d_2 = 0 \Rightarrow d_2 = 10$.

Then by Exercise 75, the distance between the two skew lines is given by $D = \dfrac{|-4-10|}{\sqrt{36+4+9}} = \dfrac{14}{7} = 2$.

Alternate solution (without reference to planes): We already know that the direction vectors of the two lines are $\mathbf{v}_1 = \langle 1, 6, 2\rangle$ and $\mathbf{v}_2 = \langle 2, 15, 6\rangle$. Then $\mathbf{n} = \mathbf{v}_1 \times \mathbf{v}_2 = \langle 6, -2, 3\rangle$ is perpendicular to both lines. Pick any point on each of the lines, say $(1, 1, 0)$ and $(1, 5, -2)$, and form the vector $\mathbf{b} = \langle 0, 4, -2\rangle$ connecting the two points. Then the distance between the two skew lines is the absolute value of the scalar projection of $\mathbf{b}$ along $\mathbf{n}$, that is,

$$D = \frac{|\mathbf{n} \cdot \mathbf{b}|}{|\mathbf{n}|} = \frac{1}{\sqrt{36+4+9}}\,|0 - 8 - 6| = \frac{14}{7} = 2.$$

79. A direction vector for L_1 is $\mathbf{v}_1 = \langle 2, 0, -1\rangle$ and a direction vector for L_2 is $\mathbf{v}_2 = \langle 3, 2, 2\rangle$. These vectors are not parallel so neither are the lines. Parametric equations for the lines are L_1: $x = 2t$, $y = 0$, $z = -t$, and L_2: $x = 1 + 3s$, $y = -1 + 2s$, $z = 1 + 2s$. No values of t and s satisfy these equations simultaneously, so the lines don't intersect and hence are skew. We can view the lines as lying in two parallel planes; a common normal vector to the planes is $\mathbf{n} = \mathbf{v}_1 \times \mathbf{v}_2 = \langle 2, -7, 4\rangle$. Line L_1 passes through the origin, so $(0, 0, 0)$ lies on one of the planes, and $(1, -1, 1)$ is a point on L_2 and therefore on the other plane. Equations of the planes then are $2x - 7y + 4z = 0$ and $2x - 7y + 4z - 13 = 0$, and by Exercise 75, the distance between the two skew lines is $D = \dfrac{|0 - (-13)|}{\sqrt{4 + 49 + 16}} = \dfrac{13}{\sqrt{69}}$.

Alternate solution (without reference to planes): Direction vectors of the two lines are $\mathbf{v}_1 = \langle 2, 0, -1\rangle$ and $\mathbf{v}_2 = \langle 3, 2, 2\rangle$. Then $\mathbf{n} = \mathbf{v}_1 \times \mathbf{v}_2 = \langle 2, -7, 4\rangle$ is perpendicular to both lines. Pick any point on each of the lines, say $(0, 0, 0)$ and $(1, -1, 1)$, and form the vector $\mathbf{b} = \langle 1, -1, 1\rangle$ connecting the two points. Then the distance between the two skew lines is the absolute value of the scalar projection of $\mathbf{b}$ along $\mathbf{n}$, that is, $D = \dfrac{|\mathbf{n} \cdot \mathbf{b}|}{|\mathbf{n}|} = \dfrac{|2 + 7 + 4|}{\sqrt{4 + 49 + 16}} = \dfrac{13}{\sqrt{69}}$.

80. A direction vector for the line L_1 is $\mathbf{v}_1 = \langle 1, 2, 2\rangle$. A normal vector for the plane P_1 is $\mathbf{n}_1 = \langle 1, -1, 2\rangle$. The vector from the point $(0, 0, 1)$ to $(3, 2, -1)$, $\langle 3, 2, -2\rangle$, is parallel to the plane P_2, as is the vector from $(0, 0, 1)$ to $(1, 2, 1)$, namely $\langle 1, 2, 0\rangle$. Thus a normal vector for P_2 is $\langle 3, 2, -2\rangle \times \langle 1, 2, 0\rangle = \langle 4, -2, 4\rangle$, or we can use $\mathbf{n}_2 = \langle 2, -1, 2\rangle$, and a direction vector for the line L_2 of intersection of these planes is $\mathbf{v}_2 = \mathbf{n}_1 \times \mathbf{n}_2 = \langle 1, -1, 2\rangle \times \langle 2, -1, 2\rangle = \langle 0, 2, 1\rangle$. Notice that the point $(3, 2, -1)$ lies on both planes, so it also lies on L_2. The lines are skew, so we can view them as lying in two parallel planes; a common normal vector to the planes is $\mathbf{n} = \mathbf{v}_1 \times \mathbf{v}_2 = \langle -2, -1, 2\rangle$. Line L_1 passes through the point $(1, 2, 6)$, so $(1, 2, 6)$ lies on one of the planes, and $(3, 2, -1)$ is a point on L_2 and therefore on the other plane. Equations of the planes then are $-2x - y + 2z - 8 = 0$ and $-2x - y + 2z + 10 = 0$, and by Exercise 75, the distance between the lines is

$$D = \frac{|-8 - 10|}{\sqrt{4 + 1 + 4}} = \frac{18}{3} = 6.$$

Alternatively, direction vectors for the lines are $\mathbf{v}_1 = \langle 1, 2, 2\rangle$ and $\mathbf{v}_2 = \langle 0, 2, 1\rangle$, so $\mathbf{n} = \mathbf{v}_1 \times \mathbf{v}_2 = \langle -2, -1, 2\rangle$ is perpendicular to both lines. Pick any point on each of the lines, say $(1, 2, 6)$ and $(3, 2, -1)$, and form the vector $\mathbf{b} = \langle 2, 0, -7\rangle$ connecting the two points. Then the distance between the two skew lines is the absolute value of the scalar projection of $\mathbf{b}$ along $\mathbf{n}$, that is, $D = \dfrac{|\mathbf{n} \cdot \mathbf{b}|}{|\mathbf{n}|} = \dfrac{|-4 + 0 - 14|}{\sqrt{4 + 1 + 4}} = \dfrac{18}{3} = 6$.

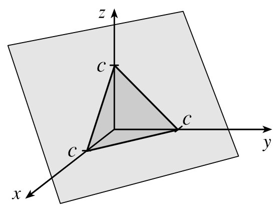
81. (a) A direction vector from tank A to tank B is $\langle 765 - 325, 675 - 810, 599 - 561\rangle = \langle 440, -135, 38\rangle$. Taking tank A's position $(325, 810, 561)$ as the initial point, parametric equations for the line of sight are $x = 325 + 440t$, $y = 810 - 135t$, $z = 561 + 38t$ for $0 \le t \le 1$.

(b) We divide the line of sight into 5 equal segments, corresponding to $\Delta t = 0.2$, and compute the elevation from the z-component of the parametric equations in part (a):

t	$z = 561 + 38t$	terrain elevation
0	561.0	
0.2	568.6	549
0.4	576.2	566
0.6	583.8	586
0.8	591.4	589
1.0	599.0	

Since the terrain is higher than the line of sight when $t = 0.6$, the tanks can't see each other.

82. (a) The planes $x + y + z = c$ have normal vector $\langle 1, 1, 1 \rangle$, so they are all parallel. Their x-, y-, and z-intercepts are all c. When $c > 0$ their intersection with the first octant is an equilateral triangle and when $c < 0$ their intersection with the octant diagonally opposite the first is an equilateral triangle.



(b) The planes $x + y + cz = 1$ have x-intercept 1, y-intercept 1, and z-intercept $1/c$. The plane with $c = 0$ is parallel to the z-axis. As c gets larger, the planes get closer to the xy-plane.

(c) The planes $y \cos\theta + z \cos\theta = 1$ have normal vectors $\langle 0, \cos\theta, \sin\theta \rangle$, which are perpendicular to the x-axis, and so the planes are parallel to the x-axis. We look at their intersection with the yz-plane. These are lines that are perpendicular to $\langle \cos\theta, \sin\theta \rangle$ and pass through $(\cos\theta, \sin\theta)$, since $\cos^2\theta + \sin^2\theta = 1$. So these are the tangent lines to the unit circle. Thus the family consists of all planes tangent to the circular cylinder with radius 1 and axis the x-axis.

83. If $a \neq 0$, then $ax + by + cz + d = 0 \;\;\Rightarrow\;\; a(x + d/a) + b(y - 0) + c(z - 0) = 0$ which by (7) is the scalar equation of the plane through the point $(-d/a, 0, 0)$ with normal vector $\langle a, b, c \rangle$. Similarly, if $b \neq 0$ (or if $c \neq 0$) the equation of the plane can be rewritten as $a(x - 0) + b(y + d/b) + c(z - 0) = 0$ [or as $a(x - 0) + b(y - 0) + c(z + d/c) = 0$] which by (7) is the scalar equation of a plane through the point $(0, -d/b, 0)$ [or the point $(0, 0, -d/c)$] with normal vector $\langle a, b, c \rangle$.

LABORATORY PROJECT Putting 3D in Perspective

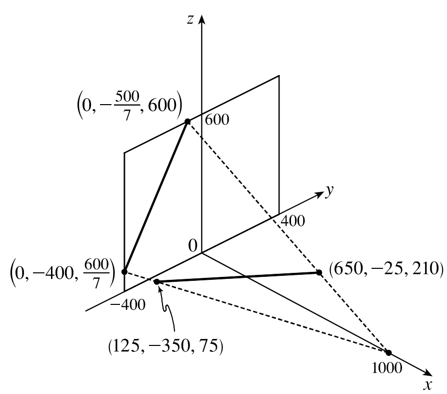
1. If we view the screen from the camera's location, the vertical clipping plane on the left passes through the points $(1000, 0, 0)$, $(0, -400, 0)$, and $(0, -400, 600)$. A vector from the first point to the second is $\mathbf{v}_1 = \langle -1000, -400, 0 \rangle$ and a vector from the first point to the third is $\mathbf{v}_2 = \langle -1000, -400, 600 \rangle$. A normal vector for the clipping plane is $\mathbf{v}_1 \times \mathbf{v}_2 = -240{,}000\,\mathbf{i} + 600{,}000\,\mathbf{j}$ or $-2\,\mathbf{i} + 5\,\mathbf{j}$, and an equation for the plane is $-2(x - 1000) + 5(y - 0) + 0(z - 0) = 0 \;\;\Rightarrow\;\; 2x - 5y = 2000$. By symmetry, the vertical clipping plane on the right is given by $2x + 5y = 2000$. The lower clipping plane is $z = 0$. The upper clipping plane passes through the points $(1000, 0, 0)$,

$(0, -400, 600)$, and $(0, 400, 600)$. Vectors from the first point to the second and third points are $\mathbf{v}_1 = \langle -1000, -400, 600\rangle$ and $\mathbf{v}_2 = \langle -1000, 400, 600\rangle$, and a normal vector for the plane is $\mathbf{v}_1 \times \mathbf{v}_2 = -480{,}000\,\mathbf{i} - 800{,}000\,\mathbf{k}$ or $3\,\mathbf{i} + 5\,\mathbf{k}$. An equation for the plane is $3(x - 1000) + 0(y - 0) + 5(z - 0) = 0 \;\Rightarrow\; 3x + 5z = 3000$.

A direction vector for the line L is $\mathbf{v} = \langle 630, 390, 162\rangle$ and taking $P_0 = (230, -285, 102)$, parametric equations are $x = 230 + 630t$, $y = -285 + 390t$, $z = 102 + 162t$. L intersects the left clipping plane when $2(230 + 630t) - 5(-285 + 390t) = 2000 \;\Rightarrow\; t = -\frac{1}{6}$. The corresponding point is $(125, -350, 75)$. L intersects the right clipping plane when $2(230 + 630t) + 5(-285 + 390t) = 2000 \;\Rightarrow\; t = \frac{593}{642}$. The corresponding point is approximately $(811.9, 75.2, 251.6)$, but this point is not contained within the viewing volume. L intersects the upper clipping plane when $3(230 + 630t) + 5(102 + 162t) = 3000 \;\Rightarrow\; t = \frac{2}{3}$, corresponding to the point $(650, -25, 210)$, and L intersects the lower clipping plane when $z = 0 \;\Rightarrow\; 102 + 162t = 0 \;\Rightarrow\; t = -\frac{17}{27}$. The corresponding point is approximately $(-166.7, -530.6, 0)$, which is not contained within the viewing volume. Thus L should be clipped at the points $(125, -350, 75)$ and $(650, -25, 210)$.

2. A sight line from the camera at $(1000, 0, 0)$ to the left endpoint $(125, -350, 75)$ of the clipped line has direction $\mathbf{v} = \langle -875, -350, 75\rangle$. Parametric equations are $x = 1000 - 875t$, $y = -350t$, $z = 75t$. This line intersects the screen when $x = 0 \;\Rightarrow\; 1000 - 875t = 0 \;\Rightarrow\; t = \frac{8}{7}$, corresponding to the point $\left(0, -400, \frac{600}{7}\right)$. Similarly, a sight line from the camera to the right endpoint $(650, -25, 210)$ of the clipped line has direction $\langle -350, -25, 210\rangle$ and parametric equations are $x = 1000 - 350t$, $y = -25t$, $z = 210t$. $x = 0 \;\Rightarrow\; 1000 - 350t = 0 \;\Rightarrow\; t = \frac{20}{7}$, corresponding to the point $\left(0, -\frac{500}{7}, 600\right)$. Thus the projection of the clipped line is the line segment between the points $\left(0, -400, \frac{600}{7}\right)$ and $\left(0, -\frac{500}{7}, 600\right)$.

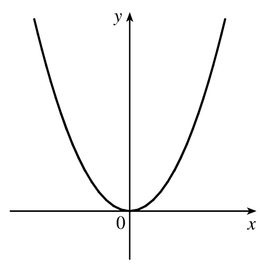
3. From Equation 12.5.4, equations for the four sides of the screen are $\mathbf{r}_1(t) = (1 - t)\langle 0, -400, 0\rangle + t\,\langle 0, -400, 600\rangle$, $\mathbf{r}_2(t) = (1 - t)\langle 0, -400, 600\rangle + t\,\langle 0, 400, 600\rangle$, $\mathbf{r}_3(t) = (1 - t)\langle 0, 400, 0\rangle + t\,\langle 0, 400, 600\rangle$, and $\mathbf{r}_4(t) = (1 - t)\langle 0, -400, 0\rangle + t\,\langle 0, 400, 0\rangle$. The clipped line segment connects the points $(125, -350, 75)$ and $(650, -25, 210)$, so an equation for the segment is $\mathbf{r}_5(t) = (1 - t)\langle 125, -350, 75\rangle + t\,\langle 650, -25, 210\rangle$. The projection of the clipped segment connects the points $\left(0, -400, \frac{600}{7}\right)$ and $\left(0, -\frac{500}{7}, 600\right)$, so an equation is $\mathbf{r}_6(t) = (1 - t)\left\langle 0, -400, \frac{600}{7}\right\rangle + t\left\langle 0, -\frac{500}{7}, 600\right\rangle$. The sight line on the left connects the points $(1000, 0, 0)$ and $\left(0, -400, \frac{600}{7}\right)$, so an equation is $\mathbf{r}_7(t) = (1 - t)\langle 1000, 0, 0\rangle + t\left\langle 0, -400, \frac{600}{7}\right\rangle$. The other sight line connects $(1000, 0, 0)$ to $\left(0, -\frac{500}{7}, 600\right)$, so an equation is $\mathbf{r}_8(t) = (1 - t)\langle 1000, 0, 0\rangle + t\left\langle 0, -\frac{500}{7}, 600\right\rangle$.



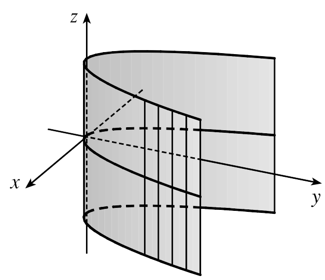
4. The vector from $(621, -147, 206)$ to $(563, 31, 242)$, $\mathbf{v}_1 = \langle -58, 178, 36\rangle$, lies in the plane of the rectangle, as does the vector from $(621, -147, 206)$ to $(657, -111, 86)$, $\mathbf{v}_2 = \langle 36, 36, -120\rangle$. A normal vector for the plane is $\mathbf{v}_1 \times \mathbf{v}_2 = \langle -1888, -142, -708\rangle$ or $\langle 8, 2, 3\rangle$, and an equation of the plane is $8x + 2y + 3z = 5292$. The line L intersects this plane when $8(230 + 630t) + 2(-285 + 390t) + 3(102 + 162t) = 5292 \quad \Rightarrow \quad t = \frac{1858}{3153} \approx 0.589$. The corresponding point is approximately $(601.25, -55.18, 197.46)$. Starting at this point, a portion of the line is hidden behind the rectangle. The line becomes visible again at the left edge of the rectangle, specifically the edge between the points $(621, -147, 206)$ and $(657, -111, 86)$. (This is most easily determined by graphing the rectangle and the line.) A plane through these two points and the camera's location, $(1000, 0, 0)$, will clip the line at the point it becomes visible. Two vectors in this plane are $\mathbf{v}_1 = \langle -379, -147, 206\rangle$ and $\mathbf{v}_2 = \langle -343, -111, 86\rangle$. A normal vector for the plane is $\mathbf{v}_1 \times \mathbf{v}_2 = \langle 10224, -38064, -8352\rangle$ and an equation of the plane is $213x - 793y - 174z = 213{,}000$. L intersects this plane when $213(230 + 630t) - 793(-285 + 390t) - 174(102 + 162t) = 213{,}000 \quad \Rightarrow \quad t = \frac{44{,}247}{203{,}268} \approx 0.2177$. The corresponding point is approximately $(367.14, -200.11, 137.26)$. Thus the portion of L that should be removed is the segment between the points $(601.25, -55.18, 197.46)$ and $(367.14, -200.11, 137.26)$.

12.6 Cylinders and Quadric Surfaces

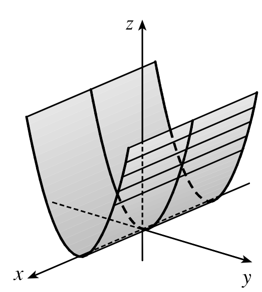
1. (a) In $\mathbb{R}^2$, the equation $y = x^2$ represents a parabola.



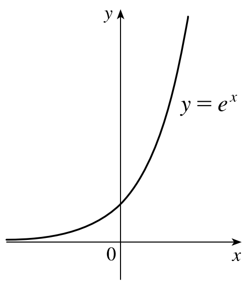
(b) In $\mathbb{R}^3$, the equation $y = x^2$ doesn't involve z, so any horizontal plane with equation $z = k$ intersects the graph in a curve with equation $y = x^2$. Thus, the surface is a parabolic cylinder, made up of infinitely many shifted copies of the same parabola. The rulings are parallel to the z-axis.



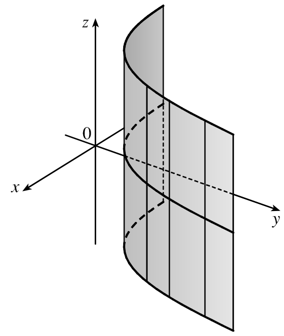
(c) In $\mathbb{R}^3$, the equation $z = y^2$ also represents a parabolic cylinder. Since x doesn't appear, the graph is formed by moving the parabola $z = y^2$ in the direction of the x-axis. Thus, the rulings of the cylinder are parallel to the x-axis.



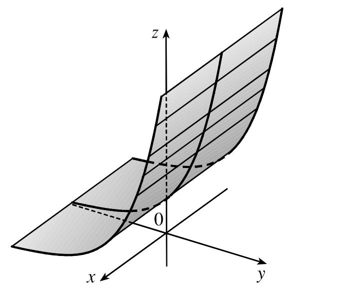
2. (a)



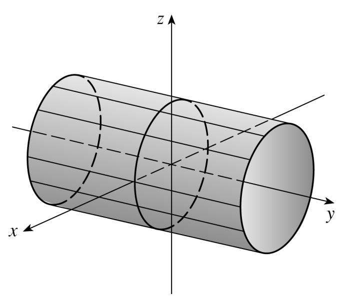
(b) Since the equation $y = e^x$ doesn't involve z, horizontal traces are copies of the curve $y = e^x$. The rulings are parallel to the z-axis.



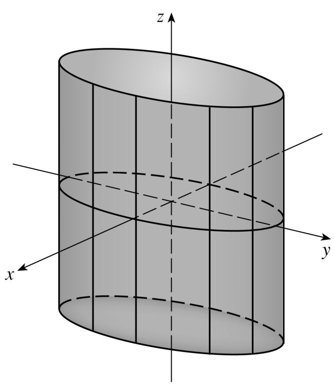
(c) The equation $z = e^y$ doesn't involve x, so vertical traces in $x = k$ (parallel to the yz-plane) are copies of the curve $z = e^y$. The rulings are parallel to the x-axis.



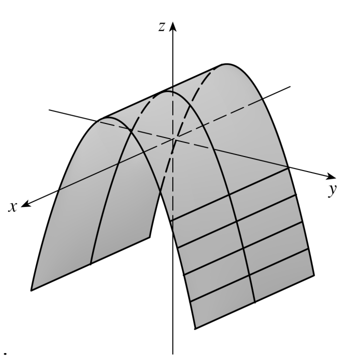
3. Since y is missing from the equation, the vertical traces $x^2 + z^2 = 1$, $y = k$, are copies of the same circle in the plane $y = k$. Thus the surface $x^2 + z^2 = 1$ is a circular cylinder with rulings parallel to the y-axis.



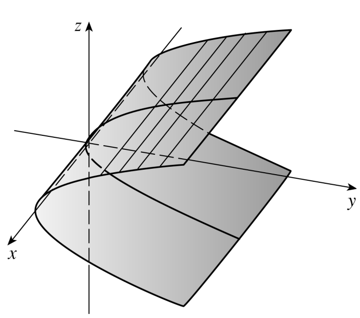
4. Since z is missing from the equation, the horizontal traces $4x^2 + y^2 = 4$, $z = k$, are copies of the same ellipse in the plane $z = k$. Thus the surface $4x^2 + y^2 = 4$ is an elliptic cylinder with rulings parallel to the z-axis.



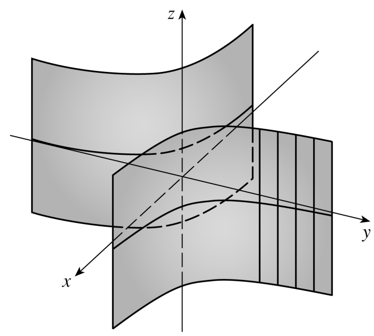
5. Since x is missing, each vertical trace $z = 1 - y^2$, $x = k$, is a copy of the same parabola in the plane $x = k$. Thus the surface $z = 1 - y^2$ is a parabolic cylinder with rulings parallel to the x-axis.



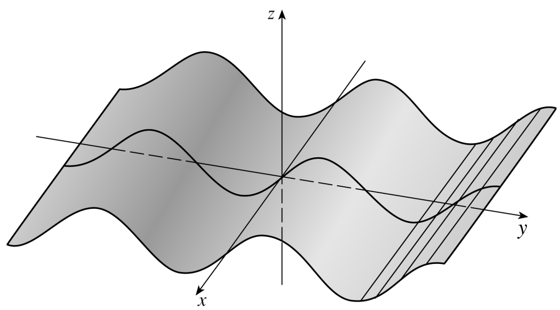
6. Since x is missing, each vertical trace $y = z^2$, $x = k$, is a copy of the same parabola in the plane $x = k$. Thus the surface $y = z^2$ is a parabolic cylinder with rulings parallel to the x-axis.



7. Since z is missing, each horizontal trace $xy = 1$, $z = k$, is a copy of the same hyperbola in the plane $z = k$. Thus the surface $xy = 1$ is a hyperbolic cylinder with rulings parallel to the z-axis.

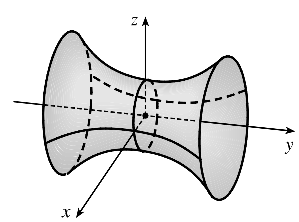


8. Since x is missing, each vertical trace $z = \sin y$, $x = k$, is a copy of a sine curve in the plane $x = k$. Thus the surface $z = \sin y$ is a cylindrical surface with rulings parallel to the x-axis.

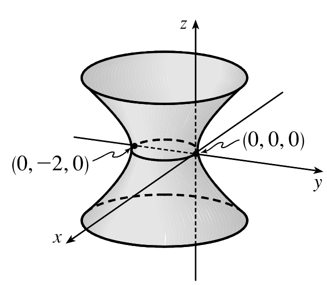


9. (a) The traces of $x^2 + y^2 - z^2 = 1$ in $x = k$ are $y^2 - z^2 = 1 - k^2$, a family of hyperbolas. (Note that the hyperbolas are oriented differently for $-1 < k < 1$ than for $k < -1$ or $k > 1$.) The traces in $y = k$ are $x^2 - z^2 = 1 - k^2$, a similar family of hyperbolas. The traces in $z = k$ are $x^2 + y^2 = 1 + k^2$, a family of circles. For $k = 0$, the trace in the xy-plane, the circle is of radius 1. As $|k|$ increases, so does the radius of the circle. This behavior, combined with the hyperbolic vertical traces, gives the graph of the hyperboloid of one sheet in Table 1.

(b) The shape of the surface is unchanged, but the hyperboloid is rotated so that its axis is the y-axis. Traces in $y = k$ are circles, while traces in $x = k$ and $z = k$ are hyperbolas.

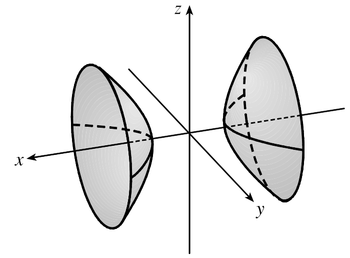


(c) Completing the square in y gives $x^2 + (y + 1)^2 - z^2 = 1$. The surface is a hyperboloid identical to the one in part (a) but shifted one unit in the negative y-direction.

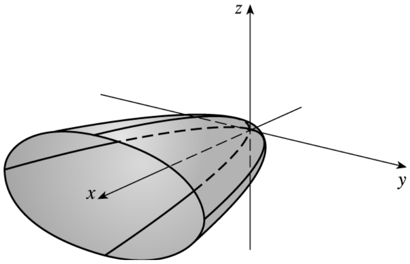


10. (a) The traces of $-x^2 - y^2 + z^2 = 1$ in $x = k$ are $-y^2 + z^2 = 1 + k^2$, a family of hyperbolas, as are the traces in $y = k$, $-x^2 + z^2 = 1 + k^2$. The traces in $z = k$ are $x^2 + y^2 = k^2 - 1$, a family of circles for $|k| > 1$. As $|k|$ increases, the radii of the circles increase; the traces are empty for $|k| < 1$. This behavior, combined with the vertical traces, gives the graph of the hyperboloid of two sheets in Table 1.

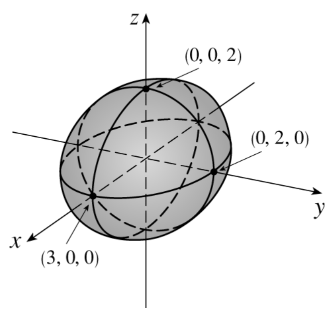
(b) The graph has the same shape as the hyperboloid in part (a) but is rotated so that its axis is the x-axis. Traces in $x = k$, $|k| > 1$, are circles, while traces in $y = k$ and $z = k$ are hyperbolas.



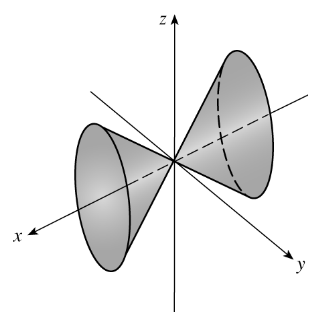
11. For $x = y^2 + 4z^2$, the traces in $x = k$ are $y^2 + 4z^2 = k$. When $k > 0$ we have a family of ellipses. When $k = 0$ we have just a point at the origin, and the trace is empty for $k < 0$. The traces in $y = k$ are $x = 4z^2 + k^2$, a family of parabolas opening in the positive x-direction. Similarly, the traces in $z = k$ are $x = y^2 + 4k^2$, a family of parabolas opening in the positive x-direction. We recognize the graph as an elliptic paraboloid with axis the x-axis and vertex the origin.



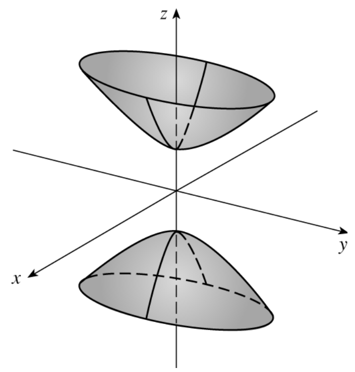
12. $4x^2 + 9y^2 + 9z^2 = 36$. The traces in $x = k$ are $9y^2 + 9z^2 = 36 - 4k^2$ $\Leftrightarrow$ $y^2 + z^2 = 4 - \frac{4}{9}k^2$, a family of circles for $|k| < 3$. (The traces are a single point for $|k| = 3$ and are empty for $|k| > 3$.) The traces in $y = k$ are $4x^2 + 9z^2 = 36 - 9k^2$, a family of ellipses for $|k| < 2$. Similarly, the traces in $z = k$ are the ellipses $4x^2 + 9y^2 = 36 - 9k^2$, $|k| < 2$. The graph is an ellipsoid centered at the origin with intercepts $x = \pm 3$, $y = \pm 2$, $z = \pm 2$.



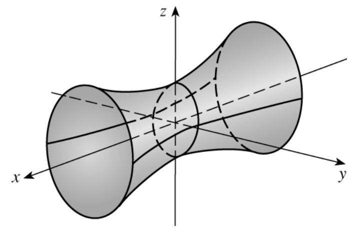
13. $x^2 = 4y^2 + z^2$. The traces in $x = k$ are the ellipses $4y^2 + z^2 = k^2$. The traces in $y = k$ are $x^2 - z^2 = 4k^2$, hyperbolas for $k \neq 0$ and two intersecting lines if $k = 0$. Similarly, the traces in $z = k$ are $x^2 - 4y^2 = k^2$, hyperbolas for $k \neq 0$ and two intersecting lines if $k = 0$. We recognize the graph as an elliptic cone with axis the x-axis and vertex the origin.



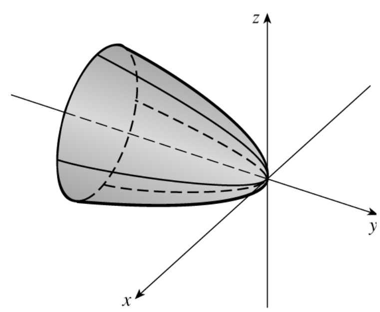
14. $z^2 - 4x^2 - y^2 = 4$. The traces in $x = k$ are the hyperbolas $z^2 - y^2 = 4 + 4k^2$, and the traces in $y = k$ are the hyperbolas $z^2 - 4x^2 = 4 + k^2$. The traces in $z = k$ are $4x^2 + y^2 = k^2 - 4$, a family of ellipses for $|k| > 2$. (The traces are a single point for $|k| = 2$ and are empty for $|k| < 2$.) The surface is a hyperboloid of two sheets with axis the z-axis.



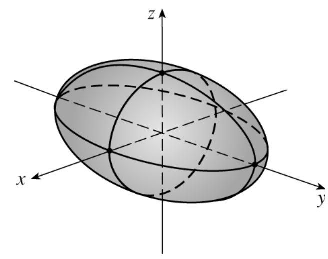
15. $9y^2 + 4z^2 = x^2 + 36$. The traces in $x = k$ are $9y^2 + 4z^2 = k^2 + 36$, a family of ellipses. The traces in $y = k$ are $4z^2 - x^2 = 9(4 - k^2)$, a family of hyperbolas for $|k| \neq 2$ and two intersecting lines when $|k| = 2$. (Note that the hyperbolas are oriented differently for $|k| < 2$ than for $|k| > 2$.) The traces in $z = k$ are $9y^2 - x^2 = 4(9 - k^2)$, a family of hyperbolas when $|k| \neq 3$ (oriented differently for $|k| < 3$ than for $|k| > 3$) and two intersecting lines when $|k| = 3$. We recognize the graph as a hyperboloid of one sheet with axis the x-axis.



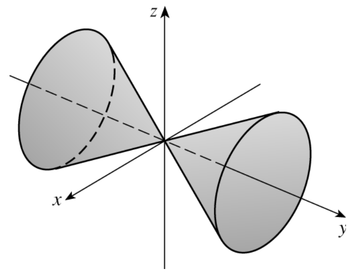
16. $3x^2 + y + 3z^2 = 0$. The traces in $x = k$ are the parabolas $y = -3z^2 - 3k^2$ which open to the left (in the negative y-direction). Traces in $y = k$ are $3x^2 + 3z^2 = -k \quad \Leftrightarrow \quad x^2 + z^2 = -\dfrac{k}{3}$, a family of circles for $k < 0$. (Traces are empty for $k > 0$ and a single point for $k = 0$.) Traces in $z = k$ are the parabolas $y = -3x^2 - 3k^2$ which open in the negative y-direction. The graph is a circular paraboloid with axis the y-axis, opening in the negative y-direction, and vertex the origin.



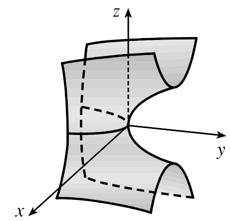
17. $\dfrac{x^2}{9} + \dfrac{y^2}{25} + \dfrac{z^2}{4} = 1$. The traces in $x = k$ are $\dfrac{y^2}{25} + \dfrac{z^2}{4} = 1 - \dfrac{k^2}{9}$, a family of ellipses for $|k| < 3$. (The traces are a single point for $|k| = 3$ and are empty for $|k| > 3$.) The traces in $y = k$ are the ellipses $\dfrac{x^2}{9} + \dfrac{z^2}{4} = 1 - \dfrac{k^2}{25}$, $|k| < 5$, and the traces in $z = k$ are the ellipses $\dfrac{x^2}{9} + \dfrac{y^2}{25} = 1 - \dfrac{k^2}{4}$, $|k| < 2$. The surface is an ellipsoid centered at the origin with intercepts $x = \pm 3$, $y = \pm 5$, $z = \pm 2$.



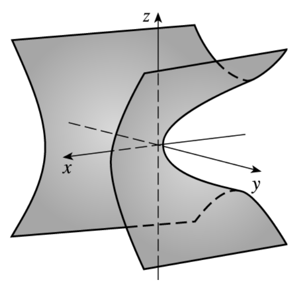
18. $3x^2 - y^2 + 3z^2 = 0$. The traces in $x = k$ are $y^2 - 3z^2 = 3k^2$, a family of hyperbolas for $k \neq 0$ and two intersecting lines if $k = 0$. Traces in $y = k$ are the circles $3x^2 + 3z^2 = k^2 \quad \Leftrightarrow \quad x^2 + z^2 = \frac{1}{3}k^2$. The traces in $z = k$ are $y^2 - 3x^2 = 3k^2$, hyperbolas for $k \neq 0$ and two intersecting lines if $k = 0$. We recognize the surface as a circular cone with axis the y-axis and vertex the origin.



19. $y = z^2 - x^2$. The traces in $x = k$ are the parabolas $y = z^2 - k^2$, opening in the positive y-direction. The traces in $y = k$ are $k = z^2 - x^2$, two intersecting lines when $k = 0$ and a family of hyperbolas for $k \neq 0$ (note that the hyperbolas are oriented differently for $k > 0$ than for $k < 0$). The traces in $z = k$ are the parabolas $y = k^2 - x^2$ which open in the negative y-direction. Thus the surface is a hyperbolic paraboloid centered at $(0, 0, 0)$.



20. $x = y^2 - z^2$. The traces in $x = k$ are $y^2 - z^2 = k$, two intersecting lines when $k = 0$ and a family of hyperbolas for $k \neq 0$ (oriented differently for $k > 0$ than for $k < 0$). The traces in $y = k$ are the parabolas $x = -z^2 + k^2$, opening in the negative x-direction, and the traces in $z = k$ are the parabolas $x = y^2 - k^2$ which open in the positive x-direction. The graph is a hyperbolic paraboloid centered at $(0, 0, 0)$.



21. This is the equation of an ellipsoid: $x^2 + 4y^2 + 9z^2 = x^2 + \dfrac{y^2}{(1/2)^2} + \dfrac{z^2}{(1/3)^2} = 1$, with x-intercepts ± 1, y-intercepts $\pm\frac{1}{2}$ and z-intercepts $\pm\frac{1}{3}$. So the major axis is the x-axis and the only possible graph is VII.

22. This is the equation of an ellipsoid: $9x^2 + 4y^2 + z^2 = \dfrac{x^2}{(1/3)^2} + \dfrac{y^2}{(1/2)^2} + z^2 = 1$, with x-intercepts $\pm\frac{1}{3}$, y-intercepts $\pm\frac{1}{2}$ and z-intercepts ± 1. So the major axis is the z-axis and the only possible graph is IV.

23. This is the equation of a hyperboloid of one sheet, with $a = b = c = 1$. Since the coefficient of y^2 is negative, the axis of the hyperboloid is the y-axis, hence the correct graph is II.

24. This is a hyperboloid of two sheets, with $a = b = c = 1$. This surface does not intersect the xz-plane at all, so the axis of the hyperboloid is the y-axis and the graph is III.

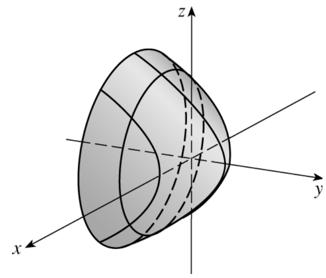
25. There are no real values of x and z that satisfy this equation for $y < 0$, so this surface does not extend to the left of the xz-plane. The surface intersects the plane $y = k > 0$ in an ellipse. Notice that y occurs to the first power whereas x and z occur to the second power. So the surface is an elliptic paraboloid with axis the y-axis. Its graph is VI.

26. This is the equation of a cone with axis the y-axis, so the graph is I.

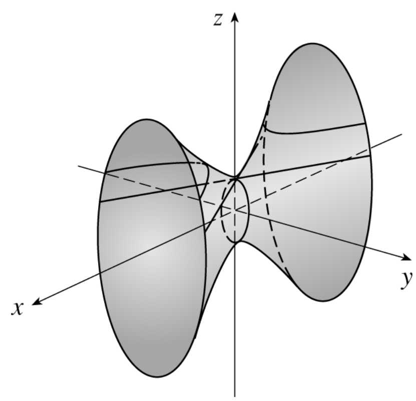
27. This surface is a cylinder because the variable y is missing from the equation. The intersection of the surface and the xz-plane is an ellipse. So the graph is VIII.

28. This is the equation of a hyperbolic paraboloid. The trace in the xy-plane is the parabola $y = x^2$. So the correct graph is V.

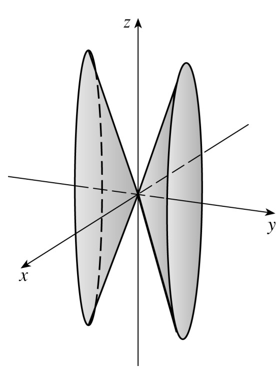
29. Vertical traces parallel to the xz-plane are circles centered at the origin whose radii increase as y decreases. (The trace in $y = 1$ is just a single point and the graph suggests that traces in $y = k$ are empty for $k > 1$.) The traces in vertical planes parallel to the yz-plane are parabolas opening to the left that shift to the left as $|x|$ increases. One surface that fits this description is a circular paraboloid, opening to the left, with vertex $(0, 1, 0)$.



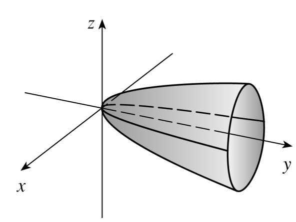
30. The vertical traces parallel to the yz-plane are ellipses that are smallest in the yz-plane and increase in size as $|x|$ increases. One surface that fits this description is a hyperboloid of one sheet with axis the x-axis. The horizontal traces in $z = k$ (hyperbolas and intersecting lines) also fit this surface, as shown in the figure.



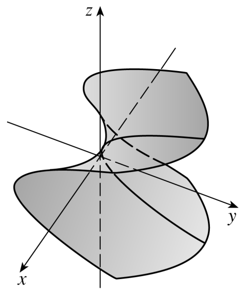
31. $y^2 = x^2 + \frac{1}{9}z^2$ or $y^2 = x^2 + \dfrac{z^2}{9}$ represents an elliptic cone with vertex $(0, 0, 0)$ and axis the y-axis.



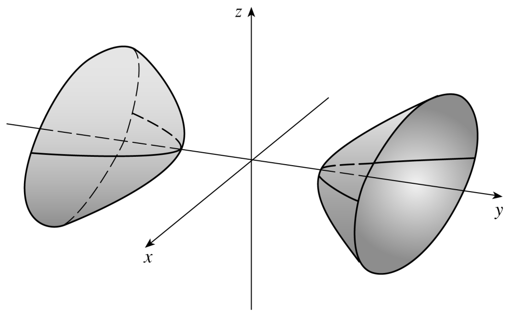
32. $4x^2 - y + 2z^2 = 0$ or $y = \dfrac{x^2}{1/4} + \dfrac{z^2}{1/2}$ or $\dfrac{y}{4} = x^2 + \dfrac{z^2}{2}$ represents an elliptic paraboloid with vertex $(0, 0, 0)$ and axis the y-axis.



33. $x^2 + 2y - 2z^2 = 0$ or $2y = 2z^2 - x^2$ or $y = z^2 - \frac{x^2}{2}$ represents a hyperbolic paraboloid with center $(0, 0, 0)$.



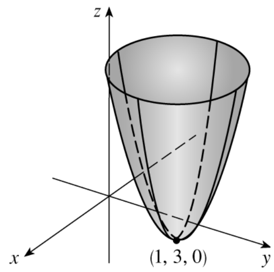
34. $y^2 = x^2 + 4z^2 + 4$ or $-x^2 + y^2 - 4z^2 = 4$ or $-\frac{x^2}{4} + \frac{y^2}{4} - z^2 = 1$ represents a hyperboloid of two sheets with axis the y-axis.



35. Completing squares in x and y gives

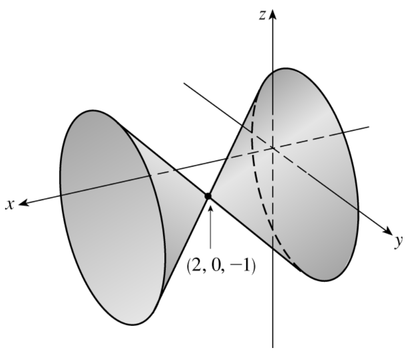
$\left(x^2 - 2x + 1\right) + \left(y^2 - 6y + 9\right) - z = 0 \quad \Leftrightarrow$

$(x-1)^2 + (y-3)^2 - z = 0$ or $z = (x-1)^2 + (y-3)^2$, a circular paraboloid opening upward with vertex $(1, 3, 0)$ and axis the vertical line $x = 1, y = 3$.



36. Completing squares in x and z gives $\left(x^2 - 4x + 4\right) - y^2 - \left(z^2 + 2z + 1\right) + 3 = 0 + 4 - 1 \quad \Leftrightarrow$

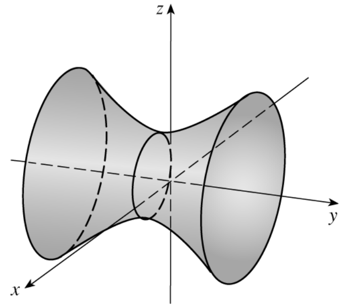
$(x-2)^2 - y^2 - (z+1)^2 = 0$ or $(x-2)^2 = y^2 + (z+1)^2$, a circular cone with vertex $(2, 0, -1)$ and axis the horizontal line $y = 0$, $z = -1$.



37. Completing squares in x and z gives

$\left(x^2 - 4x + 4\right) - y^2 + \left(z^2 - 2z + 1\right) = 0 + 4 + 1 \quad \Leftrightarrow$

$(x-2)^2 - y^2 + (z-1)^2 = 5$ or $\frac{(x-2)^2}{5} - \frac{y^2}{5} + \frac{(z-1)^2}{5} = 1$, a hyperboloid of one sheet with center $(2, 0, 1)$ and axis the horizontal line $x = 2, z = 1$.



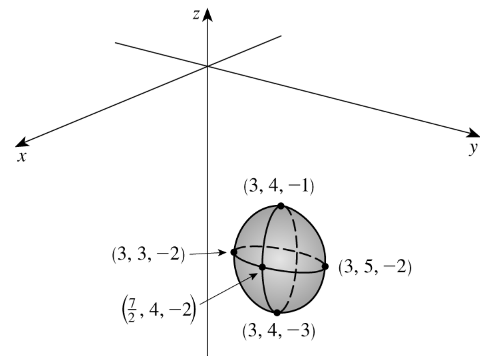
38. Completing squares in all three variables gives

$4(x^2 - 6x + 9) + (y^2 - 8y + 16) + (z^2 + 4z + 4) = -55 + 36 + 16 + 4 \quad \Leftrightarrow$

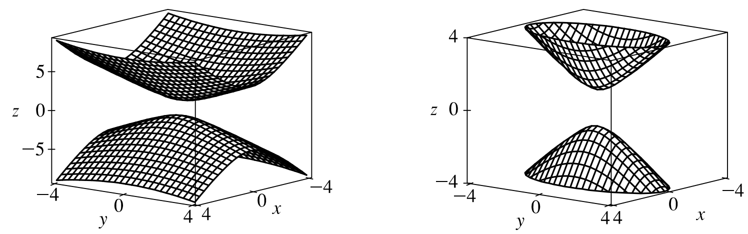
$4\,(x-3)^2 + (y-4)^2 + (z+2)^2 = 1$ or

$\dfrac{(x-3)^2}{1/4} + (y-4)^2 + (z+2)^2 = 1$, an ellipsoid with

center $(3, 4, -2)$.

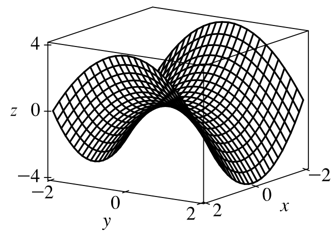


39. Solving the equation for z we get $z = \pm\sqrt{1 + 4x^2 + y^2}$, so we plot separately $z = \sqrt{1 + 4x^2 + y^2}$ and $z = -\sqrt{1 + 4x^2 + y^2}$.

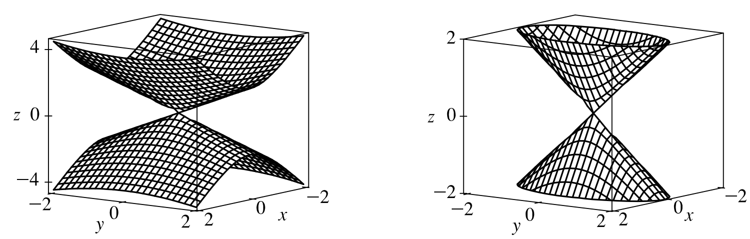


To restrict the z-range as in the second graph, we can use the option `view=-4..4` in Maple's `plot3d` command, or `PlotRange->{-4,4}` in Mathematica's `Plot3D` command.

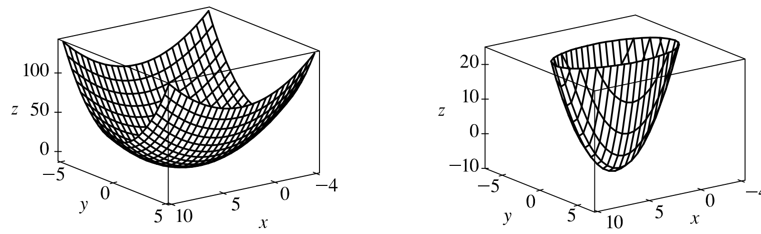
40. We plot the surface $z = x^2 - y^2$.



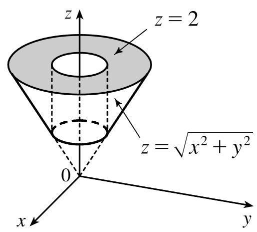
41. Solving the equation for z we get $z = \pm\sqrt{4x^2 + y^2}$, so we plot separately $z = \sqrt{4x^2 + y^2}$ and $z = -\sqrt{4x^2 + y^2}$.



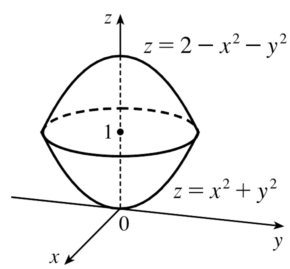
42. We plot the surface $z = x^2 - 6x + 4y^2$.



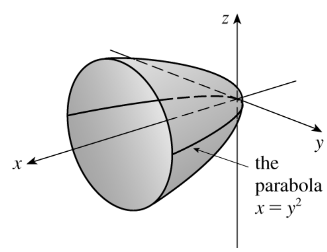
43.



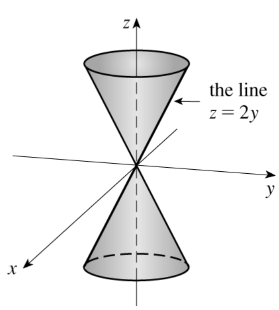
44.



45. The curve $y = \sqrt{x}$ is equivalent to $x = y^2$, $y \geq 0$. Rotating the curve about the x-axis creates a circular paraboloid with vertex at the origin, axis the x-axis, opening in the positive x-direction. The trace in the xy-plane is $x = y^2$, $z = 0$, and the trace in the xz-plane is a parabola of the same shape: $x = z^2$, $y = 0$. An equation for the surface is $x = y^2 + z^2$.



46. Rotating the line $z = 2y$ about the z-axis creates a (right) circular cone with vertex at the origin and axis the z-axis. Traces in $z = k$ ($k \neq 0$) are circles with center $(0, 0, k)$ and radius $y = z/2 = k/2$, so an equation for the trace is $x^2 + y^2 = (k/2)^2$, $z = k$. Thus an equation for the surface is $x^2 + y^2 = (z/2)^2$ or $4x^2 + 4y^2 = z^2$.



47. Let $P = (x, y, z)$ be an arbitrary point equidistant from $(-1, 0, 0)$ and the plane $x = 1$. Then the distance from P to $(-1, 0, 0)$ is $\sqrt{(x+1)^2 + y^2 + z^2}$ and the distance from P to the plane $x = 1$ is $|x - 1| / \sqrt{1^2} = |x - 1|$ (by Equation 12.5.9). So $|x - 1| = \sqrt{(x+1)^2 + y^2 + z^2} \quad \Leftrightarrow \quad (x-1)^2 = (x+1)^2 + y^2 + z^2 \quad \Leftrightarrow$ $x^2 - 2x + 1 = x^2 + 2x + 1 + y^2 + z^2 \quad \Leftrightarrow \quad -4x = y^2 + z^2$. Thus the collection of all such points P is a circular paraboloid with vertex at the origin, axis the x-axis, which opens in the negative x-direction.

48. Let $P = (x, y, z)$ be an arbitrary point whose distance from the x-axis is twice its distance from the yz-plane. The distance from P to the x-axis is $\sqrt{(x-x)^2 + y^2 + z^2} = \sqrt{y^2 + z^2}$ and the distance from P to the yz-plane ($x = 0$) is $|x|/1 = |x|$. Thus $\sqrt{y^2 + z^2} = 2|x| \quad \Leftrightarrow \quad y^2 + z^2 = 4x^2 \quad \Leftrightarrow \quad x^2 = (y^2/2^2) + (z^2/2^2)$. So the surface is a right circular cone with vertex the origin and axis the x-axis.

49. (a) An equation for an ellipsoid centered at the origin with intercepts $x = \pm a$, $y = \pm b$, and $z = \pm c$ is $\dfrac{x^2}{a^2} + \dfrac{y^2}{b^2} + \dfrac{z^2}{c^2} = 1$. Here the poles of the model intersect the z-axis at $z = \pm 6356.523$ and the equator intersects the x- and y-axes at $x = \pm 6378.137$, $y = \pm 6378.137$, so an equation is

$$\frac{x^2}{(6378.137)^2} + \frac{y^2}{(6378.137)^2} + \frac{z^2}{(6356.523)^2} = 1$$

(b) Traces in $z = k$ are the circles $\dfrac{x^2}{(6378.137)^2} + \dfrac{y^2}{(6378.137)^2} = 1 - \dfrac{k^2}{(6356.523)^2} \quad \Leftrightarrow$

$x^2 + y^2 = (6378.137)^2 - \left(\dfrac{6378.137}{6356.523}\right)^2 k^2$.

(c) To identify the traces in $y = mx$ we substitute $y = mx$ into the equation of the ellipsoid:

$$\frac{x^2}{(6378.137)^2} + \frac{(mx)^2}{(6378.137)^2} + \frac{z^2}{(6356.523)^2} = 1$$

$$\frac{(1+m^2)x^2}{(6378.137)^2} + \frac{z^2}{(6356.523)^2} = 1$$

$$\frac{x^2}{(6378.137)^2/(1+m^2)} + \frac{z^2}{(6356.523)^2} = 1$$

As expected, this is a family of ellipses.

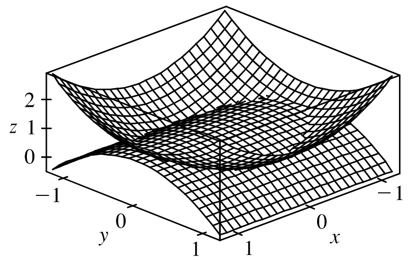
50. If we position the hyperboloid on coordinate axes so that it is centered at the origin with axis the z-axis then its equation is given by $\dfrac{x^2}{a^2} + \dfrac{y^2}{b^2} - \dfrac{z^2}{c^2} = 1$. Horizontal traces in $z = k$ are $\dfrac{x^2}{a^2} + \dfrac{y^2}{b^2} = 1 + \dfrac{k^2}{c^2}$, a family of ellipses, but we know that the traces are circles so we must have $a = b$. The trace in $z = 0$ is $\dfrac{x^2}{a^2} + \dfrac{y^2}{a^2} = 1 \quad \Leftrightarrow \quad x^2 + y^2 = a^2$ and since the minimum radius of 100 m occurs there, we must have $a = 100$. The base of the tower is the trace in $z = -500$ given by $\dfrac{x^2}{a^2} + \dfrac{y^2}{a^2} = 1 + \dfrac{(-500)^2}{c^2}$ but $a = 100$ so the trace is $x^2 + y^2 = 100^2 + 50{,}000^2 \dfrac{1}{c^2}$. We know the base is a circle of radius 140, so we must have $100^2 + 50{,}000^2 \dfrac{1}{c^2} = 140^2 \quad \Rightarrow \quad c^2 = \dfrac{50{,}000^2}{140^2 - 100^2} = \dfrac{781{,}250}{3}$ and an equation for the tower is $\dfrac{x^2}{100^2} + \dfrac{y^2}{100^2} - \dfrac{z^2}{(781{,}250)/3} = 1$ or $\dfrac{x^2}{10{,}000} + \dfrac{y^2}{10{,}000} - \dfrac{3z^2}{781{,}250} = 1$, $-500 \le z \le 500$.

51. If (a, b, c) satisfies $z = y^2 - x^2$, then $c = b^2 - a^2$. L_1: $x = a + t$, $y = b + t$, $z = c + 2(b - a)t$, L_2: $x = a + t$, $y = b - t$, $z = c - 2(b + a)t$. Substitute the parametric equations of L_1 into the equation of the hyperbolic paraboloid in order to find the points of intersection: $z = y^2 - x^2 \quad \Rightarrow$
$c + 2(b - a)t = (b + t)^2 - (a + t)^2 = b^2 - a^2 + 2(b - a)t \quad \Rightarrow \quad c = b^2 - a^2$. As this is true for all values of t,

L_1 lies on $z = y^2 - x^2$. Performing similar operations with L_2 gives: $z = y^2 - x^2 \quad \Rightarrow$ $c - 2(b+a)t = (b-t)^2 - (a+t)^2 = b^2 - a^2 - 2(b+a)t \quad \Rightarrow \quad c = b^2 - a^2$. This tells us that all of L_2 also lies on $z = y^2 - x^2$.

52. Any point on the curve of intersection must satisfy both $2x^2 + 4y^2 - 2z^2 + 6x = 2$ and $2x^2 + 4y^2 - 2z^2 - 5y = 0$. Subtracting, we get $6x + 5y = 2$, which is linear and therefore the equation of a plane. Thus the curve of intersection lies in this plane.

53.



The curve of intersection looks like a bent ellipse. The projection of this curve onto the xy-plane is the set of points $(x, y, 0)$ which satisfy $x^2 + y^2 = 1 - y^2 \quad \Leftrightarrow \quad x^2 + 2y^2 = 1 \quad \Leftrightarrow$ $x^2 + \dfrac{y^2}{\left(1/\sqrt{2}\right)^2} = 1$. This is an equation of an ellipse.

12 Review

TRUE-FALSE QUIZ

1. This is false, as the dot product of two vectors is a scalar, not a vector.

2. False. For example, if $\mathbf{u} = \mathbf{i}$ and $\mathbf{v} = -\mathbf{i}$ then $|\mathbf{u} + \mathbf{v}| = |\mathbf{0}| = 0$ but $|\mathbf{u}| + |\mathbf{v}| = 1 + 1 = 2$.

3. False. For example, if $\mathbf{u} = \mathbf{i}$ and $\mathbf{v} = \mathbf{j}$ then $|\mathbf{u} \cdot \mathbf{v}| = |0| = 0$ but $|\mathbf{u}|\,|\mathbf{v}| = 1 \cdot 1 = 1$. In fact, by Theorem 12.3.3, $|\mathbf{u} \cdot \mathbf{v}| = \big||\mathbf{u}|\,|\mathbf{v}| \cos\theta\big|$.

4. False. For example, $|\mathbf{i} \times \mathbf{i}| = |\mathbf{0}| = 0$ (see Example 12.4.2) but $|\mathbf{i}|\,|\mathbf{i}| = 1 \cdot 1 = 1$. In fact, by Theorem 12.4.9, $|\mathbf{u} \times \mathbf{v}| = |\mathbf{u}|\,|\mathbf{v}| \sin\theta$.

5. True, by Theorem 12.3.2, property 2.

6. False. Property 1 of Theorem 12.4.11 says that $\mathbf{u} \times \mathbf{v} = -\mathbf{v} \times \mathbf{u}$.

7. True. If θ is the angle between $\mathbf{u}$ and $\mathbf{v}$, then by Theorem 12.4.9, $|\mathbf{u} \times \mathbf{v}| = |\mathbf{u}|\,|\mathbf{v}| \sin\theta = |\mathbf{v}|\,|\mathbf{u}| \sin\theta = |\mathbf{v} \times \mathbf{u}|$. (Or, by Theorem 12.4.11, $|\mathbf{u} \times \mathbf{v}| = |-\mathbf{v} \times \mathbf{u}| = |-1|\,|\mathbf{v} \times \mathbf{u}| = |\mathbf{v} \times \mathbf{u}|$.)

8. This is true by Theorem 12.3.2, property 4.

9. Theorem 12.4.11, property 2 tells us that this is true.

10. This is true by Theorem 12.4.11, property 4.

11. This is true by Theorem 12.4.11, property 5.

12. In general, this assertion is false; a counterexample is $\mathbf{i} \times (\mathbf{i} \times \mathbf{j}) \neq (\mathbf{i} \times \mathbf{i}) \times \mathbf{j}$. (See the paragraph preceding Theorem 12.4.11.)

13. This is true because $\mathbf{u} \times \mathbf{v}$ is orthogonal to $\mathbf{u}$ (see Theorem 12.4.8), and the dot product of two orthogonal vectors is 0.

14. $(\mathbf{u}+\mathbf{v})\times\mathbf{v} = \mathbf{u}\times\mathbf{v}+\mathbf{v}\times\mathbf{v}$ [by Theorem 12.4.11, property 4]

$= \mathbf{u}\times\mathbf{v}+\mathbf{0}$ [by Example 12.4.2]

$= \mathbf{u}\times\mathbf{v}$, so this is true.

15. This is false. A normal vector to the plane is $\mathbf{n} = \langle 6, -2, 4\rangle$. Because $\langle 3, -1, 2\rangle = \frac{1}{2}\mathbf{n}$, the vector is parallel to $\mathbf{n}$ and hence perpendicular to the plane.

16. This is false, because according to Equation 12.5.8, $ax + by + cz + d = 0$ is the general equation of a plane.

17. This is false. In $\mathbb{R}^2$, $x^2 + y^2 = 1$ represents a circle, but $\{(x, y, z) \mid x^2 + y^2 = 1\}$ represents a *three-dimensional surface*, namely, a circular cylinder with axis the z-axis.

18. This is false. In $\mathbb{R}^3$ the graph of $y = x^2$ is a parabolic cylinder (see Example 12.6.1). A paraboloid has an equation such as $z = x^2 + y^2$.

19. False. For example, $\mathbf{i}\cdot\mathbf{j} = \mathbf{0}$ but $\mathbf{i} \neq \mathbf{0}$ and $\mathbf{j} \neq \mathbf{0}$.

20. This is false. By Corollary 12.4.10, $\mathbf{u}\times\mathbf{v} = \mathbf{0}$ for any nonzero parallel vectors $\mathbf{u}$, $\mathbf{v}$. For instance, $\mathbf{i}\times\mathbf{i} = \mathbf{0}$.

21. This is true. If $\mathbf{u}$ and $\mathbf{v}$ are both nonzero, then by (7) in Section 12.3, $\mathbf{u}\cdot\mathbf{v} = 0$ implies that $\mathbf{u}$ and $\mathbf{v}$ are orthogonal. But $\mathbf{u}\times\mathbf{v} = \mathbf{0}$ implies that $\mathbf{u}$ and $\mathbf{v}$ are parallel (see Corollary 12.4.10). Two nonzero vectors can't be both parallel and orthogonal, so at least one of $\mathbf{u}$, $\mathbf{v}$ must be $\mathbf{0}$.

22. This is true. We know $\mathbf{u}\cdot\mathbf{v} = |\mathbf{u}|\ |\mathbf{v}|\ \cos\theta$ where $|\mathbf{u}| \geq 0$, $|\mathbf{v}| \geq 0$, and $|\cos\theta| \leq 1$, so $|\mathbf{u}\cdot\mathbf{v}| = |\mathbf{u}|\ |\mathbf{v}|\ |\cos\theta| \leq |\mathbf{u}|\ |\mathbf{v}|$.

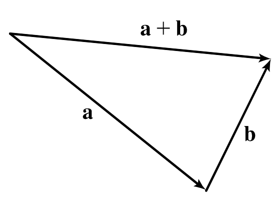
EXERCISES

1. (a) The radius of the sphere is the distance between the points $(-1, 2, 1)$ and $(6, -2, 3)$, namely, $\sqrt{[6-(-1)]^2 + (-2-2)^2 + (3-1)^2} = \sqrt{69}$. By the formula for an equation of a sphere (see page 835 [ET 795]), an equation of the sphere with center $(-1, 2, 1)$ and radius $\sqrt{69}$ is $(x+1)^2 + (y-2)^2 + (z-1)^2 = 69$.

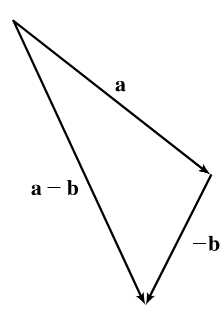
(b) The intersection of this sphere with the yz-plane is the set of points on the sphere whose x-coordinate is 0. Putting $x = 0$ into the equation, we have $(y-2)^2 + (z-1)^2 = 68, x = 0$ which represents a circle in the yz-plane with center $(0, 2, 1)$ and radius $\sqrt{68}$.

(c) Completing squares gives $(x-4)^2 + (y+1)^2 + (z+3)^2 = -1 + 16 + 1 + 9 = 25$. Thus the sphere is centered at $(4, -1, -3)$ and has radius 5.

2. (a)



(b)



(c) 
(d) 
3. $\mathbf{u}\cdot\mathbf{v} = |\mathbf{u}|\,|\mathbf{v}|\cos 45^\circ = (2)(3)\frac{\sqrt{2}}{2} = 3\sqrt{2}$. $|\mathbf{u}\times\mathbf{v}| = |\mathbf{u}|\,|\mathbf{v}|\sin 45^\circ = (2)(3)\frac{\sqrt{2}}{2} = 3\sqrt{2}$.
By the right-hand rule, $\mathbf{u}\times\mathbf{v}$ is directed out of the page.

4. (a) $2\,\mathbf{a} + 3\,\mathbf{b} = 2\,\mathbf{i} + 2\,\mathbf{j} - 4\,\mathbf{k} + 9\,\mathbf{i} - 6\,\mathbf{j} + 3\,\mathbf{k} = 11\,\mathbf{i} - 4\,\mathbf{j} - \mathbf{k}$

(b) $|\mathbf{b}| = \sqrt{9+4+1} = \sqrt{14}$

(c) $\mathbf{a}\cdot\mathbf{b} = (1)(3) + (1)(-2) + (-2)(1) = -1$

(d) $\mathbf{a}\times\mathbf{b} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 1 & -2 \\ 3 & -2 & 1 \end{vmatrix} = (1-4)\,\mathbf{i} - (1+6)\,\mathbf{j} + (-2-3)\,\mathbf{k} = -3\,\mathbf{i} - 7\,\mathbf{j} - 5\,\mathbf{k}$

(e) $\mathbf{b}\times\mathbf{c} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 3 & -2 & 1 \\ 0 & 1 & -5 \end{vmatrix} = 9\,\mathbf{i} + 15\,\mathbf{j} + 3\,\mathbf{k}$, $|\mathbf{b}\times\mathbf{c}| = 3\sqrt{9+25+1} = 3\sqrt{35}$

(f) $\mathbf{a}\cdot(\mathbf{b}\times\mathbf{c}) = \begin{vmatrix} 1 & 1 & -2 \\ 3 & -2 & 1 \\ 0 & 1 & -5 \end{vmatrix} = \begin{vmatrix} -2 & 1 \\ 1 & -5 \end{vmatrix} - \begin{vmatrix} 3 & 1 \\ 0 & -5 \end{vmatrix} - 2\begin{vmatrix} 3 & -2 \\ 0 & 1 \end{vmatrix} = 9 + 15 - 6 = 18$

(g) $\mathbf{c}\times\mathbf{c} = \mathbf{0}$ for any $\mathbf{c}$.

(h) From part (e),

$$\mathbf{a}\times(\mathbf{b}\times\mathbf{c}) = \mathbf{a}\times(9\,\mathbf{i} + 15\,\mathbf{j} + 3\,\mathbf{k}) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 1 & -2 \\ 9 & 15 & 3 \end{vmatrix}$$
$$= (3+30)\,\mathbf{i} - (3+18)\,\mathbf{j} + (15-9)\,\mathbf{k} = 33\,\mathbf{i} - 21\,\mathbf{j} + 6\,\mathbf{k}$$

(i) The scalar projection is $\operatorname{comp}_{\mathbf{a}}\mathbf{b} = |\mathbf{b}|\cos\theta = \mathbf{a}\cdot\mathbf{b}/\,|\mathbf{a}| = -\frac{1}{\sqrt{6}}$.

(j) The vector projection is $\operatorname{proj}_{\mathbf{a}}\mathbf{b} = -\dfrac{1}{\sqrt{6}}\left(\dfrac{\mathbf{a}}{|\mathbf{a}|}\right) = -\frac{1}{6}(\mathbf{i} + \mathbf{j} - 2\,\mathbf{k})$.

(k) $\cos\theta = \dfrac{\mathbf{a}\cdot\mathbf{b}}{|\mathbf{a}|\,|\mathbf{b}|} = \dfrac{-1}{\sqrt{6}\sqrt{14}} = \dfrac{-1}{2\sqrt{21}}$ and $\theta = \cos^{-1}\left(\dfrac{-1}{2\sqrt{21}}\right) \approx 96^\circ$.

5. For the two vectors to be orthogonal, we need $\langle 3, 2, x\rangle\cdot\langle 2x, 4, x\rangle = 0 \quad\Leftrightarrow\quad (3)(2x) + (2)(4) + (x)(x) = 0 \quad\Leftrightarrow$
$x^2 + 6x + 8 = 0 \quad\Leftrightarrow\quad (x+2)(x+4) = 0 \quad\Leftrightarrow\quad x = -2$ or $x = -4$.

6. We know that the cross product of two vectors is orthogonal to both given vectors. So we calculate

$(\mathbf{j}+2\,\mathbf{k})\times(\mathbf{i}-2\,\mathbf{j}+3\,\mathbf{k})=[3-(-4)]\,\mathbf{i}-(0-2)\,\mathbf{j}+(0-1)\,\mathbf{k}=7\,\mathbf{i}+2\,\mathbf{j}-\mathbf{k}$.

Then two unit vectors orthogonal to both given vectors are $\pm\dfrac{7\,\mathbf{i}+2\,\mathbf{j}-\mathbf{k}}{\sqrt{7^2+2^2+(-1)^2}}=\pm\dfrac{1}{3\sqrt{6}}\,(7\,\mathbf{i}+2\,\mathbf{j}-\mathbf{k})$,

that is, $\frac{7}{3\sqrt{6}}\,\mathbf{i}+\frac{2}{3\sqrt{6}}\,\mathbf{j}-\frac{1}{3\sqrt{6}}\,\mathbf{k}$ and $-\frac{7}{3\sqrt{6}}\,\mathbf{i}-\frac{2}{3\sqrt{6}}\,\mathbf{j}+\frac{1}{3\sqrt{6}}\,\mathbf{k}$.

7. (a) $(\mathbf{u}\times\mathbf{v})\cdot\mathbf{w}=\mathbf{u}\cdot(\mathbf{v}\times\mathbf{w})=2$

(b) $\mathbf{u}\cdot(\mathbf{w}\times\mathbf{v})=\mathbf{u}\cdot[-(\mathbf{v}\times\mathbf{w})]=-\mathbf{u}\cdot(\mathbf{v}\times\mathbf{w})=-2$

(c) $\mathbf{v}\cdot(\mathbf{u}\times\mathbf{w})=(\mathbf{v}\times\mathbf{u})\cdot\mathbf{w}=-(\mathbf{u}\times\mathbf{v})\cdot\mathbf{w}=-2$

(d) $(\mathbf{u}\times\mathbf{v})\cdot\mathbf{v}=\mathbf{u}\cdot(\mathbf{v}\times\mathbf{v})=\mathbf{u}\cdot\mathbf{0}=0$

8. $(\mathbf{a}\times\mathbf{b})\cdot[(\mathbf{b}\times\mathbf{c})\times(\mathbf{c}\times\mathbf{a})]=(\mathbf{a}\times\mathbf{b})\cdot([(\mathbf{b}\times\mathbf{c})\cdot\mathbf{a}]\,\mathbf{c}-[(\mathbf{b}\times\mathbf{c})\cdot\mathbf{c}]\,\mathbf{a})$

[by Property 6 of the cross product]

$$=(\mathbf{a}\times\mathbf{b})\cdot[(\mathbf{b}\times\mathbf{c})\cdot\mathbf{a}]\,\mathbf{c}=[\mathbf{a}\cdot(\mathbf{b}\times\mathbf{c})]\,(\mathbf{a}\times\mathbf{b})\cdot\mathbf{c}$$
$$=[\mathbf{a}\cdot(\mathbf{b}\times\mathbf{c})]\,[\mathbf{a}\cdot(\mathbf{b}\times\mathbf{c})]=[\mathbf{a}\cdot(\mathbf{b}\times\mathbf{c})]^2$$

9. For simplicity, consider a unit cube positioned with its back left corner at the origin. Vector representations of the diagonals joining the points $(0,0,0)$ to $(1,1,1)$ and $(1,0,0)$ to $(0,1,1)$ are $\langle 1,1,1\rangle$ and $\langle -1,1,1\rangle$. Let θ be the angle between these two vectors. $\langle 1,1,1\rangle\cdot\langle -1,1,1\rangle=-1+1+1=1=|\langle 1,1,1\rangle|\,|\langle -1,1,1\rangle|\cos\theta=3\cos\theta \;\Rightarrow\; \cos\theta=\frac{1}{3} \;\Rightarrow$ $\theta=\cos^{-1}\left(\frac{1}{3}\right)\approx 71^\circ$.

10. $\overrightarrow{AB}=\langle 1,3,-1\rangle$, $\overrightarrow{AC}=\langle -2,1,3\rangle$ and $\overrightarrow{AD}=\langle -1,3,1\rangle$. By Equation 12.4.13,

$$\overrightarrow{AB}\cdot\left(\overrightarrow{AC}\times\overrightarrow{AD}\right)=\begin{vmatrix}1&3&-1\\-2&1&3\\-1&3&1\end{vmatrix}=\begin{vmatrix}1&3\\3&1\end{vmatrix}-3\begin{vmatrix}-2&3\\-1&1\end{vmatrix}-\begin{vmatrix}-2&1\\-1&3\end{vmatrix}=-8-3+5=-6.$$

The volume is $\left|\overrightarrow{AB}\cdot\left(\overrightarrow{AC}\times\overrightarrow{AD}\right)\right|=6$ cubic units.

11. $\overrightarrow{AB}=\langle 1,0,-1\rangle$, $\overrightarrow{AC}=\langle 0,4,3\rangle$, so

(a) a vector perpendicular to the plane is $\overrightarrow{AB}\times\overrightarrow{AC}=\langle 0+4,-(3+0),4-0\rangle=\langle 4,-3,4\rangle$.

(b) $\frac{1}{2}\left|\overrightarrow{AB}\times\overrightarrow{AC}\right|=\frac{1}{2}\sqrt{16+9+16}=\frac{\sqrt{41}}{2}$.

12. $\mathbf{D}=4\,\mathbf{i}+3\,\mathbf{j}+6\,\mathbf{k}$, $\quad W=\mathbf{F}\cdot\mathbf{D}=12+15+60=87$ J

13. Let F_1 be the magnitude of the force directed 20° away from the direction of shore, and let F_2 be the magnitude of the other force. Separating these forces into components parallel to the direction of the resultant force and perpendicular to it gives $F_1\cos 20^\circ+F_2\cos 30^\circ=255$ **(1)**, and $F_1\sin 20^\circ-F_2\sin 30^\circ=0 \;\Rightarrow\; F_1=F_2\dfrac{\sin 30^\circ}{\sin 20^\circ}$ **(2)**. Substituting **(2)** into **(1)** gives $F_2(\sin 30^\circ\cot 20^\circ+\cos 30^\circ)=255 \;\Rightarrow\; F_2\approx 114$ N. Substituting this into **(2)** gives $F_1\approx 166$ N.

14. $|\boldsymbol{\tau}| = |\mathbf{r}|\,|\mathbf{F}|\sin\theta = (0.40)(50)\sin(90^\circ - 30^\circ) \approx 17.3$ N·m.

15. The line has direction $\mathbf{v} = \langle -3, 2, 3\rangle$. Letting $P_0 = (4, -1, 2)$, parametric equations are

$x = 4 - 3t,\ y = -1 + 2t,\ z = 2 + 3t.$

16. A direction vector for the line is $\mathbf{v} = \langle 3, 2, 1\rangle$, so parametric equations for the line are $x = 1 + 3t,\ y = 2t,\ z = -1 + t.$

17. A direction vector for the line is a normal vector for the plane, $\mathbf{n} = \langle 2, -1, 5\rangle$, and parametric equations for the line are

$x = -2 + 2t,\ y = 2 - t,\ z = 4 + 5t.$

18. Since the two planes are parallel, they will have the same normal vectors. Then we can take $\mathbf{n} = \langle 1, 4, -3\rangle$ and an equation of the plane is $1(x - 2) + 4(y - 1) - 3(z - 0) = 0$ or $x + 4y - 3z = 6$.

19. Here the vectors $\mathbf{a} = \langle 4 - 3, 0 - (-1), 2 - 1\rangle = \langle 1, 1, 1\rangle$ and $\mathbf{b} = \langle 6 - 3, 3 - (-1), 1 - 1\rangle = \langle 3, 4, 0\rangle$ lie in the plane, so $\mathbf{n} = \mathbf{a} \times \mathbf{b} = \langle -4, 3, 1\rangle$ is a normal vector to the plane and an equation of the plane is

$-4(x - 3) + 3(y - (-1)) + 1(z - 1) = 0$ or $-4x + 3y + z = -14$.

20. If we first find two nonparallel vectors in the plane, their cross product will be a normal vector to the plane. Since the given line lies in the plane, its direction vector $\mathbf{a} = \langle 2, -1, 3\rangle$ is one vector in the plane. We can verify that the given point $(1, 2, -2)$ does not lie on this line. The point $(0, 3, 1)$ is on the line (obtained by putting $t = 0$) and hence in the plane, so the vector $\mathbf{b} = \langle 0 - 1, 3 - 2, 1 - (-2)\rangle = \langle -1, 1, 3\rangle$ lies in the plane, and a normal vector is $\mathbf{n} = \mathbf{a} \times \mathbf{b} = \langle -6, -9, 1\rangle$. Thus an equation of the plane is $-6(x - 1) - 9(y - 2) + (z + 2) = 0$ or $6x + 9y - z = 26$.

21. Substitution of the parametric equations into the equation of the plane gives $2x - y + z = 2(2 - t) - (1 + 3t) + 4t = 2 \quad\Rightarrow$ $-t + 3 = 2 \quad\Rightarrow\quad t = 1$. When $t = 1$, the parametric equations give $x = 2 - 1 = 1$, $y = 1 + 3 = 4$ and $z = 4$. Therefore, the point of intersection is $(1, 4, 4)$.

22. Use the formula proven in Exercise 12.4.45(a). In the notation used in that exercise, $\mathbf{a}$ is just the direction of the line; that is, $\mathbf{a} = \langle 1, -1, 2\rangle$. A point on the line is $(1, 2, -1)$ (setting $t = 0$), and therefore $\mathbf{b} = \langle 1 - 0, 2 - 0, -1 - 0\rangle = \langle 1, 2, -1\rangle$.

Hence $d = \dfrac{|\mathbf{a} \times \mathbf{b}|}{|\mathbf{a}|} = \dfrac{|\langle 1, -1, 2\rangle \times \langle 1, 2, -1\rangle|}{\sqrt{1 + 1 + 4}} = \dfrac{|\langle -3, 3, 3\rangle|}{\sqrt{6}} = \sqrt{\dfrac{27}{6}} = \dfrac{3}{\sqrt{2}}$.

23. Since the direction vectors $\langle 2, 3, 4\rangle$ and $\langle 6, -1, 2\rangle$ aren't parallel, neither are the lines. For the lines to intersect, the three equations $1 + 2t = -1 + 6s$, $2 + 3t = 3 - s$, $3 + 4t = -5 + 2s$ must be satisfied simultaneously. Solving the first two equations gives $t = \frac{1}{5}$, $s = \frac{2}{5}$ and checking we see these values don't satisfy the third equation. Thus the lines aren't parallel and they don't intersect, so they must be skew.

24. (a) The normal vectors are $\langle 1, 1, -1\rangle$ and $\langle 2, -3, 4\rangle$. Since these vectors aren't parallel, neither are the planes parallel. Also $\langle 1, 1, -1\rangle \cdot \langle 2, -3, 4\rangle = 2 - 3 - 4 = -5 \neq 0$ so the normal vectors, and thus the planes, are not perpendicular.

(b) $\cos\theta = \dfrac{\langle 1, 1, -1\rangle \cdot \langle 2, -3, 4\rangle}{\sqrt{3}\,\sqrt{29}} = -\dfrac{5}{\sqrt{87}}$ and $\theta = \cos^{-1}\left(-\frac{5}{\sqrt{87}}\right) \approx 122^\circ$ [or we can say $\approx 58^\circ$].

25. $\mathbf{n}_1 = \langle 1, 0, -1 \rangle$ and $\mathbf{n}_2 = \langle 0, 1, 2 \rangle$. Setting $z = 0$, it is easy to see that $(1, 3, 0)$ is a point on the line of intersection of $x - z = 1$ and $y + 2z = 3$. The direction of this line is $\mathbf{v}_1 = \mathbf{n}_1 \times \mathbf{n}_2 = \langle 1, -2, 1 \rangle$. A second vector parallel to the desired plane is $\mathbf{v}_2 = \langle 1, 1, -2 \rangle$, since it is perpendicular to $x + y - 2z = 1$. Therefore, the normal of the plane in question is $\mathbf{n} = \mathbf{v}_1 \times \mathbf{v}_2 = \langle 4 - 1, 1 + 2, 1 + 2 \rangle = 3 \langle 1, 1, 1 \rangle$. Taking $(x_0, y_0, z_0) = (1, 3, 0)$, the equation we are looking for is $(x - 1) + (y - 3) + z = 0 \quad \Leftrightarrow \quad x + y + z = 4$.

26. (a) The vectors $\overrightarrow{AB} = \langle -1 - 2, -1 - 1, 10 - 1 \rangle = \langle -3, -2, 9 \rangle$ and $\overrightarrow{AC} = \langle 1 - 2, 3 - 1, -4 - 1 \rangle = \langle -1, 2, -5 \rangle$ lie in the plane, so $\mathbf{n} = \overrightarrow{AB} \times \overrightarrow{AC} = \langle -3, -2, 9 \rangle \times \langle -1, 2, -5 \rangle = \langle -8, -24, -8 \rangle$ or equivalently $\langle 1, 3, 1 \rangle$ is a normal vector to the plane. The point $A(2, 1, 1)$ lies on the plane so an equation of the plane is $1(x - 2) + 3(y - 1) + 1(z - 1) = 0$ or $x + 3y + z = 6$.

(b) The line is perpendicular to the plane so it is parallel to a normal vector for the plane, namely $\langle 1, 3, 1 \rangle$. If the line passes through $B(-1, -1, 10)$ then symmetric equations are $\dfrac{x - (-1)}{1} = \dfrac{y - (-1)}{3} = \dfrac{z - 10}{1}$ or $x + 1 = \dfrac{y + 1}{3} = z - 10$.

(c) Normal vectors for the two planes are $\mathbf{n}_1 = \langle 1, 3, 1 \rangle$ and $\mathbf{n}_2 = \langle 2, -4, -3 \rangle$. The angle θ between the planes is given by

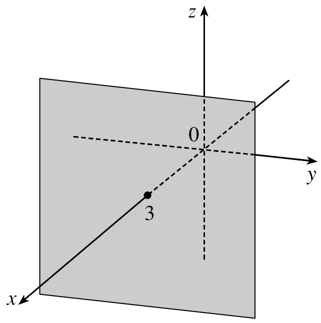
$$\cos\theta = \frac{\mathbf{n}_1 \cdot \mathbf{n}_2}{|\mathbf{n}_1|\ |\mathbf{n}_2|} = \frac{\langle 1, 3, 1 \rangle \cdot \langle 2, -4, -3 \rangle}{\sqrt{1^2 + 3^2 + 1^2}\,\sqrt{2^2 + (-4)^2 + (-3)^2}} = \frac{2 - 12 - 3}{\sqrt{11}\,\sqrt{29}} = -\frac{13}{\sqrt{319}}$$

Thus $\theta = \cos^{-1}\left(-\dfrac{13}{\sqrt{319}}\right) \approx 137^\circ$ or $180^\circ - 137^\circ = 43^\circ$.

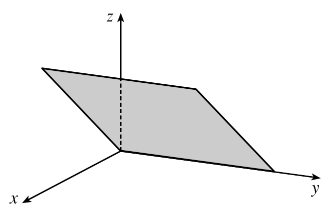
(d) From part (c), the point $(2, 0, 4)$ lies on the second plane, but notice that the point also satisfies the equation of the first plane, so the point lies on the line of intersection of the planes. A vector $\mathbf{v}$ in the direction of this intersecting line is perpendicular to the normal vectors of both planes, so take $\mathbf{v} = \mathbf{n}_1 \times \mathbf{n}_2 = \langle 1, 3, 1 \rangle \times \langle 2, -4, -3 \rangle = \langle -5, 5, -10 \rangle$ or equivalently we can take $\mathbf{v} = \langle 1, -1, 2 \rangle$. Parametric equations for the line are $x = 2 + t$, $y = -t$, $z = 4 + 2t$.

27. By Exercise 12.5.75, $D = \dfrac{|-2 - (-24)|}{\sqrt{3^2 + 1^2 + (-4)^2}} = \dfrac{22}{\sqrt{26}}$.

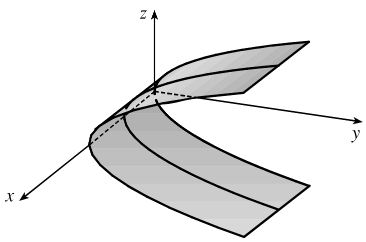
28. The equation $x = 3$ represents a plane parallel to the yz-plane and 3 units in front of it.



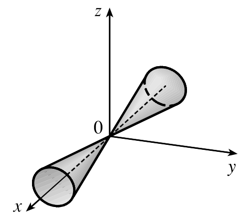
29. The equation $x = z$ represents a plane perpendicular to the xz-plane and intersecting the xz-plane in the line $x = z$, $y = 0$.



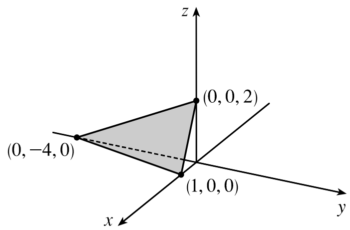
30. The equation $y = z^2$ represents a parabolic cylinder whose trace in the xz-plane is the x-axis and which opens to the right.



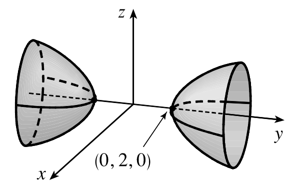
31. The equation $x^2 = y^2 + 4z^2$ represents a (right elliptical) cone with vertex at the origin and axis the x-axis.



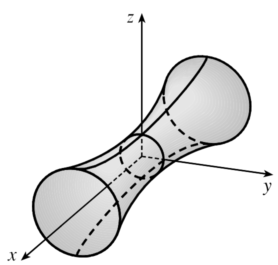
32. $4x - y + 2z = 4$ is a plane with intercepts $(1, 0, 0)$, $(0, -4, 0)$, and $(0, 0, 2)$.



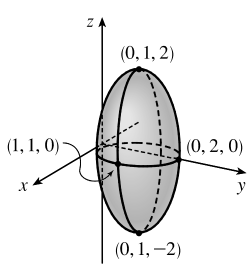
33. An equivalent equation is $-x^2 + \dfrac{y^2}{4} - z^2 = 1$, a hyperboloid of two sheets with axis the y-axis. For $|y| > 2$, traces parallel to the xz-plane are circles.



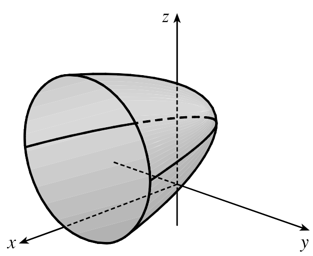
34. An equivalent equation is $-x^2 + y^2 + z^2 = 1$, a hyperboloid of one sheet with axis the x-axis.



35. Completing the square in y gives $4x^2 + 4(y-1)^2 + z^2 = 4$ or $x^2 + (y-1)^2 + \dfrac{z^2}{4} = 1$, an ellipsoid centered at $(0, 1, 0)$.



36. Completing the square in y and z gives $x = (y-1)^2 + (z-2)^2$, a circular paraboloid with vertex $(0, 1, 2)$ and axis the horizontal line $y = 1$, $z = 2$.



37. $4x^2 + y^2 = 16 \quad \Leftrightarrow \quad \dfrac{x^2}{4} + \dfrac{y^2}{16} = 1$. The equation of the ellipsoid is $\dfrac{x^2}{4} + \dfrac{y^2}{16} + \dfrac{z^2}{c^2} = 1$, since the horizontal trace in the plane $z = 0$ must be the original ellipse. The traces of the ellipsoid in the yz-plane must be circles since the surface is obtained by rotation about the x-axis. Therefore, $c^2 = 16$ and the equation of the ellipsoid is $\dfrac{x^2}{4} + \dfrac{y^2}{16} + \dfrac{z^2}{16} = 1 \quad \Leftrightarrow$

$4x^2 + y^2 + z^2 = 16$.

38. The distance from a point $P\,(x, y, z)$ to the plane $y = 1$ is $|y - 1|$, so the given condition becomes

$|y - 1| = 2\sqrt{(x-0)^2 + (y+1)^2 + (z-0)^2} \quad \Rightarrow \quad |y - 1| = 2\sqrt{x^2 + (y+1)^2 + z^2} \quad \Rightarrow$

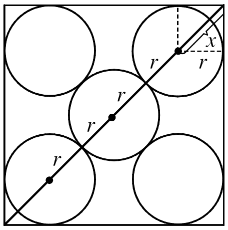
$(y-1)^2 = 4x^2 + 4(y+1)^2 + 4z^2 \quad \Leftrightarrow \quad -3 = 4x^2 + (3y^2 + 10y) + 4z^2 \quad \Leftrightarrow$

$\frac{16}{3} = 4x^2 + 3\left(y + \frac{5}{3}\right)^2 + 4z^2 \quad \Rightarrow \quad \frac{3}{4}x^2 + \frac{9}{16}\left(y + \frac{5}{3}\right)^2 + \frac{3}{4}z^2 = 1.$

This is the equation of an ellipsoid whose center is $\left(0, -\frac{5}{3}, 0\right)$.

PROBLEMS PLUS

1. Since three-dimensional situations are often difficult to visualize and work with, let us first try to find an analogous problem in two dimensions. The analogue of a cube is a square and the analogue of a sphere is a circle. Thus a similar problem in two dimensions is the following: if five circles with the same radius r are contained in a square of side 1 m so that the circles touch each other and four of the circles touch two sides of the square, find r.



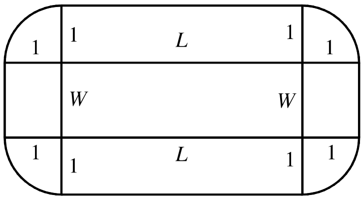
The diagonal of the square is $\sqrt{2}$. The diagonal is also $4r + 2x$. But x is the diagonal of a smaller square of side r. Therefore $x = \sqrt{2}\,r \quad \Rightarrow \quad \sqrt{2} = 4r + 2x = 4r + 2\sqrt{2}\,r = \left(4 + 2\sqrt{2}\right)r \quad \Rightarrow \quad r = \frac{\sqrt{2}}{4 + 2\sqrt{2}}$.

Let's use these ideas to solve the original three-dimensional problem. The diagonal of the cube is $\sqrt{1^2 + 1^2 + 1^2} = \sqrt{3}$. The diagonal of the cube is also $4r + 2x$ where x is the diagonal of a smaller cube with edge r. Therefore

$x = \sqrt{r^2 + r^2 + r^2} = \sqrt{3}\,r \quad \Rightarrow \quad \sqrt{3} = 4r + 2x = 4r + 2\sqrt{3}\,r = \left(4 + 2\sqrt{3}\right)r$. Thus $r = \dfrac{\sqrt{3}}{4 + 2\sqrt{3}} = \dfrac{2\sqrt{3} - 3}{2}$.

The radius of each ball is $\left(\sqrt{3} - \frac{3}{2}\right)$ m.

2. Try an analogous problem in two dimensions. Consider a rectangle with length L and width W and find the area of S in terms of L and W. Since S contains B, it has area



$$A(S) = LW + \text{ the area of two } L \times 1 \text{ rectangles}$$
$$+ \text{ the area of two } 1 \times W \text{ rectangles}$$
$$+ \text{ the area of four quarter-circles of radius 1}$$

as seen in the diagram. So $A(S) = LW + 2L + 2W + \pi \cdot 1^2$.

Now in three dimensions, the volume of S is

$$LWH + 2(L \times W \times 1) + 2(1 \times W \times H) + 2(L \times 1 \times H)$$
$$+ \text{ the volume of 4 quarter-cylinders with radius 1 and height } W$$
$$+ \text{ the volume of 4 quarter-cylinders with radius 1 and height } L$$
$$+ \text{ the volume of 4 quarter-cylinders with radius 1 and height } H$$
$$+ \text{ the volume of 8 eighths of a sphere of radius 1}$$

So

$$V(S) = LWH + 2LW + 2WH + 2LH + \pi \cdot 1^2 \cdot W + \pi \cdot 1^2 \cdot L + \pi \cdot 1^2 \cdot H + \tfrac{4}{3}\pi \cdot 1^3$$
$$= LWH + 2(LW + WH + LH) + \pi(L + W + H) + \tfrac{4}{3}\pi.$$

3. (a) We find the line of intersection L as in Example 12.5.7(b). Observe that the point $(-1, c, c)$ lies on both planes. Now since L lies in both planes, it is perpendicular to both of the normal vectors $\mathbf{n}_1$ and $\mathbf{n}_2$, and thus parallel to their cross product

$$\mathbf{n}_1 \times \mathbf{n}_2 = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ c & 1 & 1 \\ 1 & -c & c \end{vmatrix} = \langle 2c, -c^2+1, -c^2-1 \rangle$$

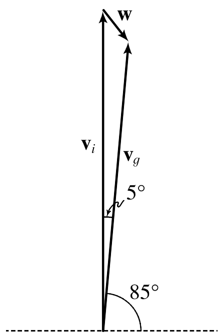
So symmetric equations of L can be written as $\dfrac{x+1}{-2c} = \dfrac{y-c}{c^2-1} = \dfrac{z-c}{c^2+1}$, provided that $c \neq 0, \pm 1$.

If $c = 0$, then the two planes are given by $y + z = 0$ and $x = -1$, so symmetric equations of L are $x = -1$, $y = -z$. If $c = -1$, then the two planes are given by $-x + y + z = -1$ and $x + y + z = -1$, and they intersect in the line $x = 0$, $y = -z - 1$. If $c = 1$, then the two planes are given by $x + y + z = 1$ and $x - y + z = 1$, and they intersect in the line $y = 0$, $x = 1 - z$.

(b) If we set $z = t$ in the symmetric equations and solve for x and y separately, we get $x + 1 = \dfrac{(t-c)(-2c)}{c^2+1}$, $y - c = \dfrac{(t-c)(c^2-1)}{c^2+1} \quad \Rightarrow \quad x = \dfrac{-2ct + (c^2-1)}{c^2+1}$, $y = \dfrac{(c^2-1)t + 2c}{c^2+1}$. Eliminating c from these equations, we have $x^2 + y^2 = t^2 + 1$. So the curve traced out by L in the plane $z = t$ is a circle with center at $(0, 0, t)$ and radius $\sqrt{t^2+1}$.

(c) The area of a horizontal cross-section of the solid is $A(z) = \pi(z^2+1)$, so $V = \int_0^1 A(z)dz = \pi\left[\frac{1}{3}z^3 + z\right]_0^1 = \frac{4\pi}{3}$.

4. (a) We consider velocity vectors for the plane and the wind. Let $\mathbf{v}_i$ be the initial, intended velocity for the plane and $\mathbf{v}_g$ the actual velocity relative to the ground. If $\mathbf{w}$ is the velocity of the wind, $\mathbf{v}_g$ is the resultant, that is, the vector sum $\mathbf{v}_i + \mathbf{w}$ as shown in the figure. We know $\mathbf{v}_i = 180\,\mathbf{j}$, and since the plane actually flew 80 km in $\frac{1}{2}$ hour, $|\mathbf{v}_g| = 160$. Thus $\mathbf{v}_g = (160\cos 85^\circ)\,\mathbf{i} + (160\sin 85^\circ)\,\mathbf{j} \approx 13.9\,\mathbf{i} + 159.4\,\mathbf{j}$. Finally, $\mathbf{v}_i + \mathbf{w} = \mathbf{v}_g$, so $\mathbf{w} = \mathbf{v}_g - \mathbf{v}_i \approx 13.9\,\mathbf{i} - 20.6\,\mathbf{j}$. Thus, the wind velocity is about $13.9\,\mathbf{i} - 20.6\,\mathbf{j}$, and the wind speed is $|\mathbf{w}| \approx \sqrt{(13.9)^2 + (-20.6)^2} \approx 24.9$ km/h.



(b) Let $\mathbf{v}$ be the velocity the pilot should have taken. The pilot would need to head a little west of north to compensate for the wind, so let θ be the angle $\mathbf{v}$ makes with the north direction. Then we can write $\mathbf{v} = \langle 180\cos(\theta + 90^\circ), 180\sin(\theta + 90^\circ)\rangle$. With the effect of the wind, the actual velocity (with respect to the ground) will be $\mathbf{v} + \mathbf{w}$, which we want to be due north. Equating horizontal components of the vectors, we must have $180\cos(\theta + 90^\circ) + 160\cos 85^\circ = 0 \quad \Rightarrow \quad \cos(\theta + 90^\circ) = -\frac{160}{180}\cos 85^\circ \approx -0.0775$, so $\theta \approx \cos^{-1}(-0.0775) - 90^\circ \approx 4.4^\circ$. Thus the pilot should have headed about 4.4° west of north.

5. $\mathbf{v}_3 = \text{proj}_{\mathbf{v}_1}\mathbf{v}_2 = \dfrac{\mathbf{v}_1 \cdot \mathbf{v}_2}{|\mathbf{v}_1|^2}\,\mathbf{v}_1 = \dfrac{5}{2^2}\,\mathbf{v}_1$ so $|\mathbf{v}_3| = \dfrac{5}{2^2}\,|\mathbf{v}_1| = \dfrac{5}{2}$,

$\mathbf{v}_4 = \text{proj}_{\mathbf{v}_2}\mathbf{v}_3 = \dfrac{\mathbf{v}_2 \cdot \mathbf{v}_3}{|\mathbf{v}_2|^2}\,\mathbf{v}_2 = \dfrac{\mathbf{v}_2 \cdot \frac{5}{2^2}\,\mathbf{v}_1}{|\mathbf{v}_2|^2}\,\mathbf{v}_2 = \dfrac{5}{2^2 \cdot 3^2}\,(\mathbf{v}_1 \cdot \mathbf{v}_2)\,\mathbf{v}_2 = \dfrac{5^2}{2^2 \cdot 3^2}\,\mathbf{v}_2 \quad\Rightarrow\quad |\mathbf{v}_4| = \dfrac{5^2}{2^2 \cdot 3^2}\,|\mathbf{v}_2| = \dfrac{5^2}{2^2 \cdot 3}$,

$\mathbf{v}_5 = \text{proj}_{\mathbf{v}_3}\mathbf{v}_4 = \dfrac{\mathbf{v}_3 \cdot \mathbf{v}_4}{|\mathbf{v}_3|^2}\,\mathbf{v}_3 = \dfrac{\frac{5}{2^2}\,\mathbf{v}_1 \cdot \frac{5^2}{2^2\,3^2}\,\mathbf{v}_2}{\left(\frac{5}{2}\right)^2}\left(\dfrac{5}{2^2}\,\mathbf{v}_1\right) = \dfrac{5^2}{2^4 \cdot 3^2}\,(\mathbf{v}_1 \cdot \mathbf{v}_2)\,\mathbf{v}_1 = \dfrac{5^3}{2^4 \cdot 3^2}\,\mathbf{v}_1 \quad\Rightarrow$

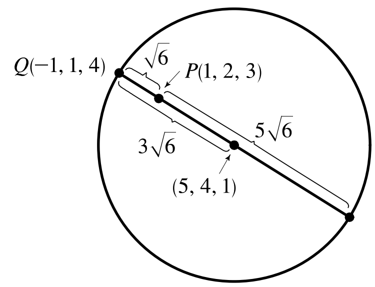
$|\mathbf{v}_5| = \dfrac{5^3}{2^4 \cdot 3^2}\,|\mathbf{v}_1| = \dfrac{5^3}{2^3 \cdot 3^2}$. Similarly, $|\mathbf{v}_6| = \dfrac{5^4}{2^4 \cdot 3^3}$, $|\mathbf{v}_7| = \dfrac{5^5}{2^5 \cdot 3^4}$, and in general, $|\mathbf{v}_n| = \dfrac{5^{n-2}}{2^{n-2} \cdot 3^{n-3}} = 3\left(\frac{5}{6}\right)^{n-2}$.

Thus

$$\sum_{n=1}^{\infty} |\mathbf{v}_n| = |\mathbf{v}_1| + |\mathbf{v}_2| + \sum_{n=3}^{\infty} 3\left(\tfrac{5}{6}\right)^{n-2} = 2 + 3 + \sum_{n=1}^{\infty} 3\left(\tfrac{5}{6}\right)^{n}$$

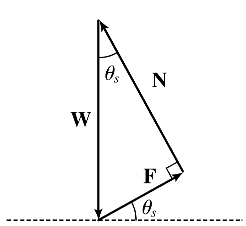
$$= 5 + \sum_{n=1}^{\infty} \tfrac{5}{2}\left(\tfrac{5}{6}\right)^{n-1} = 5 + \frac{\frac{5}{2}}{1 - \frac{5}{6}} \quad \text{[sum of a geometric series]} \quad = 5 + 15 = 20$$

6. Completing squares in the inequality $x^2 + y^2 + z^2 < 136 + 2(x + 2y + 3z)$ gives $(x-1)^2 + (y-2)^2 + (z-3)^2 < 150$ which describes the set of all points (x, y, z) whose distance from the point $P\,(1, 2, 3)$ is less than $\sqrt{150} = 5\sqrt{6}$. The distance from P to $Q\,(-1, 1, 4)$ is $\sqrt{4 + 1 + 1} = \sqrt{6}$, so the largest possible sphere that passes through Q and satisfies the stated conditions extends $5\sqrt{6}$ units in the opposite direction, giving a diameter of $6\sqrt{6}$. (See the figure.)

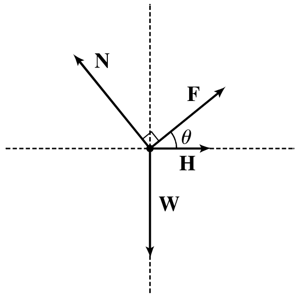


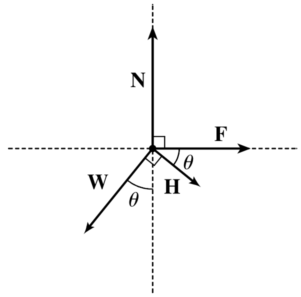
Thus the radius of the desired sphere is $3\sqrt{6}$, and its center is $3\sqrt{6}$ units from Q in the direction of P. A unit vector in this direction is $\mathbf{u} = \frac{1}{\sqrt{6}}\,\langle 2, 1, -1 \rangle$, so starting at $Q(-1, 1, 4)$ and following the vector $3\sqrt{6}\,\mathbf{u} = \langle 6, 3, -3 \rangle$ we arrive at the center of the sphere, $(5, 4, 1)$. An equation of the sphere then is $(x-5)^2 + (y-4)^2 + (z-1)^2 = \left(3\sqrt{6}\right)^2$ or $(x-5)^2 + (y-4)^2 + (z-1)^2 = 54$.

7. (a) When $\theta = \theta_s$, the block is not moving, so the sum of the forces on the block must be $\mathbf{0}$, thus $\mathbf{N} + \mathbf{F} + \mathbf{W} = \mathbf{0}$. This relationship is illustrated geometrically in the figure. Since the vectors form a right triangle, we have $\tan(\theta_s) = \dfrac{|\mathbf{F}|}{|\mathbf{N}|} = \dfrac{\mu_s n}{n} = \mu_s$.



(b) We place the block at the origin and sketch the force vectors acting on the block, including the additional horizontal force $\mathbf{H}$, with initial points at the origin. We then rotate this system so that $\mathbf{F}$ lies along the positive x-axis and the inclined plane is parallel to the x-axis. (See the following figure.)





$|\mathbf{F}|$ is maximal, so $|\mathbf{F}| = \mu_s n$ for $\theta > \theta_s$. Then the vectors, in terms of components parallel and perpendicular to the inclined plane, are

$$\mathbf{N} = n\,\mathbf{j} \qquad \mathbf{F} = (\mu_s n)\,\mathbf{i}$$

$$\mathbf{W} = (-mg\sin\theta)\,\mathbf{i} + (-mg\cos\theta)\,\mathbf{j} \qquad \mathbf{H} = (h_{\min}\cos\theta)\,\mathbf{i} + (-h_{\min}\sin\theta)\,\mathbf{j}$$

Equating components, we have

$$\mu_s n - mg\sin\theta + h_{\min}\cos\theta = 0 \quad\Rightarrow\quad h_{\min}\cos\theta + \mu_s n = mg\sin\theta \qquad \textbf{(1)}$$

$$n - mg\cos\theta - h_{\min}\sin\theta = 0 \quad\Rightarrow\quad h_{\min}\sin\theta + mg\cos\theta = n \qquad \textbf{(2)}$$

(c) Since **(2)** is solved for n, we substitute into **(1)**:

$$h_{\min}\cos\theta + \mu_s(h_{\min}\sin\theta + mg\cos\theta) = mg\sin\theta \quad\Rightarrow$$

$$h_{\min}\cos\theta + h_{\min}\mu_s\sin\theta = mg\sin\theta - mg\mu_s\cos\theta \quad\Rightarrow$$

$$h_{\min} = mg\left(\frac{\sin\theta - \mu_s\cos\theta}{\cos\theta + \mu_s\sin\theta}\right) = mg\left(\frac{\tan\theta - \mu_s}{1 + \mu_s\tan\theta}\right)$$

From part (a) we know $\mu_s = \tan\theta_s$, so this becomes $h_{\min} = mg\left(\dfrac{\tan\theta - \tan\theta_s}{1 + \tan\theta_s\tan\theta}\right)$ and using a trigonometric identity, this is $mg\tan(\theta - \theta_s)$ as desired.

Note for $\theta = \theta_s$, $h_{\min} = mg\tan 0 = 0$, which makes sense since the block is at rest for θ_s, thus no additional force $\mathbf{H}$ is necessary to prevent it from moving. As θ increases, the factor $\tan(\theta - \theta_s)$, and hence the value of $h_{\min}$, increases slowly for small values of $\theta - \theta_s$ but much more rapidly as $\theta - \theta_s$ becomes significant. This seems reasonable, as the steeper the inclined plane, the less the horizontal components of the various forces affect the movement of the block, so we would need a much larger magnitude of horizontal force to keep the block motionless. If we allow $\theta \to 90^\circ$, corresponding to the inclined plane being placed vertically, the value of $h_{\min}$ is quite large; this is to be expected, as it takes a great amount of horizontal force to keep an object from moving vertically. In fact, without friction (so $\theta_s = 0$), we would have $\theta \to 90^\circ \quad\Rightarrow\quad h_{\min} \to \infty$, and it would be impossible to keep the block from slipping.

(d) Since $h_{\max}$ is the largest value of h that keeps the block from slipping, the force of friction is keeping the block from moving *up* the inclined plane; thus, $\mathbf{F}$ is directed *down* the plane. Our system of forces is similar to that in part (b), then, except that we have $\mathbf{F} = -(\mu_s n)\,\mathbf{i}$. (Note that $|\mathbf{F}|$ is again maximal.) Following our procedure in parts (b) and (c), we equate components:

$$-\mu_s n - mg\sin\theta + h_{\max}\cos\theta = 0 \quad\Rightarrow\quad h_{\max}\cos\theta - \mu_s n = mg\sin\theta$$

$$n - mg\cos\theta - h_{\max}\sin\theta = 0 \quad\Rightarrow\quad h_{\max}\sin\theta + mg\cos\theta = n$$

Then substituting,

$$h_{\max}\cos\theta - \mu_s(h_{\max}\sin\theta + mg\cos\theta) = mg\sin\theta \quad\Rightarrow$$

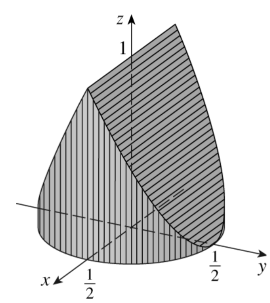
$$h_{\max}\cos\theta - h_{\max}\mu_s\sin\theta = mg\sin\theta + mg\mu_s\cos\theta \quad\Rightarrow$$

$$h_{\max} = mg\left(\frac{\sin\theta + \mu_s\cos\theta}{\cos\theta - \mu_s\sin\theta}\right) = mg\left(\frac{\tan\theta + \mu_s}{1 - \mu_s\tan\theta}\right)$$

$$= mg\left(\frac{\tan\theta + \tan\theta_s}{1 - \tan\theta_s\tan\theta}\right) = mg\tan(\theta + \theta_s)$$

We would expect $h_{\max}$ to increase as θ increases, with similar behavior as we established for $h_{\min}$, but with $h_{\max}$ values always larger than $h_{\min}$. We can see that this is the case if we graph $h_{\max}$ as a function of θ, as the curve is the graph of $h_{\min}$ translated $2\theta_s$ to the left, so the equation does seem reasonable. Notice that the equation predicts $h_{\max} \to \infty$ as $\theta \to (90^\circ - \theta_s)$. In fact, as $h_{\max}$ increases, the normal force increases as well. When $(90^\circ - \theta_s) \le \theta \le 90^\circ$, the horizontal force is completely counteracted by the sum of the normal and frictional forces, so no part of the horizontal force contributes to moving the block up the plane no matter how large its magnitude.

8. (a) The largest possible solid is achieved by starting with a circular cylinder of diameter 1 with axis the z-axis and with a height of 1. This is the largest solid that creates a square shadow with side length 1 in the y-direction and a circular disk shadow in the z-direction. For convenience, we place the base of the cylinder on the xy-plane so that it intersects the x- and y-axes at $\pm\frac{1}{2}$. We then remove as little as possible from the solid that leaves an isosceles triangle shadow in the x-direction. This is achieved by cutting the solid with planes parallel to the x-axis that intersect the z-axis at 1 and the y-axis at $\pm\frac{1}{2}$ (see the figure).



To compute the volume of this solid, we take vertical slices parallel to the xz-plane. The equation of the base of the solid is $x^2 + y^2 = \frac{1}{4}$, so a cross-section y units to the right of the origin is a rectangle with base $2\sqrt{\frac{1}{4} - y^2}$. For $0 \le y \le \frac{1}{2}$, the solid is cut off on top by the plane $z = 1 - 2y$, so the height of the rectangular cross-section is $1 - 2y$ and the cross-sectional area is $A(y) = 2\sqrt{\frac{1}{4} - y^2}\,(1 - 2y)$. The volume of the right half of the solid is

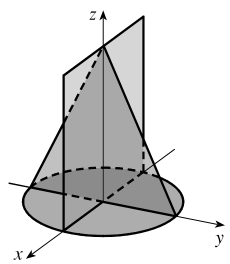
$$\int_0^{1/2} 2\sqrt{\tfrac{1}{4} - y^2}\,(1 - 2y)\,dy = 2\int_0^{1/2}\sqrt{\tfrac{1}{4} - y^2}\,dy - 4\int_0^{1/2} y\sqrt{\tfrac{1}{4} - y^2}\,dy$$

$$= 2\left[\tfrac{1}{4}\text{ area of a circle of radius }\tfrac{1}{2}\right] - 4\left[-\tfrac{1}{3}\left(\tfrac{1}{4} - y^2\right)^{3/2}\right]_0^{1/2}$$

$$= 2\left[\tfrac{1}{4}\cdot\pi\left(\tfrac{1}{2}\right)^2\right] + \tfrac{4}{3}\left[0 - \left(\tfrac{1}{4}\right)^{3/2}\right] = \tfrac{\pi}{8} - \tfrac{1}{6}$$

Thus the volume of the solid is $2\left(\frac{\pi}{8} - \frac{1}{6}\right) = \frac{\pi}{4} - \frac{1}{3} \approx 0.45$.

(b) There is not a smallest volume. We can remove portions of the solid from part (a) to create smaller and smaller volumes as long as we leave the "skeleton" shown in the figure intact (which has no volume at all and is not a solid). Thus we can create solids with arbitrarily small volume.



13 □ VECTOR FUNCTIONS

13.1 Vector Functions and Space Curves

1. The component functions $\ln(t+1)$, $\dfrac{t}{\sqrt{9-t^2}}$, and 2^t are all defined when $t+1>0 \;\Rightarrow\; t>-1$ and $9-t^2>0 \;\Rightarrow$ $-3<t<3$, so the domain of $\mathbf{r}$ is $(-1,3)$.

2. The component functions $\cos t$, $\ln t$, and $\dfrac{1}{t-2}$ are all defined when $t>0$ and $t\neq 2$, so the domain of $\mathbf{r}$ is $(0,2)\cup(2,\infty)$.

3. $\lim\limits_{t\to 0} e^{-3t} = e^0 = 1$, $\lim\limits_{t\to 0}\dfrac{t^2}{\sin^2 t} = \lim\limits_{t\to 0}\dfrac{1}{\dfrac{\sin^2 t}{t^2}} = \dfrac{1}{\lim\limits_{t\to 0}\dfrac{\sin^2 t}{t^2}} = \dfrac{1}{\left(\lim\limits_{t\to 0}\dfrac{\sin t}{t}\right)^2} = \dfrac{1}{1^2} = 1$,

and $\lim\limits_{t\to 0}\cos 2t = \cos 0 = 1$. Thus

$$\lim_{t\to 0}\left(e^{-3t}\,\mathbf{i} + \frac{t^2}{\sin^2 t}\,\mathbf{j} + \cos 2t\,\mathbf{k}\right) = \left[\lim_{t\to 0} e^{-3t}\right]\mathbf{i} + \left[\lim_{t\to 0}\frac{t^2}{\sin^2 t}\right]\mathbf{j} + \left[\lim_{t\to 0}\cos 2t\right]\mathbf{k} = \mathbf{i}+\mathbf{j}+\mathbf{k}.$$

4. $\lim\limits_{t\to 1}\dfrac{t^2-t}{t-1} = \lim\limits_{t\to 1}\dfrac{t\,(t-1)}{t-1} = \lim\limits_{t\to 1} t = 1$, $\lim\limits_{t\to 1}\sqrt{t+8} = 3$, $\lim\limits_{t\to 1}\dfrac{\sin \pi t}{\ln t} = \lim\limits_{t\to 1}\dfrac{\pi\cos\pi t}{1/t} = -\pi$ [by l'Hospital's Rule].
Thus the given limit equals $\mathbf{i}+3\,\mathbf{j}-\pi\,\mathbf{k}$.

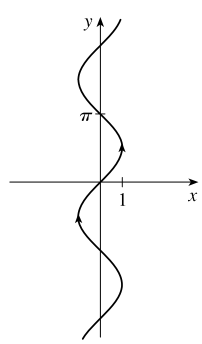
5. $\lim\limits_{t\to\infty}\dfrac{1+t^2}{1-t^2} = \lim\limits_{t\to\infty}\dfrac{(1/t^2)+1}{(1/t^2)-1} = \dfrac{0+1}{0-1} = -1$, $\lim\limits_{t\to\infty}\tan^{-1} t = \frac{\pi}{2}$, $\lim\limits_{t\to\infty}\dfrac{1-e^{-2t}}{t} = \lim\limits_{t\to\infty}\dfrac{1}{t} - \dfrac{1}{te^{2t}} = 0-0 = 0$. Thus
$\lim\limits_{t\to\infty}\left\langle \dfrac{1+t^2}{1-t^2}, \tan^{-1} t, \dfrac{1-e^{-2t}}{t}\right\rangle = \left\langle -1, \frac{\pi}{2}, 0\right\rangle$.

6. $\lim\limits_{t\to\infty} te^{-t} = \lim\limits_{t\to\infty}\dfrac{t}{e^t} = \lim\limits_{t\to\infty}\dfrac{1}{e^t} = 0$ [by l'Hospital's Rule], $\lim\limits_{t\to\infty}\dfrac{t^3+t}{2t^3-1} = \lim\limits_{t\to\infty}\dfrac{1+(1/t^2)}{2-(1/t^3)} = \dfrac{1+0}{2-0} = \dfrac{1}{2}$,

and $\lim\limits_{t\to\infty} t\sin\dfrac{1}{t} = \lim\limits_{t\to\infty}\dfrac{\sin(1/t)}{1/t} = \lim\limits_{t\to\infty}\dfrac{\cos(1/t)(-1/t^2)}{-1/t^2} = \lim\limits_{t\to\infty}\cos\dfrac{1}{t} = \cos 0 = 1$ [again by l'Hospital's Rule].

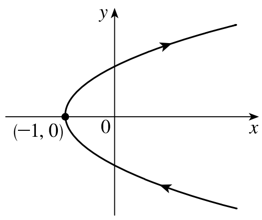
Thus $\lim\limits_{t\to\infty}\left\langle te^{-t}, \dfrac{t^3+t}{2t^3-1}, t\sin\dfrac{1}{t}\right\rangle = \left\langle 0, \frac{1}{2}, 1\right\rangle$.

7. The corresponding parametric equations for this curve are $x=\sin t$, $y=t$.
We can make a table of values, or we can eliminate the parameter: $t=y \;\Rightarrow$ $x=\sin y$, with $y\in\mathbb{R}$. By comparing different values of t, we find the direction in which t increases as indicated in the graph.

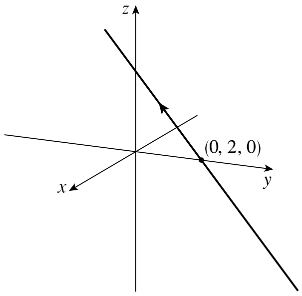


8. The corresponding parametric equations for this curve are $x = t^2 - 1,\ y = t$. We can make a table of values, or we can eliminate the parameter:

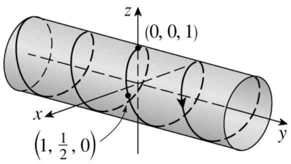
$t = y \quad \Rightarrow \quad x = y^2 - 1$, with $y \in \mathbb{R}$. Thus the curve is a parabola with vertex $(-1, 0)$ that opens to the right. By comparing different values of t, we find the direction in which t increases as indicated in the graph.



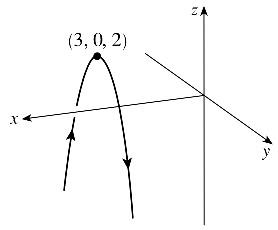
9. The corresponding parametric equations are $x = t,\ y = 2 - t,\ z = 2t$, which are parametric equations of a line through the point $(0, 2, 0)$ and with direction vector $\langle 1, -1, 2 \rangle$.



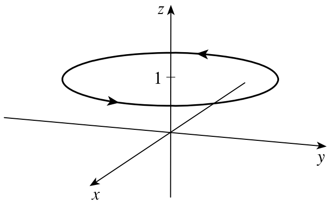
10. The corresponding parametric equations are $x = \sin \pi t,\ y = t,\ z = \cos \pi t$. Note that $x^2 + z^2 = \sin^2 \pi t + \cos^2 \pi t = 1$, so the curve lies on the circular cylinder $x^2 + z^2 = 1$. A point (x, y, z) on the curve lies directly to the left or right of the point $(x, 0, z)$ which moves clockwise (when viewed from the left) along the circle $x^2 + z^2 = 1$ in the xz-plane as t increases. Since $y = t$, the curve is a helix that spirals toward the right around the cylinder.



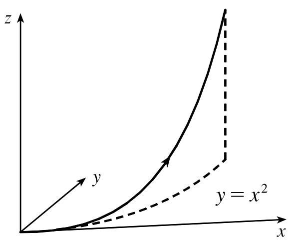
11. The corresponding parametric equations are $x = 3,\ y = t,\ z = 2 - t^2$. Eliminating the parameter in y and z gives $z = 2 - y^2$. Because $x = 3$, the curve is a parabola in the vertical plane $x = 3$ with vertex $(3, 0, 2)$.



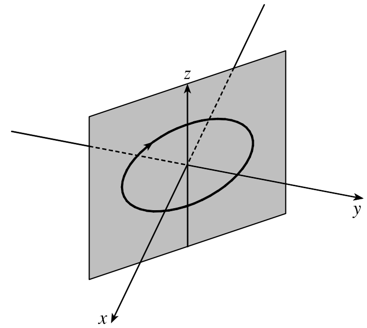
12. The corresponding parametric equations are $x = 2\cos t,\ y = 2\sin t$, $z = 1$. Eliminating the parameter in x and y gives $x^2 + y^2 = 4\cos^2 t + 4\sin^2 t = 4(\cos^2 t + \sin^2 t) = 4$. Since $z = 1$, the curve is a circle of radius 2 centered at $(0, 0, 1)$ in the horizontal plane $z = 1$.



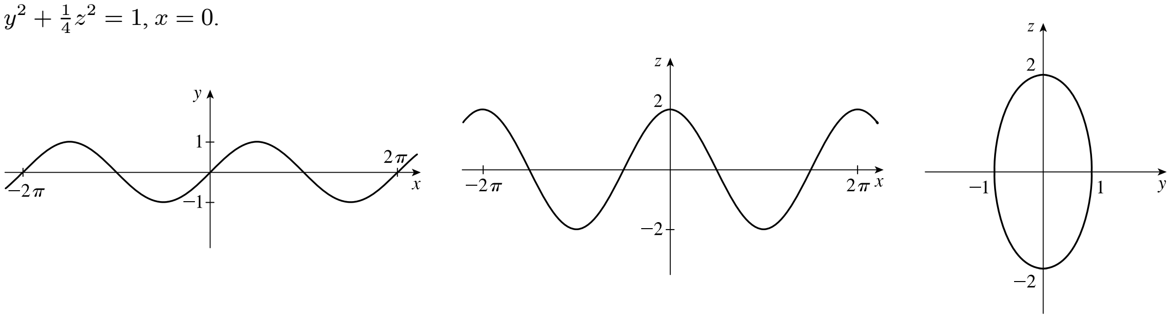
13. The parametric equations are $x = t^2$, $y = t^4$, $z = t^6$. These are positive for $t \neq 0$ and 0 when $t = 0$. So the curve lies entirely in the first octant. The projection of the graph onto the xy-plane is $y = x^2$, $y > 0$, a half parabola. The projection onto the xz-plane is $z = x^3$, $z > 0$, a half cubic, and the projection onto the yz-plane is $y^3 = z^2$.



14. If $x = \cos t,\ y = -\cos t,\ z = \sin t$, then $x^2 + z^2 = 1$ and $y^2 + z^2 = 1$, so the curve is contained in the intersection of circular cylinders along the x- and y-axes. Furthermore, $y = -x$, so the curve is an ellipse in the plane $y = -x$, centered at the origin.

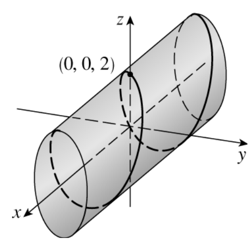


15. The projection of the curve onto the xy-plane is given by $\mathbf{r}(t) = \langle t, \sin t, 0 \rangle$ [we use 0 for the z-component] whose graph is the curve $y = \sin x$, $z = 0$. Similarly, the projection onto the xz-plane is $\mathbf{r}(t) = \langle t, 0, 2\cos t \rangle$, whose graph is the cosine wave $z = 2\cos x$, $y = 0$, and the projection onto the yz-plane is $\mathbf{r}(t) = \langle 0, \sin t, 2\cos t \rangle$ whose graph is the ellipse $y^2 + \frac{1}{4}z^2 = 1$, $x = 0$.

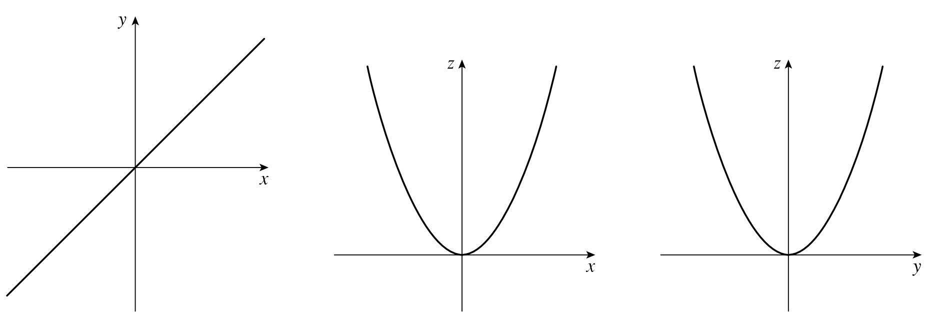


xy-plane xz-plane yz-plane

From the projection onto the yz-plane we see that the curve lies on an elliptical cylinder with axis the x-axis. The other two projections show that the curve oscillates both vertically and horizontally as we move in the x-direction, suggesting that the curve is an elliptical helix that spirals along the cylinder.



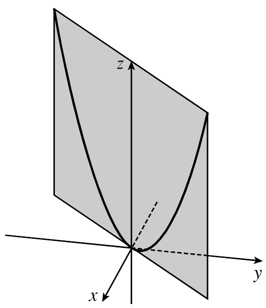
16. The projection of the curve onto the xy-plane is given by $\mathbf{r}(t) = \langle t, t, 0 \rangle$ whose graph is the line $y = x$, $z = 0$. The projection onto the xz-plane is $\mathbf{r}(t) = \langle t, 0, t^2 \rangle$ whose graph is the parabola $z = x^2$, $y = 0$. The projection onto the yz-plane is $\mathbf{r}(t) = \langle 0, t, t^2 \rangle$ whose graph is the parabola $z = y^2$, $x = 0$.



xy-plane xz-plane yz-plane

[continued]

From the projection onto the xy-plane we see that the curve lies on the vertical plane $y = x$. The other two projections show that the curve is a parabola contained in this plane.



17. Taking $\mathbf{r}_0 = \langle 2, 0, 0\rangle$ and $\mathbf{r}_1 = \langle 6, 2, -2\rangle$, we have from Equation 12.5.4

$\mathbf{r}(t) = (1-t)\,\mathbf{r}_0 + t\,\mathbf{r}_1 = (1-t)\,\langle 2,0,0\rangle + t\,\langle 6,2,-2\rangle, 0 \le t \le 1$ or $\mathbf{r}(t) = \langle 2+4t, 2t, -2t\rangle, 0 \le t \le 1.$

Parametric equations are $x = 2 + 4t,\ y = 2t,\ z = -2t,\ 0 \le t \le 1.$

18. Taking $\mathbf{r}_0 = \langle -1, 2, -2\rangle$ and $\mathbf{r}_1 = \langle -3, 5, 1\rangle$, we have from Equation 12.5.4

$\mathbf{r}(t) = (1-t)\,\mathbf{r}_0 + t\,\mathbf{r}_1 = (1-t)\,\langle -1,2,-2\rangle + t\,\langle -3,5,1\rangle, 0 \le t \le 1$ or $\mathbf{r}(t) = \langle -1-2t, 2+3t, -2+3t\rangle, 0 \le t \le 1.$

Parametric equations are $x = -1 - 2t,\ y = 2 + 3t,\ z = -2 + 3t,\ 0 \le t \le 1.$

19. Taking $\mathbf{r}_0 = \langle 0, -1, 1\rangle$ and $\mathbf{r}_1 = \left\langle \frac{1}{2}, \frac{1}{3}, \frac{1}{4}\right\rangle$, we have

$\mathbf{r}(t) = (1-t)\,\mathbf{r}_0 + t\,\mathbf{r}_1 = (1-t)\,\langle 0,-1,1\rangle + t\left\langle \frac{1}{2}, \frac{1}{3}, \frac{1}{4}\right\rangle, 0 \le t \le 1$ or $\mathbf{r}(t) = \left\langle \frac{1}{2}t, -1 + \frac{4}{3}t, 1 - \frac{3}{4}t\right\rangle, 0 \le t \le 1.$

Parametric equations are $x = \frac{1}{2}t,\ y = -1 + \frac{4}{3}t,\ z = 1 - \frac{3}{4}t,\ 0 \le t \le 1.$

20. Taking $\mathbf{r}_0 = \langle a, b, c\rangle$ and $\mathbf{r}_1 = \langle u, v, w\rangle$, we have

$\mathbf{r}(t) = (1-t)\,\mathbf{r}_0 + t\,\mathbf{r}_1 = (1-t)\,\langle a,b,c\rangle + t\,\langle u,v,w\rangle, 0 \le t \le 1$ or $\mathbf{r}(t) = \langle a + (u-a)t, b + (v-b)t, c + (w-c)t\rangle,$ $0 \le t \le 1$. Parametric equations are $x = a + (u-a)t,\ y = b + (v-b)t,\ z = c + (w-c)t,\ 0 \le t \le 1.$

21. $x = t\cos t,\ y = t,\ z = t\sin t,\ t \ge 0.$ At any point (x, y, z) on the curve, $x^2 + z^2 = t^2\cos^2 t + t^2\sin^2 t = t^2 = y^2$ so the curve lies on the circular cone $x^2 + z^2 = y^2$ with axis the y-axis. Also notice that $y \ge 0$; the graph is II.

22. $x = \cos t,\ y = \sin t,\ z = 1/(1+t^2).$ At any point on the curve we have $x^2 + y^2 = \cos^2 t + \sin^2 t = 1$, so the curve lies on the circular cylinder $x^2 + y^2 = 1$ with axis the z-axis. Notice that $0 < z \le 1$ and $z = 1$ only for $t = 0$. A point (x, y, z) on the curve lies directly above the point $(x, y, 0)$, which moves counterclockwise around the unit circle in the xy-plane as t increases, and $z \to 0$ as $t \to \pm\infty$. The graph must be VI.

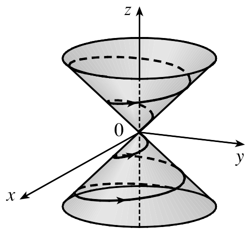
23. $x = t,\ y = 1/(1+t^2),\ z = t^2.$ At any point on the curve we have $z = x^2$, so the curve lies on a parabolic cylinder parallel to the y-axis. Notice that $0 < y \le 1$ and $z \ge 0$. Also the curve passes through $(0, 1, 0)$ when $t = 0$ and $y \to 0$, $z \to \infty$ as $t \to \pm\infty$, so the graph must be V.

24. $x = \cos t,\ y = \sin t,\ z = \cos 2t.$ $x^2 + y^2 = \cos^2 t + \sin^2 t = 1$, so the curve lies on a circular cylinder with axis the z-axis. A point (x, y, z) on the curve lies directly above or below $(x, y, 0)$, which moves around the unit circle in the xy-plane with period 2π. At the same time, the z-value of the point (x, y, z) oscillates with a period of π. So the curve repeats itself and the graph is I.

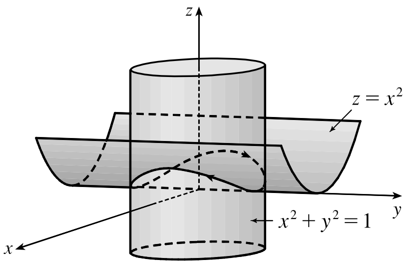
25. $x = \cos 8t,\ y = \sin 8t,\ z = e^{0.8t},\ t \geq 0.$ $x^2 + y^2 = \cos^2 8t + \sin^2 8t = 1$, so the curve lies on a circular cylinder with axis the z-axis. A point (x, y, z) on the curve lies directly above the point $(x, y, 0)$, which moves counterclockwise around the unit circle in the xy-plane as t increases. The curve starts at $(1, 0, 1)$, when $t = 0$, and $z \to \infty$ (at an increasing rate) as $t \to \infty$, so the graph is IV.

26. $x = \cos^2 t,\ y = \sin^2 t,\ z = t.$ $x + y = \cos^2 t + \sin^2 t = 1$, so the curve lies in the vertical plane $x + y = 1$. x and y are periodic, both with period π, and z increases as t increases, so the graph is III.

27. If $x = t\cos t,\ y = t\sin t,\ z = t$, then $x^2 + y^2 = t^2\cos^2 t + t^2\sin^2 t = t^2 = z^2$, so the curve lies on the cone $z^2 = x^2 + y^2$. Since $z = t$, the curve is a spiral on this cone.



28. Here $x^2 = \sin^2 t = z$ and $x^2 + y^2 = \sin^2 t + \cos^2 t = 1$, so the curve is contained in the intersection of the parabolic cylinder $z = x^2$ with the circular cylinder $x^2 + y^2 = 1$. We get the complete intersection for $0 \leq t \leq 2\pi$.



29. Here $x = 2t,\ y = e^t,\ z = e^{2t}$. Then $t = x/2 \quad \Rightarrow \quad y = e^t = e^{x/2}$, so the curve lies on the cylinder $y = e^{x/2}$. Also $z = e^{2t} = e^x$, so the curve lies on the cylinder $z = e^x$. Since $z = e^{2t} = \left(e^t\right)^2 = y^2$, the curve also lies on the parabolic cylinder $z = y^2$.

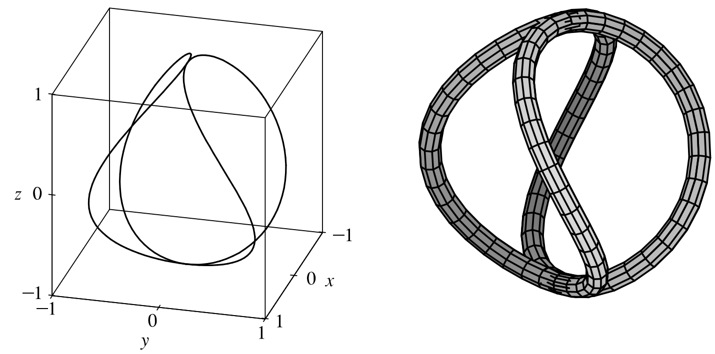
30. Here $x = t^2,\ y = \ln t,\ z = 1/t$. The domain of $\mathbf{r}$ is $(0, \infty)$, so $x = t^2 \quad \Rightarrow \quad t = \sqrt{x} \quad \Rightarrow \quad y = \ln\sqrt{x}$. Thus one surface containing the curve is the cylinder $y = \ln\sqrt{x}$ or $y = \ln x^{1/2} = \frac{1}{2}\ln x$. Also $z = 1/t = 1/\sqrt{x}$, so the curve also lies on the cylinder $z = 1/\sqrt{x}$ or $x = 1/z^2$, $z > 0$. Finally $z = 1/t \quad \Rightarrow \quad t = 1/z \quad \Rightarrow \quad y = \ln(1/z)$, so the curve also lies on the cylinder $y = \ln(1/z)$ or $y = \ln z^{-1} = -\ln z$. Note that the surface $y = \ln(xz)$ also contains the curve, since $\ln(xz) = \ln(t^2 \cdot 1/t) = \ln t = y$.

31. Parametric equations for the curve are $x = t,\ y = 0,\ z = 2t - t^2$. Substituting into the equation of the paraboloid gives $2t - t^2 = t^2 \quad \Rightarrow \quad 2t = 2t^2 \quad \Rightarrow \quad t = 0, 1$. Since $\mathbf{r}(0) = \mathbf{0}$ and $\mathbf{r}(1) = \mathbf{i} + \mathbf{k}$, the points of intersection are $(0, 0, 0)$ and $(1, 0, 1)$.

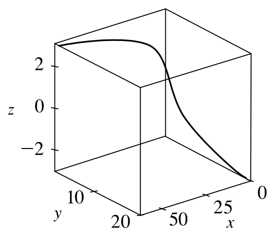
32. Parametric equations for the helix are $x = \sin t$, $y = \cos t$, $z = t$. Substituting into the equation of the sphere gives $\sin^2 t + \cos^2 t + t^2 = 5 \quad \Rightarrow \quad 1 + t^2 = 5 \quad \Rightarrow \quad t = \pm 2$. Since $\mathbf{r}(2) = \langle \sin 2, \cos 2, 2\rangle$ and $\mathbf{r}(-2) = \langle \sin(-2), \cos(-2), -2\rangle$, the points of intersection are $(\sin 2, \cos 2, 2) \approx (0.909, -0.416, 2)$ and $(\sin(-2), \cos(-2), -2) \approx (-0.909, -0.416, -2)$.

33. $\mathbf{r}(t) = \langle \cos t\ \sin 2t, \sin t\ \sin 2t, \cos 2t \rangle$.

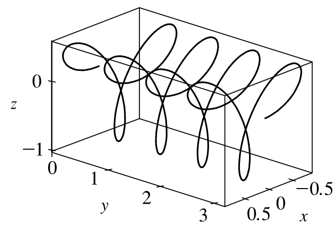
We include both a regular plot and a plot showing a tube of radius 0.08 around the curve.



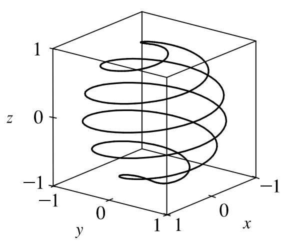
34. $\mathbf{r}(t) = \langle te^t, e^{-t}, t \rangle$



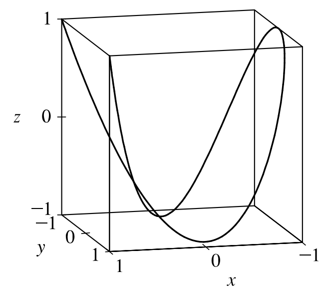
35. $\mathbf{r}(t) = \langle \sin 3t \cos t, \frac{1}{4}t, \sin 3t \sin t \rangle$



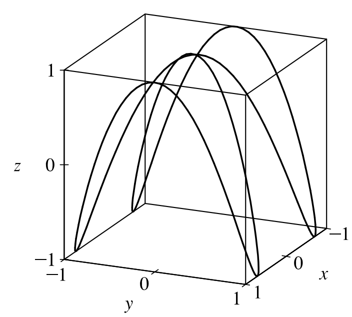
36. $\mathbf{r}(t) = \langle \cos(8 \cos t) \sin t, \sin(8 \cos t) \sin t, \cos t \rangle$



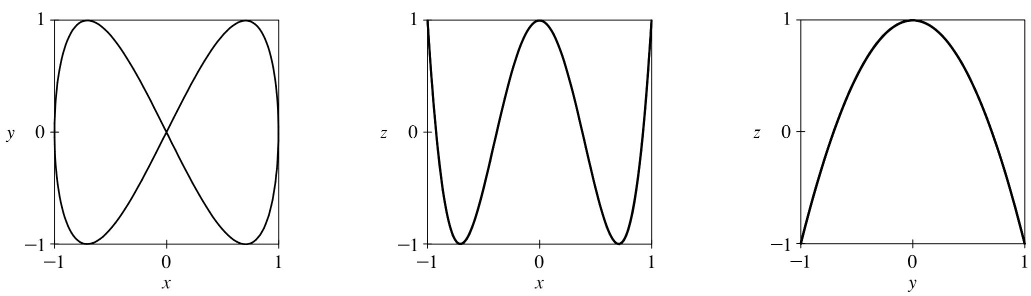
37. $\mathbf{r}(t) = \langle \cos 2t, \cos 3t, \cos 4t \rangle$



38. $x = \sin t$, $y = \sin 2t$, $z = \cos 4t$.



We graph the projections onto the coordinate planes.



xy-plane $\quad$ xz-plane $\quad$ yz-plane

From the projection onto the xy-plane we see that from above the curve appears to be shaped like a "figure eight." The curve can be visualized as this shape wrapped around an almost parabolic cylindrical surface, the profile of which is visible in the projection onto the yz-plane.

39. 
$x = (1 + \cos 16t)\cos t$, $y = (1 + \cos 16t)\sin t$, $z = 1 + \cos 16t$. At any point on the graph,

$$\begin{aligned} x^2 + y^2 &= (1 + \cos 16t)^2 \cos^2 t + (1 + \cos 16t)^2 \sin^2 t \\ &= (1 + \cos 16t)^2 = z^2, \text{ so the graph lies on the cone } x^2 + y^2 = z^2. \end{aligned}$$

From the graph at left, we see that this curve looks like the projection of a leaved two-dimensional curve onto a cone.

40. 
$x = \sqrt{1 - 0.25\cos^2 10t}\,\cos t,\ \ y = \sqrt{1 - 0.25\cos^2 10t}\,\sin t,$

$z = 0.5\cos 10t$. At any point on the graph,

$$\begin{aligned} x^2 + y^2 + z^2 &= (1 - 0.25\cos^2 10t)\cos^2 t \\ &\quad + (1 - 0.25\cos^2 10t)\sin^2 t + 0.25\cos^2 t \\ &= 1 - 0.25\cos^2 10t + 0.25\cos^2 10t = 1, \end{aligned}$$

so the graph lies on the sphere $x^2 + y^2 + z^2 = 1$, and since $z = 0.5\cos 10t$ the graph resembles a trigonometric curve with ten peaks projected onto the sphere. We get the complete graph for $0 \le t \le 2\pi$.

41. If $t = -1$, then $x = 1,\ y = 4,\ z = 0$, so the curve passes through the point $(1, 4, 0)$. If $t = 3$, then $x = 9,\ y = -8,\ z = 28$, so the curve passes through the point $(9, -8, 28)$. For the point $(4, 7, -6)$ to be on the curve, we require $y = 1 - 3t = 7 \quad \Rightarrow$ $t = -2$. But then $z = 1 + (-2)^3 = -7 \ne -6$, so $(4, 7, -6)$ is not on the curve.

42. The projection of the curve C of intersection onto the xy-plane is the circle $x^2 + y^2 = 4$, $z = 0$. Then we can write $x = 2\cos t,\ y = 2\sin t,\ 0 \le t \le 2\pi$. Since C also lies on the surface $z = xy$, we have $z = xy = (2\cos t)(2\sin t) = 4\cos t \sin t$, or $2\sin(2t)$. Then parametric equations for C are $x = 2\cos t,\ y = 2\sin t,$ $z = 2\sin(2t),\ 0 \le t \le 2\pi$, and the corresponding vector function is $\mathbf{r}(t) = 2\cos t\,\mathbf{i} + 2\sin t\,\mathbf{j} + 2\sin(2t)\,\mathbf{k}$, $0 \le t \le 2\pi$.

43. Both equations are solved for z, so we can substitute to eliminate z: $\sqrt{x^2 + y^2} = 1 + y \quad \Rightarrow \quad x^2 + y^2 = 1 + 2y + y^2 \quad \Rightarrow$ $x^2 = 1 + 2y \quad \Rightarrow \quad y = \frac{1}{2}(x^2 - 1)$. We can form parametric equations for the curve C of intersection by choosing a parameter $x = t$, then $y = \frac{1}{2}(t^2 - 1)$ and $z = 1 + y = 1 + \frac{1}{2}(t^2 - 1) = \frac{1}{2}(t^2 + 1)$. Thus a vector function representing C is $\mathbf{r}(t) = t\,\mathbf{i} + \frac{1}{2}(t^2 - 1)\,\mathbf{j} + \frac{1}{2}(t^2 + 1)\,\mathbf{k}$.

44. The projection of the curve C of intersection onto the xy-plane is the parabola $y = x^2$, $z = 0$. Then we can choose the parameter $x = t \quad \Rightarrow \quad y = t^2$. Since C also lies on the surface $z = 4x^2 + y^2$, we have $z = 4x^2 + y^2 = 4t^2 + (t^2)^2$. Then parametric equations for C are $x = t,\ y = t^2,\ z = 4t^2 + t^4$, and the corresponding vector function is $\mathbf{r}(t) = t\,\mathbf{i} + t^2\,\mathbf{j} + (4t^2 + t^4)\,\mathbf{k}$.

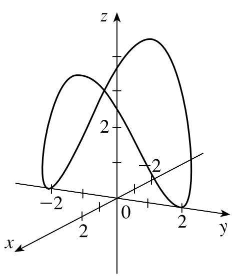
45. The projection of the curve C of intersection onto the xy-plane is the circle $x^2 + y^2 = 1$, $z = 0$, so we can write $x = \cos t$, $y = \sin t$, $0 \le t \le 2\pi$. Since C also lies on the surface $z = x^2 - y^2$, we have $z = x^2 - y^2 = \cos^2 t - \sin^2 t$ or $\cos 2t$. Thus parametric equations for C are $x = \cos t$, $y = \sin t$, $z = \cos 2t$, $0 \le t \le 2\pi$, and the corresponding vector function is $\mathbf{r}(t) = \cos t\,\mathbf{i} + \sin t\,\mathbf{j} + \cos 2t\,\mathbf{k}$, $0 \le t \le 2\pi$.

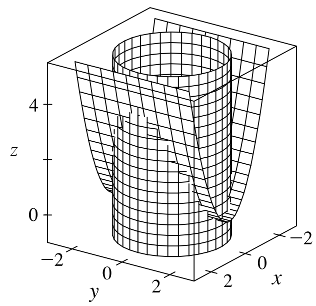
46. The projection of the curve C of intersection onto the xz-plane is the circle $x^2 + z^2 = 1$, $y = 0$, so we can write $x = \cos t$, $z = \sin t$, $0 \le t \le 2\pi$. C also lies on the surface $x^2 + y^2 + 4z^2 = 4$, and since $y \ge 0$ we can write

$$y = \sqrt{4 - x^2 - 4z^2} = \sqrt{4 - \cos^2 t - 4\sin^2 t} = \sqrt{4 - \cos^2 t - 4(1 - \cos^2 t)} = \sqrt{3\cos^2 t} = \sqrt{3}\,|\cos t\,|$$

Thus parametric equations for C are $x = \cos t$, $y = \sqrt{3}\,|\cos t\,|$, $z = \sin t$, $0 \le t \le 2\pi$, and the corresponding vector function is $\mathbf{r}(t) = \cos t\,\mathbf{i} + \sqrt{3}\,|\cos t\,|\,\mathbf{j} + \sin t\,\mathbf{k}$, $0 \le t \le 2\pi$.

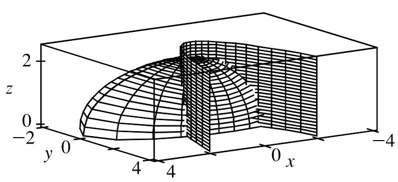
47.

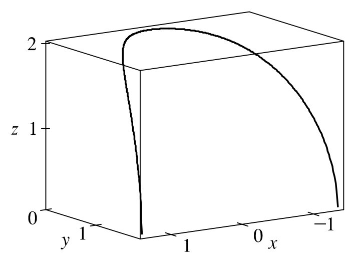




The projection of the curve C of intersection onto the xy-plane is the circle $x^2 + y^2 = 4$, $z = 0$. Then we can write $x = 2\cos t$, $y = 2\sin t$, $0 \le t \le 2\pi$. Since C also lies on the surface $z = x^2$, we have $z = x^2 = (2\cos t)^2 = 4\cos^2 t$. Then parametric equations for C are $x = 2\cos t$, $y = 2\sin t$, $z = 4\cos^2 t$, $0 \le t \le 2\pi$.

48.





$x = t \;\Rightarrow\; y = t^2 \;\Rightarrow\; 4z^2 = 16 - x^2 - 4y^2 = 16 - t^2 - 4t^4 \;\Rightarrow\; z = \sqrt{4 - \left(\frac{1}{2}t\right)^2 - t^4}$.

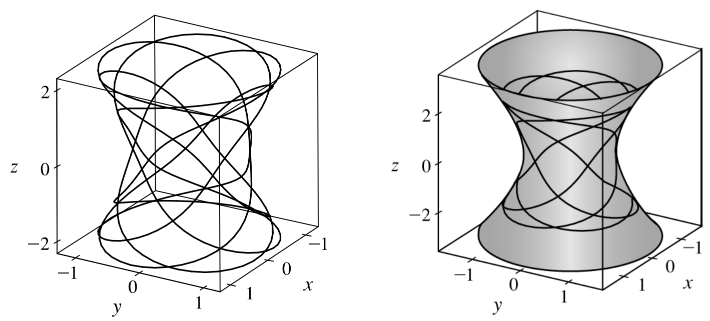
Note that z is positive because the intersection is with the top half of the ellipsoid. Hence the curve is given by $x = t$, $y = t^2$, $z = \sqrt{4 - \frac{1}{4}t^2 - t^4}$.

49. For the particles to collide, we require $\mathbf{r}_1(t) = \mathbf{r}_2(t) \;\Leftrightarrow\; \langle t^2, 7t - 12, t^2 \rangle = \langle 4t - 3, t^2, 5t - 6 \rangle$. Equating components gives $t^2 = 4t - 3$, $7t - 12 = t^2$, and $t^2 = 5t - 6$. From the first equation, $t^2 - 4t + 3 = 0 \;\Leftrightarrow\; (t - 3)(t - 1) = 0$ so $t = 1$ or $t = 3$. $t = 1$ does not satisfy the other two equations, but $t = 3$ does. The particles collide when $t = 3$, at the point $(9, 9, 9)$.

50. The particles collide provided $\mathbf{r}_1(t) = \mathbf{r}_2(t) \;\Leftrightarrow\; \langle t, t^2, t^3 \rangle = \langle 1 + 2t, 1 + 6t, 1 + 14t \rangle$. Equating components gives $t = 1 + 2t$, $t^2 = 1 + 6t$, and $t^3 = 1 + 14t$. The first equation gives $t = -1$, but this does not satisfy the other equations, so the particles do not collide. For the paths to intersect, we need to find a value for t and a value for s where $\mathbf{r}_1(t) = \mathbf{r}_2(s) \;\Leftrightarrow$

$\langle t, t^2, t^3\rangle = \langle 1+2s, 1+6s, 1+14s\rangle$. Equating components, $t = 1+2s$, $t^2 = 1+6s$, and $t^3 = 1+14s$. Substituting the first equation into the second gives $(1+2s)^2 = 1+6s \Rightarrow 4s^2 - 2s = 0 \Rightarrow 2s(2s-1) = 0 \Rightarrow s = 0$ or $s = \frac{1}{2}$. From the first equation, $s = 0 \Rightarrow t = 1$ and $s = \frac{1}{2} \Rightarrow t = 2$. Checking, we see that both pairs of values satisfy the third equation. Thus the paths intersect twice, at the point $(1,1,1)$ when $s = 0$ and $t = 1$, and at $(2,4,8)$ when $s = \frac{1}{2}$ and $t = 2$.

51. (a) We plot the parametric equations for $0 \le t \le 2\pi$ in the first figure. We get a better idea of the shape of the curve if we plot it simultaneously with the hyperboloid of one sheet from part (b), as shown in the second figure.



(b) Here $x = \frac{27}{26}\sin 8t - \frac{8}{39}\sin 18t$, $y = -\frac{27}{26}\cos 8t + \frac{8}{39}\cos 18t$, $z = \frac{144}{65}\sin 5t$.

For any point on the curve,

$$\begin{aligned} x^2 + y^2 &= \left(\tfrac{27}{26}\sin 8t - \tfrac{8}{39}\sin 18t\right)^2 + \left(-\tfrac{27}{26}\cos 8t + \tfrac{8}{39}\cos 18t\right)^2 \\ &= \tfrac{27^2}{26^2}\sin^2 8t - 2\cdot\tfrac{27\cdot 8}{26\cdot 39}\sin 8t\sin 18t + \tfrac{64}{39^2}\sin^2 18t \\ &\qquad + \tfrac{27^2}{26^2}\cos^2 8t - 2\cdot\tfrac{27\cdot 8}{26\cdot 39}\cos 8t\cos 18t + \tfrac{64}{39^2}\cos^2 18t \\ &= \tfrac{27^2}{26^2}\left(\sin^2 8t + \cos^2 8t\right) + \tfrac{64}{39^2}\left(\sin^2 18t + \cos^2 18t\right) - \tfrac{72}{169}\left(\sin 8t\sin 18t + \cos 8t\cos 18t\right) \\ &= \tfrac{27^2}{26^2} + \tfrac{64}{39^2} - \tfrac{72}{169}\cos(18t - 8t) = \tfrac{27^2}{26^2} + \tfrac{64}{39^2} - \tfrac{72}{169}\cos 10t \end{aligned}$$

using the trigonometric identities $\sin^2\theta + \cos^2\theta = 1$ and $\cos(x-y) = \cos x\cos y + \sin x\sin y$. Also

$z^2 = \frac{144^2}{65^2}\sin^2 5t$, and the identity $\sin^2 x = \dfrac{1-\cos 2x}{2}$ gives $z^2 = \frac{144^2}{65^2}\cdot\frac{1}{2}\left[1 - \cos(2\cdot 5t)\right] = \frac{144^2}{2\cdot 65^2} - \frac{144^2}{2\cdot 65^2}\cos 10t$.

Then

$$\begin{aligned} 144(x^2+y^2) - 25z^2 &= 144\left(\tfrac{27^2}{26^2} + \tfrac{64}{39^2} - \tfrac{72}{169}\cos 10t\right) - 25\left(\tfrac{144^2}{2\cdot 65^2} - \tfrac{144^2}{2\cdot 65^2}\cos 10t\right) \\ &= 144\left(\tfrac{27^2}{26^2} + \tfrac{64}{39^2} - \tfrac{25\cdot 144}{2\cdot 65^2} - \tfrac{72}{169}\cos 10t + \tfrac{25\cdot 144}{2\cdot 65^2}\cos 10t\right) \\ &= 144\left(\tfrac{27^2}{26^2} + \tfrac{64}{39^2} - \tfrac{72}{169} - \tfrac{72}{169}\cos 10t + \tfrac{72}{169}\cos 10t\right) = 144\left(\tfrac{25}{36}\right) = 100 \end{aligned}$$

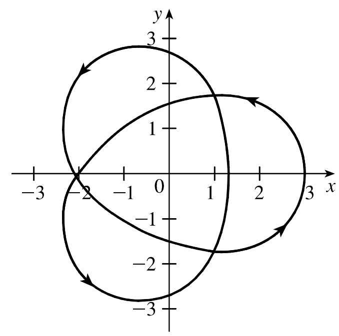
Thus the curve lies on the surface $144(x^2+y^2) - 25z^2 = 100$ or $144x^2 + 144y^2 - 25z^2 = 100$, a hyperboloid of one sheet with axis the z-axis.

52. The projection of the curve onto the xy-plane is given by the parametric equations $x = (2 + \cos 1.5t)\cos t$, $y = (2 + \cos 1.5t)\sin t$. If we convert to polar coordinates, we have

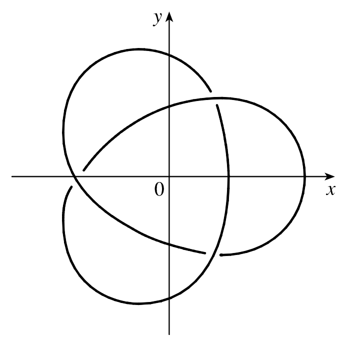
$r^2 = x^2 + y^2 = [(2 + \cos 1.5t)\cos t]^2 + [(2 + \cos 1.5t)\sin t]^2 = (2 + \cos 1.5t)^2(\cos^2 t + \sin^2 t) = (2 + \cos 1.5t)^2 \quad \Rightarrow$

$r = 2 + \cos 1.5t$. Also, $\tan\theta = \dfrac{y}{x} = \dfrac{(2 + \cos 1.5t)\sin t}{(2 + \cos 1.5t)\cos t} = \tan t \quad \Rightarrow \quad \theta = t$.

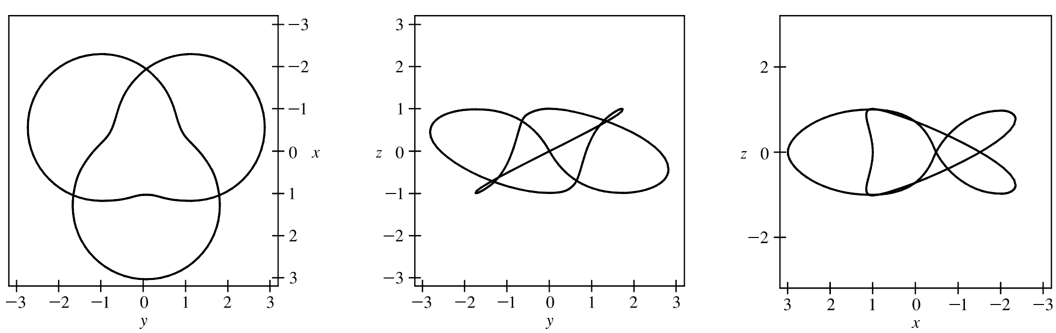
Thus the polar equation of the curve is $r = 2 + \cos 1.5\theta$. At $\theta = 0$, we have $r = 3$, and r decreases to 1 as θ increases to $\frac{2\pi}{3}$. For $\frac{2\pi}{3} \le \theta \le \frac{4\pi}{3}$, r increases to 3; r decreases to 1 again at $\theta = 2\pi$, increases to 3 at $\theta = \frac{8\pi}{3}$, decreases to 1 at $\theta = \frac{10\pi}{3}$, and completes the closed curve by increasing to 3 at $\theta = 4\pi$. We sketch an approximate graph as shown in the figure.



We can determine how the curve passes over itself by investigating the maximum and minimum values of z for $0 \le t \le 4\pi$. Since $z = \sin 1.5t$, z is maximized where $\sin 1.5t = 1 \quad \Rightarrow \quad 1.5t = \frac{\pi}{2}, \frac{5\pi}{2}$, or $\frac{9\pi}{2} \quad \Rightarrow$ $t = \frac{\pi}{3}, \frac{5\pi}{3}$, or 3π. z is minimized where $\sin 1.5t = -1 \quad \Rightarrow$ $1.5t = \frac{3\pi}{2}, \frac{7\pi}{2}$, or $\frac{11\pi}{2} \quad \Rightarrow \quad t = \pi, \frac{7\pi}{3}$, or $\frac{11\pi}{3}$. Note that these are precisely the values for which $\cos 1.5t = 0 \quad \Rightarrow \quad r = 2$, and on the graph of the projection, these six points appear to be at the three self-intersections we see. Comparing the maximum and minimum values of z at these intersections, we can determine where the curve passes over itself, as indicated in the figure.

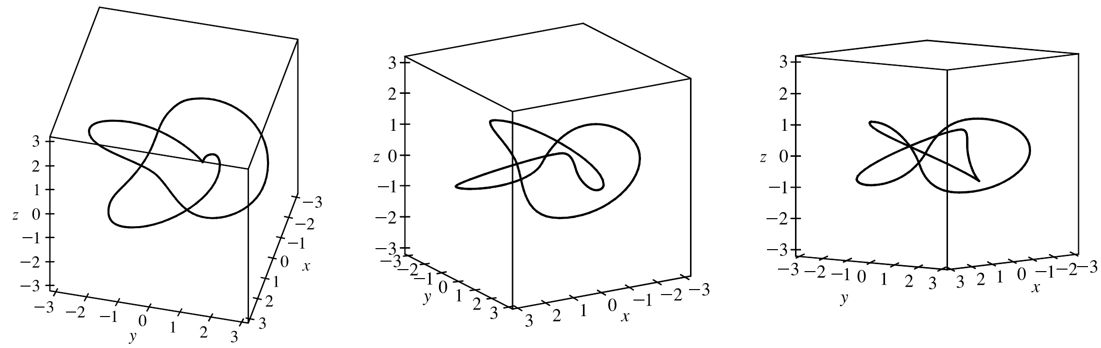


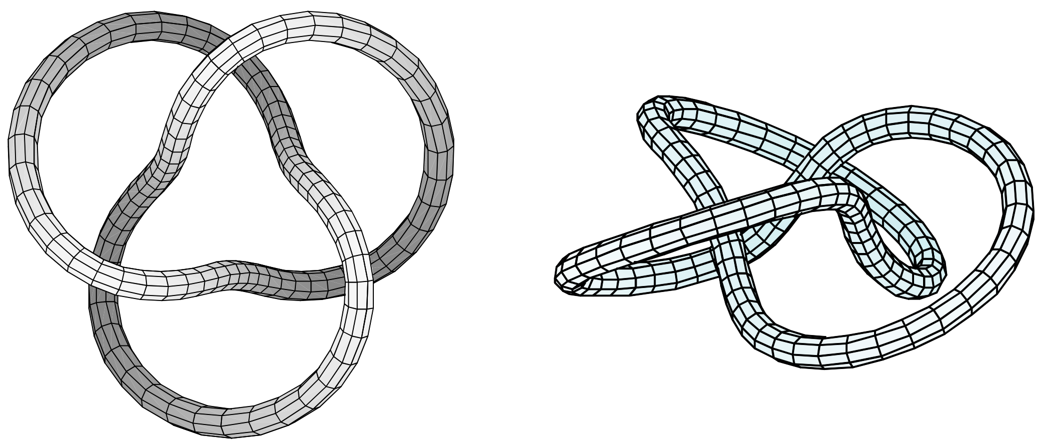
We show a computer-drawn graph of the curve from above, as well as views from the front and from the right side.



Top view Front view Side view

The top view graph shows a more accurate representation of the projection of the trefoil knot onto the xy-plane (the axes are rotated 90°). Notice the indentations the graph exhibits at the points corresponding to $r = 1$. Finally, we graph several additional viewpoints of the trefoil knot, along with two plots showing a tube of radius 0.2 around the curve.





53. Let $\mathbf{u}(t) = \langle u_1(t), u_2(t), u_3(t)\rangle$ and $\mathbf{v}(t) = \langle v_1(t), v_2(t), v_3(t)\rangle$. In each part of this problem the basic procedure is to use Equation 1 and then analyze the individual component functions using the limit properties we have already developed for real-valued functions.

(a) $\lim\limits_{t\to a} \mathbf{u}(t) + \lim\limits_{t\to a} \mathbf{v}(t) = \left\langle \lim\limits_{t\to a} u_1(t), \lim\limits_{t\to a} u_2(t), \lim\limits_{t\to a} u_3(t)\right\rangle + \left\langle \lim\limits_{t\to a} v_1(t), \lim\limits_{t\to a} v_2(t), \lim\limits_{t\to a} v_3(t)\right\rangle$ and the limits of these component functions must each exist since the vector functions both possess limits as $t \to a$. Then adding the two vectors and using the addition property of limits for real-valued functions, we have that

$$\begin{aligned}\lim_{t\to a} \mathbf{u}(t) + \lim_{t\to a} \mathbf{v}(t) &= \left\langle \lim_{t\to a} u_1(t) + \lim_{t\to a} v_1(t), \lim_{t\to a} u_2(t) + \lim_{t\to a} v_2(t), \lim_{t\to a} u_3(t) + \lim_{t\to a} v_3(t)\right\rangle \\ &= \left\langle \lim_{t\to a} \left[u_1(t) + v_1(t)\right], \lim_{t\to a} \left[u_2(t) + v_2(t)\right], \lim_{t\to a} \left[u_3(t) + v_3(t)\right]\right\rangle \\ &= \lim_{t\to a} \langle u_1(t) + v_1(t), u_2(t) + v_2(t), u_3(t) + v_3(t)\rangle \qquad \text{[using (1) backward]} \\ &= \lim_{t\to a} \left[\mathbf{u}(t) + \mathbf{v}(t)\right]\end{aligned}$$

(b) $$\begin{aligned}\lim_{t\to a} c\mathbf{u}(t) &= \lim_{t\to a} \langle cu_1(t), cu_2(t), cu_3(t)\rangle = \left\langle \lim_{t\to a} cu_1(t), \lim_{t\to a} cu_2(t), \lim_{t\to a} cu_3(t)\right\rangle \\ &= \left\langle c\lim_{t\to a} u_1(t), c\lim_{t\to a} u_2(t), c\lim_{t\to a} u_3(t)\right\rangle = c\left\langle \lim_{t\to a} u_1(t), \lim_{t\to a} u_2(t), \lim_{t\to a} u_3(t)\right\rangle \\ &= c\lim_{t\to a} \langle u_1(t), u_2(t), u_3(t)\rangle = c\lim_{t\to a} \mathbf{u}(t)\end{aligned}$$

(c) $\lim\limits_{t\to a}\mathbf{u}(t)\cdot\lim\limits_{t\to a}\mathbf{v}(t)=\left\langle\lim\limits_{t\to a}u_1(t),\lim\limits_{t\to a}u_2(t),\lim\limits_{t\to a}u_3(t)\right\rangle\cdot\left\langle\lim\limits_{t\to a}v_1(t),\lim\limits_{t\to a}v_2(t),\lim\limits_{t\to a}v_3(t)\right\rangle$

$$=\left[\lim_{t\to a}u_1(t)\right]\left[\lim_{t\to a}v_1(t)\right]+\left[\lim_{t\to a}u_2(t)\right]\left[\lim_{t\to a}v_2(t)\right]+\left[\lim_{t\to a}u_3(t)\right]\left[\lim_{t\to a}v_3(t)\right]$$

$$=\lim_{t\to a}u_1(t)v_1(t)+\lim_{t\to a}u_2(t)v_2(t)+\lim_{t\to a}u_3(t)v_3(t)$$

$$=\lim_{t\to a}\left[u_1(t)v_1(t)+u_2(t)v_2(t)+u_3(t)v_3(t)\right]=\lim_{t\to a}\left[\mathbf{u}(t)\cdot\mathbf{v}(t)\right]$$

(d) $\lim\limits_{t\to a}\mathbf{u}(t)\times\lim\limits_{t\to a}\mathbf{v}(t)=\left\langle\lim\limits_{t\to a}u_1(t),\lim\limits_{t\to a}u_2(t),\lim\limits_{t\to a}u_3(t)\right\rangle\times\left\langle\lim\limits_{t\to a}v_1(t),\lim\limits_{t\to a}v_2(t),\lim\limits_{t\to a}v_3(t)\right\rangle$

$$=\Big\langle\left[\lim_{t\to a}u_2(t)\right]\left[\lim_{t\to a}v_3(t)\right]-\left[\lim_{t\to a}u_3(t)\right]\left[\lim_{t\to a}v_2(t)\right],$$
$$\left[\lim_{t\to a}u_3(t)\right]\left[\lim_{t\to a}v_1(t)\right]-\left[\lim_{t\to a}u_1(t)\right]\left[\lim_{t\to a}v_3(t)\right],$$
$$\left[\lim_{t\to a}u_1(t)\right]\left[\lim_{t\to a}v_2(t)\right]-\left[\lim_{t\to a}u_2(t)\right]\left[\lim_{t\to a}v_1(t)\right]\Big\rangle$$

$$=\Big\langle\lim_{t\to a}\left[u_2(t)v_3(t)-u_3(t)v_2(t)\right],\lim_{t\to a}\left[u_3(t)v_1(t)-u_1(t)v_3(t)\right],$$
$$\lim_{t\to a}\left[u_1(t)v_2(t)-u_2(t)v_1(t)\right]\Big\rangle$$

$$=\lim_{t\to a}\langle u_2(t)v_3(t)-u_3(t)v_2(t),u_3\,(t)\,v_1(t)-u_1(t)v_3(t),u_1(t)v_2(t)-u_2(t)v_1(t)\rangle$$

$$=\lim_{t\to a}\left[\mathbf{u}(t)\times\mathbf{v}(t)\right]$$

54. Let $\mathbf{r}(t)=\langle f\,(t)\,,g\,(t)\,,h\,(t)\rangle$ and $\mathbf{b}=\langle b_1,b_2,b_3\rangle$. If $\lim\limits_{t\to a}\mathbf{r}(t)=\mathbf{b}$, then $\lim\limits_{t\to a}\mathbf{r}(t)$ exists, so by (1),

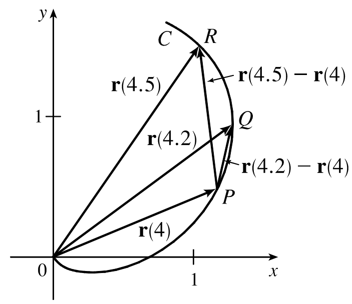
$\mathbf{b}=\lim\limits_{t\to a}\mathbf{r}(t)=\left\langle\lim\limits_{t\to a}f(t),\lim\limits_{t\to a}g(t),\lim\limits_{t\to a}h(t)\right\rangle$. By the definition of equal vectors we have $\lim\limits_{t\to a}f(t)=b_1$, $\lim\limits_{t\to a}g(t)=b_2$ and $\lim\limits_{t\to a}h(t)=b_3$. But these are limits of real-valued functions, so by the definition of limits, for every $\varepsilon>0$ there exists $\delta_1>0$, $\delta_2>0$, $\delta_3>0$ so that if $0<|t-a|<\delta_1$ then $|f(t)-b_1|<\varepsilon/3$, if $0<|t-a|<\delta_2$ then $|g(t)-b_2|<\varepsilon/3$, and if $0<|t-a|<\delta_3$ then $|h(t)-b_3|<\varepsilon/3$. Letting $\delta=$ minimum of $\{\delta_1,\delta_2,\delta_3\}$, then if $0<|t-a|<\delta$ we have $|f(t)-b_1|+|g(t)-b_2|+|h(t)-b_3|<\varepsilon/3+\varepsilon/3+\varepsilon/3=\varepsilon$. But

$$|\mathbf{r}(t)-\mathbf{b}|=|\langle f(t)-b_1,g(t)-b_2,h(t)-b_3\rangle|=\sqrt{(f(t)-b_1)^2+(g(t)-b_2)^2+(h(t)-b_3)^2}$$
$$\le\sqrt{[f(t)-b_1]^2}+\sqrt{[g(t)-b_2]^2}+\sqrt{[h(t)-b_3]^2}=|f(t)-b_1|+|g(t)-b_2|+|h(t)-b_3|$$

Thus for every $\varepsilon>0$ there exists $\delta>0$ such that if $0<|t-a|<\delta$ then $|\mathbf{r}(t)-\mathbf{b}|\le|f(t)-b_1|+|g(t)-b_2|+|h(t)-b_3|<\varepsilon$. Conversely, suppose for every $\varepsilon>0$, there exists $\delta>0$ such that if $0<|t-a|<\delta$ then $|\mathbf{r}(t)-\mathbf{b}|<\varepsilon\quad\Leftrightarrow\quad|\langle f(t)-b_1,g(t)-b_2,h(t)-b_3\rangle|<\varepsilon\quad\Leftrightarrow$ $\sqrt{[f(t)-b_1]^2+[g(t)-b_2]^2+[h(t)-b_3]^2}<\varepsilon\quad\Leftrightarrow\quad[f(t)-b_1]^2+[g(t)-b_2]^2+[h(t)-b_3]^2<\varepsilon^2$. But each term on the left side of the last inequality is positive, so if $0<|t-a|<\delta$, then $[f(t)-b_1]^2<\varepsilon^2$, $[g(t)-b_2]^2<\varepsilon^2$ and $[h(t)-b_3]^2<\varepsilon^2$ or, taking the square root of both sides in each of the above, $|f(t)-b_1|<\varepsilon$, $|g(t)-b_2|<\varepsilon$ and $|h(t)-b_3|<\varepsilon$. And by definition of limits of real-valued functions we have $\lim\limits_{t\to a}f(t)=b_1$, $\lim\limits_{t\to a}g(t)=b_2$ and $\lim\limits_{t\to a}h(t)=b_3$. But by (1), $\lim\limits_{t\to a}\mathbf{r}(t)=\left\langle\lim\limits_{t\to a}f(t),\lim\limits_{t\to a}g(t),\lim\limits_{t\to a}h(t)\right\rangle$, so $\lim\limits_{t\to a}\mathbf{r}(t)=\langle b_1,b_2,b_3\rangle=\mathbf{b}$.

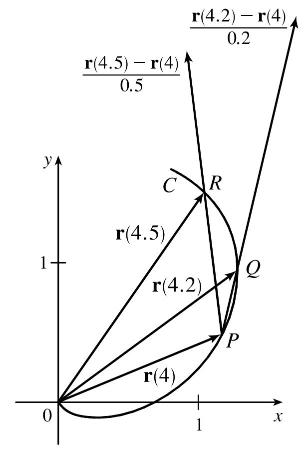
13.2 Derivatives and Integrals of Vector Functions

1. (a)



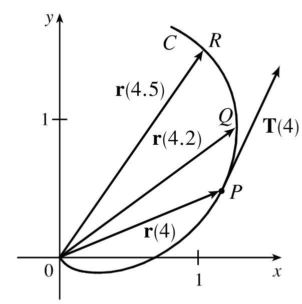
(b) $\dfrac{\mathbf{r}(4.5)-\mathbf{r}(4)}{0.5} = 2[\mathbf{r}(4.5)-\mathbf{r}(4)]$, so we draw a vector in the same direction but with twice the length of the vector $\mathbf{r}(4.5)-\mathbf{r}(4)$.

$\dfrac{\mathbf{r}(4.2)-\mathbf{r}(4)}{0.2} = 5[\mathbf{r}(4.2)-\mathbf{r}(4)]$, so we draw a vector in the same direction but with 5 times the length of the vector $\mathbf{r}(4.2)-\mathbf{r}(4)$.

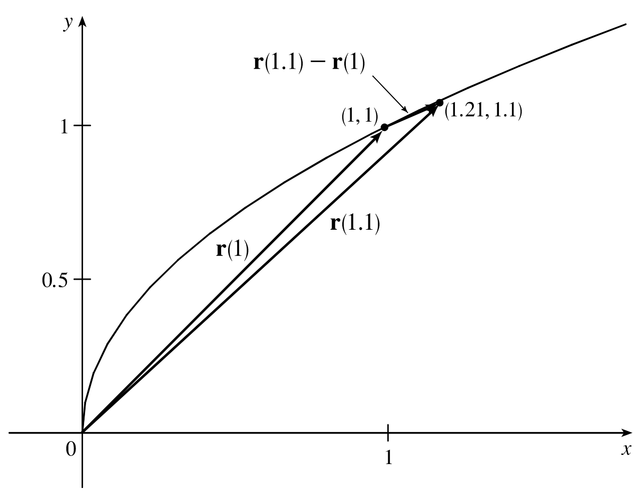


(c) By Definition 1, $\mathbf{r}'(4) = \lim\limits_{h\to 0} \dfrac{\mathbf{r}(4+h)-\mathbf{r}(4)}{h}$. $\mathbf{T}(4) = \dfrac{\mathbf{r}'(4)}{|\mathbf{r}'(4)|}$.

(d) $\mathbf{T}(4)$ is a unit vector in the same direction as $\mathbf{r}'(4)$, that is, parallel to the tangent line to the curve at $\mathbf{r}(4)$ with length 1.

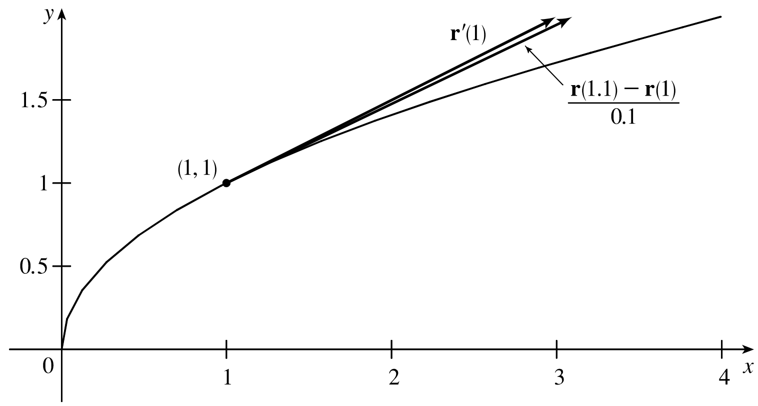


2. (a) The curve can be represented by the parametric equations $x = t^2$, $y = t$, $0 \le t \le 2$. Eliminating the parameter, we have $x = y^2$, $0 \le y \le 2$, a portion of which we graph here, along with the vectors $\mathbf{r}(1)$, $\mathbf{r}(1.1)$, and $\mathbf{r}(1.1)-\mathbf{r}(1)$.



(b) Since $\mathbf{r}(t) = \langle t^2, t \rangle$, we differentiate components, giving $\mathbf{r}'(t) = \langle 2t, 1 \rangle$, so $\mathbf{r}'(1) = \langle 2, 1 \rangle$.

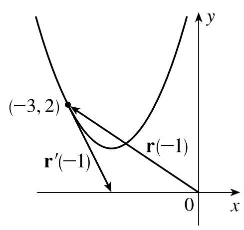
$$\frac{\mathbf{r}(1.1) - \mathbf{r}(1)}{0.1} = \frac{\langle 1.21, 1.1 \rangle - \langle 1, 1 \rangle}{0.1} = 10 \langle 0.21, 0.1 \rangle = \langle 2.1, 1 \rangle.$$



As we can see from the graph, these vectors are very close in length and direction. $\mathbf{r}'(1)$ is defined to be $\lim\limits_{h \to 0} \dfrac{\mathbf{r}(1+h) - \mathbf{r}(1)}{h}$, and we recognize $\dfrac{\mathbf{r}(1.1) - \mathbf{r}(1)}{0.1}$ as the expression after the limit sign with $h = 0.1$. Since h is close to 0, we would expect $\dfrac{\mathbf{r}(1.1) - \mathbf{r}(1)}{0.1}$ to be a vector close to $\mathbf{r}'(1)$.

3. $\mathbf{r}(t) = \langle t - 2, t^2 + 1 \rangle$, $\mathbf{r}(-1) = \langle -3, 2 \rangle$. Since $(x+2)^2 = t^2 = y - 1 \;\Rightarrow\; y = (x+2)^2 + 1$, the curve is a parabola.

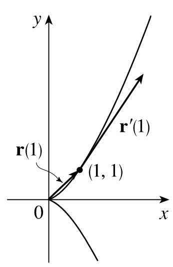
(a), (c)



(b) $\mathbf{r}'(t) = \langle 1, 2t \rangle$, $\mathbf{r}'(-1) = \langle 1, -2 \rangle$

4. $\mathbf{r}(t) = \langle t^2, t^3 \rangle$, $\mathbf{r}(1) = \langle 1, 1 \rangle$. Since $x = t^2 = (t^3)^{2/3} = y^{2/3}$, the curve is the graph of $x = y^{2/3}$.

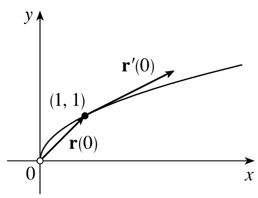
(a), (c)



(b) $\mathbf{r}'(t) = \langle 2t, 3t^2 \rangle$, $\mathbf{r}'(1) = \langle 2, 3 \rangle$

5. $\mathbf{r}(t) = e^{2t}\,\mathbf{i} + e^t\,\mathbf{j}$, $\mathbf{r}(0) = \mathbf{i} + \mathbf{j}$. Since $x = e^{2t} = (e^t)^2 = y^2$, the curve is part of a parabola. Note that here $x > 0$, $y > 0$.

(a), (c)

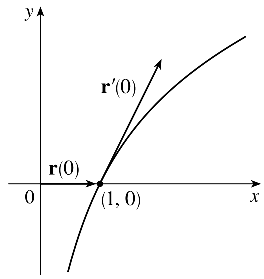


(b) $\mathbf{r}'(t) = 2e^{2t}\,\mathbf{i} + e^t\,\mathbf{j}$, $\mathbf{r}'(0) = 2\,\mathbf{i} + \mathbf{j}$

6. $\mathbf{r}(t) = e^t\,\mathbf{i} + 2t\,\mathbf{j}$, $\mathbf{r}(0) = \mathbf{i}$.

Since $x = e^t \;\Leftrightarrow\; t = \ln x$ and $y = 2t = 2\ln x$, the curve is the graph of $y = 2\ln x$.

(a), (c)



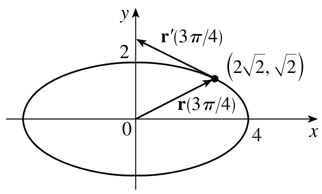
(b) $\mathbf{r}'(t) = e^t\,\mathbf{i} + 2\,\mathbf{j}$,

$\mathbf{r}'(0) = \mathbf{i} + 2\,\mathbf{j}$

7. $\mathbf{r}(t) = 4\sin t\,\mathbf{i} - 2\cos t\,\mathbf{j}$, $\mathbf{r}(3\pi/4) = 4(\sqrt{2}/2)\,\mathbf{i} - 2(-\sqrt{2}/2)\,\mathbf{j} = 2\sqrt{2}\,\mathbf{i} + \sqrt{2}\,\mathbf{j}$.

Here $(x/4)^2 + (y/2)^2 = \sin^2 t + \cos^2 t = 1$, so the curve is the ellipse $\dfrac{x^2}{16} + \dfrac{y^2}{4} = 1$.

(a), (c)



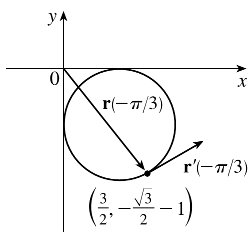
(b) $\mathbf{r}'(t) = 4\cos t\,\mathbf{i} + 2\sin t\,\mathbf{j}$,

$\mathbf{r}'(3\pi/4) = -2\sqrt{2}\,\mathbf{i} + \sqrt{2}\,\mathbf{j}$.

8. $\mathbf{r}(t) = (\cos t + 1)\,\mathbf{i} + (\sin t - 1)\,\mathbf{j}$, $\mathbf{r}(-\pi/3) = \left(\frac{1}{2} + 1\right)\mathbf{i} + \left(-\frac{\sqrt{3}}{2} - 1\right)\mathbf{j} = \frac{3}{2}\,\mathbf{i} + \left(-\frac{\sqrt{3}}{2} - 1\right)\mathbf{j} \approx 1.5\,\mathbf{i} - 1.87\,\mathbf{j}$.

Here $(x-1)^2 + (y+1)^2 = \cos^2 t + \sin^2 t = 1$, so the curve is a circle of radius 1 with center $(1, -1)$.

(a), (c)



(b) $\mathbf{r}'(t) = -\sin t\,\mathbf{i} + \cos t\,\mathbf{j}$,

$\mathbf{r}'(-\pi/3) = \frac{\sqrt{3}}{2}\,\mathbf{i} + \frac{1}{2}\,\mathbf{j} \approx 0.87\,\mathbf{i} + 0.5\,\mathbf{j}$

9. $\mathbf{r}(t) = \left\langle \sqrt{t-2}, 3, \; 1/t^2 \right\rangle \quad \Rightarrow$

$$\mathbf{r}'(t) = \left\langle \frac{d}{dt}\left[\sqrt{t-2}\right], \frac{d}{dt}[3], \frac{d}{dt}\left[1/t^2\right] \right\rangle = \left\langle \tfrac{1}{2}(t-2)^{-1/2}, 0, -2t^{-3} \right\rangle = \left\langle \frac{1}{2\sqrt{t-2}}, 0, -\frac{2}{t^3} \right\rangle$$

10. $\mathbf{r}(t) = \left\langle e^{-t}, t - t^3, \ln t \right\rangle \quad \Rightarrow \quad \mathbf{r}'(t) = \left\langle -e^{-t}, 1 - 3t^2, 1/t \right\rangle$

11. $\mathbf{r}(t) = t^2\,\mathbf{i} + \cos\left(t^2\right)\,\mathbf{j} + \sin^2 t\,\mathbf{k} \quad \Rightarrow$

$$\mathbf{r}'(t) = 2t\,\mathbf{i} + \left[-\sin(t^2) \cdot 2t\right]\mathbf{j} + (2\sin t \cdot \cos t)\,\mathbf{k} = 2t\,\mathbf{i} - 2t\sin(t^2)\,\mathbf{j} + 2\sin t\cos t\,\mathbf{k}$$

12. $\mathbf{r}(t) = \dfrac{1}{1+t}\,\mathbf{i} + \dfrac{t}{1+t}\,\mathbf{j} + \dfrac{t^2}{1+t}\,\mathbf{k} \quad \Rightarrow$

$$\mathbf{r}'(t) = \frac{0 - 1(1)}{(1+t)^2}\,\mathbf{i} + \frac{(1+t)\cdot 1 - t(1)}{(1+t)^2}\,\mathbf{j} + \frac{(1+t)\cdot 2t - t^2(1)}{(1+t)^2}\,\mathbf{k} = -\frac{1}{(1+t)^2}\,\mathbf{i} + \frac{1}{(1+t)^2}\,\mathbf{j} + \frac{t^2 + 2t}{(1+t)^2}\,\mathbf{k}$$

13. $\mathbf{r}(t) = t\sin t\,\mathbf{i} + e^t\cos t\,\mathbf{j} + \sin t\cos t\,\mathbf{k} \quad \Rightarrow$

$$\begin{aligned} \mathbf{r}'(t) &= [t\cdot\cos t + (\sin t)\cdot 1]\,\mathbf{i} + \left[e^t(-\sin t) + (\cos t)e^t\right]\mathbf{j} + [(\sin t)(-\sin t) + (\cos t)(\cos t)]\,\mathbf{k} \\ &= (t\cos t + \sin t)\,\mathbf{i} + e^t\left(\cos t - \sin t\right)\mathbf{j} + \left(\cos^2 t - \sin^2 t\right)\mathbf{k} \end{aligned}$$

14. $\mathbf{r}(t) = \sin^2 at\,\mathbf{i} + te^{bt}\,\mathbf{j} + \cos^2 ct\,\mathbf{k} \quad\Rightarrow$

$$\mathbf{r}'(t) = [2(\sin at)\cdot(\cos at)(a)]\,\mathbf{i} + \left[t\cdot e^{bt}(b) + e^{bt}\cdot 1\right]\mathbf{j} + [2(\cos ct)\cdot(-\sin ct)(c)]\,\mathbf{k}$$
$$= 2a\sin at\cos at\,\mathbf{i} + e^{bt}\,(bt+1)\,\mathbf{j} - 2c\sin ct\cos ct\,\mathbf{k}$$

15. $\mathbf{r}'(t) = \mathbf{0} + \mathbf{b} + 2t\,\mathbf{c} = \mathbf{b} + 2t\,\mathbf{c}$ by Formulas 1 and 3 of Theorem 3.

16. To find $\mathbf{r}'(t)$, we first expand $\mathbf{r}(t) = t\,\mathbf{a}\times(\mathbf{b}+t\,\mathbf{c}) = t(\mathbf{a}\times\mathbf{b}) + t^2(\mathbf{a}\times\mathbf{c})$, so $\mathbf{r}'(t) = \mathbf{a}\times\mathbf{b} + 2t(\mathbf{a}\times\mathbf{c})$.

17. $\mathbf{r}(t) = \left\langle t^2-2t, 1+3t, \frac{1}{3}t^3+\frac{1}{2}t^2\right\rangle \quad\Rightarrow\quad \mathbf{r}'(t) = \left\langle 2t-2, 3, t^2+t\right\rangle \quad\Rightarrow\quad \mathbf{r}'(2) = \langle 2,3,6\rangle$.

So $|\mathbf{r}'(2)| = \sqrt{2^2+3^2+6^2} = \sqrt{49} = 7$ and $\mathbf{T}(2) = \dfrac{\mathbf{r}'(2)}{|\mathbf{r}'(2)|} = \frac{1}{7}\langle 2,3,6\rangle = \left\langle \frac{2}{7}, \frac{3}{7}, \frac{6}{7}\right\rangle$.

18. $\mathbf{r}(t) = \left\langle \tan^{-1}t, 2e^{2t}, 8te^t\right\rangle \quad\Rightarrow\quad \mathbf{r}'(t) = \left\langle 1/(1+t^2), 4e^{2t}, 8te^t+8e^t\right\rangle \quad\Rightarrow\quad \mathbf{r}'(0) = \langle 1,4,8\rangle$.

So $|\mathbf{r}'(0)| = \sqrt{1^2+4^2+8^2} = \sqrt{81} = 9$ and $\mathbf{T}(0) = \dfrac{\mathbf{r}'(0)}{|\mathbf{r}'(0)|} = \frac{1}{9}\langle 1,4,8\rangle = \left\langle \frac{1}{9}, \frac{4}{9}, \frac{8}{9}\right\rangle$.

19. $\mathbf{r}'(t) = -\sin t\,\mathbf{i} + 3\,\mathbf{j} + 4\cos 2t\,\mathbf{k} \quad\Rightarrow\quad \mathbf{r}'(0) = 3\,\mathbf{j} + 4\,\mathbf{k}$. Thus

$$\mathbf{T}(0) = \frac{\mathbf{r}'(0)}{|\mathbf{r}'(0)|} = \frac{1}{\sqrt{0^2+3^2+4^2}}\,(3\,\mathbf{j}+4\,\mathbf{k}) = \tfrac{1}{5}(3\,\mathbf{j}+4\,\mathbf{k}) = \tfrac{3}{5}\,\mathbf{j} + \tfrac{4}{5}\,\mathbf{k}.$$

20. $\mathbf{r}'(t) = 2\sin t\cos t\,\mathbf{i} - 2\cos t\sin t\,\mathbf{j} + 2\tan t\sec^2 t\,\mathbf{k} \quad\Rightarrow$

$\mathbf{r}'\left(\frac{\pi}{4}\right) = 2\cdot\frac{\sqrt{2}}{2}\cdot\frac{\sqrt{2}}{2}\,\mathbf{i} - 2\cdot\frac{\sqrt{2}}{2}\cdot\frac{\sqrt{2}}{2}\,\mathbf{j} + 2\cdot 1\cdot(\sqrt{2})^2\,\mathbf{k} = \mathbf{i} - \mathbf{j} + 4\,\mathbf{k}$ and $\left|\mathbf{r}'\left(\frac{\pi}{4}\right)\right| = \sqrt{1+1+16} = \sqrt{18} = 3\sqrt{2}$. Thus

$$\mathbf{T}\left(\tfrac{\pi}{4}\right) = \frac{\mathbf{r}'\left(\frac{\pi}{4}\right)}{\left|\mathbf{r}'\left(\frac{\pi}{4}\right)\right|} = \frac{1}{3\sqrt{2}}\,(\mathbf{i}-\mathbf{j}+4\,\mathbf{k}) = \frac{1}{3\sqrt{2}}\,\mathbf{i} - \frac{1}{3\sqrt{2}}\,\mathbf{j} + \frac{4}{3\sqrt{2}}\,\mathbf{k}.$$

21. $\mathbf{r}(t) = \left\langle t, t^2, t^3\right\rangle \quad\Rightarrow\quad \mathbf{r}'(t) = \left\langle 1, 2t, 3t^2\right\rangle$. Then $\mathbf{r}'(1) = \langle 1,2,3\rangle$ and $|\mathbf{r}'(1)| = \sqrt{1^2+2^2+3^2} = \sqrt{14}$, so

$\mathbf{T}(1) = \dfrac{\mathbf{r}'(1)}{|\mathbf{r}'(1)|} = \frac{1}{\sqrt{14}}\langle 1,2,3\rangle = \left\langle \frac{1}{\sqrt{14}}, \frac{2}{\sqrt{14}}, \frac{3}{\sqrt{14}}\right\rangle$. $\quad\mathbf{r}''(t) = \langle 0, 2, 6t\rangle$, so

$$\mathbf{r}'(t)\times\mathbf{r}''(t) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ 1 & 2t & 3t^2 \\ 0 & 2 & 6t \end{vmatrix} = \begin{vmatrix} 2t & 3t^2 \\ 2 & 6t \end{vmatrix}\mathbf{i} - \begin{vmatrix} 1 & 3t^2 \\ 0 & 6t \end{vmatrix}\mathbf{j} + \begin{vmatrix} 1 & 2t \\ 0 & 2 \end{vmatrix}\mathbf{k}$$
$$= (12t^2 - 6t^2)\,\mathbf{i} - (6t-0)\,\mathbf{j} + (2-0)\,\mathbf{k} = \left\langle 6t^2, -6t, 2\right\rangle$$

22. $\mathbf{r}(t) = \left\langle e^{2t}, e^{-2t}, te^{2t}\right\rangle \quad\Rightarrow\quad \mathbf{r}'(t) = \left\langle 2e^{2t}, -2e^{-2t}, (2t+1)e^{2t}\right\rangle \quad\Rightarrow\quad \mathbf{r}'(0) = \left\langle 2e^0, -2e^0, (0+1)e^0\right\rangle = \langle 2,-2,1\rangle$

and $|\mathbf{r}'(0)| = \sqrt{2^2+(-2)^2+1^2} = 3$. Then $\mathbf{T}(0) = \dfrac{\mathbf{r}'\,(0)}{|\mathbf{r}'\,(0)|} = \frac{1}{3}\langle 2,-2,1\rangle = \left\langle \frac{2}{3}, -\frac{2}{3}, \frac{1}{3}\right\rangle$.

$\mathbf{r}''(t) = \left\langle 4e^{2t}, 4e^{-2t}, (4t+4)e^{2t}\right\rangle \quad\Rightarrow\quad \mathbf{r}''(0) = \left\langle 4e^0, 4e^0, (0+4)e^0\right\rangle = \langle 4,4,4\rangle$.

$$\mathbf{r}'(t)\cdot\mathbf{r}''(t) = \left\langle 2e^{2t}, -2e^{-2t}, (2t+1)e^{2t}\right\rangle\cdot\left\langle 4e^{2t}, 4e^{-2t}, (4t+4)e^{2t}\right\rangle$$
$$= (2e^{2t})(4e^{2t}) + (-2e^{-2t})(4e^{-2t}) + ((2t+1)e^{2t})((4t+4)e^{2t})$$
$$= 8e^{4t} - 8e^{-4t} + (8t^2+12t+4)e^{4t} = (8t^2+12t+12)e^{4t} - 8e^{-4t}$$

23. The vector equation for the curve is $\mathbf{r}(t) = \left\langle t^2 + 1, 4\sqrt{t}, e^{t^2 - t} \right\rangle$, so $\mathbf{r}'(t) = \left\langle 2t, 2/\sqrt{t}, (2t-1)e^{t^2-t} \right\rangle$. The point $(2, 4, 1)$ corresponds to $t = 1$, so the tangent vector there is $\mathbf{r}'(1) = \langle 2, 2, 1 \rangle$. Thus, the tangent line goes through the point $(2, 4, 1)$ and is parallel to the vector $\langle 2, 2, 1 \rangle$. Parametric equations are $x = 2 + 2t$, $y = 4 + 2t$, $z = 1 + t$.

24. The vector equation for the curve is $\mathbf{r}(t) = \langle \ln(t+1), t\cos 2t, 2^t \rangle$, so $\mathbf{r}'(t) = \langle 1/(t+1), \cos 2t - 2t\sin 2t, 2^t \ln 2 \rangle$. The point $(0, 0, 1)$ corresponds to $t = 0$, so the tangent vector there is $\mathbf{r}'(0) = \langle 1, 1, \ln 2 \rangle$. Thus, the tangent line goes through the point $(0, 0, 1)$ and is parallel to the vector $\langle 1, 1, \ln 2 \rangle$. Parametric equations are $x = 0 + 1 \cdot t = t$, $y = 0 + 1 \cdot t = t$, $z = 1 + (\ln 2)t$.

25. The vector equation for the curve is $\mathbf{r}(t) = \langle e^{-t}\cos t, e^{-t}\sin t, e^{-t} \rangle$, so

$$\begin{aligned} \mathbf{r}'(t) &= \langle e^{-t}(-\sin t) + (\cos t)(-e^{-t}), e^{-t}\cos t + (\sin t)(-e^{-t}), (-e^{-t}) \rangle \\ &= \langle -e^{-t}(\cos t + \sin t), e^{-t}(\cos t - \sin t), -e^{-t} \rangle \end{aligned}$$

The point $(1, 0, 1)$ corresponds to $t = 0$, so the tangent vector there is $\mathbf{r}'(0) = \langle -e^0(\cos 0 + \sin 0), e^0(\cos 0 - \sin 0), -e^0 \rangle = \langle -1, 1, -1 \rangle$. Thus, the tangent line is parallel to the vector $\langle -1, 1, -1 \rangle$ and parametric equations are $x = 1 + (-1)t = 1 - t$, $y = 0 + 1 \cdot t = t$, $z = 1 + (-1)t = 1 - t$.

26. The vector equation for the curve is $\mathbf{r}(t) = \langle \sqrt{t^2+3}, \ln(t^2+3), t \rangle$, so $\mathbf{r}'(t) = \langle t/\sqrt{t^2+3}, 2t/(t^2+3), 1 \rangle$. At $(2, \ln 4, 1)$, $t = 1$ and $\mathbf{r}'(1) = \left\langle \frac{1}{2}, \frac{1}{2}, 1 \right\rangle$. Thus, parametric equations of the tangent line are $x = 2 + \frac{1}{2}t$, $y = \ln 4 + \frac{1}{2}t$, $z = 1 + t$.

27. First we parametrize the curve C of intersection. The projection of C onto the xy-plane is contained in the circle $x^2 + y^2 = 25$, $z = 0$, so we can write $x = 5\cos t$, $y = 5\sin t$. C also lies on the cylinder $y^2 + z^2 = 20$, and $z \geq 0$ near the point $(3, 4, 2)$, so we can write $z = \sqrt{20 - y^2} = \sqrt{20 - 25\sin^2 t}$. A vector equation then for C is

$\mathbf{r}(t) = \left\langle 5\cos t, 5\sin t, \sqrt{20 - 25\sin^2 t} \right\rangle \Rightarrow \mathbf{r}'(t) = \left\langle -5\sin t, 5\cos t, \frac{1}{2}(20 - 25\sin^2 t)^{-1/2}(-50\sin t\cos t) \right\rangle$.

The point $(3, 4, 2)$ corresponds to $t = \cos^{-1}\left(\frac{3}{5}\right)$, so the tangent vector there is

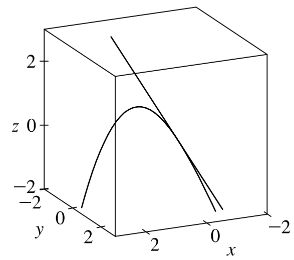
$\mathbf{r}'\left(\cos^{-1}\left(\frac{3}{5}\right)\right) = \left\langle -5\left(\frac{4}{5}\right), 5\left(\frac{3}{5}\right), \frac{1}{2}\left(20 - 25\left(\frac{4}{5}\right)^2\right)^{-1/2}\left(-50\left(\frac{4}{5}\right)\left(\frac{3}{5}\right)\right) \right\rangle = \langle -4, 3, -6 \rangle$.

The tangent line is parallel to this vector and passes through $(3, 4, 2)$, so a vector equation for the line is $\mathbf{r}(t) = (3 - 4t)\mathbf{i} + (4 + 3t)\mathbf{j} + (2 - 6t)\mathbf{k}$.

28. $\mathbf{r}(t) = \langle 2\cos t, 2\sin t, e^t \rangle \Rightarrow \mathbf{r}'(t) = \langle -2\sin t, 2\cos t, e^t \rangle$. The tangent line to the curve is parallel to the plane when the curve's tangent vector is orthogonal to the plane's normal vector. Thus we require $\langle -2\sin t, 2\cos t, e^t \rangle \cdot \langle \sqrt{3}, 1, 0 \rangle = 0 \Rightarrow$ $-2\sqrt{3}\sin t + 2\cos t + 0 = 0 \Rightarrow \tan t = \frac{1}{\sqrt{3}} \Rightarrow t = \frac{\pi}{6}$ [since $0 \leq t \leq \pi$].

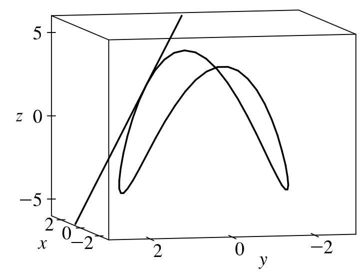
$\mathbf{r}\left(\frac{\pi}{6}\right) = \left\langle \sqrt{3}, 1, e^{\pi/6} \right\rangle$, so the point is $(\sqrt{3}, 1, e^{\pi/6})$.

29. $\mathbf{r}(t) = \langle t, e^{-t}, 2t - t^2 \rangle \Rightarrow \mathbf{r}'(t) = \langle 1, -e^{-t}, 2 - 2t \rangle$. At $(0, 1, 0)$, $t = 0$ and $\mathbf{r}'(0) = \langle 1, -1, 2 \rangle$. Thus, parametric equations of the tangent line are $x = t$, $y = 1 - t$, $z = 2t$.

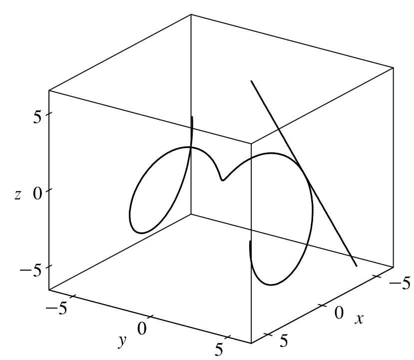


30. $\mathbf{r}(t) = \langle 2\cos t, 2\sin t, 4\cos 2t \rangle$,

$\mathbf{r}'(t) = \langle -2\sin t, 2\cos t, -8\sin 2t \rangle$. At $(\sqrt{3}, 1, 2)$, $t = \frac{\pi}{6}$ and $\mathbf{r}'(\frac{\pi}{6}) = \langle -1, \sqrt{3}, -4\sqrt{3} \rangle$. Thus, parametric equations of the tangent line are $x = \sqrt{3} - t$, $y = 1 + \sqrt{3}\,t$, $z = 2 - 4\sqrt{3}\,t$.



31. $\mathbf{r}(t) = \langle t\cos t, t, t\sin t \rangle \Rightarrow \mathbf{r}'(t) = \langle \cos t - t\sin t, 1, t\cos t + \sin t \rangle$. At $(-\pi, \pi, 0)$, $t = \pi$ and $\mathbf{r}'(\pi) = \langle -1, 1, -\pi \rangle$. Thus, parametric equations of the tangent line are $x = -\pi - t$, $y = \pi + t$, $z = -\pi t$.



32. (a) The tangent line at $t = 0$ is the line through the point with position vector $\mathbf{r}(0) = \langle \sin 0, 2\sin 0, \cos 0 \rangle = \langle 0, 0, 1 \rangle$, and in the direction of the tangent vector, $\mathbf{r}'(0) = \langle \pi\cos 0, 2\pi\cos 0, -\pi\sin 0 \rangle = \langle \pi, 2\pi, 0 \rangle$. So an equation of the line is $\langle x, y, z \rangle = \mathbf{r}(0) + u\,\mathbf{r}'(0) = \langle 0 + \pi u, 0 + 2\pi u, 1 \rangle = \langle \pi u, 2\pi u, 1 \rangle$.

$\mathbf{r}\left(\frac{1}{2}\right) = \left\langle \sin\frac{\pi}{2}, 2\sin\frac{\pi}{2}, \cos\frac{\pi}{2} \right\rangle = \langle 1, 2, 0 \rangle$,

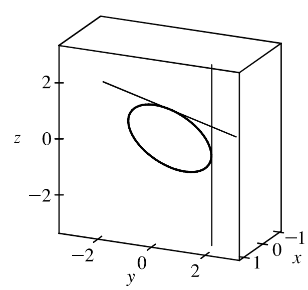
$\mathbf{r}'\left(\frac{1}{2}\right) = \left\langle \pi\cos\frac{\pi}{2}, 2\pi\cos\frac{\pi}{2}, -\pi\sin\frac{\pi}{2} \right\rangle = \langle 0, 0, -\pi \rangle$.

So the equation of the second line is

$\langle x, y, z \rangle = \langle 1, 2, 0 \rangle + v\,\langle 0, 0, -\pi \rangle = \langle 1, 2, -\pi v \rangle$.

The lines intersect where $\langle \pi u, 2\pi u, 1 \rangle = \langle 1, 2, -\pi v \rangle$, so the point of intersection is $(1, 2, 1)$.

(b)



33. The angle of intersection of the two curves is the angle between the two tangent vectors to the curves at the point of intersection. Since $\mathbf{r}_1'(t) = \langle 1, 2t, 3t^2 \rangle$ and $t = 0$ at $(0, 0, 0)$, $\mathbf{r}_1'(0) = \langle 1, 0, 0 \rangle$ is a tangent vector to $\mathbf{r}_1$ at $(0, 0, 0)$. Similarly,

$\mathbf{r}_2'(t) = \langle \cos t, 2\cos 2t, 1\rangle$ and since $\mathbf{r}_2(0) = \langle 0,0,0\rangle$, $\mathbf{r}_2'(0) = \langle 1,2,1\rangle$ is a tangent vector to $\mathbf{r}_2$ at $(0,0,0)$. If θ is the angle between these two tangent vectors, then $\cos\theta = \frac{1}{\sqrt{1}\sqrt{6}}\langle 1,0,0\rangle \cdot \langle 1,2,1\rangle = \frac{1}{\sqrt{6}}$ and $\theta = \cos^{-1}\left(\frac{1}{\sqrt{6}}\right) \approx 66°$.

34. To find the point of intersection, we must find the values of t and s which satisfy the following three equations simultaneously: $t = 3 - s$, $1 - t = s - 2$, $3 + t^2 = s^2$. Solving the last two equations gives $t = 1$, $s = 2$ (check these in the first equation). Thus the point of intersection is $(1,0,4)$. To find the angle θ of intersection, we proceed as in Exercise 33. The tangent vectors to the respective curves at $(1,0,4)$ are $\mathbf{r}_1'(1) = \langle 1,-1,2\rangle$ and $\mathbf{r}_2'(2) = \langle -1,1,4\rangle$. So

$\cos\theta = \frac{1}{\sqrt{6}\sqrt{18}}(-1-1+8) = \frac{6}{6\sqrt{3}} = \frac{1}{\sqrt{3}}$ and $\theta = \cos^{-1}\left(\frac{1}{\sqrt{3}}\right) \approx 55°$.

Note: In Exercise 33, the curves intersect when the value of both parameters is zero. However, as seen in this exercise, it is not necessary for the parameters to be of equal value at the point of intersection.

35.
$$\begin{aligned}\int_0^2 (t\,\mathbf{i} - t^3\,\mathbf{j} + 3t^5\,\mathbf{k})\,dt &= \left(\int_0^2 t\,dt\right)\mathbf{i} - \left(\int_0^2 t^3\,dt\right)\mathbf{j} + \left(\int_0^2 3t^5\,dt\right)\mathbf{k} \\ &= \left[\tfrac{1}{2}t^2\right]_0^2\mathbf{i} - \left[\tfrac{1}{4}t^4\right]_0^2\mathbf{j} + \left[\tfrac{1}{2}t^6\right]_0^2\mathbf{k} \\ &= \tfrac{1}{2}(4-0)\,\mathbf{i} - \tfrac{1}{4}(16-0)\,\mathbf{j} + \tfrac{1}{2}(64-0)\,\mathbf{k} = 2\,\mathbf{i} - 4\,\mathbf{j} + 32\,\mathbf{k}\end{aligned}$$

36.
$$\begin{aligned}\int_1^4 \left(2t^{3/2}\,\mathbf{i} + (t+1)\sqrt{t}\,\mathbf{k}\right)dt &= \left(\int_1^4 2t^{3/2}\,dt\right)\mathbf{i} + \left[\int_1^4 (t^{3/2} + t^{1/2})\,dt\right]\mathbf{k} \\ &= \left[\tfrac{4}{5}t^{5/2}\right]_1^4\mathbf{i} + \left[\tfrac{2}{5}t^{5/2} + \tfrac{2}{3}t^{3/2}\right]_1^4\mathbf{k} \\ &= \tfrac{4}{5}(4^{5/2}-1)\,\mathbf{i} + \left(\tfrac{2}{5}(4)^{5/2} + \tfrac{2}{3}(4)^{3/2} - \tfrac{2}{5} - \tfrac{2}{3}\right)\mathbf{k} \\ &= \tfrac{4}{5}(31)\,\mathbf{i} + \left(\tfrac{2}{5}(32) + \tfrac{2}{3}(8) - \tfrac{2}{5} - \tfrac{2}{3}\right)\mathbf{k} = \tfrac{124}{5}\,\mathbf{i} + \tfrac{256}{15}\,\mathbf{k}\end{aligned}$$

37.
$$\begin{aligned}\int_0^1 \left(\frac{1}{t+1}\,\mathbf{i} + \frac{1}{t^2+1}\,\mathbf{j} + \frac{t}{t^2+1}\,\mathbf{k}\right)dt &= \left(\int_0^1 \frac{1}{t+1}\,dt\right)\mathbf{i} + \left(\int_0^1 \frac{1}{t^2+1}\,dt\right)\mathbf{j} + \left(\int_0^1 \frac{t}{t^2+1}\,dt\right)\mathbf{k} \\ &= \left[\ln|t+1|\right]_0^1\mathbf{i} + \left[\tan^{-1}t\right]_0^1\mathbf{j} + \left[\tfrac{1}{2}\ln(t^2+1)\right]_0^1\mathbf{k} \\ &= (\ln 2 - \ln 1)\,\mathbf{i} + \left(\tfrac{\pi}{4} - 0\right)\mathbf{j} + \tfrac{1}{2}(\ln 2 - \ln 1)\,\mathbf{k} = \ln 2\,\mathbf{i} + \tfrac{\pi}{4}\,\mathbf{j} + \tfrac{1}{2}\ln 2\,\mathbf{k}\end{aligned}$$

38. $\int_0^{\pi/4}(\sec t\tan t\,\mathbf{i} + t\cos 2t\,\mathbf{j} + \sin^2 2t\cos 2t\,\mathbf{k})\,dt$

$$= \left(\int_0^{\pi/4}\sec t\tan t\,dt\right)\mathbf{i} + \left(\int_0^{\pi/4} t\cos 2t\,dt\right)\mathbf{j} + \left(\int_0^{\pi/4}\sin^2 2t\cos 2t\,dt\right)\mathbf{k}$$

$$= \left[\sec t\right]_0^{\pi/4}\mathbf{i} + \left(\left[\tfrac{1}{2}t\sin 2t\right]_0^{\pi/4} - \int_0^{\pi/4}\tfrac{1}{2}\sin 2t\,dt\right)\mathbf{j} + \left[\tfrac{1}{6}\sin^3 2t\right]_0^{\pi/4}\mathbf{k}$$

[For the y-component, integrate by parts with $u = t$, $dv = \cos 2t\,dt$.]

$$= \left(\sec\tfrac{\pi}{4} - \sec 0\right)\mathbf{i} + \left(\tfrac{\pi}{8}\sin\tfrac{\pi}{2} - 0 - \left[-\tfrac{1}{4}\cos 2t\right]_0^{\pi/4}\right)\mathbf{j} + \tfrac{1}{6}\left(\sin^3\tfrac{\pi}{2} - \sin^3 0\right)\mathbf{k}$$

$$= (\sqrt{2}-1)\,\mathbf{i} + \left(\tfrac{\pi}{8} + \tfrac{1}{4}\cos\tfrac{\pi}{2} - \tfrac{1}{4}\cos 0\right)\mathbf{j} + \tfrac{1}{6}(1-0)\,\mathbf{k} = (\sqrt{2}-1)\,\mathbf{i} + \left(\tfrac{\pi}{8} - \tfrac{1}{4}\right)\mathbf{j} + \tfrac{1}{6}\,\mathbf{k}$$

39.
$$\begin{aligned}\int(\sec^2 t\,\mathbf{i} + t(t^2+1)^3\,\mathbf{j} + t^2\ln t\,\mathbf{k})\,dt &= \left(\int \sec^2 t\,dt\right)\mathbf{i} + \left(\int t(t^2+1)^3\,dt\right)\mathbf{j} + \left(\int t^2\ln t\,dt\right)\mathbf{k} \\ &= \tan t\,\mathbf{i} + \tfrac{1}{8}(t^2+1)^4\,\mathbf{j} + \left(\tfrac{1}{3}t^3\ln t - \tfrac{1}{9}t^3\right)\mathbf{k} + \mathbf{C},\end{aligned}$$

where $\mathbf{C}$ is a vector constant of integration. [For the z-component, integrate by parts with $u = \ln t$, $dv = t^2\,dt$.]

40. $\int \left(te^{2t}\,\mathbf{i} + \frac{t}{1-t}\,\mathbf{j} + \frac{1}{\sqrt{1-t^2}}\,\mathbf{k} \right) dt = \left(\int te^{2t}\,dt \right) \mathbf{i} + \left(\int \frac{t}{1-t}\,dt \right) \mathbf{j} + \left(\int \frac{1}{\sqrt{1-t^2}}\,dt \right) \mathbf{k}$

$$= \left(\tfrac{1}{2}te^{2t} - \int \tfrac{1}{2}e^{2t}\,dt \right) \mathbf{i} + \left[\int \left(-1 + \frac{1}{1-t} \right) dt \right] \mathbf{j} + \left(\int \frac{1}{\sqrt{1-t^2}}\,dt \right) \mathbf{k}$$

$$= \left(\tfrac{1}{2}te^{2t} - \tfrac{1}{4}e^{2t} \right) \mathbf{i} + \left(-t - \ln|\,1-t\,| \right) \mathbf{j} + \sin^{-1} t\,\mathbf{k} + \mathbf{C}$$

41. $\mathbf{r}'(t) = 2t\,\mathbf{i} + 3t^2\,\mathbf{j} + \sqrt{t}\,\mathbf{k} \quad \Rightarrow \quad \mathbf{r}(t) = t^2\,\mathbf{i} + t^3\,\mathbf{j} + \frac{2}{3}t^{3/2}\,\mathbf{k} + \mathbf{C}$, where $\mathbf{C}$ is a constant vector.

But $\mathbf{i} + \mathbf{j} = \mathbf{r}(1) = \mathbf{i} + \mathbf{j} + \frac{2}{3}\mathbf{k} + \mathbf{C}$. Thus $\mathbf{C} = -\frac{2}{3}\mathbf{k}$ and $\mathbf{r}(t) = t^2\,\mathbf{i} + t^3\,\mathbf{j} + \left(\frac{2}{3}t^{3/2} - \frac{2}{3} \right) \mathbf{k}$.

42. $\mathbf{r}'(t) = t\,\mathbf{i} + e^t\,\mathbf{j} + te^t\,\mathbf{k} \quad \Rightarrow \quad \mathbf{r}(t) = \frac{1}{2}t^2\,\mathbf{i} + e^t\,\mathbf{j} + \left(te^t - e^t \right)\,\mathbf{k} + \mathbf{C}$. But $\mathbf{i} + \mathbf{j} + \mathbf{k} = \mathbf{r}(0) = \mathbf{j} - \mathbf{k} + \mathbf{C}$.

Thus $\mathbf{C} = \mathbf{i} + 2\,\mathbf{k}$ and $\mathbf{r}(t) = \left(\frac{1}{2}t^2 + 1 \right) \mathbf{i} + e^t\,\mathbf{j} + \left(te^t - e^t + 2 \right) \mathbf{k}$.

For Exercises 43–46, let $\mathbf{u}(t) = \langle u_1(t), u_2(t), u_3(t) \rangle$ and $\mathbf{v}(t) = \langle v_1(t), v_2(t), v_3(t) \rangle$. In each of these exercises, the procedure is to apply Theorem 2 so that the corresponding properties of derivatives of real-valued functions can be used.

43. $\frac{d}{dt}\left[\mathbf{u}(t) + \mathbf{v}(t) \right] = \frac{d}{dt} \langle u_1(t) + v_1(t), u_2(t) + v_2(t), u_3(t) + v_3(t) \rangle$

$$= \left\langle \frac{d}{dt}\left[u_1(t) + v_1(t) \right], \frac{d}{dt}\left[u_2(t) + v_2(t) \right], \frac{d}{dt}\left[u_3(t) + v_3(t) \right] \right\rangle$$

$$= \langle u_1'(t) + v_1'(t), u_2'(t) + v_2'(t), u_3'(t) + v_3'(t) \rangle$$

$$= \langle u_1'(t), u_2'(t), u_3'(t) \rangle + \langle v_1'(t), v_2'(t), v_3'(t) \rangle = \mathbf{u}'(t) + \mathbf{v}'(t)$$

44. $\frac{d}{dt}\left[f(t)\,\mathbf{u}(t) \right] = \frac{d}{dt} \langle f(t)u_1(t), f(t)u_2(t), f(t)u_3(t) \rangle$

$$= \left\langle \frac{d}{dt}\left[f(t)u_1(t) \right], \frac{d}{dt}\left[f(t)u_2(t) \right], \frac{d}{dt}\left[f(t)u_3(t) \right] \right\rangle$$

$$= \langle f'(t)u_1(t) + f(t)u_1'(t), f'(t)u_2(t) + f(t)u_2'(t), f'(t)u_3(t) + f(t)u_3'(t) \rangle$$

$$= f'(t) \langle u_1(t), u_2(t), u_3(t) \rangle + f(t) \langle u_1'(t), u_2'(t), u_3'(t) \rangle = f'(t)\,\mathbf{u}(t) + f(t)\,\mathbf{u}'(t)$$

45. $\frac{d}{dt}\left[\mathbf{u}(t) \times \mathbf{v}(t) \right] = \frac{d}{dt} \langle u_2(t)v_3(t) - u_3(t)v_2(t), u_3(t)v_1(t) - u_1(t)v_3(t), u_1(t)v_2(t) - u_2(t)v_1(t) \rangle$

$$\begin{aligned} = \langle & u_2'v_3(t) + u_2(t)v_3'(t) - u_3'(t)v_2(t) - u_3(t)v_2'(t), \\ & u_3'(t)v_1(t) + u_3(t)v_1'(t) - u_1'(t)v_3(t) - u_1(t)v_3'(t), \\ & u_1'(t)v_2(t) + u_1(t)v_2'(t) - u_2'(t)v_1(t) - u_2(t)v_1'(t) \rangle \end{aligned}$$

$$\begin{aligned} = & \langle u_2'(t)v_3(t) - u_3'(t)v_2(t), u_3'(t)v_1(t) - u_1'(t)v_3(t), u_1'(t)v_2(t) - u_2'(t)v_1(t) \rangle \\ & + \langle u_2(t)v_3'(t) - u_3(t)v_2'(t), u_3(t)v_1'(t) - u_1(t)v_3'(t), u_1(t)v_2'(t) - u_2(t)v_1'(t) \rangle \end{aligned}$$

$$= \mathbf{u}'(t) \times \mathbf{v}(t) + \mathbf{u}(t) \times \mathbf{v}'(t)$$

Alternate solution: Let $\mathbf{r}(t) = \mathbf{u}(t) \times \mathbf{v}(t)$. Then

$$\begin{aligned} \mathbf{r}(t+h) - \mathbf{r}(t) &= \left[\mathbf{u}(t+h) \times \mathbf{v}(t+h) \right] - \left[\mathbf{u}(t) \times \mathbf{v}(t) \right] \\ &= \left[\mathbf{u}(t+h) \times \mathbf{v}(t+h) \right] - \left[\mathbf{u}(t) \times \mathbf{v}(t) \right] + \left[\mathbf{u}(t+h) \times \mathbf{v}(t) \right] - \left[\mathbf{u}(t+h) \times \mathbf{v}(t) \right] \\ &= \mathbf{u}(t+h) \times \left[\mathbf{v}(t+h) - \mathbf{v}(t) \right] + \left[\mathbf{u}(t+h) - \mathbf{u}(t) \right] \times \mathbf{v}(t) \end{aligned}$$

(Be careful of the order of the cross product.) Dividing through by h and taking the limit as $h \to 0$ we have

$$\mathbf{r}'(t) = \lim_{h\to 0} \frac{\mathbf{u}(t+h) \times [\mathbf{v}(t+h) - \mathbf{v}(t)]}{h} + \lim_{h\to 0} \frac{[\mathbf{u}(t+h) - \mathbf{u}(t)] \times \mathbf{v}(t)}{h} = \mathbf{u}(t) \times \mathbf{v}'(t) + \mathbf{u}'(t) \times \mathbf{v}(t)$$

by Exercise 13.1.53(a) and Definition 1.

46. $\frac{d}{dt}\left[\mathbf{u}(f(t))\right] = \frac{d}{dt}\left\langle u_1(f(t)), u_2(f(t)), u_3(f(t))\right\rangle = \left\langle \frac{d}{dt}\left[u_1(f(t))\right], \frac{d}{dt}\left[u_2(f(t))\right], \frac{d}{dt}\left[u_3(f(t))\right]\right\rangle$

$$= \langle f'(t)u_1'(f(t)), f'(t)u_2'(f(t)), f'(t)u_3'(f(t))\rangle = f'(t)\,\mathbf{u}'(t)$$

47. $\frac{d}{dt}\left[\mathbf{u}(t)\cdot\mathbf{v}(t)\right] = \mathbf{u}'(t)\cdot\mathbf{v}(t) + \mathbf{u}(t)\cdot\mathbf{v}'(t)$ [by Formula 4 of Theorem 3]

$$= \langle \cos t, -\sin t, 1\rangle \cdot \langle t, \cos t, \sin t\rangle + \langle \sin t, \cos t, t\rangle \cdot \langle 1, -\sin t, \cos t\rangle$$
$$= t\cos t - \cos t\,\sin t + \sin t + \sin t - \cos t\,\sin t + t\cos t$$
$$= 2t\cos t + 2\sin t - 2\cos t\,\sin t$$

48. $\frac{d}{dt}\left[\mathbf{u}(t)\times\mathbf{v}(t)\right] = \mathbf{u}'(t)\times\mathbf{v}(t) + \mathbf{u}(t)\times\mathbf{v}'(t)$ [by Formula 5 of Theorem 3]

$$= \langle \cos t, -\sin t, 1\rangle \times \langle t, \cos t, \sin t\rangle + \langle \sin t, \cos t, t\rangle \times \langle 1, -\sin t, \cos t\rangle$$
$$= \left\langle -\sin^2 t - \cos t, t - \cos t\,\sin t, \cos^2 t + t\sin t\right\rangle + \left\langle \cos^2 t + t\sin t, t - \cos t\,\sin t, -\sin^2 t - \cos t\right\rangle$$
$$= \left\langle \cos^2 t - \sin^2 t - \cos t + t\sin t, 2t - 2\cos t\,\sin t, \cos^2 t - \sin^2 t - \cos t + t\sin t\right\rangle$$

49. By Formula 4 of Theorem 3, $f'(t) = \mathbf{u}'(t)\cdot\mathbf{v}(t) + \mathbf{u}(t)\cdot\mathbf{v}'(t)$, and $\mathbf{v}'(t) = \left\langle 1, 2t, 3t^2\right\rangle$, so

$f'(2) = \mathbf{u}'(2)\cdot\mathbf{v}(2) + \mathbf{u}(2)\cdot\mathbf{v}'(2) = \langle 3,0,4\rangle\cdot\langle 2,4,8\rangle + \langle 1,2,-1\rangle\cdot\langle 1,4,12\rangle = 6+0+32+1+8-12 = 35.$

50. By Formula 5 of Theorem 3, $\mathbf{r}'(t) = \mathbf{u}'(t)\times\mathbf{v}(t) + \mathbf{u}(t)\times\mathbf{v}'(t)$, so

$$\mathbf{r}'(2) = \mathbf{u}'(2)\times\mathbf{v}(2) + \mathbf{u}(2)\times\mathbf{v}'(2) = \langle 3,0,4\rangle\times\langle 2,4,8\rangle + \langle 1,2,-1\rangle\times\langle 1,4,12\rangle$$
$$= \langle -16,-16,12\rangle + \langle 28,-13,2\rangle = \langle 12,-29,14\rangle$$

51. $\mathbf{r}(t) = \mathbf{a}\cos\omega t + \mathbf{b}\sin\omega t \quad\Rightarrow\quad \mathbf{r}'(t) = -\mathbf{a}\,\omega\sin\omega t + \mathbf{b}\,\omega\cos\omega t$ by Formulas 1 and 3 of Theorem 3. Then

$\mathbf{r}(t)\times\mathbf{r}'(t) = (\mathbf{a}\cos\omega t + \mathbf{b}\sin\omega t)\times(-\mathbf{a}\,\omega\sin\omega t + \mathbf{b}\,\omega\cos\omega t)$

$$= (\mathbf{a}\cos\omega t + \mathbf{b}\sin\omega t)\times(-\mathbf{a}\,\omega\sin\omega t) + (\mathbf{a}\cos\omega t + \mathbf{b}\sin\omega t)\times(\mathbf{b}\,\omega\cos\omega t)$$
[by Property 3 of Theorem 12.4.11]

$$= \mathbf{a}\cos\omega t\times(-\mathbf{a}\,\omega\sin\omega t) + \mathbf{b}\sin\omega t\times(-\mathbf{a}\,\omega\sin\omega t) + \mathbf{a}\cos\omega t\times\mathbf{b}\,\omega\cos\omega t + \mathbf{b}\sin\omega t\times\mathbf{b}\,\omega\cos\omega t$$
[by Property 4]

$$= (\cos\omega t)(-\omega\sin\omega t)(\mathbf{a}\times\mathbf{a}) + (\sin\omega t)(-\omega\sin\omega t)(\mathbf{b}\times\mathbf{a}) + (\cos\omega t)(\omega\cos\omega t)(\mathbf{a}\times\mathbf{b}) + (\sin\omega t)(\omega\cos\omega t)(\mathbf{b}\times\mathbf{b})$$
[by Property 2]

$$= \mathbf{0} + \left(\omega\sin^2\omega t\right)(\mathbf{a}\times\mathbf{b}) + \left(\omega\cos^2\omega t\right)(\mathbf{a}\times\mathbf{b}) + \mathbf{0}$$
[by Property 1 and Example 12.4.2]

$$= \omega\left(\sin^2\omega t + \cos^2\omega t\right)(\mathbf{a}\times\mathbf{b}) = \omega\,(\mathbf{a}\times\mathbf{b}) = \omega\,\mathbf{a}\times\mathbf{b}$$
[by Property 2]

52. From Exercise 51, $\mathbf{r}'(t) = -\mathbf{a}\,\omega\sin\omega t + \mathbf{b}\,\omega\cos\omega t \quad\Rightarrow\quad \mathbf{r}''(t) = -\mathbf{a}\,\omega^2\cos\omega t - \mathbf{b}\,\omega^2\sin\omega t$. Then

$$\begin{aligned}\mathbf{r}''(t) + \omega^2\mathbf{r}(t) &= \left(-\mathbf{a}\,\omega^2\cos\omega t - \mathbf{b}\,\omega^2\sin\omega t\right) + \omega^2\left(\mathbf{a}\cos\omega t + \mathbf{b}\sin\omega t\right)\\ &= -\mathbf{a}\,\omega^2\cos\omega t - \mathbf{b}\,\omega^2\sin\omega t + \mathbf{a}\,\omega^2\cos\omega t + \mathbf{b}\,\omega^2\sin\omega t = \mathbf{0}\end{aligned}$$

53. $\dfrac{d}{dt}\left[\mathbf{r}(t)\times\mathbf{r}'(t)\right] = \mathbf{r}'(t)\times\mathbf{r}'(t) + \mathbf{r}(t)\times\mathbf{r}''(t)$ by Formula 5 of Theorem 3. But $\mathbf{r}'(t)\times\mathbf{r}'(t) = \mathbf{0}$ (by Example 12.4.2).

Thus, $\dfrac{d}{dt}\left[\mathbf{r}(t)\times\mathbf{r}'(t)\right] = \mathbf{r}(t)\times\mathbf{r}''(t)$.

54.
$$\begin{aligned}\frac{d}{dt}\left(\mathbf{u}(t)\cdot\left[\mathbf{v}(t)\times\mathbf{w}(t)\right]\right) &= \mathbf{u}'(t)\cdot\left[\mathbf{v}(t)\times\mathbf{w}(t)\right] + \mathbf{u}(t)\cdot\frac{d}{dt}\left[\mathbf{v}(t)\times\mathbf{w}(t)\right]\\ &= \mathbf{u}'(t)\cdot\left[\mathbf{v}(t)\times\mathbf{w}(t)\right] + \mathbf{u}(t)\cdot\left[\mathbf{v}'(t)\times\mathbf{w}(t) + \mathbf{v}(t)\times\mathbf{w}'(t)\right]\\ &= \mathbf{u}'(t)\cdot\left[\mathbf{v}(t)\times\mathbf{w}(t)\right] + \mathbf{u}(t)\cdot\left[\mathbf{v}'(t)\times\mathbf{w}(t)\right] + \mathbf{u}(t)\cdot\left[\mathbf{v}(t)\times\mathbf{w}'(t)\right]\\ &= \mathbf{u}'(t)\cdot\left[\mathbf{v}(t)\times\mathbf{w}(t)\right] - \mathbf{v}'(t)\cdot\left[\mathbf{u}(t)\times\mathbf{w}(t)\right] + \mathbf{w}'(t)\cdot\left[\mathbf{u}(t)\times\mathbf{v}(t)\right]\end{aligned}$$

55. $\dfrac{d}{dt}\left|\mathbf{r}(t)\right| = \dfrac{d}{dt}\left[\mathbf{r}(t)\cdot\mathbf{r}(t)\right]^{1/2} = \frac{1}{2}\left[\mathbf{r}(t)\cdot\mathbf{r}(t)\right]^{-1/2}\left[2\mathbf{r}(t)\cdot\mathbf{r}'(t)\right] = \dfrac{1}{\left|\mathbf{r}(t)\right|}\,\mathbf{r}(t)\cdot\mathbf{r}'(t)$

56. Since $\mathbf{r}(t)\cdot\mathbf{r}'(t) = 0$, we have $0 = 2\mathbf{r}(t)\cdot\mathbf{r}'(t) = \dfrac{d}{dt}\left[\mathbf{r}(t)\cdot\mathbf{r}(t)\right] = \dfrac{d}{dt}\left|\mathbf{r}(t)\right|^2$. Thus $\left|\mathbf{r}(t)\right|^2$, and so $\left|\mathbf{r}(t)\right|$, is a constant, and hence the curve lies on a sphere with center the origin.

57. Since $\mathbf{u}(t) = \mathbf{r}(t)\cdot\left[\mathbf{r}'(t)\times\mathbf{r}''(t)\right]$,

$$\begin{aligned}\mathbf{u}'(t) &= \mathbf{r}'(t)\cdot\left[\mathbf{r}'(t)\times\mathbf{r}''(t)\right] + \mathbf{r}(t)\cdot\frac{d}{dt}\left[\mathbf{r}'(t)\times\mathbf{r}''(t)\right]\\ &= 0 + \mathbf{r}(t)\cdot\left[\mathbf{r}''(t)\times\mathbf{r}''(t) + \mathbf{r}'(t)\times\mathbf{r}'''(t)\right] &&\left[\text{since } \mathbf{r}'(t)\perp\mathbf{r}'(t)\times\mathbf{r}''(t)\right]\\ &= \mathbf{r}(t)\cdot\left[\mathbf{r}'(t)\times\mathbf{r}'''(t)\right] &&\left[\text{since } \mathbf{r}''(t)\times\mathbf{r}''(t) = \mathbf{0}\right]\end{aligned}$$

58. The tangent vector $\mathbf{r}'(t)$ is defined as $\displaystyle\lim_{h\to 0}\frac{\mathbf{r}(t+h)-\mathbf{r}(t)}{h}$. Here we assume that this limit exists and $\mathbf{r}'(t)\neq\mathbf{0}$; then we know that this vector lies on the tangent line to the curve. As in Figure 1, let points P and Q have position vectors $\mathbf{r}(t)$ and $\mathbf{r}(t+h)$. The vector $\mathbf{r}(t+h)-\mathbf{r}(t)$ points from P to Q, so $\mathbf{r}(t+h)-\mathbf{r}(t) = \overrightarrow{PQ}$. If $h > 0$ then $t < t+h$, so Q lies "ahead" of P on the curve. If h is sufficiently small (we can take h to be as small as we like since $h\to 0$) then $\overrightarrow{PQ}$ approximates the curve from P to Q and hence points approximately in the direction of the curve as t increases. Since h is positive, $\dfrac{1}{h}\,\overrightarrow{PQ} = \dfrac{\mathbf{r}(t+h)-\mathbf{r}(t)}{h}$ points in the same direction. If $h < 0$, then $t > t+h$ so Q lies "behind" P on the curve. For h sufficiently small, $\overrightarrow{PQ}$ approximates the curve but points in the direction of decreasing t. However, h is negative, so $\dfrac{1}{h}\,\overrightarrow{PQ} = \dfrac{\mathbf{r}(t+h)-\mathbf{r}(t)}{h}$ points in the opposite direction, that is, in the direction of increasing t. In both cases, the difference quotient $\dfrac{\mathbf{r}(t+h)-\mathbf{r}(t)}{h}$ points in the direction of increasing t. The tangent vector $\mathbf{r}'(t)$ is the limit of this difference quotient, so it must also point in the direction of increasing t.

13.3 Arc Length and Curvature

1. $\mathbf{r}(t) = \langle t, 3\cos t, 3\sin t\rangle \Rightarrow \mathbf{r}'(t) = \langle 1, -3\sin t, 3\cos t\rangle \Rightarrow$

$|\mathbf{r}'(t)| = \sqrt{1^2 + (-3\sin t)^2 + (3\cos t)^2} = \sqrt{1 + 9(\sin^2 t + \cos^2 t)} = \sqrt{10}.$

Then using Formula 3, we have $L = \int_{-5}^{5} |\mathbf{r}'(t)|\,dt = \int_{-5}^{5} \sqrt{10}\,dt = \sqrt{10}\,t\Big]_{-5}^{5} = 10\sqrt{10}.$

2. $\mathbf{r}(t) = \left\langle 2t, t^2, \frac{1}{3}t^3\right\rangle \Rightarrow \mathbf{r}'(t) = \left\langle 2, 2t, t^2\right\rangle \Rightarrow$

$|\mathbf{r}'(t)| = \sqrt{2^2 + (2t)^2 + (t^2)^2} = \sqrt{4 + 4t^2 + t^4} = \sqrt{(2+t^2)^2} = 2 + t^2$ for $0 \le t \le 1$. Then using Formula 3, we have $L = \int_0^1 |\mathbf{r}'(t)|\,dt = \int_0^1 (2 + t^2)\,dt = 2t + \frac{1}{3}t^3\Big]_0^1 = \frac{7}{3}.$

3. $\mathbf{r}(t) = \sqrt{2}\,t\,\mathbf{i} + e^t\mathbf{j} + e^{-t}\mathbf{k} \Rightarrow \mathbf{r}'(t) = \sqrt{2}\,\mathbf{i} + e^t\mathbf{j} - e^{-t}\mathbf{k} \Rightarrow$

$|\mathbf{r}'(t)| = \sqrt{\left(\sqrt{2}\right)^2 + (e^t)^2 + (-e^{-t})^2} = \sqrt{2 + e^{2t} + e^{-2t}} = \sqrt{(e^t + e^{-t})^2} = e^t + e^{-t}$ [since $e^t + e^{-t} > 0$].

Then $L = \int_0^1 |\mathbf{r}'(t)|\,dt = \int_0^1 (e^t + e^{-t})\,dt = \left[e^t - e^{-t}\right]_0^1 = e - e^{-1}.$

4. $\mathbf{r}(t) = \cos t\,\mathbf{i} + \sin t\,\mathbf{j} + \ln\cos t\,\mathbf{k} \Rightarrow \mathbf{r}'(t) = -\sin t\,\mathbf{i} + \cos t\,\mathbf{j} + \dfrac{-\sin t}{\cos t}\,\mathbf{k} = -\sin t\,\mathbf{i} + \cos t\,\mathbf{j} - \tan t\,\mathbf{k},$

$|\mathbf{r}'(t)| = \sqrt{(-\sin t)^2 + \cos^2 t + (-\tan t)^2} = \sqrt{1 + \tan^2 t} = \sqrt{\sec^2 t} = |\sec t|$. Since $\sec t > 0$ for $0 \le t \le \pi/4$, here we can say $|\mathbf{r}'(t)| = \sec t$. Then

$$\begin{aligned} L &= \int_0^{\pi/4} \sec t\,dt = \Big[\ln|\sec t + \tan t|\Big]_0^{\pi/4} = \ln\left|\sec\tfrac{\pi}{4} + \tan\tfrac{\pi}{4}\right| - \ln|\sec 0 + \tan 0| \\ &= \ln\left|\sqrt{2} + 1\right| - \ln|1 + 0| = \ln(\sqrt{2} + 1). \end{aligned}$$

5. $\mathbf{r}(t) = \mathbf{i} + t^2\,\mathbf{j} + t^3\,\mathbf{k} \Rightarrow \mathbf{r}'(t) = 2t\,\mathbf{j} + 3t^2\,\mathbf{k} \Rightarrow |\mathbf{r}'(t)| = \sqrt{4t^2 + 9t^4} = t\sqrt{4 + 9t^2}$ [since $t \ge 0$].

Then $L = \int_0^1 |\mathbf{r}'(t)|\,dt = \int_0^1 t\sqrt{4 + 9t^2}\,dt = \frac{1}{18}\cdot\frac{2}{3}(4 + 9t^2)^{3/2}\Big]_0^1 = \frac{1}{27}(13^{3/2} - 4^{3/2}) = \frac{1}{27}(13^{3/2} - 8).$

6. $\mathbf{r}(t) = t^2\,\mathbf{i} + 9t\,\mathbf{j} + 4t^{3/2}\,\mathbf{k} \Rightarrow \mathbf{r}'(t) = 2t\,\mathbf{i} + 9\,\mathbf{j} + 6\sqrt{t}\,\mathbf{k} \Rightarrow$

$|\mathbf{r}'(t)| = \sqrt{4t^2 + 81 + 36t} = \sqrt{(2t + 9)^2} = |2t + 9| = 2t + 9$ [since $2t + 9 \ge 0$ for $1 \le t \le 4$]. Then

$L = \int_1^4 |\mathbf{r}'(t)|\,dt = \int_1^4 (2t + 9)\,dt = \Big[t^2 + 9t\Big]_1^4 = 52 - 10 = 42.$

7. $\mathbf{r}(t) = \left\langle t^2, t^3, t^4\right\rangle \Rightarrow \mathbf{r}'(t) = \left\langle 2t, 3t^2, 4t^3\right\rangle \Rightarrow |\mathbf{r}'(t)| = \sqrt{(2t)^2 + (3t^2)^2 + (4t^3)^2} = \sqrt{4t^2 + 9t^4 + 16t^6}$, so

$L = \int_0^2 |\mathbf{r}'(t)|\,dt = \int_0^2 \sqrt{4t^2 + 9t^4 + 16t^6}\,dt \approx 18.6833.$

8. $\mathbf{r}(t) = \left\langle t, e^{-t}, te^{-t}\right\rangle \Rightarrow \mathbf{r}'(t) = \left\langle 1, -e^{-t}, (1 - t)e^{-t}\right\rangle \Rightarrow$

$|\mathbf{r}'(t)| = \sqrt{1^2 + (-e^{-t})^2 + [(1 - t)e^{-t}]^2} = \sqrt{1 + e^{-2t} + (1 - t)^2e^{-2t}} = \sqrt{1 + (2 - 2t + t^2)e^{-2t}}$, so

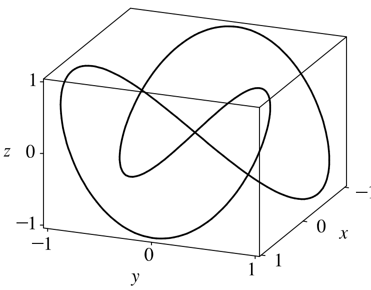
$L = \int_1^3 |\mathbf{r}'(t)|\,dt = \int_1^3 \sqrt{1 + (2 + 2t + t^2)e^{-2t}}\,dt \approx 2.0454.$

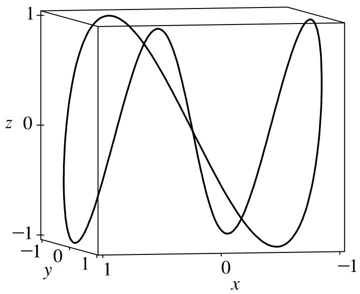
9. $\mathbf{r}(t) = \langle \cos \pi t, 2t, \sin 2\pi t \rangle \quad \Rightarrow \quad \mathbf{r}'(t) = \langle -\pi \sin \pi t, 2, 2\pi \cos 2\pi t \rangle \quad \Rightarrow \quad |\mathbf{r}'(t)| = \sqrt{\pi^2 \sin^2 \pi t + 4 + 4\pi^2 \cos^2 2\pi t}$.

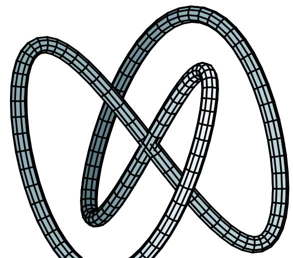
The point $(1, 0, 0)$ corresponds to $t = 0$ and $(1, 4, 0)$ corresponds to $t = 2$, so the length is

$L = \int_0^2 |\mathbf{r}'(t)|\, dt = \int_0^2 \sqrt{\pi^2 \sin^2 \pi t + 4 + 4\pi^2 \cos^2 2\pi t}\, dt \approx 10.3311$.

10. We plot two different views of the curve with parametric equations $x = \sin t$, $y = \sin 2t$, $z = \sin 3t$. To help visualize the curve, we also include a plot showing a tube of radius 0.07 around the curve.







The complete curve is given by the parameter interval $[0, 2\pi]$ and we have $\mathbf{r}'(t) = \langle \cos t, 2\cos 2t, 3\cos 3t \rangle \quad \Rightarrow$

$|\mathbf{r}'(t)| = \sqrt{\cos^2 t + 4\cos^2 2t + 9\cos^2 3t}$, so $L = \int_0^{2\pi} |\mathbf{r}'(t)|\; dt = \int_0^{2\pi} \sqrt{\cos^2 t + 4\cos^2 2t + 9\cos^2 3t}\, dt \approx 16.0264$.

11. The projection of the curve C onto the xy-plane is the curve $x^2 = 2y$ or $y = \frac{1}{2}x^2$, $z = 0$. Then we can choose the parameter $x = t \quad \Rightarrow \quad y = \frac{1}{2}t^2$. Since C also lies on the surface $3z = xy$, we have $z = \frac{1}{3}xy = \frac{1}{3}(t)(\frac{1}{2}t^2) = \frac{1}{6}t^3$. Then parametric equations for C are $x = t$, $y = \frac{1}{2}t^2$, $z = \frac{1}{6}t^3$ and the corresponding vector equation is $\mathbf{r}(t) = \left\langle t, \frac{1}{2}t^2, \frac{1}{6}t^3 \right\rangle$. The origin corresponds to $t = 0$ and the point $(6, 18, 36)$ corresponds to $t = 6$, so

$$L = \int_0^6 |\mathbf{r}'(t)|\, dt = \int_0^6 \left|\left\langle 1, t, \tfrac{1}{2}t^2 \right\rangle\right|\, dt = \int_0^6 \sqrt{1^2 + t^2 + \left(\tfrac{1}{2}t^2\right)^2}\, dt = \int_0^6 \sqrt{1 + t^2 + \tfrac{1}{4}t^4}\, dt$$
$$= \int_0^6 \sqrt{(1 + \tfrac{1}{2}t^2)^2}\, dt = \int_0^6 (1 + \tfrac{1}{2}t^2)\, dt = \left[t + \tfrac{1}{6}t^3\right]_0^6 = 6 + 36 = 42$$

12. Let C be the curve of intersection. The projection of C onto the xy-plane is the ellipse $4x^2 + y^2 = 4$ or $x^2 + y^2/4 = 1$, $z = 0$. Then we can write $x = \cos t$, $y = 2\sin t$, $0 \le t \le 2\pi$. Since C also lies on the plane $x + y + z = 2$, we have $z = 2 - x - y = 2 - \cos t - 2\sin t$. Then parametric equations for C are $x = \cos t$, $y = 2\sin t$, $z = 2 - \cos t - 2\sin t$, $0 \le t \le 2\pi$, and the corresponding vector equation is $\mathbf{r}(t) = \langle \cos t, 2\sin t, 2 - \cos t - 2\sin t \rangle$. Differentiating gives

$\mathbf{r}'(t) = \langle -\sin t, 2\cos t, \sin t - 2\cos t \rangle \quad \Rightarrow$

$|\mathbf{r}'(t)| = \sqrt{(-\sin t)^2 + (2\cos t)^2 + (\sin t - 2\cos t)^2} = \sqrt{2\sin^2 t + 8\cos^2 t - 4\sin t\, \cos t}$. The length of C is

$L = \int_0^{2\pi} |\mathbf{r}'(t)|\, dt = \int_0^{2\pi} \sqrt{2\sin^2 t + 8\cos^2 t - 4\sin t\, \cos t}\, dt \approx 13.5191$.

13. (a) $\mathbf{r}(t) = (5 - t)\,\mathbf{i} + (4t - 3)\,\mathbf{j} + 3t\,\mathbf{k} \quad \Rightarrow \quad \mathbf{r}'(t) = -\mathbf{i} + 4\,\mathbf{j} + 3\,\mathbf{k}$ and $\frac{ds}{dt} = |\mathbf{r}'(t)| = \sqrt{1 + 16 + 9} = \sqrt{26}$. The point $P\,(4, 1, 3)$ corresponds to $t = 1$, so the arc length function from P is

$s(t) = \int_1^t |\mathbf{r}'(u)|\,du = \int_1^t \sqrt{26}\,du = \sqrt{26}\,u\big|_1^t = \sqrt{26}\,(t-1)$. Since $s = \sqrt{26}\,(t-1)$, we have $t = \dfrac{s}{\sqrt{26}} + 1$.

Substituting for t in the original equation, the reparametrization of the curve with respect to arc length is

$$\begin{aligned}\mathbf{r}(t(s)) &= \left[5 - \left(\frac{s}{\sqrt{26}} + 1\right)\right]\mathbf{i} + \left[4\left(\frac{s}{\sqrt{26}} + 1\right) - 3\right]\mathbf{j} + 3\left(\frac{s}{\sqrt{26}} + 1\right)\mathbf{k} \\ &= \left(4 - \frac{s}{\sqrt{26}}\right)\mathbf{i} + \left(\frac{4s}{\sqrt{26}} + 1\right)\mathbf{j} + \left(\frac{3s}{\sqrt{26}} + 3\right)\mathbf{k}\end{aligned}$$

(b) The point 4 units along the curve from P has position vector

$\mathbf{r}(t(4)) = \left(4 - \dfrac{4}{\sqrt{26}}\right)\mathbf{i} + \left(\dfrac{4(4)}{\sqrt{26}} + 1\right)\mathbf{j} + \left(\dfrac{3(4)}{\sqrt{26}} + 3\right)\mathbf{k}$, so the point is $\left(4 - \dfrac{4}{\sqrt{26}}, \dfrac{16}{\sqrt{26}} + 1, \dfrac{12}{\sqrt{26}} + 3\right)$.

14. (a) $\mathbf{r}(t) = e^t \sin t\,\mathbf{i} + e^t \cos t\,\mathbf{j} + \sqrt{2}\,e^t\,\mathbf{k} \;\Rightarrow\; \mathbf{r}'(t) = e^t(\cos t + \sin t)\,\mathbf{i} + e^t(\cos t - \sin t)\,\mathbf{j} + \sqrt{2}\,e^t\,\mathbf{k}$ and

$$\begin{aligned}\frac{ds}{dt} = |\mathbf{r}'(t)| &= \sqrt{e^{2t}(\cos t + \sin t)^2 + e^{2t}(\cos t - \sin t)^2 + 2e^{2t}} \\ &= \sqrt{e^{2t}\left[2(\cos^2 t + \sin^2 t) + 2\cos t \sin t - 2\cos t \sin t + 2\right]} = \sqrt{4e^{2t}} = 2e^t\end{aligned}$$

The point $P\left(0, 1, \sqrt{2}\right)$ corresponds to $t = 0$, so the arc length function from P is

$s(t) = \int_0^t |\mathbf{r}'(u)|\,du = \int_0^t 2e^u\,du = 2e^u\big|_0^t = 2(e^t - 1)$. Since $s = 2(e^t - 1)$, we have $e^t = \dfrac{s}{2} + 1 \;\Leftrightarrow$

$t = \ln\left(\frac{1}{2}s + 1\right)$. Substituting for t in the original equation, the reparametrization of the curve with respect to arc length is

$\mathbf{r}(t(s)) = \left(\frac{1}{2}s + 1\right)\sin\left(\ln\left(\frac{1}{2}s + 1\right)\right)\mathbf{i} + \left(\frac{1}{2}s + 1\right)\cos\left(\ln\left(\frac{1}{2}s + 1\right)\right)\mathbf{j} + \left(\frac{\sqrt{2}}{2}s + \sqrt{2}\right)\mathbf{k}$.

(b) The point 4 units along the curve from P has position vector

$\mathbf{r}(t(4)) = \left(\frac{1}{2}(4) + 1\right)\sin\left(\ln\left(\frac{1}{2}(4) + 1\right)\right)\mathbf{i} + \left(\frac{1}{2}(4) + 1\right)\cos\left(\ln\left(\frac{1}{2}(4) + 1\right)\right)\mathbf{j} + \left(\frac{\sqrt{2}}{2}(4) + \sqrt{2}\right)\mathbf{k}$, so the point is

$\left(3\sin(\ln 3), 3\cos(\ln 3), 3\sqrt{2}\right)$.

15. Here $\mathbf{r}(t) = \langle 3\sin t, 4t, 3\cos t\rangle$, so $\mathbf{r}'(t) = \langle 3\cos t, 4, -3\sin t\rangle$ and $|\mathbf{r}'(t)| = \sqrt{9\cos^2 t + 16 + 9\sin^2 t} = \sqrt{25} = 5$.

The point $(0, 0, 3)$ corresponds to $t = 0$, so the arc length function beginning at $(0, 0, 3)$ and measuring in the positive direction is given by $s(t) = \int_0^t |\mathbf{r}'(u)|\,du = \int_0^t 5\,du = 5t$. $s(t) = 5 \;\Rightarrow\; 5t = 5 \;\Rightarrow\; t = 1$, thus your location after moving 5 units along the curve is $(3\sin 1, 4, 3\cos 1)$.

16. $\mathbf{r}(t) = \left(\dfrac{2}{t^2 + 1} - 1\right)\mathbf{i} + \dfrac{2t}{t^2 + 1}\mathbf{j} \;\Rightarrow\; \mathbf{r}'(t) = \dfrac{-4t}{(t^2 + 1)^2}\mathbf{i} + \dfrac{-2t^2 + 2}{(t^2 + 1)^2}\mathbf{j}$,

$$\frac{ds}{dt} = |\mathbf{r}'(t)| = \sqrt{\left[\frac{-4t}{(t^2 + 1)^2}\right]^2 + \left[\frac{-2t^2 + 2}{(t^2 + 1)^2}\right]^2} = \sqrt{\frac{4t^4 + 8t^2 + 4}{(t^2 + 1)^4}} = \sqrt{\frac{4(t^2 + 1)^2}{(t^2 + 1)^4}} = \sqrt{\frac{4}{(t^2 + 1)^2}} = \frac{2}{t^2 + 1}.$$

Since the initial point $(1, 0)$ corresponds to $t = 0$, the arc length function is

$s(t) = \displaystyle\int_0^t |\mathbf{r}'(u)|\,du = \int_0^t \frac{2}{u^2 + 1}\,du = 2\arctan t$. Then $\arctan t = \frac{1}{2}s \;\Rightarrow\; t = \tan\frac{1}{2}s$. Substituting, we have

$$\mathbf{r}(t(s)) = \left[\frac{2}{\tan^2\left(\frac{1}{2}s\right)+1} - 1\right]\mathbf{i} + \frac{2\tan\left(\frac{1}{2}s\right)}{\tan^2\left(\frac{1}{2}s\right)+1}\mathbf{j} = \frac{1-\tan^2\left(\frac{1}{2}s\right)}{1+\tan^2\left(\frac{1}{2}s\right)}\mathbf{i} + \frac{2\tan\left(\frac{1}{2}s\right)}{\sec^2\left(\frac{1}{2}s\right)}\mathbf{j}$$

$$= \frac{1-\tan^2\left(\frac{1}{2}s\right)}{\sec^2\left(\frac{1}{2}s\right)}\mathbf{i} + 2\tan\left(\tfrac{1}{2}s\right)\cos^2\left(\tfrac{1}{2}s\right)\mathbf{j} = \left[\cos^2\left(\tfrac{1}{2}s\right) - \sin^2\left(\tfrac{1}{2}s\right)\right]\mathbf{i} + 2\sin\left(\tfrac{1}{2}s\right)\cos\left(\tfrac{1}{2}s\right)\mathbf{j} = \cos s\,\mathbf{i} + \sin s\,\mathbf{j}$$

With this parametrization, we recognize the function as representing the unit circle. Note here that the curve approaches, but does not include, the point $(-1, 0)$, since $\cos s = -1$ for $s = \pi + 2k\pi$ (k an integer) but then $t = \tan\left(\frac{1}{2}s\right)$ is undefined.

17. (a) $\mathbf{r}(t) = \langle t, 3\cos t, 3\sin t\rangle \Rightarrow \mathbf{r}'(t) = \langle 1, -3\sin t, 3\cos t\rangle \Rightarrow |\mathbf{r}'(t)| = \sqrt{1 + 9\sin^2 t + 9\cos^2 t} = \sqrt{10}$.

Then $\mathbf{T}(t) = \dfrac{\mathbf{r}'(t)}{|\mathbf{r}'(t)|} = \frac{1}{\sqrt{10}}\langle 1, -3\sin t, 3\cos t\rangle$ or $\left\langle \frac{1}{\sqrt{10}}, -\frac{3}{\sqrt{10}}\sin t, \frac{3}{\sqrt{10}}\cos t\right\rangle$.

$\mathbf{T}'(t) = \frac{1}{\sqrt{10}}\langle 0, -3\cos t, -3\sin t\rangle \Rightarrow |\mathbf{T}'(t)| = \frac{1}{\sqrt{10}}\sqrt{0 + 9\cos^2 t + 9\sin^2 t} = \frac{3}{\sqrt{10}}$. Thus

$\mathbf{N}(t) = \dfrac{\mathbf{T}'(t)}{|\mathbf{T}'(t)|} = \dfrac{1/\sqrt{10}}{3/\sqrt{10}}\langle 0, -3\cos t, -3\sin t\rangle = \langle 0, -\cos t, -\sin t\rangle$.

(b) $\kappa(t) = \dfrac{|\mathbf{T}'(t)|}{|\mathbf{r}'(t)|} = \dfrac{3/\sqrt{10}}{\sqrt{10}} = \dfrac{3}{10}$

18. (a) $\mathbf{r}(t) = \left\langle t^2, \sin t - t\cos t, \cos t + t\sin t\right\rangle \Rightarrow$

$\mathbf{r}'(t) = \langle 2t, \cos t + t\sin t - \cos t, -\sin t + t\cos t + \sin t\rangle = \langle 2t, t\sin t, t\cos t\rangle \Rightarrow$

$|\mathbf{r}'(t)| = \sqrt{4t^2 + t^2\sin^2 t + t^2\cos^2 t} = \sqrt{4t^2 + t^2(\cos^2 t + \sin^2 t)} = \sqrt{5t^2} = \sqrt{5}\,t$ [since $t > 0$]. Then

$\mathbf{T}(t) = \dfrac{\mathbf{r}'(t)}{|\mathbf{r}'(t)|} = \dfrac{1}{\sqrt{5}\,t}\langle 2t, t\sin t, t\cos t\rangle = \frac{1}{\sqrt{5}}\langle 2, \sin t, \cos t\rangle$. $\mathbf{T}'(t) = \frac{1}{\sqrt{5}}\langle 0, \cos t, -\sin t\rangle \Rightarrow$

$|\mathbf{T}'(t)| = \frac{1}{\sqrt{5}}\sqrt{0 + \cos^2 t + \sin^2 t} = \frac{1}{\sqrt{5}}$. Thus $\mathbf{N}(t) = \dfrac{\mathbf{T}'(t)}{|\mathbf{T}'(t)|} = \dfrac{1/\sqrt{5}}{1/\sqrt{5}}\langle 0, \cos t, -\sin t\rangle = \langle 0, \cos t, -\sin t\rangle$.

(b) $\kappa(t) = \dfrac{|\mathbf{T}'(t)|}{|\mathbf{r}'(t)|} = \dfrac{1/\sqrt{5}}{\sqrt{5}\,t} = \dfrac{1}{5t}$

19. (a) $\mathbf{r}(t) = \left\langle \sqrt{2}\,t, e^t, e^{-t}\right\rangle \Rightarrow \mathbf{r}'(t) = \left\langle \sqrt{2}, e^t, -e^{-t}\right\rangle \Rightarrow |\mathbf{r}'(t)| = \sqrt{2 + e^{2t} + e^{-2t}} = \sqrt{(e^t + e^{-t})^2} = e^t + e^{-t}$.

Then

$\mathbf{T}(t) = \dfrac{\mathbf{r}'(t)}{|\mathbf{r}'(t)|} = \dfrac{1}{e^t + e^{-t}}\left\langle \sqrt{2}, e^t, -e^{-t}\right\rangle = \dfrac{1}{e^{2t}+1}\left\langle \sqrt{2}\,e^t, e^{2t}, -1\right\rangle$ $\left[\text{after multiplying by } \dfrac{e^t}{e^t}\right]$ and

$$\mathbf{T}'(t) = \frac{1}{e^{2t}+1}\left\langle \sqrt{2}\,e^t, 2e^{2t}, 0\right\rangle - \frac{2e^{2t}}{(e^{2t}+1)^2}\left\langle \sqrt{2}\,e^t, e^{2t}, -1\right\rangle$$

$$= \frac{1}{(e^{2t}+1)^2}\left[(e^{2t}+1)\left\langle \sqrt{2}\,e^t, 2e^{2t}, 0\right\rangle - 2e^{2t}\left\langle \sqrt{2}\,e^t, e^{2t}, -1\right\rangle\right] = \frac{1}{(e^{2t}+1)^2}\left\langle \sqrt{2}\,e^t\left(1 - e^{2t}\right), 2e^{2t}, 2e^{2t}\right\rangle$$

Then

$$|\mathbf{T}'(t)| = \frac{1}{(e^{2t}+1)^2}\sqrt{2e^{2t}(1 - 2e^{2t} + e^{4t}) + 4e^{4t} + 4e^{4t}} = \frac{1}{(e^{2t}+1)^2}\sqrt{2e^{2t}(1 + 2e^{2t} + e^{4t})}$$

$$= \frac{1}{(e^{2t}+1)^2}\sqrt{2e^{2t}\left(1 + e^{2t}\right)^2} = \frac{\sqrt{2}\,e^t(1 + e^{2t})}{(e^{2t}+1)^2} = \frac{\sqrt{2}\,e^t}{e^{2t}+1}$$

Therefore

$$\mathbf{N}(t)=\frac{\mathbf{T}'(t)}{|\mathbf{T}'(t)|}=\frac{e^{2t}+1}{\sqrt{2}\,e^t}\frac{1}{(e^{2t}+1)^2}\left\langle\sqrt{2}\,e^t(1-e^{2t}),2e^{2t},2e^{2t}\right\rangle$$
$$=\frac{1}{\sqrt{2}\,e^t(e^{2t}+1)}\left\langle\sqrt{2}\,e^t(1-e^{2t}),2e^{2t},2e^{2t}\right\rangle=\frac{1}{e^{2t}+1}\left\langle 1-e^{2t},\sqrt{2}\,e^t,\sqrt{2}\,e^t\right\rangle$$

(b) $\kappa(t)=\dfrac{|\mathbf{T}'(t)|}{|\mathbf{r}'(t)|}=\dfrac{\sqrt{2}\,e^t}{e^{2t}+1}\cdot\dfrac{1}{e^t+e^{-t}}=\dfrac{\sqrt{2}\,e^t}{e^{3t}+2e^t+e^{-t}}=\dfrac{\sqrt{2}\,e^{2t}}{e^{4t}+2e^{2t}+1}=\dfrac{\sqrt{2}\,e^{2t}}{(e^{2t}+1)^2}$

20. (a) $\mathbf{r}(t)=\left\langle t,\frac{1}{2}t^2,t^2\right\rangle \Rightarrow \mathbf{r}'(t)=\langle 1,t,2t\rangle \Rightarrow |\mathbf{r}'(t)|=\sqrt{1+t^2+4t^2}=\sqrt{1+5t^2}$. Then

$$\mathbf{T}(t)=\frac{\mathbf{r}'(t)}{|\mathbf{r}'(t)|}=\frac{1}{\sqrt{1+5t^2}}\langle 1,t,2t\rangle.$$

$$\mathbf{T}'(t)=\frac{-5t}{(1+5t^2)^{3/2}}\langle 1,t,2t\rangle+\frac{1}{\sqrt{1+5t^2}}\langle 0,1,2\rangle \qquad \text{[by Formula 3 of Theorem 13.2.3]}$$
$$=\frac{1}{(1+5t^2)^{3/2}}\left(\left\langle -5t,-5t^2,-10t^2\right\rangle+\left\langle 0,1+5t^2,2+10t^2\right\rangle\right)=\frac{1}{(1+5t^2)^{3/2}}\langle -5t,1,2\rangle$$

$$|\mathbf{T}'(t)|=\frac{1}{(1+5t^2)^{3/2}}\sqrt{25t^2+1+4}=\frac{1}{(1+5t^2)^{3/2}}\sqrt{25t^2+5}=\frac{\sqrt{5}\sqrt{5t^2+1}}{(1+5t^2)^{3/2}}=\frac{\sqrt{5}}{1+5t^2}$$

Thus $\mathbf{N}(t)=\dfrac{\mathbf{T}'(t)}{|\mathbf{T}'(t)|}=\dfrac{1+5t^2}{\sqrt{5}}\cdot\dfrac{1}{(1+5t^2)^{3/2}}\langle -5t,1,2\rangle=\dfrac{1}{\sqrt{5+25t^2}}\langle -5t,1,2\rangle.$

(b) $\kappa(t)=\dfrac{|\mathbf{T}'(t)|}{|\mathbf{r}'(t)|}=\dfrac{\sqrt{5}/(1+5t^2)}{\sqrt{1+5t^2}}=\dfrac{\sqrt{5}}{(1+5t^2)^{3/2}}$

21. $\mathbf{r}(t)=t^3\,\mathbf{j}+t^2\,\mathbf{k} \Rightarrow \mathbf{r}'(t)=3t^2\,\mathbf{j}+2t\,\mathbf{k},\quad \mathbf{r}''(t)=6t\,\mathbf{j}+2\,\mathbf{k},\quad |\mathbf{r}'(t)|=\sqrt{0^2+(3t^2)^2+(2t)^2}=\sqrt{9t^4+4t^2},$

$\mathbf{r}'(t)\times\mathbf{r}''(t)=-6t^2\,\mathbf{i},\quad |\mathbf{r}'(t)\times\mathbf{r}''(t)|=6t^2$. Then $\kappa(t)=\dfrac{|\mathbf{r}'(t)\times\mathbf{r}''(t)|}{|\mathbf{r}'(t)|^3}=\dfrac{6t^2}{\left(\sqrt{9t^4+4t^2}\right)^3}=\dfrac{6t^2}{(9t^4+4t^2)^{3/2}}.$

22. $\mathbf{r}(t)=t\,\mathbf{i}+t^2\,\mathbf{j}+e^t\,\mathbf{k} \Rightarrow \mathbf{r}'(t)=\mathbf{i}+2t\,\mathbf{j}+e^t\,\mathbf{k},\quad \mathbf{r}''(t)=2\,\mathbf{j}+e^t\,\mathbf{k},$

$|\mathbf{r}'(t)|=\sqrt{1^2+(2t)^2+(e^t)^2}=\sqrt{1+4t^2+e^{2t}},\quad \mathbf{r}'(t)\times\mathbf{r}''(t)=(2t-2)e^t\,\mathbf{i}-e^t\,\mathbf{j}+2\,\mathbf{k},$

$|\mathbf{r}'(t)\times\mathbf{r}''(t)|=\sqrt{[(2t-2)e^t]^2+(-e^t)^2+2^2}=\sqrt{(2t-2)^2e^{2t}+e^{2t}+4}=\sqrt{(4t^2-8t+5)e^{2t}+4}.$

Then $\kappa(t)=\dfrac{|\mathbf{r}'(t)\times\mathbf{r}''(t)|}{|\mathbf{r}'(t)|^3}=\dfrac{\sqrt{(4t^2-8t+5)e^{2t}+4}}{\left(\sqrt{1+4t^2+e^{2t}}\right)^3}=\dfrac{\sqrt{(4t^2-8t+5)e^{2t}+4}}{(1+4t^2+e^{2t})^{3/2}}.$

23. $\mathbf{r}(t)=\sqrt{6}\,t^2\,\mathbf{i}+2t\,\mathbf{j}+2t^3\,\mathbf{k} \Rightarrow \mathbf{r}'(t)=2\sqrt{6}\,t\,\mathbf{i}+2\,\mathbf{j}+6t^2\,\mathbf{k},\quad \mathbf{r}''(t)=2\sqrt{6}\,\mathbf{i}+12t\,\mathbf{k},$

$|\mathbf{r}'(t)|=\sqrt{24t^2+4+36t^4}=\sqrt{4(9t^4+6t^2+1)}=\sqrt{4(3t^2+1)^2}=2(3t^2+1),$

$\mathbf{r}'(t)\times\mathbf{r}''(t)=24t\,\mathbf{i}-12\sqrt{6}\,t^2\,\mathbf{j}-4\sqrt{6}\,\mathbf{k},$

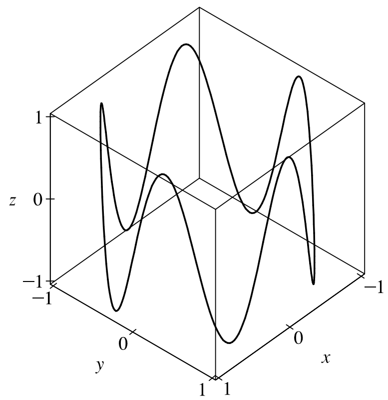
$|\mathbf{r}'(t)\times\mathbf{r}''(t)|=\sqrt{576t^2+864t^4+96}=\sqrt{96(9t^4+6t^2+1)}=\sqrt{96(3t^2+1)^2}=4\sqrt{6}\,(3t^2+1).$

Then $\kappa(t)=\dfrac{|\mathbf{r}'(t)\times\mathbf{r}''(t)|}{|\mathbf{r}'(t)|^3}=\dfrac{4\sqrt{6}\,(3t^2+1)}{8(3t^2+1)^3}=\dfrac{\sqrt{6}}{2(3t^2+1)^2}.$

24. $\mathbf{r}(t) = \langle t^2, \ln t, t\ln t\rangle \quad\Rightarrow\quad \mathbf{r}'(t) = \langle 2t, 1/t, 1+\ln t\rangle, \quad \mathbf{r}''(t) = \langle 2, -1/t^2, 1/t\rangle$. The point $(1,0,0)$ corresponds to $t=1$, and $\mathbf{r}'(1) = \langle 2,1,1\rangle$, $|\mathbf{r}'(1)| = \sqrt{2^2+1^2+1^2} = \sqrt{6}$, $\mathbf{r}''(1) = \langle 2,-1,1\rangle$, $\mathbf{r}'(1)\times\mathbf{r}''(1) = \langle 2,0,-4\rangle$, $|\mathbf{r}'(1)\times\mathbf{r}''(1)| = \sqrt{2^2+0^2+(-4)^2} = \sqrt{20} = 2\sqrt{5}$. Then $\kappa(1) = \dfrac{|\mathbf{r}'(1)\times\mathbf{r}''(1)|}{|\mathbf{r}'(1)|^3} = \dfrac{2\sqrt{5}}{(\sqrt{6})^3} = \dfrac{2\sqrt{5}}{6\sqrt{6}}$ or $\dfrac{\sqrt{30}}{18}$.

25. $\mathbf{r}(t) = \langle t, t^2, t^3\rangle \quad\Rightarrow\quad \mathbf{r}'(t) = \langle 1, 2t, 3t^2\rangle$. The point $(1,1,1)$ corresponds to $t=1$, and $\mathbf{r}'(1) = \langle 1,2,3\rangle \quad\Rightarrow$ $|\mathbf{r}'(1)| = \sqrt{1+4+9} = \sqrt{14}$. $\mathbf{r}''(t) = \langle 0,2,6t\rangle \quad\Rightarrow\quad \mathbf{r}''(1) = \langle 0,2,6\rangle$. $\mathbf{r}'(1)\times\mathbf{r}''(1) = \langle 6,-6,2\rangle$, so $|\mathbf{r}'(1)\times\mathbf{r}''(1)| = \sqrt{36+36+4} = \sqrt{76}$. Then $\kappa(1) = \dfrac{|\mathbf{r}'(1)\times\mathbf{r}''(1)|}{|\mathbf{r}'(1)|^3} = \dfrac{\sqrt{76}}{\sqrt{14}^3} = \dfrac{1}{7}\sqrt{\dfrac{19}{14}}$.

26.



Note that we get the complete curve for $0 \le t < 2\pi$.

$\mathbf{r}(t) = \langle \cos t, \sin t, \sin 5t\rangle \quad\Rightarrow\quad \mathbf{r}'(t) = \langle -\sin t, \cos t, 5\cos 5t\rangle$, $\mathbf{r}''(t) = \langle -\cos t, -\sin t, -25\sin 5t\rangle$. The point $(1,0,0)$ corresponds to $t=0$, and $\mathbf{r}'(0) = \langle 0,1,5\rangle \quad\Rightarrow$ $|\mathbf{r}'(0)| = \sqrt{0^2+1^2+5^2} = \sqrt{26}$, $\mathbf{r}''(0) = \langle -1,0,0\rangle$, $\mathbf{r}'(0)\times\mathbf{r}''(0) = \langle 0,-5,1\rangle \quad\Rightarrow$ $|\mathbf{r}'(0)\times\mathbf{r}''(0)| = \sqrt{0^2+(-5)^2+1^2} = \sqrt{26}$. The curvature at the point $(1,0,0)$ is $\kappa(0) = \dfrac{|\mathbf{r}'(0)\times\mathbf{r}''(0)|}{|\mathbf{r}'(0)|^3} = \dfrac{\sqrt{26}}{(\sqrt{26})^3} = \dfrac{1}{26}$.

27. $f(x) = x^4, \quad f'(x) = 4x^3, \quad f''(x) = 12x^2, \quad \kappa(x) = \dfrac{|f''(x)|}{[1+(f'(x))^2]^{3/2}} = \dfrac{|12x^2|}{[1+(4x^3)^2]^{3/2}} = \dfrac{12x^2}{(1+16x^6)^{3/2}}$

28. $f(x) = \tan x, \quad f'(x) = \sec^2 x, \quad f''(x) = 2\sec x\cdot\sec x\,\tan x = 2\sec^2 x\,\tan x$,

$$\kappa(x) = \frac{|f''(x)|}{[1+(f'(x))^2]^{3/2}} = \frac{|2\sec^2 x\,\tan x|}{[1+(\sec^2 x)^2]^{3/2}} = \frac{2\sec^2 x\,|\tan x|}{(1+\sec^4 x)^{3/2}}$$

29. $f(x) = xe^x, \quad f'(x) = xe^x + e^x, \quad f''(x) = xe^x + 2e^x$,

$$\kappa(x) = \frac{|f''(x)|}{[1+(f'(x))^2]^{3/2}} = \frac{|xe^x+2e^x|}{[1+(xe^x+e^x)^2]^{3/2}} = \frac{|x+2|\,e^x}{[1+(xe^x+e^x)^2]^{3/2}}$$

30. $y' = \dfrac{1}{x}, \quad y'' = -\dfrac{1}{x^2}$,

$$\kappa(x) = \frac{|y''(x)|}{\left[1+(y'(x))^2\right]^{3/2}} = \left|\frac{-1}{x^2}\right|\frac{1}{(1+1/x^2)^{3/2}} = \frac{1}{x^2}\frac{(x^2)^{3/2}}{(x^2+1)^{3/2}} = \frac{|x|}{(x^2+1)^{3/2}} = \frac{x}{(x^2+1)^{3/2}} \quad [\text{since } x>0].$$

To find the maximum curvature, we first find the critical numbers of $\kappa(x)$:

$$\kappa'(x) = \frac{(x^2+1)^{3/2} - x\left(\frac{3}{2}\right)(x^2+1)^{1/2}(2x)}{[(x^2+1)^{3/2}]^2} = \frac{(x^2+1)^{1/2}[(x^2+1)-3x^2]}{(x^2+1)^3} = \frac{1-2x^2}{(x^2+1)^{5/2}};$$

$\kappa'(x) = 0 \quad\Rightarrow\quad 1-2x^2 = 0$, so the only critical number in the domain is $x = \frac{1}{\sqrt{2}}$. Since $\kappa'(x) > 0$ for $0 < x < \frac{1}{\sqrt{2}}$

and $\kappa'(x) < 0$ for $x > \frac{1}{\sqrt{2}}$, $\kappa(x)$ attains its maximum at $x = \frac{1}{\sqrt{2}}$. Thus, the maximum curvature occurs at $\left(\frac{1}{\sqrt{2}}, \ln\frac{1}{\sqrt{2}}\right)$.

Since $\lim\limits_{x\to\infty} \dfrac{x}{(x^2+1)^{3/2}} = 0$, $\kappa(x)$ approaches 0 as $x \to \infty$.

31. Since $y' = y'' = e^x$, the curvature is $\kappa(x) = \dfrac{|y''(x)|}{[1+(y'(x))^2]^{3/2}} = \dfrac{e^x}{(1+e^{2x})^{3/2}} = e^x(1+e^{2x})^{-3/2}$.

To find the maximum curvature, we first find the critical numbers of $\kappa(x)$:

$$\kappa'(x) = e^x(1+e^{2x})^{-3/2} + e^x\left(-\tfrac{3}{2}\right)(1+e^{2x})^{-5/2}(2e^{2x}) = e^x\frac{1+e^{2x}-3e^{2x}}{(1+e^{2x})^{5/2}} = e^x\frac{1-2e^{2x}}{(1+e^{2x})^{5/2}}.$$

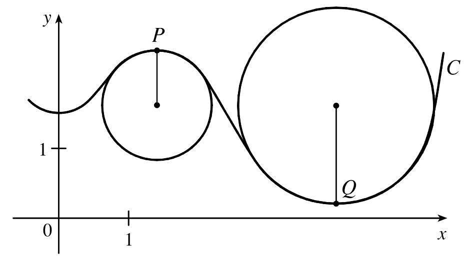
$\kappa'(x) = 0$ when $1 - 2e^{2x} = 0$, so $e^{2x} = \frac{1}{2}$ or $x = -\frac{1}{2}\ln 2$. And since $1 - 2e^{2x} > 0$ for $x < -\frac{1}{2}\ln 2$ and $1 - 2e^{2x} < 0$ for $x > -\frac{1}{2}\ln 2$, the maximum curvature is attained at the point $\left(-\frac{1}{2}\ln 2, e^{(-\ln 2)/2}\right) = \left(-\frac{1}{2}\ln 2, \frac{1}{\sqrt{2}}\right)$.

Since $\lim\limits_{x\to\infty} e^x(1+e^{2x})^{-3/2} = 0$, $\kappa(x)$ approaches 0 as $x \to \infty$.

32. We can take the parabola as having its vertex at the origin and opening upward, so the equation is $f(x) = ax^2$, $a > 0$. Then by Equation 11, $\kappa(x) = \dfrac{|f''(x)|}{[1+(f'(x))^2]^{3/2}} = \dfrac{|2a|}{[1+(2ax)^2]^{3/2}} = \dfrac{2a}{(1+4a^2x^2)^{3/2}}$, thus $\kappa(0) = 2a$. We want $\kappa(0) = 4$, so $a = 2$ and the equation is $y = 2x^2$.

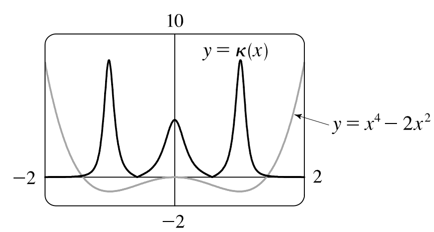
33. (a) C appears to be changing direction more quickly at P than Q, so we would expect the curvature to be greater at P.

(b) First we sketch approximate osculating circles at P and Q. Using the axes scale as a guide, we measure the radius of the osculating circle at P to be approximately 0.8 units, thus $\rho = \dfrac{1}{\kappa} \Rightarrow \kappa = \dfrac{1}{\rho} \approx \dfrac{1}{0.8} \approx 1.3$. Similarly, we estimate the radius of the osculating circle at Q to be 1.4 units, so $\kappa = \dfrac{1}{\rho} \approx \dfrac{1}{1.4} \approx 0.7$.



34. $y = x^4 - 2x^2 \Rightarrow y' = 4x^3 - 4x$, $y'' = 12x^2 - 4$, and

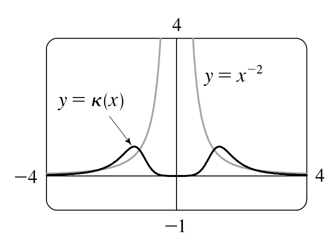
$\kappa(x) = \dfrac{|y''|}{\left[1+(y')^2\right]^{3/2}} = \dfrac{\left|12x^2-4\right|}{\left[1+(4x^3-4x)^2\right]^{3/2}}$. The graph of the curvature here is what we would expect. The graph of $y = x^4 - 2x^2$ appears to be bending most sharply at the origin and near $x = \pm 1$.



35. $y = x^{-2} \Rightarrow y' = -2x^{-3}$, $y'' = 6x^{-4}$, and

$\kappa(x) = \dfrac{|y''|}{\left[1+(y')^2\right]^{3/2}} = \dfrac{\left|6x^{-4}\right|}{\left[1+(-2x^{-3})^2\right]^{3/2}} = \dfrac{6}{x^4\,(1+4x^{-6})^{3/2}}$.

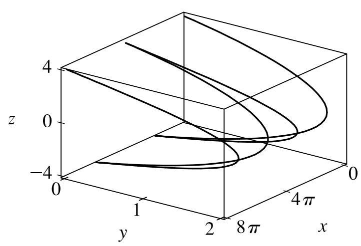
The appearance of the two humps in this graph is perhaps a little surprising, but it is explained by the fact that $y = x^{-2}$ increases asymptotically at the origin from both directions, and so its graph has very little bend there. [Note that $\kappa(0)$ is undefined.]

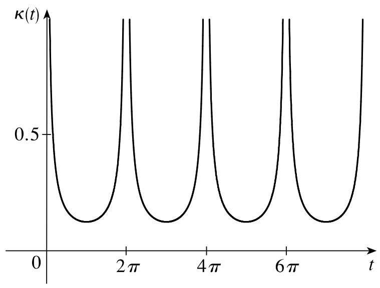


36. $\mathbf{r}(t) = \langle t - \sin t, 1 - \cos t, 4\cos(t/2)\rangle \Rightarrow \mathbf{r}'(t) = \langle 1 - \cos t, \sin t, -2\sin(t/2)\rangle$, $\mathbf{r}''(t) = \langle \sin t, \cos t, -\cos(t/2)\rangle$.

Using a CAS, $\mathbf{r}'(t) \times \mathbf{r}''(t) = \left\langle -2\sin^3(t/2), -\sin(t/2)\sin t, \cos t - 1\right\rangle$, $|\mathbf{r}'(t) \times \mathbf{r}''(t)| = \sqrt{3 - 4\cos t + \cos 2t}$ or $2\sqrt{2}\sin^2(t/2)$, and $|\mathbf{r}'(t)| = 2\sqrt{1 - \cos t}$ or $2\sqrt{2}\,|\sin(t/2)|$. (To compute cross products in Maple, use the `VectorCalculus` or `LinearAlgebra` package and the `CrossProduct(a,b)` command. Here loading the `RealDomain` package will give simpler results. In Mathematica, use `Cross[a,b]`.)

Then $\kappa(t) = \dfrac{|\mathbf{r}'(t) \times \mathbf{r}''(t)|}{|\mathbf{r}'(t)|^3} = \dfrac{\sqrt{3 - 4\cos t + \cos 2t}}{8\,(1 - \cos t)^{3/2}}$ or $\dfrac{1}{4\sqrt{2 - 2\cos t}}$ or $\dfrac{1}{8\,|\sin(t/2)|}$. We plot the space curve and its curvature function for $0 \le t \le 8\pi$ below.





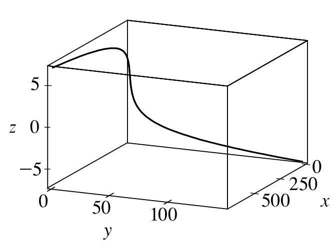
The asymptotes in the graph of $\kappa(t)$ correspond to the sharp cusps we see in the graph of $\mathbf{r}(t)$. The space curve bends most sharply as it approaches these cusps (mostly in the x-direction) and bends most gradually between these, near its intersections with the xy-plane, where $t = \pi + 2n\pi$ (n an integer). (The bending we see in the z-direction on the curve near these points is deceiving; most of the curvature occurs in the x-direction.) The curvature graph has local minima at these values of t.

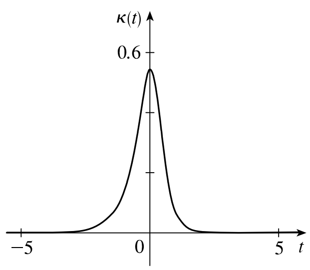
37. $\mathbf{r}(t) = \left\langle te^t, e^{-t}, \sqrt{2}t\right\rangle \Rightarrow \mathbf{r}'(t) = \left\langle (t+1)e^t, -e^{-t}, \sqrt{2}\right\rangle$, $\mathbf{r}''(t) = \left\langle (t+2)e^t, e^{-t}, 0\right\rangle$. Then

$\mathbf{r}'(t) \times \mathbf{r}''(t) = \left\langle -\sqrt{2}e^{-t}, \sqrt{2}(t+2)e^t, 2t+3\right\rangle$, $|\mathbf{r}'(t) \times \mathbf{r}''(t)| = \sqrt{2e^{-2t} + 2(t+2)^2e^{2t} + (2t+3)^2}$,

$|\mathbf{r}'(t)| = \sqrt{(t+1)^2e^{2t} + e^{-2t} + 2}$, and $\kappa(t) = \dfrac{|\mathbf{r}'(t) \times \mathbf{r}''(t)|}{|\mathbf{r}'(t)|^3} = \dfrac{\sqrt{2e^{-2t} + 2(t+2)^2e^{2t} + (2t+3)^2}}{\left[(t+1)^2e^{2t} + e^{-2t} + 2\right]^{3/2}}$.

We plot the space curve and its curvature function for $-5 \le t \le 5$ below.



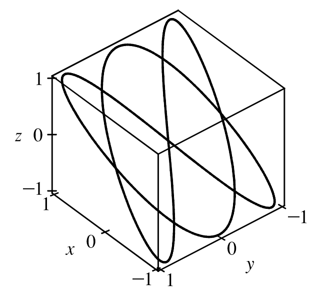


From the graph of $\kappa(t)$ we see that curvature is maximized for $t = 0$, so the curve bends most sharply at the point $(0, 1, 0)$. The curve bends more gradually as we move away from this point, becoming almost linear. This is reflected in the curvature graph, where $\kappa(t)$ becomes nearly 0 as $|t|$ increases.

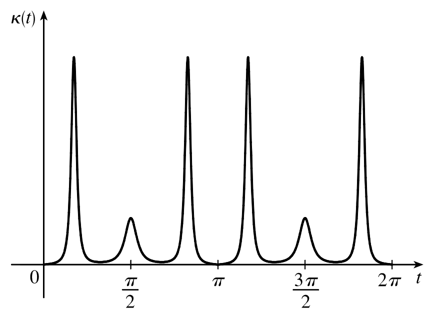
38. Notice that the curve a is highest for the same x-values at which curve b is turning more sharply, and a is 0 or near 0 where b is nearly straight. So, a must be the graph of $y = \kappa(x)$, and b is the graph of $y = f(x)$.

39. Notice that the curve b has two inflection points at which the graph appears almost straight. We would expect the curvature to be 0 or nearly 0 at these values, but the curve a isn't near 0 there. Thus, a must be the graph of $y = f(x)$ rather than the graph of curvature, and b is the graph of $y = \kappa(x)$.

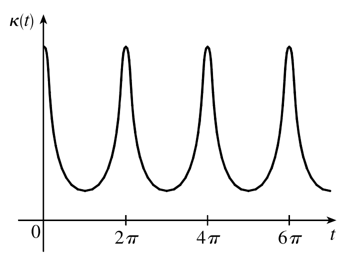
40. (a) The complete curve is given by $0 \le t \le 2\pi$. Curvature appears to have a local (or absolute) maximum at 6 points. (Look at points where the curve appears to turn more sharply.)



(b) Using a CAS, we find (after simplifying)
$\kappa(t) = \dfrac{3\sqrt{2}\sqrt{(5\sin t + \sin 5t)^2}}{(9\cos 6t + 2\cos 4t + 11)^{3/2}}$. (To compute cross products in Maple, use the `VectorCalculus` or `LinearAlgebra` package and the `CrossProduct(a,b)` command; in Mathematica, use `Cross[a,b]`.) The graph shows 6 local (or absolute) maximum points for $0 \le t \le 2\pi$, as observed in part (a).



41. Using a CAS, we find (after simplifying)
$\kappa(t) = \dfrac{6\sqrt{4\cos^2 t - 12\cos t + 13}}{(17 - 12\cos t)^{3/2}}$. (To compute cross products in Maple, use the `VectorCalculus` or `LinearAlgebra` package and the `CrossProduct(a,b)` command; in Mathematica, use `Cross[a,b]`.) Curvature is largest at integer multiples of 2π.



42. Here $\mathbf{r}(t) = \langle f(t), g(t)\rangle$, $\quad \mathbf{r}'(t) = \langle f'(t), g'(t)\rangle$, $\quad \mathbf{r}''(t) = \langle f''(t), g''(t)\rangle$,

$|\mathbf{r}'(t)|^3 = \left[\sqrt{(f'(t))^2 + (g'(t))^2}\,\right]^3 = [(f'(t))^2 + (g'(t))^2]^{3/2} = (\dot{x}^2 + \dot{y}^2)^{3/2}$, and

$|\mathbf{r}'(t) \times \mathbf{r}''(t)| = |\langle 0, 0, f'(t)\,g''(t) - f''(t)\,g'(t)\rangle| = \left[(\dot{x}\ddot{y} - \ddot{x}\dot{y})^2\right]^{1/2} = |\dot{x}\ddot{y} - \dot{y}\ddot{x}|$. Thus $\kappa(t) = \dfrac{|\dot{x}\ddot{y} - \dot{y}\ddot{x}|}{[\dot{x}^2 + \dot{y}^2]^{3/2}}$.

43. $x = t^2 \;\Rightarrow\; \dot{x} = 2t \;\Rightarrow\; \ddot{x} = 2, \quad y = t^3 \;\Rightarrow\; \dot{y} = 3t^2 \;\Rightarrow\; \ddot{y} = 6t$.

Then $\kappa(t) = \dfrac{|\dot{x}\ddot{y} - \dot{y}\ddot{x}|}{[\dot{x}^2 + \dot{y}^2]^{3/2}} = \dfrac{|(2t)(6t) - (3t^2)(2)|}{[(2t)^2 + (3t^2)^2]^{3/2}} = \dfrac{|12t^2 - 6t^2|}{(4t^2 + 9t^4)^{3/2}} = \dfrac{6t^2}{(4t^2 + 9t^4)^{3/2}}$.

44. $x = a\cos\omega t \;\Rightarrow\; \dot{x} = -a\omega\sin\omega t \;\Rightarrow\; \ddot{x} = -a\omega^2\cos\omega t,$

$y = b\sin\omega t \;\Rightarrow\; \dot{y} = b\omega\cos\omega t \;\Rightarrow\; \ddot{y} = -b\omega^2\sin\omega t$. Then

$$\kappa(t) = \frac{|\dot{x}\ddot{y} - \dot{y}\ddot{x}|}{[\dot{x}^2 + \dot{y}^2]^{3/2}} = \frac{\left|(-a\omega\sin\omega t)(-b\omega^2\sin\omega t) - (b\omega\cos\omega t)(-a\omega^2\cos\omega t)\right|}{[(-a\omega\sin\omega t)^2 + (b\omega\cos\omega t)^2]^{3/2}}$$
$$= \frac{\left|ab\omega^3\sin^2\omega t + ab\omega^3\cos^2\omega t\right|}{(a^2\omega^2\sin^2\omega t + b^2\omega^2\cos^2\omega t)^{3/2}} = \frac{\left|ab\omega^3\right|}{(a^2\omega^2\sin^2\omega t + b^2\omega^2\cos^2\omega t)^{3/2}}$$

45. $x = e^t\cos t \;\Rightarrow\; \dot{x} = e^t(\cos t - \sin t) \;\Rightarrow\; \ddot{x} = e^t(-\sin t - \cos t) + e^t(\cos t - \sin t) = -2e^t\sin t,$

$y = e^t\sin t \;\Rightarrow\; \dot{y} = e^t(\cos t + \sin t) \;\Rightarrow\; \ddot{y} = e^t(-\sin t + \cos t) + e^t(\cos t + \sin t) = 2e^t\cos t$. Then

$$\kappa(t) = \frac{|\dot{x}\ddot{y} - \dot{y}\ddot{x}|}{[\dot{x}^2 + \dot{y}^2]^{3/2}} = \frac{\left|e^t(\cos t - \sin t)(2e^t\cos t) - e^t(\cos t + \sin t)(-2e^t\sin t)\right|}{([e^t(\cos t - \sin t)]^2 + [e^t(\cos t + \sin t)]^2)^{3/2}}$$
$$= \frac{\left|2e^{2t}(\cos^2 t - \sin t\cos t + \sin t\cos t + \sin^2 t)\right|}{\left[e^{2t}(\cos^2 t - 2\cos t\sin t + \sin^2 t + \cos^2 t + 2\cos t\sin t + \sin^2 t)\right]^{3/2}} = \frac{\left|2e^{2t}(1)\right|}{[e^{2t}(1+1)]^{3/2}} = \frac{2e^{2t}}{e^{3t}(2)^{3/2}} = \frac{1}{\sqrt{2}\,e^t}$$

46. $f(x) = e^{cx}$, $f'(x) = ce^{cx}$, $f''(x) = c^2e^{cx}$. Using Formula 11 we have

$\kappa(x) = \dfrac{|f''(x)|}{[1 + (f'(x))^2]^{3/2}} = \dfrac{\left|c^2e^{cx}\right|}{[1 + (ce^{cx})^2]^{3/2}} = \dfrac{c^2e^{cx}}{(1 + c^2e^{2cx})^{3/2}}$ so the curvature at $x = 0$ is

$\kappa(0) = \dfrac{c^2}{(1 + c^2)^{3/2}}$. To determine the maximum value for $\kappa(0)$, let $f(c) = \dfrac{c^2}{(1 + c^2)^{3/2}}$. Then

$f'(c) = \dfrac{2c\cdot(1 + c^2)^{3/2} - c^2\cdot\frac{3}{2}(1 + c^2)^{1/2}(2c)}{[(1 + c^2)^{3/2}]^2} = \dfrac{(1 + c^2)^{1/2}\left[2c(1 + c^2) - 3c^3\right]}{(1 + c^2)^3} = \dfrac{(2c - c^3)}{(1 + c^2)^{5/2}}$. We have a critical number when $2c - c^3 = 0 \;\Rightarrow\; c(2 - c^2) = 0 \;\Rightarrow\; c = 0$ or $c = \pm\sqrt{2}$. $f'(c)$ is positive for $c < -\sqrt{2}$, $0 < c < \sqrt{2}$ and negative elsewhere, so f achieves its maximum value when $c = \sqrt{2}$ or $-\sqrt{2}$. In either case, $\kappa(0) = \dfrac{2}{3^{3/2}}$, so the members of the family with the largest value of $\kappa(0)$ are $f(x) = e^{\sqrt{2}x}$ and $f(x) = e^{-\sqrt{2}x}$.

47. $\left(1, \frac{2}{3}, 1\right)$ corresponds to $t = 1$. $\mathbf{T}(t) = \dfrac{\mathbf{r}'(t)}{|\mathbf{r}'(t)|} = \dfrac{\left\langle 2t, 2t^2, 1\right\rangle}{\sqrt{4t^2 + 4t^4 + 1}} = \dfrac{\left\langle 2t, 2t^2, 1\right\rangle}{2t^2 + 1}$, so $\mathbf{T}(1) = \left\langle \frac{2}{3}, \frac{2}{3}, \frac{1}{3}\right\rangle$.

$$\mathbf{T}'(t) = -4t(2t^2 + 1)^{-2}\left\langle 2t, 2t^2, 1\right\rangle + (2t^2 + 1)^{-1}\left\langle 2, 4t, 0\right\rangle \qquad \text{[by Formula 3 of Theorem 13.2.3]}$$
$$= (2t^2 + 1)^{-2}\left\langle -8t^2 + 4t^2 + 2, -8t^3 + 8t^3 + 4t, -4t\right\rangle = 2(2t^2 + 1)^{-2}\left\langle 1 - 2t^2, 2t, -2t\right\rangle$$

$$\mathbf{N}(t) = \frac{\mathbf{T}'(t)}{|\mathbf{T}'(t)|} = \frac{2(2t^2 + 1)^{-2}\left\langle 1 - 2t^2, 2t, -2t\right\rangle}{2(2t^2 + 1)^{-2}\sqrt{(1 - 2t^2)^2 + (2t)^2 + (-2t)^2}} = \frac{\left\langle 1 - 2t^2, 2t, -2t\right\rangle}{\sqrt{1 - 4t^2 + 4t^4 + 8t^2}} = \frac{\left\langle 1 - 2t^2, 2t, -2t\right\rangle}{1 + 2t^2}$$

$\mathbf{N}(1) = \left\langle -\frac{1}{3}, \frac{2}{3}, -\frac{2}{3}\right\rangle$ and $\mathbf{B}(1) = \mathbf{T}(1)\times\mathbf{N}(1) = \left\langle -\frac{4}{9} - \frac{2}{9}, -\left(-\frac{4}{9} + \frac{1}{9}\right), \frac{4}{9} + \frac{2}{9}\right\rangle = \left\langle -\frac{2}{3}, \frac{1}{3}, \frac{2}{3}\right\rangle$.

48. $(1, 0, 0)$ corresponds to $t = 0$. $\mathbf{r}(t) = \langle \cos t, \sin t, \ln\cos t\rangle$, and in Exercise 4 we found that $\mathbf{r}'(t) = \langle -\sin t, \cos t, -\tan t\rangle$ and $|\mathbf{r}'(t)| = |\sec t|$. Here we can assume $-\frac{\pi}{2} < t < \frac{\pi}{2}$ and then $\sec t > 0 \;\Rightarrow\; |\mathbf{r}'(t)| = \sec t$.

$\mathbf{T}(t) = \dfrac{\mathbf{r}'(t)}{|\mathbf{r}'(t)|} = \dfrac{\langle -\sin t, \cos t, -\tan t\rangle}{\sec t} = \left\langle -\sin t\cos t, \cos^2 t, -\sin t\right\rangle$ and $\mathbf{T}(0) = \langle 0, 1, 0\rangle$.

$\mathbf{T}'(t) = \langle -[(\sin t)(-\sin t) + (\cos t)(\cos t)], 2(\cos t)(-\sin t), -\cos t\rangle = \left\langle \sin^2 t - \cos^2 t, -2\sin t\cos t, -\cos t\right\rangle$, so

$\mathbf{N}(0) = \dfrac{\mathbf{T}'(0)}{|\mathbf{T}'(0)|} = \dfrac{\langle -1, 0, -1\rangle}{\sqrt{1+0+1}} = \dfrac{1}{\sqrt{2}}\langle -1, 0, -1\rangle = \left\langle -\frac{1}{\sqrt{2}}, 0, -\frac{1}{\sqrt{2}}\right\rangle$.

Finally, $\mathbf{B}(0) = \mathbf{T}(0)\times\mathbf{N}(0) = \langle 0, 1, 0\rangle \times \left\langle -\frac{1}{\sqrt{2}}, 0, -\frac{1}{\sqrt{2}}\right\rangle = \left\langle -\frac{1}{\sqrt{2}}, 0, \frac{1}{\sqrt{2}}\right\rangle$.

49. $\mathbf{r}(t) = \langle \sin 2t, -\cos 2t, 4t\rangle \;\Rightarrow\; \mathbf{r}'(t) = \langle 2\cos 2t, 2\sin 2t, 4\rangle$. The point $(0, 1, 2\pi)$ corresponds to $t = \pi/2$, and the normal plane there has normal vector $\mathbf{r}'(\pi/2) = \langle -2, 0, 4\rangle$. An equation for the normal plane is $-2(x-0) + 0(y-1) + 4(z-2\pi) = 0$ or $-2x + 4z = 8\pi$ or $x - 2z = -4\pi$.

$\mathbf{T}(t) = \dfrac{\mathbf{r}'(t)}{|\mathbf{r}'(t)|} = \dfrac{\langle 2\cos 2t, 2\sin 2t, 4\rangle}{\sqrt{4\cos^2 2t + 4\sin^2 2t + 16}} = \dfrac{1}{2\sqrt{5}}\langle 2\cos 2t, 2\sin 2t, 4\rangle = \dfrac{1}{\sqrt{5}}\langle \cos 2t, \sin 2t, 2\rangle \;\Rightarrow$

$\mathbf{T}'(t) = \frac{1}{\sqrt{5}}\langle -2\sin 2t, 2\cos 2t, 0\rangle \;\Rightarrow\; |\mathbf{T}'(t)| = \frac{1}{\sqrt{5}}\sqrt{4\sin^2 2t + 4\cos^2 2t} = \frac{2}{\sqrt{5}}$, and

$\mathbf{N}(t) = \dfrac{\mathbf{T}'(t)}{|\mathbf{T}'(t)|} = \langle -\sin 2t, \cos 2t, 0\rangle$. Then $\mathbf{T}(\pi/2) = \frac{1}{\sqrt{5}}\langle -1, 0, 2\rangle$, $\mathbf{N}(\pi/2) = \langle 0, -1, 0\rangle$, and

$\mathbf{B}(\pi/2) = \mathbf{T}(\pi/2)\times\mathbf{N}(\pi/2) = \frac{1}{\sqrt{5}}\langle 2, 0, 1\rangle$. Since $\mathbf{B}(\pi/2)$ is normal to the osculating plane, so is $\langle 2, 0, 1\rangle$, and an equation of the plane is $2(x-0) + 0(y-1) + 1(z-2\pi) = 0$ or $2x + z = 2\pi$.

50. $\mathbf{r}(t) = \left\langle \ln t, 2t, t^2\right\rangle \;\Rightarrow\; \mathbf{r}'(t) = \langle 1/t, 2, 2t\rangle$. The point $(0, 2, 1)$ corresponds to $t = 1$, and the normal plane there has normal vector $\mathbf{r}'(1) = \langle 1, 2, 2\rangle$. An equation for the normal plane is $1(x-0) + 2(y-2) + 2(z-1) = 0$ or $x + 2y + 2z = 6$.

$|\mathbf{r}'(t)| = \sqrt{1/t^2 + 4 + 4t^2} = \sqrt{[(1/t) + 2t]^2} = (1/t) + 2t \quad [\text{since } t > 0]$ and then

$\mathbf{T}(t) = \dfrac{\mathbf{r}'(t)}{|\mathbf{r}'(t)|} = \dfrac{\langle 1/t, 2, 2t\rangle}{(1/t) + 2t} = \dfrac{1}{1+2t^2}\left\langle 1, 2t, 2t^2\right\rangle \quad \left[\text{after multiplying by } \dfrac{t}{t}\right]$. By Formula 3 of Theorem 13.2.3,

$$\begin{aligned}\mathbf{T}'(t) &= -\frac{4t}{(1+2t^2)^2}\left\langle 1, 2t, 2t^2\right\rangle + \frac{1}{1+2t^2}\langle 0, 2, 4t\rangle \\ &= \frac{1}{(1+2t^2)^2}\left\langle -4t, -8t^2 + 2(1+2t^2), -8t^3 + 4t(1+2t^2)\right\rangle = \frac{1}{(1+2t^2)^2}\left\langle -4t, 2-4t^2, 4t\right\rangle\end{aligned}$$

Then

$$\begin{aligned}|\mathbf{T}'(t)| &= \frac{1}{(1+2t^2)^2}\sqrt{16t^2 + (2-4t^2)^2 + 16t^2} = \frac{1}{(1+2t^2)^2}\sqrt{16t^2 + 4 + 16t^4} \\ &= \frac{1}{(1+2t^2)^2}\cdot 2\sqrt{(1+2t^2)^2} = \frac{2}{1+2t^2}\end{aligned}$$

and $\mathbf{N}(t) = \dfrac{\mathbf{T}'(t)}{|\mathbf{T}'(t)|} = \dfrac{1}{2(1+2t^2)}\left\langle -4t, 2-4t^2, 4t\right\rangle = \dfrac{1}{1+2t^2}\left\langle -2t, 1-2t^2, 2t\right\rangle$.

Thus $\mathbf{T}(1) = \frac{1}{3}\langle 1, 2, 2\rangle$, $\mathbf{N}(1) = \frac{1}{3}\langle -2, -1, 2\rangle$, and $\mathbf{B}(1) = \mathbf{T}(1) \times \mathbf{N}(1) = \frac{1}{9}\langle 6, -6, 3\rangle$ is normal to the osculating plane. We can take the parallel vector $\langle 2, -2, 1\rangle$ as a normal vector for the plane, so an equation is

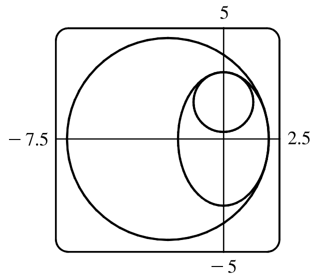
$2(x - 0) - 2(y - 2) + 1(z - 1) = 0$ or $2x - 2y + z = -3$.

Note: Since $\mathbf{r}'(1)$ is parallel to $\mathbf{T}(1)$ and $\mathbf{T}'(1)$ is parallel to $\mathbf{N}(1)$, we could have taken $\mathbf{r}'(1) \times \mathbf{T}'(1)$ as a normal vector for the plane.

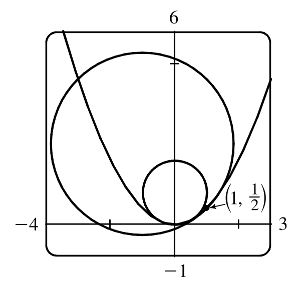
51. The ellipse is given by the parametric equations $x = 2\cos t$, $y = 3\sin t$, so using the result from Exercise 42,

$$\kappa(t) = \frac{|\dot{x}\ddot{y} - \ddot{x}\dot{y}|}{[\dot{x}^2 + \dot{y}^2]^{3/2}} = \frac{|(-2\sin t)(-3\sin t) - (3\cos t)(-2\cos t)|}{(4\sin^2 t + 9\cos^2 t)^{3/2}} = \frac{6}{(4\sin^2 t + 9\cos^2 t)^{3/2}}.$$

At $(2, 0)$, $t = 0$. Now $\kappa(0) = \frac{6}{27} = \frac{2}{9}$, so the radius of the osculating circle is $1/\kappa(0) = \frac{9}{2}$ and its center is $\left(-\frac{5}{2}, 0\right)$. Its equation is therefore $\left(x + \frac{5}{2}\right)^2 + y^2 = \frac{81}{4}$. At $(0, 3)$, $t = \frac{\pi}{2}$, and $\kappa\left(\frac{\pi}{2}\right) = \frac{6}{8} = \frac{3}{4}$. So the radius of the osculating circle is $\frac{4}{3}$ and its center is $\left(0, \frac{5}{3}\right)$. Hence its equation is $x^2 + \left(y - \frac{5}{3}\right)^2 = \frac{16}{9}$.



52. $y = \frac{1}{2}x^2 \quad\Rightarrow\quad y' = x$ and $y'' = 1$, so Formula 11 gives $\kappa(x) = \dfrac{1}{(1 + x^2)^{3/2}}$. So the curvature at $(0, 0)$ is $\kappa(0) = 1$ and the osculating circle has radius 1 and center $(0, 1)$, and hence equation $x^2 + (y - 1)^2 = 1$. The curvature at $\left(1, \frac{1}{2}\right)$ is $\kappa(1) = \dfrac{1}{(1 + 1^2)^{3/2}} = \dfrac{1}{2\sqrt{2}}$. The tangent line to the parabola at $\left(1, \frac{1}{2}\right)$ has slope 1, so the normal line has slope -1. Thus the center of the osculating circle lies in the direction of the unit vector $\left\langle -\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}\right\rangle$. The circle has radius $2\sqrt{2}$, so its center has position vector $\left\langle 1, \frac{1}{2}\right\rangle + 2\sqrt{2}\left\langle -\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}\right\rangle = \left\langle -1, \frac{5}{2}\right\rangle$. So the equation of the circle is $(x + 1)^2 + \left(y - \frac{5}{2}\right)^2 = 8$.



53. Here $\mathbf{r}(t) = \langle t^3, 3t, t^4\rangle$, and $\mathbf{r}'(t) = \langle 3t^2, 3, 4t^3\rangle$ is normal to the normal plane for any t. The given plane has normal vector $\langle 6, 6, -8\rangle$, and the planes are parallel when their normal vectors are parallel. Thus we need to find a value for t where $\langle 3t^2, 3, 4t^3\rangle = k\langle 6, 6, -8\rangle$ for some $k \neq 0$. From the y-component we see that $k = \frac{1}{2}$, and $\langle 3t^2, 3, 4t^3\rangle = \frac{1}{2}\langle 6, 6, -8\rangle = \langle 3, 3, -4\rangle$ for $t = -1$. Thus the planes are parallel at the point $(-1, -3, 1)$.

54. To find the osculating plane, we first calculate the unit tangent and normal vectors.

In Maple, we use the `VectorCalculus` package and set `r:=<t^3,3*t,t^4>;`. After differentiating, the `Normalize` command converts the tangent vector to the unit tangent vector: `T:=Normalize(diff(r,t));`. After simplifying, we find that $\mathbf{T}(t) = \dfrac{\langle 3t^2, 3, 4t^3 \rangle}{\sqrt{16t^6 + 9t^4 + 9}}$. We use a similar procedure to compute the unit normal vector,

`N:=Normalize(diff(T,t));`. After simplifying, we have $\mathbf{N}(t) = \dfrac{\langle -t(8t^6 - 9), -3t^3(3 + 8t^2), 6t^2(t^4 + 3) \rangle}{\sqrt{t^2(4t^6 + 36t^2 + 9)(16t^6 + 9t^4 + 9)}}$. Then

we use the command `B:=CrossProduct(T,N);`. After simplification, we find that $\mathbf{B}(t) = \dfrac{\langle 6t^2, -2t^4, -3t \rangle}{\sqrt{t^2(4t^6 + 36t^2 + 9)}}$.

In Mathematica, we define the vector function `r={t^3,3*t,t^4}` and use the command `Dt` to differentiate. We find $\mathbf{T}(t)$ by dividing the result by its magnitude, computed using the `Norm` command. (You may wish to include the option `Element[t,Reals]` to obtain simpler expressions.) $\mathbf{N}(t)$ is found similarly, and we use `Cross[T,N]` to find $\mathbf{B}(t)$.

Now $\mathbf{B}(t)$ is parallel to $\langle 6t^2, -2t^4, -3t \rangle$, so if $\mathbf{B}(t)$ is parallel to $\langle 1, 1, 1 \rangle$ for some $t \neq 0$ [since $\mathbf{B}(0) = \mathbf{0}$], then $\langle 6t^2, -2t^4, -3t \rangle = k \langle 1, 1, 1 \rangle$ for some value of k. But then $6t^2 = -2t^4 = -3t$ which has no solution for $t \neq 0$. So there is no such osculating plane.

55. First we parametrize the curve of intersection. We can choose $y = t$; then $x = y^2 = t^2$ and $z = x^2 = t^4$, and the curve is given by $\mathbf{r}(t) = \langle t^2, t, t^4 \rangle$. $\mathbf{r}'(t) = \langle 2t, 1, 4t^3 \rangle$ and the point $(1, 1, 1)$ corresponds to $t = 1$, so $\mathbf{r}'(1) = \langle 2, 1, 4 \rangle$ is a normal vector for the normal plane. Thus an equation of the normal plane is

$2(x-1) + 1(y-1) + 4(z-1) = 0$ or $2x + y + 4z = 7$. $\mathbf{T}(t) = \dfrac{\mathbf{r}'(t)}{|\mathbf{r}'(t)|} = \dfrac{1}{\sqrt{4t^2 + 1 + 16t^6}} \langle 2t, 1, 4t^3 \rangle$ and

$\mathbf{T}'(t) = -\frac{1}{2}(4t^2 + 1 + 16t^6)^{-3/2}(8t + 96t^5) \langle 2t, 1, 4t^3 \rangle + (4t^2 + 1 + 16t^6)^{-1/2} \langle 2, 0, 12t^2 \rangle$. A normal vector for the osculating plane is $\mathbf{B}(1) = \mathbf{T}(1) \times \mathbf{N}(1)$, but $\mathbf{r}'(1) = \langle 2, 1, 4 \rangle$ is parallel to $\mathbf{T}(1)$ and

$\mathbf{T}'(1) = -\frac{1}{2}(21)^{-3/2}(104)\langle 2, 1, 4 \rangle + (21)^{-1/2}\langle 2, 0, 12 \rangle = \frac{2}{21\sqrt{21}} \langle -31, -26, 22 \rangle$ is parallel to $\mathbf{N}(1)$ as is $\langle -31, -26, 22 \rangle$, so $\langle 2, 1, 4 \rangle \times \langle -31, -26, 22 \rangle = \langle 126, -168, -21 \rangle$ is normal to the osculating plane. Thus an equation for the osculating plane is $126(x-1) - 168(y-1) - 21(z-1) = 0$ or $6x - 8y - z = -3$.

56. $\mathbf{r}(t) = \langle t + 2, 1 - t, \frac{1}{2}t^2 \rangle \quad \Rightarrow \quad \mathbf{r}'(t) = \langle 1, -1, t \rangle, \quad \mathbf{T}(t) = \dfrac{\mathbf{r}'(t)}{|\mathbf{r}'(t)|} = \dfrac{1}{\sqrt{2 + t^2}} \langle 1, -1, t \rangle,$

$$\begin{aligned} \mathbf{T}'(t) &= -\tfrac{1}{2}(2 + t^2)^{-3/2}(2t)\langle 1, -1, t \rangle + (2 + t^2)^{-1/2} \langle 0, 0, 1 \rangle \\ &= -(2 + t^2)^{-3/2} \left[t\langle 1, -1, t \rangle - (2 + t^2)\langle 0, 0, 1 \rangle \right] = \tfrac{-1}{(2+t^2)^{3/2}} \langle t, -t, -2 \rangle \end{aligned}$$

A normal vector for the osculating plane is $\mathbf{B}(t) = \mathbf{T}(t) \times \mathbf{N}(t)$, but $\mathbf{r}'(t) = \langle 1, -1, t \rangle$ is parallel to $\mathbf{T}(t)$ and $\langle t, -t, -2 \rangle$ is parallel to $\mathbf{T}'(t)$ and hence parallel to $\mathbf{N}(t)$, so $\langle 1, -1, t \rangle \times \langle t, -t, -2 \rangle = \langle t^2 + 2, t^2 + 2, 0 \rangle$ is normal to the osculating plane for any t. All such vectors are parallel to $\langle 1, 1, 0 \rangle$, so at any point $\left(t + 2, 1 - t, \frac{1}{2}t^2\right)$ on the curve, an equation for the osculating plane is $1[x - (t + 2)] + 1[y - (1 - t)] + 0\left(z - \frac{1}{2}t^2\right) = 0$ or $x + y = 3$. Because the osculating plane at every point on the curve is the same, we can conclude that the curve itself lies in that same plane. In fact, we can easily verify that the parametric equations of the curve satisfy $x + y = 3$.

57. $\mathbf{r}(t) = \left\langle e^t \cos t, e^t \sin t, e^t \right\rangle \quad \Rightarrow \quad \mathbf{r}'(t) = \left\langle e^t(\cos t - \sin t), e^t(\cos t + \sin t), e^t \right\rangle$ so

$$|\mathbf{r}'(t)| = \sqrt{e^{2t}(\cos t - \sin t)^2 + e^{2t}(\cos t + \sin t)^2 + e^{2t}}$$
$$= \sqrt{e^{2t}\left[2(\cos^2 t + \sin^2 t) - 2\cos t \sin t + 2\cos t \sin t + 1\right]} = \sqrt{3e^{2t}} = \sqrt{3}\,e^t$$

and $\mathbf{T}(t) = \dfrac{\mathbf{r}'(t)}{|\mathbf{r}'(t)|} = \dfrac{1}{\sqrt{3}\,e^t}\left\langle e^t(\cos t - \sin t), e^t(\cos t + \sin t), e^t\right\rangle = \dfrac{1}{\sqrt{3}}\langle \cos t - \sin t, \cos t + \sin t, 1\rangle$. The vector $\mathbf{k} = \langle 0, 0, 1\rangle$ is parallel to the z-axis, so for any t, the angle α between $\mathbf{T}(t)$ and the z-axis is given by

$\cos\alpha = \dfrac{\mathbf{T}(t)\cdot\mathbf{k}}{|\mathbf{T}(t)|\,|\mathbf{k}|} = \dfrac{\frac{1}{\sqrt{3}}\langle \cos t - \sin t, \cos t + \sin t, 1\rangle \cdot \langle 0,0,1\rangle}{\frac{1}{\sqrt{3}}\sqrt{(\cos t - \sin t)^2 + (\cos t + \sin t)^2 + 1}\,\sqrt{1}} = \dfrac{1}{\sqrt{2(\cos^2 t + \sin^2 t) + 1}} = \dfrac{1}{\sqrt{3}}$. Thus the angle is constant; specifically, $\alpha = \cos^{-1}(1/\sqrt{3}) \approx 54.7^\circ$.

$\mathbf{N}(t) = \dfrac{\mathbf{T}'(t)}{|\mathbf{T}'(t)|} = \dfrac{(1/\sqrt{3}\,)\,\langle -\sin t - \cos t, -\sin t + \cos t, 0\rangle}{(1/\sqrt{3}\,)\sqrt{2\left(\sin^2 t + \cos^2 t\right)}} = \dfrac{1}{\sqrt{2}}\langle -\sin t - \cos t, -\sin t + \cos t, 0\rangle$, and the angle β made with the z-axis is given by $\cos\beta = \dfrac{\mathbf{N}(t)\cdot\mathbf{k}}{|\mathbf{N}(t)|\,|\mathbf{k}|} = 0$, so $\beta = 90^\circ$.

$\mathbf{B}(t) = \mathbf{T}(t)\times\mathbf{N}(t) = \frac{1}{\sqrt{6}}\langle \sin t - \cos t, -\sin t - \cos t, 2\rangle$ and the angle γ made with the z-axis is given by

$\cos\gamma = \dfrac{\mathbf{B}(t)\cdot\mathbf{k}}{|\mathbf{B}(t)|\,|\mathbf{k}|} = \dfrac{\frac{1}{\sqrt{6}}\langle \sin t - \cos t, -\sin t - \cos t, 2\rangle\cdot\langle 0,0,1\rangle}{\frac{1}{\sqrt{6}}\sqrt{(\sin t - \cos t)^2 + (-\sin t - \cos t)^2 + 4}\,\sqrt{1}} = \dfrac{2}{\sqrt{6}}$ or equivalently $\dfrac{\sqrt{6}}{3}$. Again the angle is constant; specifically, $\gamma = \cos^{-1}(2/\sqrt{6}) \approx 35.3^\circ$.

58. If vectors $\mathbf{T}$ and $\mathbf{B}$ lie in the rectifying plane then $\mathbf{N}$ is a normal vector for the plane, as it is orthogonal to both $\mathbf{T}$ and $\mathbf{B}$. The point $\left(\sqrt{2}/2, \sqrt{2}/2, 1\right)$ corresponds to $t = \pi/4$, so we can take $\mathbf{T}'(\pi/4)$ as a normal vector for the plane [since it is parallel to $\mathbf{N}(\pi/4)$]. $\quad \mathbf{r}(t) = \sin t\,\mathbf{i} + \cos t\,\mathbf{j} + \tan t\,\mathbf{k} \quad \Rightarrow \quad \mathbf{r}'(t) = \cos t\,\mathbf{i} - \sin t\,\mathbf{j} + \sec^2 t\,\mathbf{k}$ and $|\mathbf{r}'(t)| = \sqrt{\cos^2 t + \sin^2 t + \sec^4 t} = \sqrt{1 + \sec^4 t}$. Then $\mathbf{T}(t) = \dfrac{\mathbf{r}'(t)}{|\mathbf{r}'(t)|} = \dfrac{1}{\sqrt{1 + \sec^4 t}}\left(\cos t\,\mathbf{i} - \sin t\,\mathbf{j} + \sec^2 t\,\mathbf{k}\right)$. By Formula 3 of Theorem 13.2.3,

$\mathbf{T}'(t) = -\dfrac{2\sec^4 t\tan t}{(1 + \sec^4 t)^{3/2}}\left(\cos t\,\mathbf{i} - \sin t\,\mathbf{j} + \sec^2 t\,\mathbf{k}\right) + \dfrac{1}{\sqrt{1 + \sec^4 t}}\left(-\sin t\,\mathbf{i} - \cos t\,\mathbf{j} + 2\sec^2 t\tan t\,\mathbf{k}\right)$ and

$$\mathbf{T}'(\pi/4) = -\frac{2(\sqrt{2}\,)^4(1)}{[1 + (\sqrt{2}\,)^4]^{3/2}}\left(\frac{\sqrt{2}}{2}\,\mathbf{i} - \frac{\sqrt{2}}{2}\,\mathbf{j} + (\sqrt{2}\,)^2\,\mathbf{k}\right) + \frac{1}{\sqrt{1 + (\sqrt{2}\,)^4}}\left(-\frac{\sqrt{2}}{2}\,\mathbf{i} - \frac{\sqrt{2}}{2}\,\mathbf{j} + 2(\sqrt{2}\,)^2(1)\,\mathbf{k}\right)$$
$$= -\frac{8}{5\sqrt{5}}\left(\frac{\sqrt{2}}{2}\,\mathbf{i} - \frac{\sqrt{2}}{2}\,\mathbf{j} + 2\,\mathbf{k}\right) + \frac{1}{\sqrt{5}}\left(-\frac{\sqrt{2}}{2}\,\mathbf{i} - \frac{\sqrt{2}}{2}\,\mathbf{j} + 4\,\mathbf{k}\right) = -\frac{13\sqrt{2}}{10\sqrt{5}}\,\mathbf{i} + \frac{3\sqrt{2}}{10\sqrt{5}}\,\mathbf{j} + \frac{4}{5\sqrt{5}}\,\mathbf{k}$$

We can take the parallel vector $-13\sqrt{2}\,\mathbf{i} + 3\sqrt{2}\,\mathbf{j} + 8\,\mathbf{k}$ as a normal for the plane, so an equation for the plane is $-13\sqrt{2}\left(x - \frac{\sqrt{2}}{2}\right) + 3\sqrt{2}\left(y - \frac{\sqrt{2}}{2}\right) + 8\,(z - 1) = 0$ or $-13\sqrt{2}\,x + 3\sqrt{2}\,y + 8z = -2$ or $13x - 3y - 4\sqrt{2}\,z = \sqrt{2}$.

59. $\kappa = \left|\dfrac{d\mathbf{T}}{ds}\right| = \left|\dfrac{d\mathbf{T}/dt}{ds/dt}\right| = \dfrac{|d\mathbf{T}/dt|}{ds/dt}$ and $\mathbf{N} = \dfrac{d\mathbf{T}/dt}{|d\mathbf{T}/dt|}$, so $\kappa\mathbf{N} = \dfrac{\left|\dfrac{d\mathbf{T}}{dt}\right| \dfrac{d\mathbf{T}}{dt}}{\left|\dfrac{d\mathbf{T}}{dt}\right| \dfrac{ds}{dt}} = \dfrac{d\mathbf{T}/dt}{ds/dt} = \dfrac{d\mathbf{T}}{ds}$ by the Chain Rule.

60. For a plane curve, $\mathbf{T} = |\mathbf{T}|\cos\phi\,\mathbf{i} + |\mathbf{T}|\sin\phi\,\mathbf{j} = \cos\phi\,\mathbf{i} + \sin\phi\,\mathbf{j}$. Then

$\dfrac{d\mathbf{T}}{ds} = \left(\dfrac{d\mathbf{T}}{d\phi}\right)\left(\dfrac{d\phi}{ds}\right) = (-\sin\phi\,\mathbf{i} + \cos\phi\,\mathbf{j})\left(\dfrac{d\phi}{ds}\right)$ and $\left|\dfrac{d\mathbf{T}}{ds}\right| = |-\sin\phi\,\mathbf{i} + \cos\phi\,\mathbf{j}|\left|\dfrac{d\phi}{ds}\right| = \left|\dfrac{d\phi}{ds}\right|$. Hence for a plane curve, the curvature is $\kappa = |d\phi/ds|$.

61. (a) $|\mathbf{B}| = 1 \;\Rightarrow\; \mathbf{B}\cdot\mathbf{B} = 1 \;\Rightarrow\; \dfrac{d}{ds}(\mathbf{B}\cdot\mathbf{B}) = 0 \;\Rightarrow\; 2\,\dfrac{d\mathbf{B}}{ds}\cdot\mathbf{B} = 0 \;\Rightarrow\; \dfrac{d\mathbf{B}}{ds} \perp \mathbf{B}$

(b) $\mathbf{B} = \mathbf{T}\times\mathbf{N} \;\Rightarrow$

$$\begin{aligned}\frac{d\mathbf{B}}{ds} &= \frac{d}{ds}(\mathbf{T}\times\mathbf{N}) = \frac{d}{dt}(\mathbf{T}\times\mathbf{N})\,\frac{1}{ds/dt} = \frac{d}{dt}(\mathbf{T}\times\mathbf{N})\,\frac{1}{|\mathbf{r}'(t)|} = [(\mathbf{T}'\times\mathbf{N}) + (\mathbf{T}\times\mathbf{N}')]\,\frac{1}{|\mathbf{r}'(t)|}\\ &= \left[\left(\mathbf{T}'\times\frac{\mathbf{T}'}{|\mathbf{T}'|}\right) + (\mathbf{T}\times\mathbf{N}')\right]\frac{1}{|\mathbf{r}'(t)|} = \frac{\mathbf{T}\times\mathbf{N}'}{|\mathbf{r}'(t)|} \quad\Rightarrow\quad \frac{d\mathbf{B}}{ds}\perp\mathbf{T}\end{aligned}$$

(c) $\mathbf{B} = \mathbf{T}\times\mathbf{N} \;\Rightarrow\; \mathbf{T}\perp\mathbf{N}$, $\mathbf{B}\perp\mathbf{T}$ and $\mathbf{B}\perp\mathbf{N}$. So $\mathbf{B}$, $\mathbf{T}$ and $\mathbf{N}$ form an orthogonal set of vectors in the three-dimensional space $\mathbb{R}^3$. From parts (a) and (b), $d\mathbf{B}/ds$ is perpendicular to both $\mathbf{B}$ and $\mathbf{T}$, so $d\mathbf{B}/ds$ is parallel to $\mathbf{N}$. Therefore, $d\mathbf{B}/ds = -\tau(s)\mathbf{N}$, where $\tau(s)$ is a scalar.

(d) Since $\mathbf{B} = \mathbf{T}\times\mathbf{N}$, $\mathbf{T}\perp\mathbf{N}$ and both $\mathbf{T}$ and $\mathbf{N}$ are unit vectors, $\mathbf{B}$ is a unit vector mutually perpendicular to both $\mathbf{T}$ and $\mathbf{N}$. For a plane curve, $\mathbf{T}$ and $\mathbf{N}$ always lie in the plane of the curve, so that $\mathbf{B}$ is a constant unit vector always perpendicular to the plane. Thus $d\mathbf{B}/ds = \mathbf{0}$, but $d\mathbf{B}/ds = -\tau(s)\mathbf{N}$ and $\mathbf{N}\neq\mathbf{0}$, so $\tau(s) = 0$.

62. $\mathbf{N} = \mathbf{B}\times\mathbf{T} \;\Rightarrow$

$$\begin{aligned}\frac{d\mathbf{N}}{ds} &= \frac{d}{ds}(\mathbf{B}\times\mathbf{T}) = \frac{d\mathbf{B}}{ds}\times\mathbf{T} + \mathbf{B}\times\frac{d\mathbf{T}}{ds} && \text{[by Formula 5 of Theorem 13.2.3]}\\ &= -\tau\mathbf{N}\times\mathbf{T} + \mathbf{B}\times\kappa\mathbf{N} && \text{[by Formulas 3 and 1]}\\ &= -\tau(\mathbf{N}\times\mathbf{T}) + \kappa(\mathbf{B}\times\mathbf{N}) && \text{[by Property 2 of Theorem 12.4.11]}\end{aligned}$$

But $\mathbf{B}\times\mathbf{N} = \mathbf{B}\times(\mathbf{B}\times\mathbf{T}) = (\mathbf{B}\cdot\mathbf{T})\,\mathbf{B} - (\mathbf{B}\cdot\mathbf{B})\,\mathbf{T}$ [by Property 6 of Theorem 12.4.11] $= -\mathbf{T} \;\Rightarrow$ $d\mathbf{N}/ds = \tau(\mathbf{T}\times\mathbf{N}) - \kappa\mathbf{T} = -\kappa\,\mathbf{T} + \tau\,\mathbf{B}$.

63. (a) $\mathbf{r}' = s'\,\mathbf{T} \;\Rightarrow\; \mathbf{r}'' = s''\,\mathbf{T} + s'\,\mathbf{T}' = s''\,\mathbf{T} + s'\,\dfrac{d\mathbf{T}}{ds}s' = s''\,\mathbf{T} + \kappa(s')^2\,\mathbf{N}$ by the first Serret-Frenet formula.

(b) Using part (a), we have

$$\begin{aligned}\mathbf{r}'\times\mathbf{r}'' &= (s'\,\mathbf{T})\times[s''\,\mathbf{T} + \kappa(s')^2\,\mathbf{N}]\\ &= [(s'\,\mathbf{T})\times(s''\,\mathbf{T})] + \left[(s'\mathbf{T})\times(\kappa(s')^2\,\mathbf{N})\right] && \text{[by Property 3 of Theorem 12.4.11]}\\ &= (s's'')(\mathbf{T}\times\mathbf{T}) + \kappa(s')^3(\mathbf{T}\times\mathbf{N}) = \mathbf{0} + \kappa(s')^3\,\mathbf{B} = \kappa(s')^3\,\mathbf{B}\end{aligned}$$

(c) Using part (a), we have

$$\begin{aligned}\mathbf{r}''' &= [s''\,\mathbf{T} + \kappa(s')^2\,\mathbf{N}]' = s'''\,\mathbf{T} + s''\,\mathbf{T}' + \kappa'(s')^2\,\mathbf{N} + 2\kappa s's''\,\mathbf{N} + \kappa(s')^2\,\mathbf{N}' \\ &= s'''\,\mathbf{T} + s''\frac{d\mathbf{T}}{ds}\,s' + \kappa'(s')^2\,\mathbf{N} + 2\kappa s's''\,\mathbf{N} + \kappa(s')^2\,\frac{d\mathbf{N}}{ds}\,s' \\ &= s'''\,\mathbf{T} + s''s'\kappa\,\mathbf{N} + \kappa'(s')^2\,\mathbf{N} + 2\kappa s's''\,\mathbf{N} + \kappa(s')^3(-\kappa\,\mathbf{T} + \tau\,\mathbf{B}) \qquad \text{[by the second formula]} \\ &= [s''' - \kappa^2(s')^3]\,\mathbf{T} + [3\kappa s's'' + \kappa'(s')^2]\,\mathbf{N} + \kappa\tau(s')^3\,\mathbf{B}\end{aligned}$$

(d) Using parts (b) and (c) and the facts that $\mathbf{B}\cdot\mathbf{T}=0$, $\mathbf{B}\cdot\mathbf{N}=0$, and $\mathbf{B}\cdot\mathbf{B}=1$, we get

$$\frac{(\mathbf{r}'\times\mathbf{r}'')\cdot\mathbf{r}'''}{|\mathbf{r}'\times\mathbf{r}''|^2} = \frac{\kappa(s')^3\,\mathbf{B}\cdot\left\{[s'''-\kappa^2(s')^3]\,\mathbf{T} + [3\kappa s's''+\kappa'(s')^2]\,\mathbf{N} + \kappa\tau(s')^3\,\mathbf{B}\right\}}{|\kappa(s')^3\,\mathbf{B}|^2} = \frac{\kappa(s')^3\kappa\tau(s')^3}{[\kappa(s')^3]^2} = \tau.$$

64. First we find the quantities required to compute κ:

$$\mathbf{r}'(t) = \langle -a\sin t, a\cos t, b\rangle \quad\Rightarrow\quad \mathbf{r}''(t) = \langle -a\cos t, -a\sin t, 0\rangle \quad\Rightarrow\quad \mathbf{r}'''(t) = \langle a\sin t, -a\cos t, 0\rangle$$

$$|\mathbf{r}'(t)| = \sqrt{(-a\sin t)^2 + (a\cos t)^2 + b^2} = \sqrt{a^2+b^2}$$

$$\mathbf{r}'(t)\times\mathbf{r}''(t) = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ -a\sin t & a\cos t & b \\ -a\cos t & -a\sin t & 0 \end{vmatrix} = ab\sin t\,\mathbf{i} - ab\cos t\,\mathbf{j} + a^2\,\mathbf{k}$$

$$|\mathbf{r}'(t)\times\mathbf{r}''(t)| = \sqrt{(ab\sin t)^2 + (-ab\cos t)^2 + (a^2)^2} = \sqrt{a^2b^2+a^4}$$

$$(\mathbf{r}'(t)\times\mathbf{r}''(t))\cdot\mathbf{r}'''(t) = (ab\sin t)(a\sin t) + (-ab\cos t)(-a\cos t) + (a^2)(0) = a^2 b$$

Then by Theorem 10, $\kappa(t) = \dfrac{|\mathbf{r}'(t)\times\mathbf{r}''(t)|}{|\mathbf{r}'(t)|^3} = \dfrac{\sqrt{a^2b^2+a^4}}{\left(\sqrt{a^2+b^2}\right)^3} = \dfrac{a\sqrt{a^2+b^2}}{\left(\sqrt{a^2+b^2}\right)^3} = \dfrac{a}{a^2+b^2}$ which is a constant.

From Exercise 63(d), the torsion τ is given by $\tau = \dfrac{(\mathbf{r}'\times\mathbf{r}'')\cdot\mathbf{r}'''}{|\mathbf{r}'\times\mathbf{r}''|^2} = \dfrac{a^2b}{\left(\sqrt{a^2b^2+a^4}\right)^2} = \dfrac{b}{a^2+b^2}$ which is also a constant.

65. $\mathbf{r} = \left\langle t, \frac{1}{2}t^2, \frac{1}{3}t^3\right\rangle \quad\Rightarrow\quad \mathbf{r}' = \left\langle 1, t, t^2\right\rangle,\ \mathbf{r}'' = \langle 0, 1, 2t\rangle,\ \mathbf{r}''' = \langle 0,0,2\rangle \quad\Rightarrow\quad \mathbf{r}'\times\mathbf{r}'' = \left\langle t^2, -2t, 1\right\rangle \quad\Rightarrow$

$$\tau = \frac{(\mathbf{r}'\times\mathbf{r}'')\cdot\mathbf{r}'''}{|\mathbf{r}'\times\mathbf{r}''|^2} = \frac{\left\langle t^2,-2t,1\right\rangle\cdot\langle 0,0,2\rangle}{t^4+4t^2+1} = \frac{2}{t^4+4t^2+1}$$

66. $\mathbf{r} = \langle \sinh t, \cosh t, t\rangle \quad\Rightarrow\quad \mathbf{r}' = \langle \cosh t, \sinh t, 1\rangle, \mathbf{r}'' = \langle \sinh t, \cosh t, 0\rangle, \mathbf{r}''' = \langle \cosh t, \sinh t, 0\rangle \quad\Rightarrow$

$\mathbf{r}'\times\mathbf{r}'' = \left\langle -\cosh t, \sinh t, \cosh^2 t - \sinh^2 t\right\rangle = \langle -\cosh t, \sinh t, 1\rangle \quad\Rightarrow$

$$\kappa = \frac{|\mathbf{r}'\times\mathbf{r}''|}{|\mathbf{r}'|^3} = \frac{|\langle -\cosh t,\sinh t,1\rangle|}{|\langle\cosh t,\sinh t,1\rangle|^3} = \frac{\sqrt{\cosh^2 t+\sinh^2 t+1}}{\left(\cosh^2 t+\sinh^2 t+1\right)^{3/2}} = \frac{1}{\cosh^2 t+\sinh^2 t+1} = \frac{1}{2\cosh^2 t},$$

$$\tau = \frac{(\mathbf{r}'\times\mathbf{r}'')\cdot\mathbf{r}'''}{|\mathbf{r}'\times\mathbf{r}''|^2} = \frac{\langle -\cosh t,\sinh t,1\rangle\cdot\langle\cosh t,\sinh t,0\rangle}{\cosh^2 t+\sinh^2 t+1} = \frac{-\cosh^2 t+\sinh^2 t}{2\cosh^2 t} = \frac{-1}{2\cosh^2 t}$$

So at the point $(0,1,0)$, $t=0$, and $\kappa = \frac{1}{2}$ and $\tau = -\frac{1}{2}$.

67. For one helix, the vector equation is $\mathbf{r}(t) = \langle 10\cos t, 10\sin t, 34t/(2\pi)\rangle$ (measuring in angstroms), because the radius of each helix is 10 angstroms, and z increases by 34 angstroms for each increase of 2π in t. Using the arc length formula, letting t go from 0 to $2.9 \times 10^8 \times 2\pi$, we find the approximate length of each helix to be

$$L = \int_0^{2.9\times10^8\times2\pi} |\mathbf{r}'(t)|\,dt = \int_0^{2.9\times10^8\times2\pi} \sqrt{(-10\sin t)^2 + (10\cos t)^2 + \left(\tfrac{34}{2\pi}\right)^2}\,dt = \sqrt{100 + \left(\tfrac{34}{2\pi}\right)^2}\,t\Big]_0^{2.9\times10^8\times2\pi}$$

$$= 2.9\times10^8\times2\pi\sqrt{100 + \left(\tfrac{34}{2\pi}\right)^2} \approx 2.07\times10^{10}\text{ Å — more than two meters!}$$

68. (a) For the function $F(x) = \begin{cases} 0 & \text{if } x < 0 \\ P(x) & \text{if } 0 < x < 1 \\ 1 & \text{if } x \geq 1 \end{cases}$ to be continuous, we must have $P(0) = 0$ and $P(1) = 1$.

For F' to be continuous, we must have $P'(0) = P'(1) = 0$. The curvature of the curve $y = F(x)$ at the point $(x, F(x))$ is $\kappa(x) = \dfrac{|F''(x)|}{\left(1 + [F'(x)]^2\right)^{3/2}}$. For $\kappa(x)$ to be continuous, we must have $P''(0) = P''(1) = 0$.

Write $P(x) = ax^5 + bx^4 + cx^3 + dx^2 + ex + f$. Then $P'(x) = 5ax^4 + 4bx^3 + 3cx^2 + 2dx + e$ and $P''(x) = 20ax^3 + 12bx^2 + 6cx + 2d$. Our six conditions are:

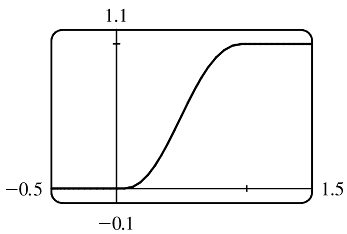
$$P(0) = 0 \;\Rightarrow\; f = 0 \quad \textbf{(1)} \qquad P(1) = 1 \;\Rightarrow\; a+b+c+d+e+f = 1 \quad \textbf{(2)}$$

$$P'(0) = 0 \;\Rightarrow\; e = 0 \quad \textbf{(3)} \qquad P'(1) = 0 \;\Rightarrow\; 5a+4b+3c+2d+e = 0 \quad \textbf{(4)}$$

$$P''(0) = 0 \;\Rightarrow\; d = 0 \quad \textbf{(5)} \qquad P''(1) = 0 \;\Rightarrow\; 20a+12b+6c+2d = 0 \quad \textbf{(6)}$$

From **(1)**, **(3)**, and **(5)**, we have $d = e = f = 0$. Thus **(2)**, **(4)** and **(6)** become **(7)** $a + b + c = 1$, **(8)** $5a + 4b + 3c = 0$, and **(9)** $10a + 6b + 3c = 0$. Subtracting **(8)** from **(9)** gives **(10)** $5a + 2b = 0$. Multiplying **(7)** by 3 and subtracting from **(8)** gives **(11)** $2a + b = -3$. Multiplying **(11)** by 2 and subtracting from **(10)** gives $a = 6$. By **(10)**, $b = -15$. By **(7)**, $c = 10$. Thus, $P(x) = 6x^5 - 15x^4 + 10x^3$.

(b)



13.4 Motion in Space: Velocity and Acceleration

1. (a) If $\mathbf{r}(t) = x(t)\,\mathbf{i} + y(t)\,\mathbf{j} + z(t)\,\mathbf{k}$ is the position vector of the particle at time t, then the average velocity over the time interval $[0, 1]$ is

$$\mathbf{v}_{\text{ave}} = \frac{\mathbf{r}(1) - \mathbf{r}(0)}{1 - 0} = \frac{(4.5\,\mathbf{i} + 6.0\,\mathbf{j} + 3.0\,\mathbf{k}) - (2.7\,\mathbf{i} + 9.8\,\mathbf{j} + 3.7\,\mathbf{k})}{1} = 1.8\,\mathbf{i} - 3.8\,\mathbf{j} - 0.7\,\mathbf{k}$$

Similarly, over the other intervals we have

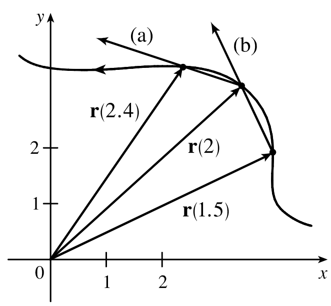
$$[0.5, 1]: \quad \mathbf{v}_{\text{ave}} = \frac{\mathbf{r}(1) - \mathbf{r}(0.5)}{1 - 0.5} = \frac{(4.5\,\mathbf{i} + 6.0\,\mathbf{j} + 3.0\,\mathbf{k}) - (3.5\,\mathbf{i} + 7.2\,\mathbf{j} + 3.3\,\mathbf{k})}{0.5} = 2.0\,\mathbf{i} - 2.4\,\mathbf{j} - 0.6\,\mathbf{k}$$

$$[1, 2]: \quad \mathbf{v}_{\text{ave}} = \frac{\mathbf{r}(2) - \mathbf{r}(1)}{2 - 1} = \frac{(7.3\,\mathbf{i} + 7.8\,\mathbf{j} + 2.7\,\mathbf{k}) - (4.5\,\mathbf{i} + 6.0\,\mathbf{j} + 3.0\,\mathbf{k})}{1} = 2.8\,\mathbf{i} + 1.8\,\mathbf{j} - 0.3\,\mathbf{k}$$

$$[1, 1.5]: \quad \mathbf{v}_{\text{ave}} = \frac{\mathbf{r}(1.5) - \mathbf{r}(1)}{1.5 - 1} = \frac{(5.9\,\mathbf{i} + 6.4\,\mathbf{j} + 2.8\,\mathbf{k}) - (4.5\,\mathbf{i} + 6.0\,\mathbf{j} + 3.0\,\mathbf{k})}{0.5} = 2.8\,\mathbf{i} + 0.8\,\mathbf{j} - 0.4\,\mathbf{k}$$

(b) We can estimate the velocity at $t = 1$ by averaging the average velocities over the time intervals $[0.5, 1]$ and $[1, 1.5]$: $\mathbf{v}(1) \approx \frac{1}{2}[(2\,\mathbf{i} - 2.4\,\mathbf{j} - 0.6\,\mathbf{k}) + (2.8\,\mathbf{i} + 0.8\,\mathbf{j} - 0.4\,\mathbf{k})] = 2.4\,\mathbf{i} - 0.8\,\mathbf{j} - 0.5\,\mathbf{k}$. Then the speed is $|\mathbf{v}(1)| \approx \sqrt{(2.4)^2 + (-0.8)^2 + (-0.5)^2} \approx 2.58$.

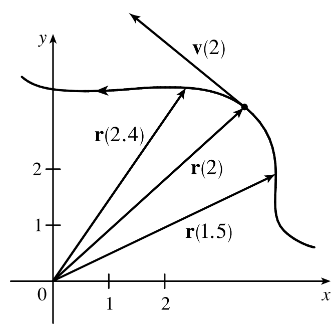
2. (a) The average velocity over $2 \le t \le 2.4$ is $\dfrac{\mathbf{r}(2.4) - \mathbf{r}(2)}{2.4 - 2} = 2.5\,[\mathbf{r}(2.4) - \mathbf{r}(2)]$, so we sketch a vector in the same direction but 2.5 times the length of $[\mathbf{r}(2.4) - \mathbf{r}(2)]$.



(b) The average velocity over $1.5 \le t \le 2$ is $\dfrac{\mathbf{r}(2) - \mathbf{r}(1.5)}{2 - 1.5} = 2[\mathbf{r}(2) - \mathbf{r}(1.5)]$, so we sketch a vector in the same direction but twice the length of $[\mathbf{r}(2) - \mathbf{r}(1.5)]$.

(c) Using Equation 2 we have $\mathbf{v}(2) = \lim\limits_{h \to 0} \dfrac{\mathbf{r}(2 + h) - \mathbf{r}(2)}{h}$.

(d) $\mathbf{v}(2)$ is tangent to the curve at $\mathbf{r}(2)$ and points in the direction of increasing t. Its length is the speed of the particle at $t = 2$. We can estimate the speed by averaging the lengths of the vectors found in parts (a) and (b) which represent the average speed over $2 \le t \le 2.4$ and $1.5 \le t \le 2$ respectively. Using the axes scale as a guide, we estimate the vectors to have lengths 2.8 and 2.7. Thus, we estimate the speed at $t = 2$ to be $|\mathbf{v}(2)| \approx \frac{1}{2}(2.8 + 2.7) = 2.75$ and we draw the velocity vector $\mathbf{v}(2)$ with this length.



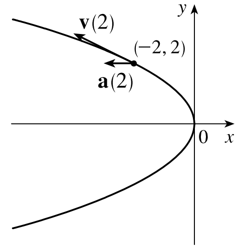
3. $\mathbf{r}(t) = \left\langle -\frac{1}{2}t^2, t \right\rangle \quad \Rightarrow$ At $t = 2$:

$\mathbf{v}(t) = \mathbf{r}'(t) = \langle -t, 1 \rangle$ $\qquad \mathbf{v}(2) = \langle -2, 1 \rangle$

$\mathbf{a}(t) = \mathbf{r}''(t) = \langle -1, 0 \rangle$ $\qquad \mathbf{a}(2) = \langle -1, 0 \rangle$

$|\mathbf{v}(t)| = \sqrt{t^2 + 1}$

Notice that $x = -\frac{1}{2}y^2$, so the path is a parabola.



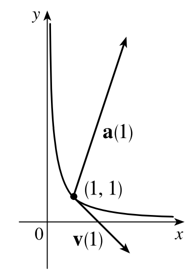
4. $\mathbf{r}(t) = \langle t^2, 1/t^2 \rangle \quad \Rightarrow$ At $t = 1$:

$\mathbf{v}(t) = \mathbf{r}'(t) = \langle 2t, -2/t^3 \rangle$ $\qquad \mathbf{v}(1) = \langle 2, -2 \rangle$

$\mathbf{a}(t) = \mathbf{r}''(t) = \langle 2, 6/t^4 \rangle$ $\qquad \mathbf{a}(1) = \langle 2, 6 \rangle$

$|\mathbf{v}(t)| = \sqrt{4t^2 + 4/t^6} = 2\sqrt{t^2 + 1/t^6}$

Notice that $y = 1/x$ and $x > 0$, so the path is part of the hyperbola $y = 1/x$.



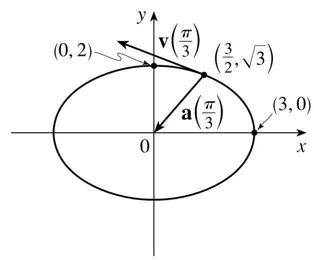
5. $\mathbf{r}(t) = 3\cos t\,\mathbf{i} + 2\sin t\,\mathbf{j} \quad \Rightarrow$ At $t = \pi/3$:

$\mathbf{v}(t) = -3\sin t\,\mathbf{i} + 2\cos t\,\mathbf{j}$ $\qquad \mathbf{v}\left(\frac{\pi}{3}\right) = -\frac{3\sqrt{3}}{2}\,\mathbf{i} + \mathbf{j}$

$\mathbf{a}(t) = -3\cos t\,\mathbf{i} - 2\sin t\,\mathbf{j}$ $\qquad \mathbf{a}\left(\frac{\pi}{3}\right) = -\frac{3}{2}\,\mathbf{i} - \sqrt{3}\,\mathbf{j}$

$$|\mathbf{v}(t)| = \sqrt{9\sin^2 t + 4\cos^2 t} = \sqrt{5\sin^2 t + 4\sin^2 t + 4\cos^2 t} = \sqrt{4 + 5\sin^2 t}$$

Notice that $x^2/9 + y^2/4 = \sin^2 t + \cos^2 t = 1$, so the path is an ellipse.



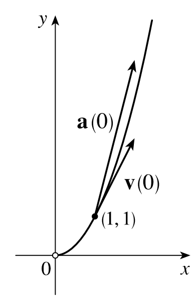
6. $\mathbf{r}(t) = e^t\,\mathbf{i} + e^{2t}\,\mathbf{j} \quad \Rightarrow$ At $t = 0$:

$\mathbf{v}(t) = e^t\,\mathbf{i} + 2e^{2t}\,\mathbf{j}$ $\qquad \mathbf{v}(0) = \mathbf{i} + 2\,\mathbf{j}$

$\mathbf{a}(t) = e^t\,\mathbf{i} + 4e^{2t}\,\mathbf{j}$ $\qquad \mathbf{a}(0) = \mathbf{i} + 4\,\mathbf{j}$

$|\mathbf{v}(t)| = \sqrt{e^{2t} + 4e^{4t}} = e^t\sqrt{1 + 4e^{2t}}$

Notice that $y = e^{2t} = \left(e^t\right)^2 = x^2$, so the particle travels along a parabola, but $x = e^t$, so $x > 0$.



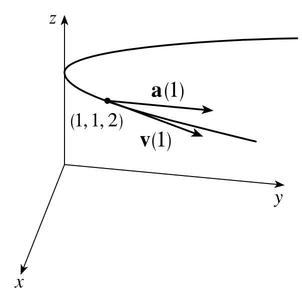
7. $\mathbf{r}(t) = t\,\mathbf{i} + t^2\,\mathbf{j} + 2\,\mathbf{k} \quad \Rightarrow$ At $t = 1$:

$\mathbf{v}(t) = \mathbf{i} + 2t\,\mathbf{j}$ $\qquad \mathbf{v}(1) = \mathbf{i} + 2\,\mathbf{j}$

$\mathbf{a}(t) = 2\,\mathbf{j}$ $\qquad \mathbf{a}(1) = 2\,\mathbf{j}$

$|\mathbf{v}(t)| = \sqrt{1 + 4t^2}$

Here $x = t, y = t^2 \quad \Rightarrow \quad y = x^2$ and $z = 2$, so the path of the particle is a parabola in the plane $z = 2$.



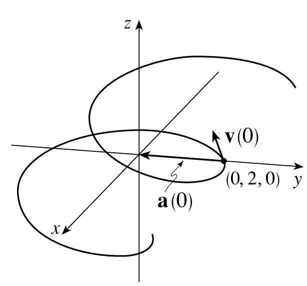
8. $\mathbf{r}(t) = t\,\mathbf{i} + 2\cos t\,\mathbf{j} + \sin t\,\mathbf{k} \quad \Rightarrow$ At $t = 0$:

$\mathbf{v}(t) = \mathbf{i} - 2\sin t\,\mathbf{j} + \cos t\,\mathbf{k}$ $\qquad \mathbf{v}(0) = \mathbf{i} + \mathbf{k}$

$\mathbf{a}(t) = -2\cos t\,\mathbf{j} - \sin t\,\mathbf{k}$ $\qquad \mathbf{a}(0) = -2\,\mathbf{j}$

$|\mathbf{v}(t)| = \sqrt{1 + 4\sin^2 t + \cos^2 t} = \sqrt{2 + 3\sin^2 t}$

Since $y^2/4 + z^2 = 1$, $x = t$, the path of the particle is an elliptical helix about the x-axis.



9. $\mathbf{r}(t) = \langle t^2 + t, t^2 - t, t^3 \rangle \quad \Rightarrow \quad \mathbf{v}(t) = \mathbf{r}'(t) = \langle 2t+1, 2t-1, 3t^2 \rangle, \quad \mathbf{a}(t) = \mathbf{v}'(t) = \langle 2, 2, 6t \rangle,$

$|\mathbf{v}(t)| = \sqrt{(2t+1)^2 + (2t-1)^2 + (3t^2)^2} = \sqrt{9t^4 + 8t^2 + 2}.$

10. $\mathbf{r}(t) = \langle 2\cos t, 3t, 2\sin t \rangle \quad \Rightarrow \quad \mathbf{v}(t) = \mathbf{r}'(t) = \langle -2\sin t, 3, 2\cos t \rangle, \quad \mathbf{a}(t) = \mathbf{v}'(t) = \langle -2\cos t, 0, -2\sin t \rangle,$

$|\mathbf{v}(t)| = \sqrt{4\sin^2 t + 9 + 4\cos^2 t} = \sqrt{13}.$

11. $\mathbf{r}(t) = \sqrt{2}\, t\,\mathbf{i} + e^t\,\mathbf{j} + e^{-t}\,\mathbf{k} \quad \Rightarrow \quad \mathbf{v}(t) = \mathbf{r}'(t) = \sqrt{2}\,\mathbf{i} + e^t\,\mathbf{j} - e^{-t}\,\mathbf{k}, \quad \mathbf{a}(t) = \mathbf{v}'(t) = e^t\,\mathbf{j} + e^{-t}\,\mathbf{k},$

$|\mathbf{v}(t)| = \sqrt{2 + e^{2t} + e^{-2t}} = \sqrt{(e^t + e^{-t})^2} = e^t + e^{-t}.$

12. $\mathbf{r}(t) = t^2\,\mathbf{i} + 2t\,\mathbf{j} + \ln t\,\mathbf{k} \quad \Rightarrow \quad \mathbf{v}(t) = \mathbf{r}'(t) = 2t\,\mathbf{i} + 2\,\mathbf{j} + (1/t)\,\mathbf{k}, \quad \mathbf{a}(t) = \mathbf{v}'(t) = 2\,\mathbf{i} - (1/t^2)\,\mathbf{k},$

$|\mathbf{v}(t)| = \sqrt{4t^2 + 4 + (1/t^2)} = \sqrt{[2t + (1/t)]^2} = |2t + (1/t)|.$

13. $\mathbf{r}(t) = e^t \langle \cos t, \sin t, t \rangle \quad \Rightarrow$

$\mathbf{v}(t) = \mathbf{r}'(t) = e^t \langle \cos t, \sin t, t \rangle + e^t \langle -\sin t, \cos t, 1 \rangle = e^t \langle \cos t - \sin t, \sin t + \cos t, t+1 \rangle$

$$\begin{aligned}\mathbf{a}(t) = \mathbf{v}'(t) &= e^t \langle \cos t - \sin t - \sin t - \cos t, \sin t + \cos t + \cos t - \sin t, t + 1 + 1 \rangle \\ &= e^t \langle -2\sin t, 2\cos t, t+2 \rangle\end{aligned}$$

$$\begin{aligned}|\mathbf{v}(t)| &= e^t \sqrt{\cos^2 t + \sin^2 t - 2\cos t \sin t + \sin^2 t + \cos^2 t + 2\sin t \cos t + t^2 + 2t + 1} \\ &= e^t \sqrt{t^2 + 2t + 3}\end{aligned}$$

14. $\mathbf{r}(t) = \langle t^2, \sin t - t\cos t, \cos t + t\sin t \rangle \quad \Rightarrow$

$\mathbf{v}(t) = \mathbf{r}'(t) = \langle 2t, \cos t - (-t\sin t + \cos t), -\sin t + t\cos t + \sin t \rangle = \langle 2t, t\sin t, t\cos t \rangle,$

$\mathbf{a}(t) = \mathbf{v}'(t) = \langle 2, t\cos t + \sin t, -t\sin t + \cos t \rangle,$

$|\mathbf{v}(t)| = \sqrt{4t^2 + t^2\sin^2 t + t^2\cos^2 t} = \sqrt{4t^2 + t^2} = \sqrt{5t^2} = \sqrt{5}\, t \quad$ [since $t \geq 0$].

15. $\mathbf{a}(t) = 2\,\mathbf{i} + 2t\,\mathbf{k} \quad \Rightarrow \quad \mathbf{v}(t) = \int \mathbf{a}(t)\,dt = \int (2\,\mathbf{i} + 2t\,\mathbf{k})\,dt = 2t\,\mathbf{i} + t^2\,\mathbf{k} + \mathbf{C}$. Then $\mathbf{v}(0) = \mathbf{C}$ but we were given that $\mathbf{v}(0) = 3\,\mathbf{i} - \mathbf{j}$, so $\mathbf{C} = 3\,\mathbf{i} - \mathbf{j}$ and $\mathbf{v}(t) = 2t\,\mathbf{i} + t^2\,\mathbf{k} + 3\,\mathbf{i} - \mathbf{j} = (2t+3)\,\mathbf{i} - \mathbf{j} + t^2\,\mathbf{k}$.

$\mathbf{r}(t) = \int \mathbf{v}(t)\,dt = \int \left[(2t+3)\,\mathbf{i} - \mathbf{j} + t^2\,\mathbf{k}\right] dt = (t^2 + 3t)\,\mathbf{i} - t\,\mathbf{j} + \frac{1}{3}t^3\,\mathbf{k} + \mathbf{D}$. Here $\mathbf{r}(0) = \mathbf{D}$ and we were given that $\mathbf{r}(0) = \mathbf{j} + \mathbf{k}$, so $\mathbf{D} = \mathbf{j} + \mathbf{k}$ and $\mathbf{r}(t) = (t^2 + 3t)\,\mathbf{i} + (1 - t)\,\mathbf{j} + \left(\frac{1}{3}t^3 + 1\right)\mathbf{k}$.

16. $\mathbf{a}(t) = \sin t\,\mathbf{i} + 2\cos t\,\mathbf{j} + 6t\,\mathbf{k} \quad \Rightarrow \quad \mathbf{v}(t) = \int \mathbf{a}(t)\,dt = \int (\sin t\,\mathbf{i} + 2\cos t\,\mathbf{j} + 6t\,\mathbf{k})\,dt = -\cos t\,\mathbf{i} + 2\sin t\,\mathbf{j} + 3t^2\,\mathbf{k} + \mathbf{C}$.

Then $\mathbf{v}(0) = -\mathbf{i} + \mathbf{C}$ but we were given that $\mathbf{v}(0) = -\mathbf{k}$, so $-\mathbf{i} + \mathbf{C} = -\mathbf{k} \quad \Rightarrow \quad \mathbf{C} = \mathbf{i} - \mathbf{k}$ and $\mathbf{v}(t) = (1 - \cos t)\,\mathbf{i} + 2\sin t\,\mathbf{j} + (3t^2 - 1)\,\mathbf{k}$.

$\mathbf{r}(t) = \int \mathbf{v}(t)\,dt = \int \left[(1 - \cos t)\,\mathbf{i} + 2\sin t\,\mathbf{j} + (3t^2 - 1)\,\mathbf{k}\right] dt = (t - \sin t)\,\mathbf{i} - 2\cos t\,\mathbf{j} + (t^3 - t)\,\mathbf{k} + \mathbf{D}$. Here $\mathbf{r}(0) = -2\,\mathbf{j} + \mathbf{D}$ and we were given that $\mathbf{r}(0) = \mathbf{j} - 4\,\mathbf{k}$, so $\mathbf{D} = 3\,\mathbf{j} - 4\,\mathbf{k}$ and $\mathbf{r}(t) = (t - \sin t)\,\mathbf{i} + (3 - 2\cos t)\,\mathbf{j} + (t^3 - t - 4)\,\mathbf{k}$.

17. (a) $\mathbf{a}(t) = 2t\,\mathbf{i} + \sin t\,\mathbf{j} + \cos 2t\,\mathbf{k} \quad\Rightarrow$

$\mathbf{v}(t) = \int (2t\,\mathbf{i} + \sin t\,\mathbf{j} + \cos 2t\,\mathbf{k})\,dt = t^2\,\mathbf{i} - \cos t\,\mathbf{j} + \frac{1}{2}\sin 2t\,\mathbf{k} + \mathbf{C}$

and $\mathbf{i} = \mathbf{v}(0) = -\mathbf{j} + \mathbf{C}$, so $\mathbf{C} = \mathbf{i} + \mathbf{j}$

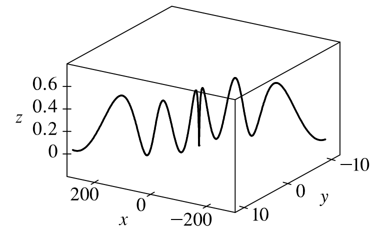
and $\mathbf{v}(t) = \left(t^2 + 1\right)\mathbf{i} + (1 - \cos t)\,\mathbf{j} + \frac{1}{2}\sin 2t\,\mathbf{k}$.

$$\mathbf{r}(t) = \int\left[\left(t^2+1\right)\,\mathbf{i} + (1-\cos t)\,\mathbf{j} + \tfrac{1}{2}\sin 2t\,\mathbf{k}\right]dt$$

$$= \left(\tfrac{1}{3}t^3 + t\right)\,\mathbf{i} + (t - \sin t)\,\mathbf{j} - \tfrac{1}{4}\cos 2t\,\mathbf{k} + \mathbf{D}$$

But $\mathbf{j} = \mathbf{r}(0) = -\frac{1}{4}\,\mathbf{k} + \mathbf{D}$, so $\mathbf{D} = \mathbf{j} + \frac{1}{4}\,\mathbf{k}$ and $\mathbf{r}(t) = \left(\frac{1}{3}t^3 + t\right)\mathbf{i} + (t - \sin t + 1)\,\mathbf{j} + \left(\frac{1}{4} - \frac{1}{4}\cos 2t\right)\mathbf{k}$.

(b)



18. (a) $\mathbf{a}(t) = t\,\mathbf{i} + e^t\,\mathbf{j} + e^{-t}\,\mathbf{k} \quad\Rightarrow$

$\mathbf{v}(t) = \int\left(t\,\mathbf{i} + e^t\,\mathbf{j} + e^{-t}\,\mathbf{k}\right)dt = \frac{1}{2}t^2\,\mathbf{i} + e^t\,\mathbf{j} - e^{-t}\,\mathbf{k} + \mathbf{C}$

and $\mathbf{k} = \mathbf{v}(0) = \mathbf{j} - \mathbf{k} + \mathbf{C}$, so $\mathbf{C} = -\mathbf{j} + 2\,\mathbf{k}$

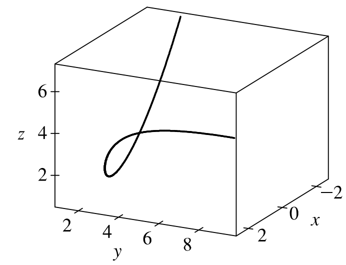
and $\mathbf{v}(t) = \frac{1}{2}t^2\,\mathbf{i} + \left(e^t - 1\right)\,\mathbf{j} + \left(2 - e^{-t}\right)\,\mathbf{k}$.

$$\mathbf{r}(t) = \int\left[\tfrac{1}{2}t^2\,\mathbf{i} + (e^t - 1)\,\mathbf{j} + (2 - e^{-t})\,\mathbf{k}\right]dt$$

$$= \tfrac{1}{6}t^3\,\mathbf{i} + (e^t - t)\,\mathbf{j} + (e^{-t} + 2t)\,\mathbf{k} + \mathbf{D}$$

But $\mathbf{j} + \mathbf{k} = \mathbf{r}(0) = \mathbf{j} + \mathbf{k} + \mathbf{D}$, so $\mathbf{D} = \mathbf{0}$ and $\mathbf{r}(t) = \frac{1}{6}t^3\,\mathbf{i} + (e^t - t)\,\mathbf{j} + (e^{-t} + 2t)\,\mathbf{k}$.

(b)



19. $\mathbf{r}(t) = \langle t^2, 5t, t^2 - 16t\rangle \quad\Rightarrow\quad \mathbf{v}(t) = \langle 2t, 5, 2t - 16\rangle$, $|\mathbf{v}(t)| = \sqrt{4t^2 + 25 + 4t^2 - 64t + 256} = \sqrt{8t^2 - 64t + 281}$

and $\dfrac{d}{dt}\,|\mathbf{v}(t)| = \frac{1}{2}(8t^2 - 64t + 281)^{-1/2}(16t - 64)$. This is zero if and only if the numerator is zero, that is,

$16t - 64 = 0$ or $t = 4$. Since $\dfrac{d}{dt}\,|\mathbf{v}(t)| < 0$ for $t < 4$ and $\dfrac{d}{dt}\,|\mathbf{v}(t)| > 0$ for $t > 4$, the minimum speed of $\sqrt{153}$ is attained

at $t = 4$ units of time.

20. Since $\mathbf{r}(t) = t^3\,\mathbf{i} + t^2\,\mathbf{j} + t^3\,\mathbf{k}$, $\mathbf{a}(t) = \mathbf{r}''(t) = 6t\,\mathbf{i} + 2\,\mathbf{j} + 6t\,\mathbf{k}$. By Newton's Second Law,

$\mathbf{F}(t) = m\,\mathbf{a}(t) = 6mt\,\mathbf{i} + 2m\,\mathbf{j} + 6mt\,\mathbf{k}$ is the required force.

21. $|\mathbf{F}(t)| = 20$ N in the direction of the positive z-axis, so $\mathbf{F}(t) = 20\,\mathbf{k}$. Also $m = 4$ kg, $\mathbf{r}(0) = \mathbf{0}$ and $\mathbf{v}(0) = \mathbf{i} - \mathbf{j}$.

Since $20\mathbf{k} = \mathbf{F}(t) = 4\,\mathbf{a}(t)$, $\mathbf{a}(t) = 5\,\mathbf{k}$. Then $\mathbf{v}(t) = 5t\,\mathbf{k} + \mathbf{c}_1$ where $\mathbf{c}_1 = \mathbf{i} - \mathbf{j}$ so $\mathbf{v}(t) = \mathbf{i} - \mathbf{j} + 5t\,\mathbf{k}$ and the

speed is $|\mathbf{v}(t)| = \sqrt{1 + 1 + 25t^2} = \sqrt{25t^2 + 2}$. Also $\mathbf{r}(t) = t\,\mathbf{i} - t\,\mathbf{j} + \frac{5}{2}t^2\,\mathbf{k} + \mathbf{c}_2$ and $\mathbf{0} = \mathbf{r}(0)$, so $\mathbf{c}_2 = \mathbf{0}$

and $\mathbf{r}(t) = t\,\mathbf{i} - t\,\mathbf{j} + \frac{5}{2}t^2\,\mathbf{k}$.

22. The argument here is the same as that in Example 13.2.4 with $\mathbf{r}(t)$ replaced by $\mathbf{v}(t)$ and $\mathbf{r}'(t)$ replaced by $\mathbf{a}(t)$.

23. $|\mathbf{v}(0)| = 200$ m/s and, since the angle of elevation is $60°$, a unit vector in the direction of the velocity is

$(\cos 60°)\mathbf{i} + (\sin 60°)\mathbf{j} = \frac{1}{2}\mathbf{i} + \frac{\sqrt{3}}{2}\,\mathbf{j}$. Thus $\mathbf{v}(0) = 200\left(\frac{1}{2}\mathbf{i} + \frac{\sqrt{3}}{2}\,\mathbf{j}\right) = 100\,\mathbf{i} + 100\,\sqrt{3}\,\mathbf{j}$ and if we set up the axes so that the

projectile starts at the origin, then $\mathbf{r}(0) = \mathbf{0}$. Ignoring air resistance, the only force is that due to gravity, so

$\mathbf{F}(t) = m\mathbf{a}(t) = -mg\,\mathbf{j}$ where $g \approx 9.8$ m/s^2. Thus $\mathbf{a}(t) = -9.8\,\mathbf{j}$ and, integrating, we have $\mathbf{v}(t) = -9.8t\,\mathbf{j} + \mathbf{C}$. But

$100\,\mathbf{i} + 100\sqrt{3}\,\mathbf{j} = \mathbf{v}(0) = \mathbf{C}$, so $\mathbf{v}(t) = 100\,\mathbf{i} + \left(100\sqrt{3} - 9.8t\right)\mathbf{j}$ and then (integrating again)

$\mathbf{r}(t) = 100\,t\,\mathbf{i} + \left(100\sqrt{3}\,t - 4.9t^2\right)\mathbf{j} + \mathbf{D}$ where $\mathbf{0} = \mathbf{r}(0) = \mathbf{D}$. Thus the position function of the projectile is

$\mathbf{r}(t) = 100\,t\,\mathbf{i} + \left(100\sqrt{3}\,t - 4.9t^2\right)\mathbf{j}$.

(a) Parametric equations for the projectile are $x(t) = 100t$, $y(t) = 100\sqrt{3}\,t - 4.9t^2$. The projectile reaches the ground when

$y(t) = 0$ (and $t > 0$) $\Rightarrow$ $100\sqrt{3}\,t - 4.9t^2 = t\left(100\sqrt{3} - 4.9t\right) = 0$ $\Rightarrow$ $t = \frac{100\sqrt{3}}{4.9} \approx 35.3$ s. So the range is

$x\left(\frac{100\sqrt{3}}{4.9}\right) = 100\left(\frac{100\sqrt{3}}{4.9}\right) \approx 3535$ m.

(b) The maximum height is reached when $y(t)$ has a critical number (or equivalently, when the vertical component

of velocity is 0): $y'(t) = 0$ $\Rightarrow$ $100\sqrt{3} - 9.8t = 0$ $\Rightarrow$ $t = \frac{100\sqrt{3}}{9.8} \approx 17.7$ s. Thus the maximum height is

$y\left(\frac{100\sqrt{3}}{9.8}\right) = 100\sqrt{3}\left(\frac{100\sqrt{3}}{9.8}\right) - 4.9\left(\frac{100\sqrt{3}}{9.8}\right)^2 \approx 1531$ m.

(c) From part (a), impact occurs at $t = \frac{100\sqrt{3}}{4.9}$ s. Thus, the velocity at impact is

$\mathbf{v}\left(\frac{100\sqrt{3}}{4.9}\right) = 100\,\mathbf{i} + \left[100\sqrt{3} - 9.8\left(\frac{100\sqrt{3}}{4.9}\right)\right]\mathbf{j} = 100\,\mathbf{i} - 100\sqrt{3}\,\mathbf{j}$ and the speed is

$\left|\mathbf{v}\left(\frac{100\sqrt{3}}{4.9}\right)\right| = \sqrt{10{,}000 + 30{,}000} = 200$ m/s.

24. As in Exercise 23, $\mathbf{v}(t) = 100\,\mathbf{i} + \left(100\sqrt{3} - 9.8t\right)\mathbf{j}$ and $\mathbf{r}(t) = 100\,t\,\mathbf{i} + \left(100\sqrt{3}\,t - 4.9t^2\right)\mathbf{j} + \mathbf{D}$.

But $\mathbf{r}(0) = 100\,\mathbf{j}$, so $\mathbf{D} = 100\,\mathbf{j}$ and $\mathbf{r}(t) = 100\,t\,\mathbf{i} + \left(100 + 100\sqrt{3}\,t - 4.9t^2\right)\mathbf{j}$.

(a) $y = 0$ $\Rightarrow$ $100 + 100\sqrt{3}\,t - 4.9t^2 = 0$ or $4.9t^2 - 100\sqrt{3}\,t - 100 = 0$. From the quadratic formula we have

$t = \dfrac{100\sqrt{3} \pm \sqrt{(-100\sqrt{3})^2 - 4(4.9)(-100)}}{2(4.9)} = \dfrac{100\sqrt{3} \pm \sqrt{31{,}960}}{9.8}$. Taking the positive t-value gives

$t = \frac{100\sqrt{3} + \sqrt{31{,}960}}{9.8} \approx 35.9$ s. Thus the range is $x = 100 \cdot \frac{100\sqrt{3} + \sqrt{31{,}960}}{9.8} \approx 3592$ m.

(b) The maximum height is attained when $\dfrac{dy}{dt} = 0$ $\Rightarrow$ $100\sqrt{3} - 9.8t = 0$ $\Rightarrow$ $t = \frac{100\sqrt{3}}{9.8} \approx 17.7$ s and the

maximum height is $100 + 100\sqrt{3}\left(\frac{100\sqrt{3}}{9.8}\right) - 4.9\left(\frac{100\sqrt{3}}{9.8}\right)^2 \approx 1631$ m.

Alternate solution: Because the projectile is fired in the same direction and with the same velocity as in Exercise 23, but from a point 100 m higher, the maximum height reached is 100 m higher than that found in Exercise 23, that is, $1531\text{ m} + 100\text{ m} = 1631$ m.

(c) From part (a), impact occurs at $t = \frac{100\sqrt{3} + \sqrt{31{,}960}}{9.8}$ s. Thus the velocity at impact is

$\mathbf{v}\left(\frac{100\sqrt{3} + \sqrt{31{,}960}}{9.8}\right) = 100\,\mathbf{i} + \left[100\sqrt{3} - 9.8\left(\frac{100\sqrt{3} + \sqrt{31{,}960}}{9.8}\right)\right]\mathbf{j} = 100\,\mathbf{i} - \sqrt{31{,}960}\,\mathbf{j}$ and the speed is

$|\mathbf{v}| = \sqrt{10{,}000 + 31{,}960} = \sqrt{41{,}960} \approx 205$ m/s.

25. As in Example 5, $\mathbf{r}(t) = (v_0 \cos 45°)t\,\mathbf{i} + \left[(v_0 \sin 45°)t - \frac{1}{2}gt^2\right]\mathbf{j} = \frac{1}{2}\left[v_0\sqrt{2}\,t\,\mathbf{i} + \left(v_0\sqrt{2}\,t - gt^2\right)\mathbf{j}\right]$. The ball lands when $y = 0$ (and $t > 0$) $\Rightarrow$ $t = \dfrac{v_0\sqrt{2}}{g}$ s. Now since it lands 90 m away, $90 = x = \frac{1}{2}v_0\sqrt{2}\,\dfrac{v_0\sqrt{2}}{g}$ or $v_0^2 = 90g$ and the initial velocity is $v_0 = \sqrt{90g} \approx 30$ m/s.

26. Let α be the angle of elevation. Here $v_0 = 400$ m/s and from Example 5, the horizontal distance traveled by the projectile is $d = \dfrac{v_0^2 \sin 2\alpha}{g}$. We want $\dfrac{400^2 \sin 2\alpha}{g} = 3000$ $\Rightarrow$ $\sin 2\alpha = \dfrac{3000g}{400^2} \approx 0.1838$ $\Rightarrow$ $2\alpha \approx \sin^{-1}(0.1838) \approx 10.6°$ or $2\alpha \approx 180° - 10.6° = 169.4°$. Thus two angles of elevation are $\alpha \approx 5.3°$ and $\alpha \approx 84.7°$.

27. As in Example 5, $\mathbf{r}(t) = (v_0 \cos 36°)t\,\mathbf{i} + \left[(v_0 \sin 36°)t - \frac{1}{2}gt^2\right]\mathbf{j}$ and then $\mathbf{v}(t) = \mathbf{r}'(t) = (v_0 \cos 36°)\,\mathbf{i} + [(v_0 \sin 36°) - gt]\,\mathbf{j}$. The shell reaches its maximum height when the vertical component of velocity is zero, so $(v_0 \sin 36°) - gt = 0$ $\Rightarrow$ $t = \dfrac{v_0 \sin 36°}{g}$. The vertical height of the shell at that time is 1600 ft, so

$$(v_0 \sin 36°)\left(\frac{v_0 \sin 36°}{g}\right) - \tfrac{1}{2}g\left(\frac{v_0 \sin 36°}{g}\right)^2 = 1600 \quad\Rightarrow\quad \left(\frac{v_0^2 \sin^2 36°}{g}\right) - \frac{1}{2}\left(\frac{v_0^2 \sin^2 36°}{g}\right) = 1600 \quad\Rightarrow$$

$$\frac{v_0^2 \sin^2 36°}{2g} = 1600 \quad\Rightarrow\quad v_0^2 = \frac{1600(2g)}{\sin^2 36°} \quad\Rightarrow\quad v_0 = \sqrt{\frac{3200g}{\sin^2 36°}} \approx \frac{\sqrt{3200(32)}}{\sin 36°} \approx 544 \text{ ft/s}.$$

28. Here $v_0 = 115$ ft/s, the angle of elevation is $\alpha = 50°$, and if we place the origin at home plate, then $\mathbf{r}(0) = 3\,\mathbf{j}$. As in Example 5, we have $\mathbf{r}\,(t) = -\frac{1}{2}gt^2\,\mathbf{j} + t\,\mathbf{v}_0 + \mathbf{D}$ where $\mathbf{D} = \mathbf{r}(0) = 3\,\mathbf{j}$ and $\mathbf{v}_0 = v_0 \cos\alpha\,\mathbf{i} + v_0 \sin\alpha\,\mathbf{j}$, so $\mathbf{r}(t) = (v_0 \cos\alpha)t\,\mathbf{i} + \left[(v_0 \sin\alpha)t - \frac{1}{2}gt^2 + 3\right]\mathbf{j}$. Thus, parametric equations for the trajectory of the ball are $x = (v_0 \cos\alpha)t$, $y = (v_0 \sin\alpha)t - \frac{1}{2}gt^2 + 3$. The ball reaches the fence when $x = 400$ $\Rightarrow$ $(v_0 \cos\alpha)t = 400$ $\Rightarrow$ $t = \dfrac{400}{v_0 \cos\alpha} = \dfrac{400}{115 \cos 50°} \approx 5.41$ s. At this time, the height of the ball is $y = (v_0 \sin\alpha)t - \frac{1}{2}gt^2 + 3 \approx (115 \sin 50°)(5.41) - \frac{1}{2}(32)(5.41)^2 + 3 \approx 11.2$ ft. Since the fence is 10 ft high, the ball clears the fence.

29. Place the catapult at the origin and assume the catapult is 100 meters from the city, so the city lies between $(100, 0)$ and $(600, 0)$. The initial speed is $v_0 = 80$ m/s and let θ be the angle the catapult is set at. As in Example 5, the trajectory of the catapulted rock is given by $\mathbf{r}\,(t) = (80 \cos\theta)t\,\mathbf{i} + \left[(80 \sin\theta)t - 4.9t^2\right]\mathbf{j}$. The top of the near city wall is at $(100, 15)$, which the rock will hit when $(80 \cos\theta)\,t = 100$ $\Rightarrow$ $t = \dfrac{5}{4\cos\theta}$ and $(80 \sin\theta)t - 4.9t^2 = 15$ $\Rightarrow$ $80 \sin\theta \cdot \dfrac{5}{4\cos\theta} - 4.9\left(\dfrac{5}{4\cos\theta}\right)^2 = 15$ $\Rightarrow$ $100 \tan\theta - 7.65625 \sec^2\theta = 15$. Replacing $\sec^2\theta$ with $\tan^2\theta + 1$ gives $7.65625 \tan^2\theta - 100 \tan\theta + 22.65625 = 0$. Using the quadratic formula, we have $\tan\theta \approx 0.230635, 12.8306$ $\Rightarrow$ $\theta \approx 13.0°, 85.5°$. So for $13.0° < \theta < 85.5°$, the rock will land beyond the near city wall. The base of the far wall is located at $(600, 0)$ which the rock hits if $(80\cos\theta)t = 600 \quad\Rightarrow\quad t = \dfrac{15}{2\cos\theta}$ and $(80\sin\theta)t - 4.9t^2 = 0 \quad\Rightarrow$

$80\sin\theta \cdot \dfrac{15}{2\cos\theta} - 4.9\left(\dfrac{15}{2\cos\theta}\right)^2 = 0 \quad\Rightarrow\quad 600\tan\theta - 275.625\sec^2\theta = 0 \quad\Rightarrow$

$275.625\tan^2\theta - 600\tan\theta + 275.625 = 0$. Solutions are $\tan\theta \approx 0.658678, 1.51819 \quad\Rightarrow\quad \theta \approx 33.4^\circ, 56.6^\circ$. Thus the rock lands beyond the enclosed city ground for $33.4^\circ < \theta < 56.6^\circ$, and the angles that allow the rock to land on city ground are $13.0^\circ < \theta < 33.4^\circ$, $56.6^\circ < \theta < 85.5^\circ$. If you consider that the rock can hit the far wall and bounce back into the city, we calculate the angles that cause the rock to hit the top of the wall at $(600, 15)$: $(80\cos\theta)t = 600 \quad\Rightarrow\quad t = \dfrac{15}{2\cos\theta}$ and $(80\sin\theta)t - 4.9t^2 = 15 \quad\Rightarrow\quad 600\tan\theta - 275.625\sec^2\theta = 15 \quad\Rightarrow\quad 275.625\tan^2\theta - 600\tan\theta + 290.625 = 0$. Solutions are $\tan\theta \approx 0.727506, 1.44936 \quad\Rightarrow\quad \theta \approx 36.0^\circ, 55.4^\circ$, so the catapult should be set with angle θ where $13.0^\circ < \theta < 36.0^\circ$, $55.4^\circ < \theta < 85.5^\circ$.

30. If we place the projectile at the origin then, as in Example 5, $\mathbf{r}(t) = (v_0\cos\alpha)t\,\mathbf{i} + \left[(v_0\sin\alpha)t - \frac{1}{2}gt^2\right]\mathbf{j}$ and $\mathbf{v}(t) = (v_0\cos\alpha)\,\mathbf{i} + [(v_0\sin\alpha) - gt]\,\mathbf{j}$. The maximum height is reached when the vertical component of velocity is zero, so $(v_0\sin\alpha) - gt = 0 \quad\Rightarrow\quad t = \dfrac{v_0\sin\alpha}{g}$, and the corresponding height is the vertical component of the position function:

$$(v_0\sin\alpha)t - \tfrac{1}{2}gt^2 = (v_0\sin\alpha)\left(\frac{v_0\sin\alpha}{g}\right) - \tfrac{1}{2}g\left(\frac{v_0\sin\alpha}{g}\right)^2 = \frac{1}{2g}v_0^2\sin^2\alpha$$

Half that time is $t = \dfrac{v_0\sin\alpha}{2g}$, when the height of the projectile is

$$\begin{aligned}(v_0\sin\alpha)t - \tfrac{1}{2}gt^2 &= (v_0\sin\alpha)\left(\frac{v_0\sin\alpha}{2g}\right) - \tfrac{1}{2}g\left(\frac{v_0\sin\alpha}{2g}\right)^2 \\ &= \frac{1}{2g}v_0^2\sin^2\alpha - \frac{1}{8g}v_0^2\sin^2\alpha = \frac{3}{8g}v_0^2\sin^2\alpha = \frac{3}{4}\left(\frac{1}{2g}v_0^2\sin^2\alpha\right)\end{aligned}$$

or three-quarters of the maximum height.

31. Here $\mathbf{a}(t) = -4\,\mathbf{j} - 32\,\mathbf{k}$ so $\mathbf{v}(t) = -4t\,\mathbf{j} - 32t\,\mathbf{k} + \mathbf{v}_0 = -4t\,\mathbf{j} - 32t\,\mathbf{k} + 50\,\mathbf{i} + 80\,\mathbf{k} = 50\,\mathbf{i} - 4t\,\mathbf{j} + (80 - 32t)\,\mathbf{k}$ and $\mathbf{r}(t) = 50t\,\mathbf{i} - 2t^2\,\mathbf{j} + (80t - 16t^2)\,\mathbf{k}$ (note that $\mathbf{r}_0 = \mathbf{0}$). The ball lands when the z-component of $\mathbf{r}(t)$ is zero and $t > 0$: $80t - 16t^2 = 16t(5 - t) = 0 \quad\Rightarrow\quad t = 5$. The position of the ball then is $\mathbf{r}(5) = 50(5)\,\mathbf{i} - 2(5)^2\,\mathbf{j} + [80(5) - 16(5)^2]\,\mathbf{k} = 250\,\mathbf{i} - 50\,\mathbf{j}$ or equivalently the point $(250, -50, 0)$. This is a distance of $\sqrt{250^2 + (-50)^2 + 0^2} = \sqrt{65{,}000} \approx 255$ ft from the origin at an angle of $\tan^{-1}\left(\frac{50}{250}\right) \approx 11.3^\circ$ from the eastern direction toward the south. The speed of the ball is $|\mathbf{v}(5)| = |50\,\mathbf{i} - 20\,\mathbf{j} - 80\,\mathbf{k}| = \sqrt{50^2 + (-20)^2 + (-80)^2} = \sqrt{9300} \approx 96.4$ ft/s.

32. Place the ball at the origin and consider $\mathbf{j}$ to be pointing in the northward direction with $\mathbf{i}$ pointing east and $\mathbf{k}$ pointing upward. Force $=$ mass $\times$ acceleration $\quad\Rightarrow\quad$ acceleration $=$ force/mass, so the wind applies a constant acceleration of $4\text{ N}/0.8\text{ kg} = 5\text{ m/s}^2$ in the easterly direction. Combined with the acceleration due to gravity, the acceleration acting on the ball is $\mathbf{a}(t) = 5\,\mathbf{i} - 9.8\,\mathbf{k}$. Then $\mathbf{v}(t) = \int \mathbf{a}(t)\,dt = 5t\,\mathbf{i} - 9.8t\,\mathbf{k} + \mathbf{C}$ where $\mathbf{C}$ is a constant vector.

We know $\mathbf{v}(0) = \mathbf{C} = -30\cos 30^\circ\,\mathbf{j} + 30\sin 30^\circ\,\mathbf{k} = -15\sqrt{3}\,\mathbf{j} + 15\,\mathbf{k} \quad\Rightarrow\quad \mathbf{C} = -15\sqrt{3}\,\mathbf{j} + 15\,\mathbf{k}$ and

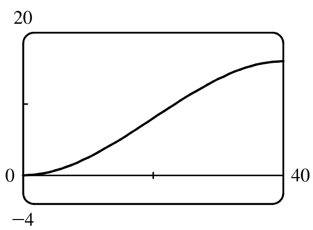
$\mathbf{v}(t) = 5t\,\mathbf{i} - 15\sqrt{3}\,\mathbf{j} + (15 - 9.8t)\,\mathbf{k}$. $\mathbf{r}(t) = \int \mathbf{v}(t)\,dt = 2.5t^2\,\mathbf{i} - 15\sqrt{3}\,t\,\mathbf{j} + \left(15t - 4.9t^2\right)\mathbf{k} + \mathbf{D}$ but $\mathbf{r}(0) = \mathbf{D} = \mathbf{0}$

so $\mathbf{r}(t) = 2.5t^2\,\mathbf{i} - 15\sqrt{3}\,t\,\mathbf{j} + \left(15t - 4.9t^2\right)\mathbf{k}$. The ball lands when $15t - 4.9t^2 = 0 \quad\Rightarrow\quad t = 0,\ t = 15/4.9 \approx 3.0612$ s,

so the ball lands at approximately $\mathbf{r}(3.0612) \approx 23.43\,\mathbf{i} - 79.53\,\mathbf{j}$ which is 82.9 m away in the direction S 16.4°E. Its speed is

approximately $|\mathbf{v}(3.0612)| \approx \left|15.306\,\mathbf{i} - 15\sqrt{3}\,\mathbf{j} - 15\,\mathbf{k}\right| \approx 33.68$ m/s.

33. (a) After t seconds, the boat will be $5t$ meters west of point A. The velocity of the water at that location is $\frac{3}{400}(5t)(40 - 5t)\,\mathbf{j}$. The velocity of the boat in still water is $5\,\mathbf{i}$, so the resultant velocity of the boat is $\mathbf{v}(t) = 5\,\mathbf{i} + \frac{3}{400}(5t)(40 - 5t)\,\mathbf{j} = 5\mathbf{i} + \left(\frac{3}{2}t - \frac{3}{16}t^2\right)\mathbf{j}$. Integrating, we obtain $\mathbf{r}(t) = 5t\,\mathbf{i} + \left(\frac{3}{4}t^2 - \frac{1}{16}t^3\right)\mathbf{j} + \mathbf{C}$. If we place the origin at A (and consider $\mathbf{j}$ to coincide with the northern direction) then $\mathbf{r}(0) = \mathbf{0} \quad\Rightarrow\quad \mathbf{C} = \mathbf{0}$ and we have $\mathbf{r}(t) = 5t\,\mathbf{i} + \left(\frac{3}{4}t^2 - \frac{1}{16}t^3\right)\mathbf{j}$. The boat reaches the east bank after 8 s, and it is located at $\mathbf{r}(8) = 5(8)\mathbf{i} + \left(\frac{3}{4}(8)^2 - \frac{1}{16}(8)^3\right)\mathbf{j} = 40\,\mathbf{i} + 16\,\mathbf{j}$. Thus the boat is 16 m downstream.



(b) Let α be the angle north of east that the boat heads. Then the velocity of the boat in still water is given by $5(\cos\alpha)\,\mathbf{i} + 5(\sin\alpha)\,\mathbf{j}$. At t seconds, the boat is $5(\cos\alpha)t$ meters from the west bank, at which point the velocity of the water is $\frac{3}{400}[5(\cos\alpha)t][40 - 5(\cos\alpha)t]\ \mathbf{j}$. The resultant velocity of the boat is given by

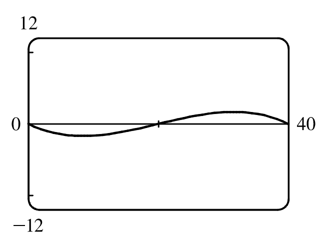
$\mathbf{v}(t) = 5(\cos\alpha)\,\mathbf{i} + \left[5\sin\alpha + \frac{3}{400}(5t\cos\alpha)(40 - 5t\cos\alpha)\right]\mathbf{j} = (5\cos\alpha)\,\mathbf{i} + \left(5\sin\alpha + \frac{3}{2}t\cos\alpha - \frac{3}{16}t^2\cos^2\alpha\right)\mathbf{j}$.

Integrating, $\mathbf{r}(t) = (5t\cos\alpha)\,\mathbf{i} + \left(5t\sin\alpha + \frac{3}{4}t^2\cos\alpha - \frac{1}{16}t^3\cos^2\alpha\right)\mathbf{j}$ (where we have again placed the origin at A). The boat will reach the east bank when $5t\cos\alpha = 40 \quad\Rightarrow\quad t = \dfrac{40}{5\cos\alpha} = \dfrac{8}{\cos\alpha}$.

In order to land at point $B(40, 0)$ we need $5t\sin\alpha + \frac{3}{4}t^2\cos\alpha - \frac{1}{16}t^3\cos^2\alpha = 0 \quad\Rightarrow$

$$5\left(\frac{8}{\cos\alpha}\right)\sin\alpha + \frac{3}{4}\left(\frac{8}{\cos\alpha}\right)^2\cos\alpha - \frac{1}{16}\left(\frac{8}{\cos\alpha}\right)^3\cos^2\alpha = 0 \quad\Rightarrow\quad \frac{1}{\cos\alpha}(40\sin\alpha + 48 - 32) = 0 \quad\Rightarrow$$

$40\sin\alpha + 16 = 0 \quad\Rightarrow\quad \sin\alpha = -\frac{2}{5}$. Thus $\alpha = \sin^{-1}\left(-\frac{2}{5}\right) \approx -23.6^\circ$, so the boat should head 23.6° south of east (upstream). The path does seem realistic. The boat initially heads upstream to counteract the effect of the current. Near the center of the river, the current is stronger and the boat is pushed downstream. When the boat nears the eastern bank, the current is slower and the boat is able to progress upstream to arrive at point B.



34. As in Exercise 33(b), let α be the angle north of east that the boat heads, so the velocity of the boat in still water is given by $5(\cos\alpha)\,\mathbf{i} + 5(\sin\alpha)\,\mathbf{j}$. At t seconds, the boat is $5(\cos\alpha)t$ meters from the west bank, at which point the velocity of the water is $3\sin(\pi x/40)\,\mathbf{j} = 3\sin[\pi\cdot 5(\cos\alpha)t/40]\,\mathbf{j} = 3\sin\left(\frac{\pi}{8}t\cos\alpha\right)\mathbf{j}$. The resultant velocity of the boat then is given by $\mathbf{v}(t) = 5(\cos\alpha)\,\mathbf{i} + \left[5\sin\alpha + 3\sin\left(\frac{\pi}{8}t\cos\alpha\right)\right]\mathbf{j}$. Integrating,

$$\mathbf{r}(t) = (5t\cos\alpha)\,\mathbf{i} + \left[5t\sin\alpha - \frac{24}{\pi\cos\alpha}\cos\left(\tfrac{\pi}{8}t\cos\alpha\right)\right]\mathbf{j} + \mathbf{C}.$$

If we place the origin at A then $\mathbf{r}(0) = \mathbf{0} \;\Rightarrow\; -\dfrac{24}{\pi\cos\alpha}\mathbf{j} + \mathbf{C} = \mathbf{0} \;\Rightarrow\; \mathbf{C} = \dfrac{24}{\pi\cos\alpha}\mathbf{j}$ and

$\mathbf{r}(t) = (5t\cos\alpha)\,\mathbf{i} + \left[5t\sin\alpha - \dfrac{24}{\pi\cos\alpha}\cos\left(\tfrac{\pi}{8}t\cos\alpha\right) + \dfrac{24}{\pi\cos\alpha}\right]\mathbf{j}$. The boat will reach the east bank when

$5t\cos\alpha = 40 \;\Rightarrow\; t = \dfrac{8}{\cos\alpha}$. In order to land at point $B(40,0)$ we need

$$5t\sin\alpha - \frac{24}{\pi\cos\alpha}\cos\left(\tfrac{\pi}{8}t\cos\alpha\right) + \frac{24}{\pi\cos\alpha} = 0 \;\Rightarrow$$

$$5\left(\frac{8}{\cos\alpha}\right)\sin\alpha - \frac{24}{\pi\cos\alpha}\cos\left[\frac{\pi}{8}\left(\frac{8}{\cos\alpha}\right)\cos\alpha\right] + \frac{24}{\pi\cos\alpha} = 0 \;\Rightarrow\; \frac{1}{\cos\alpha}\left(40\sin\alpha - \frac{24}{\pi}\cos\pi + \frac{24}{\pi}\right) = 0 \;\Rightarrow$$

$40\sin\alpha + \dfrac{48}{\pi} = 0 \;\Rightarrow\; \sin\alpha = -\dfrac{6}{5\pi}$. Thus $\alpha = \sin^{-1}\left(-\dfrac{6}{5\pi}\right) \approx -22.5^\circ$, so the boat should head 22.5° south of east.

35. If $\mathbf{r}'(t) = \mathbf{c}\times\mathbf{r}(t)$ then $\mathbf{r}'(t)$ is perpendicular to both $\mathbf{c}$ and $\mathbf{r}(t)$. Remember that $\mathbf{r}'(t)$ points in the direction of motion, so if $\mathbf{r}'(t)$ is always perpendicular to $\mathbf{c}$, the path of the particle must lie in a plane perpendicular to $\mathbf{c}$. But $\mathbf{r}'(t)$ is also perpendicular to the position vector $\mathbf{r}(t)$ which confines the path to a sphere centered at the origin. Considering both restrictions, the path must be contained in a circle that lies in a plane perpendicular to $\mathbf{c}$, and the circle is centered on a line through the origin in the direction of $\mathbf{c}$.

36. (a) From Equation 7 we have $\mathbf{a} = v'\mathbf{T} + \kappa v^2\mathbf{N}$. If a particle moves along a straight line, then $\kappa = 0$ [see Section 13.3], so the acceleration vector becomes $\mathbf{a} = v'\mathbf{T}$. Because the acceleration vector is a scalar multiple of the unit tangent vector, it is parallel to the tangent vector.

(b) If the speed of the particle is constant, then $v' = 0$ and Equation 7 gives $\mathbf{a} = \kappa v^2\mathbf{N}$. Thus the acceleration vector is parallel to the unit normal vector (which is perpendicular to the tangent vector and points in the direction that the curve is turning).

37. $\mathbf{r}(t) = (t^2+1)\,\mathbf{i} + t^3\,\mathbf{j} \;\Rightarrow\; \mathbf{r}'(t) = 2t\,\mathbf{i} + 3t^2\,\mathbf{j}$,

$|\mathbf{r}'(t)| = \sqrt{(2t)^2 + (3t^2)^2} = \sqrt{4t^2+9t^4} = t\sqrt{4+9t^2}$ [since $t \geq 0$], $\mathbf{r}''(t) = 2\,\mathbf{i} + 6t\,\mathbf{j}$, $\mathbf{r}'(t)\times\mathbf{r}''(t) = 6t^2\,\mathbf{k}$.

Then Equation 9 gives $a_T = \dfrac{\mathbf{r}'(t)\cdot\mathbf{r}''(t)}{|\mathbf{r}'(t)|} = \dfrac{(2t)(2) + (3t^2)(6t)}{t\sqrt{4+9t^2}} = \dfrac{4t + 18t^3}{t\sqrt{4+9t^2}} = \dfrac{4+18t^2}{\sqrt{4+9t^2}}$

$$\left[\begin{aligned} &\text{or by Equation 8,}\quad a_T = v' = \frac{d}{dt}\left[t\sqrt{4+9t^2}\,\right] = t\cdot\tfrac{1}{2}\left(4+9t^2\right)^{-1/2}(18t) + \left(4+9t^2\right)^{1/2}\cdot 1 \\ &\qquad\qquad = \left(4+9t^2\right)^{-1/2}\left(9t^2 + 4 + 9t^2\right) = (4+18t^2)/\sqrt{4+9t^2} \end{aligned}\right]$$

and Equation 10 gives $a_N = \dfrac{|\mathbf{r}'(t)\times\mathbf{r}''(t)|}{|\mathbf{r}'(t)|} = \dfrac{6t^2}{t\sqrt{4+9t^2}} = \dfrac{6t}{\sqrt{4+9t^2}}$.

38. $\mathbf{r}(t) = 2t^2\,\mathbf{i} + \left(\frac{2}{3}t^3 - 2t\right)\mathbf{j} \quad\Rightarrow\quad \mathbf{r}'(t) = 4t\,\mathbf{i} + (2t^2 - 2)\,\mathbf{j}$,

$|\mathbf{r}'(t)| = \sqrt{16t^2 + (2t^2 - 2)^2} = \sqrt{4t^4 + 8t^2 + 4} = \sqrt{4\,(t^2+1)^2} = 2(t^2+1)$,

$\mathbf{r}''(t) = 4\,\mathbf{i} + 4t\,\mathbf{j}, \quad \mathbf{r}'(t)\times\mathbf{r}''(t) = (8t^2+8)\,\mathbf{k}$. Then Equation 9 gives

$$a_T = \frac{\mathbf{r}'(t)\cdot\mathbf{r}''(t)}{|\mathbf{r}'(t)|} = \frac{(4t)(4) + (2t^2-2)(4t)}{2(t^2+1)} = \frac{8t(t^2+1)}{2(t^2+1)} = 4t \quad \left[\text{or by Equation 8, } a_T = v' = \frac{d}{dt}\left[2(t^2+1)\right] = 4t\right]$$

and Equation 10 gives $a_N = \dfrac{|\mathbf{r}'(t)\times\mathbf{r}''(t)|}{|\mathbf{r}'(t)|} = \dfrac{8(t^2+1)}{2(t^2+1)} = 4$.

39. $\mathbf{r}(t) = \cos t\,\mathbf{i} + \sin t\,\mathbf{j} + t\,\mathbf{k} \quad\Rightarrow\quad \mathbf{r}'(t) = -\sin t\,\mathbf{i} + \cos t\,\mathbf{j} + \mathbf{k}, \quad |\mathbf{r}'(t)| = \sqrt{\sin^2 t + \cos^2 t + 1} = \sqrt{2}$,

$\mathbf{r}''(t) = -\cos t\,\mathbf{i} - \sin t\,\mathbf{j}, \quad \mathbf{r}'(t)\times\mathbf{r}''(t) = \sin t\,\mathbf{i} - \cos t\,\mathbf{j} + \mathbf{k}$.

Then $a_T = \dfrac{\mathbf{r}'(t)\cdot\mathbf{r}''(t)}{|\mathbf{r}'(t)|} = \dfrac{\sin t\,\cos t - \sin t\,\cos t}{\sqrt{2}} = 0$ and $a_N = \dfrac{|\mathbf{r}'(t)\times\mathbf{r}''(t)|}{|\mathbf{r}'(t)|} = \dfrac{\sqrt{\sin^2 t + \cos^2 t + 1}}{\sqrt{2}} = \dfrac{\sqrt{2}}{\sqrt{2}} = 1$.

40. $\mathbf{r}(t) = t\,\mathbf{i} + 2e^t\,\mathbf{j} + e^{2t}\,\mathbf{k} \quad\Rightarrow\quad \mathbf{r}'(t) = \mathbf{i} + 2e^t\,\mathbf{j} + 2e^{2t}\,\mathbf{k}, \quad |\mathbf{r}'(t)| = \sqrt{1 + 4e^{2t} + 4e^{4t}} = \sqrt{(1+2e^{2t})^2} = 1 + 2e^{2t}$,

$\mathbf{r}''(t) = 2e^t\,\mathbf{j} + 4e^{2t}\,\mathbf{k}, \quad \mathbf{r}'(t)\times\mathbf{r}''(t) = 4e^{3t}\,\mathbf{i} - 4e^{2t}\,\mathbf{j} + 2e^t\,\mathbf{k}$,

$|\mathbf{r}'(t)\times\mathbf{r}''(t)| = \sqrt{16e^{6t} + 16e^{4t} + 4e^{2t}} = \sqrt{4e^{2t}(2e^{2t}+1)^2} = 2e^t(2e^{2t}+1)$. Then

$$a_T = \frac{\mathbf{r}'(t)\cdot\mathbf{r}''(t)}{|\mathbf{r}'(t)|} = \frac{4e^{2t} + 8e^{4t}}{1 + 2e^{2t}} = \frac{4e^{2t}(1+2e^{2t})}{1+2e^{2t}} = 4e^{2t} \text{ and } a_N = \frac{|\mathbf{r}'(t)\times\mathbf{r}''(t)|}{|\mathbf{r}'(t)|} = \frac{2e^t(2e^{2t}+1)}{1+2e^{2t}} = 2e^t.$$

41. $\mathbf{r}(t) = \ln t\,\mathbf{i} + (t^2 + 3t)\,\mathbf{j} + 4\sqrt{t}\,\mathbf{k} \quad\Rightarrow\quad \mathbf{r}'(t) = (1/t)\,\mathbf{i} + (2t+3)\,\mathbf{j} + (2/\sqrt{t}\,)\,\mathbf{k} \quad\Rightarrow$

$\mathbf{r}''(t) = (-1/t^2)\,\mathbf{i} + 2\,\mathbf{j} - (1/t^{3/2})\,\mathbf{k}$. The point $(0, 4, 4)$ corresponds to $t = 1$, where

$\mathbf{r}'(1) = \mathbf{i} + 5\,\mathbf{j} + 2\,\mathbf{k}, \quad \mathbf{r}''(1) = -\mathbf{i} + 2\,\mathbf{j} - \mathbf{k}$, and $\mathbf{r}'(1)\times\mathbf{r}''(1) = -9\,\mathbf{i} - \mathbf{j} + 7\,\mathbf{k}$. Thus at the point $(0, 4, 4)$,

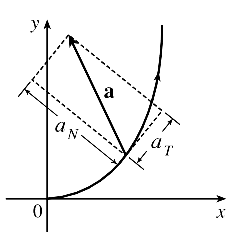
$$a_T = \frac{\mathbf{r}'(1)\cdot\mathbf{r}''(1)}{|\mathbf{r}'(1)|} = \frac{-1 + 10 - 2}{\sqrt{1 + 25 + 4}} = \frac{7}{\sqrt{30}} \text{ and } a_N = \frac{|\mathbf{r}'(1)\times\mathbf{r}''(1)|}{|\mathbf{r}'(1)|} = \frac{\sqrt{81 + 1 + 49}}{\sqrt{30}} = \sqrt{\frac{131}{30}}.$$

42. $\mathbf{r}(t) = t^{-1}\,\mathbf{i} + t^{-2}\,\mathbf{j} + t^{-3}\,\mathbf{k} \quad\Rightarrow\quad \mathbf{r}'(t) = -t^{-2}\,\mathbf{i} - 2t^{-3}\,\mathbf{j} - 3t^{-4}\,\mathbf{k} \quad\Rightarrow\quad \mathbf{r}''(t) = 2t^{-3}\,\mathbf{i} + 6t^{-4}\,\mathbf{j} + 12t^{-5}\,\mathbf{k}$. The point $(1, 1, 1)$ corresponds to $t = 1$, where $\mathbf{r}'(1) = -\mathbf{i} - 2\,\mathbf{j} - 3\,\mathbf{k}, \quad \mathbf{r}''(1) = 2\,\mathbf{i} + 6\,\mathbf{j} + 12\,\mathbf{k}$, and

$\mathbf{r}'(1)\times\mathbf{r}''(1) = -6\,\mathbf{i} + 6\,\mathbf{j} - 2\,\mathbf{k}$. Thus at the point $(1, 1, 1)$, $a_T = \dfrac{\mathbf{r}'(1)\cdot\mathbf{r}''(1)}{|\mathbf{r}'(1)|} = \dfrac{-2 - 12 - 36}{\sqrt{1 + 4 + 9}} = -\dfrac{50}{\sqrt{14}}$ and

$$a_N = \frac{|\mathbf{r}'(1)\times\mathbf{r}''(1)|}{|\mathbf{r}'(1)|} = \frac{\sqrt{36 + 36 + 4}}{\sqrt{14}} = \sqrt{\frac{76}{14}} = \sqrt{\frac{38}{7}}.$$

43. The tangential component of $\mathbf{a}$ is the length of the projection of $\mathbf{a}$ onto $\mathbf{T}$, so we sketch the scalar projection of $\mathbf{a}$ in the tangential direction to the curve and estimate its length to be 4.5 (using the fact that $\mathbf{a}$ has length 10 as a guide). Similarly, the normal component of $\mathbf{a}$ is the length of the projection of $\mathbf{a}$ onto $\mathbf{N}$, so we sketch the scalar projection of $\mathbf{a}$ in the normal direction to the curve and estimate its length to be 9.0. Thus $a_T \approx 4.5\text{ cm/s}^2$ and $a_N \approx 9.0\text{ cm/s}^2$.



44. $\mathbf{L}(t) = m\,\mathbf{r}(t) \times \mathbf{v}(t) \quad \Rightarrow$

$$\mathbf{L}'(t) = m[\mathbf{r}'(t) \times \mathbf{v}(t) + \mathbf{r}\,(t) \times \mathbf{v}'(t)] \qquad \text{[by Formula 5 of Theorem 13.2.3]}$$
$$= m[\mathbf{v}(t) \times \mathbf{v}(t) + \mathbf{r}(t) \times \mathbf{v}'(t)] = m[\mathbf{0} + \mathbf{r}(t) \times \mathbf{a}\,(t)] = \boldsymbol{\tau}(t)$$

So if the torque is always $\mathbf{0}$, then $\mathbf{L}'(t) = \mathbf{0}$ for all t, and so $\mathbf{L}(t)$ is constant.

45. If the engines are turned off at time t, then the spacecraft will continue to travel in the direction of $\mathbf{v}(t)$, so we need a t such that for some scalar $s > 0$, $\mathbf{r}(t) + s\,\mathbf{v}(t) = \langle 6, 4, 9 \rangle$. $\quad \mathbf{v}(t) = \mathbf{r}'(t) = \mathbf{i} + \dfrac{1}{t}\,\mathbf{j} + \dfrac{8t}{(t^2+1)^2}\,\mathbf{k} \quad \Rightarrow$

$$\mathbf{r}(t) + s\,\mathbf{v}(t) = \left\langle 3 + t + s, 2 + \ln t + \frac{s}{t}, 7 - \frac{4}{t^2+1} + \frac{8st}{(t^2+1)^2} \right\rangle \quad \Rightarrow \quad 3 + t + s = 6 \quad \Rightarrow \quad s = 3 - t,$$

so $7 - \dfrac{4}{t^2+1} + \dfrac{8(3-t)t}{(t^2+1)^2} = 9 \quad \Leftrightarrow \quad \dfrac{24t - 12t^2 - 4}{(t^2+1)^2} = 2 \quad \Leftrightarrow \quad t^4 + 8t^2 - 12t + 3 = 0.$

It is easily seen that $t = 1$ is a root of this polynomial. Also $2 + \ln 1 + \dfrac{3-1}{1} = 4$, so $t = 1$ is the desired solution.

46. (a) $m\,\dfrac{d\mathbf{v}}{dt} = \dfrac{dm}{dt}\,\mathbf{v}_e \quad \Leftrightarrow \quad \dfrac{d\mathbf{v}}{dt} = \dfrac{1}{m}\,\dfrac{dm}{dt}\,\mathbf{v}_e$. Integrating both sides of this equation with respect to t gives

$$\int_0^t \frac{d\mathbf{v}}{du}\,du = \mathbf{v}_e \int_0^t \frac{1}{m}\,\frac{dm}{du}\,du \quad \Rightarrow \quad \int_{\mathbf{v}(0)}^{\mathbf{v}(t)} d\mathbf{v} = \mathbf{v}_e \int_{m(0)}^{m(t)} \frac{dm}{m} \quad \text{[Substitution Rule]} \quad \Rightarrow$$

$$\mathbf{v}(t) - \mathbf{v}(0) = \ln\!\left(\frac{m(t)}{m(0)}\right)\mathbf{v}_e \quad \Rightarrow \quad \mathbf{v}(t) = \mathbf{v}(0) - \ln\!\left(\frac{m(0)}{m(t)}\right)\mathbf{v}_e.$$

(b) $|\mathbf{v}(t)| = 2\,|\mathbf{v}_e|$, and $|\mathbf{v}(0)| = 0$. Therefore, by part (a), $2\,|\mathbf{v}_e| = \left| -\ln\!\left(\dfrac{m(0)}{m(t)}\right)\mathbf{v}_e \right| \quad \Rightarrow$

$$2\,|\mathbf{v}_e| = \ln\!\left(\frac{m(0)}{m\,(t)}\right)|\mathbf{v}_e|. \quad \left[\textit{Note: } m(0) > m(t) \text{ so that } \ln\!\left(\frac{m(0)}{m(t)}\right) > 0\right] \quad \Rightarrow \quad m(t) = e^{-2}m(0).$$

Thus $\dfrac{m(0) - e^{-2}m(0)}{m(0)} = 1 - e^{-2}$ is the fraction of the initial mass that is burned as fuel.

APPLIED PROJECT Kepler's Laws

1. With $\mathbf{r} = (r\cos\theta)\,\mathbf{i} + (r\sin\theta)\,\mathbf{j}$ and $\mathbf{h} = \alpha\,\mathbf{k}$ where $\alpha > 0$,

(a) $\mathbf{h} = \mathbf{r} \times \mathbf{r}' = [(r\cos\theta)\,\mathbf{i} + (r\sin\theta)\,\mathbf{j}] \times \left[\left(r'\cos\theta - r\sin\theta\,\dfrac{d\theta}{dt}\right)\mathbf{i} + \left(r'\sin\theta + r\cos\theta\,\dfrac{d\theta}{dt}\right)\mathbf{j}\right]$

$$= \left[rr'\cos\theta\sin\theta + r^2\cos^2\theta\,\frac{d\theta}{dt} - rr'\cos\theta\sin\theta + r^2\sin^2\theta\,\frac{d\theta}{dt}\right]\mathbf{k} = r^2\,\frac{d\theta}{dt}\,\mathbf{k}$$

(b) Since $\mathbf{h} = \alpha\,\mathbf{k}$, $\alpha > 0$, $\alpha = |\mathbf{h}|$. But by part (a), $\alpha = |\mathbf{h}| = r^2\,(d\theta/dt)$.

(c) $A(t) = \frac{1}{2}\int_{\theta_0}^{\theta} |\mathbf{r}|^2\,d\theta = \frac{1}{2}\int_{t_0}^{t} r^2\,(d\theta/dt)\,dt$ in polar coordinates. Thus, by the Fundamental Theorem of Calculus,

$$\frac{dA}{dt} = \frac{r^2}{2}\,\frac{d\theta}{dt}.$$

(d) $\dfrac{dA}{dt} = \dfrac{r^2}{2}\dfrac{d\theta}{dt} = \dfrac{h}{2} =$ constant since $\mathbf{h}$ is a constant vector and $h = |\mathbf{h}|$.

2. (a) Since $dA/dt = \frac{1}{2}h$, a constant, $A(t) = \frac{1}{2}ht + c_1$. But $A(0) = 0$, so $A(t) = \frac{1}{2}ht$. But $A(T) =$ area of the ellipse $= \pi ab$ and $A(T) = \frac{1}{2}hT$, so $T = 2\pi ab/h$.

(b) $h^2/(GM) = ed$ where e is the eccentricity of the ellipse. But $a = ed/(1 - e^2)$ or $ed = a(1 - e^2)$ and $1 - e^2 = b^2/a^2$. Hence $h^2/(GM) = ed = b^2/a$.

(c) $T^2 = \dfrac{4\pi a^2 b^2}{h^2} = 4\pi^2 a^2 b^2 \dfrac{a}{GMb^2} = \dfrac{4\pi^2}{GM}a^3$.

3. From Problem 2, $T^2 = \dfrac{4\pi^2}{GM}a^3$. $T \approx 365.25\ \text{days} \times 24 \cdot 60^2\ \dfrac{\text{seconds}}{\text{day}} \approx 3.1558 \times 10^7\ \text{seconds}$. Therefore

$a^3 = \dfrac{GMT^2}{4\pi^2} \approx \dfrac{(6.67 \times 10^{-11})(1.99 \times 10^{30})(3.1558 \times 10^7)^2}{4\pi^2} \approx 3.348 \times 10^{33}\ \text{m}^3 \quad \Rightarrow \quad a \approx 1.496 \times 10^{11}$ m. Thus, the length of the major axis of the earth's orbit (that is, $2a$) is approximately $2.99 \times 10^{11}\ \text{m} = 2.99 \times 10^8$ km.

4. We can adapt the equation $T^2 = \dfrac{4\pi^2}{GM}a^3$ from Problem 2(c) with the earth at the center of the system, so T is the period of the satellite's orbit about the earth, M is the mass of the earth, and a is the length of the semimajor axis of the satellite's orbit (measured from the earth's center). Since we want the satellite to remain fixed above a particular point on the earth's equator, T must coincide with the period of the earth's own rotation, so $T = 24$ h $= 86{,}400$ s. The mass of the earth is $M = 5.98 \times 10^{24}$ kg, so $a = \left(\dfrac{T^2 GM}{4\pi^2}\right)^{1/3} \approx \left[\dfrac{(86{,}400)^2(6.67 \times 10^{-11})(5.98 \times 10^{24})}{4\pi^2}\right]^{1/3} \approx 4.23 \times 10^7$ m. If we assume a circular orbit, the radius of the orbit is a, and since the radius of the earth is 6.37×10^6 m, the required altitude above the earth's surface for the satellite is $4.23 \times 10^7 - 6.37 \times 10^6 \approx 3.59 \times 10^7$ m, or 35,900 km.

13 Review

TRUE-FALSE QUIZ

1. True. If we reparametrize the curve by replacing $u = t^3$, we have $\mathbf{r}(u) = u\,\mathbf{i} + 2u\,\mathbf{j} + 3u\,\mathbf{k}$, which is a line through the origin with direction vector $\mathbf{i} + 2\,\mathbf{j} + 3\,\mathbf{k}$.

2. True. Parametric equations for the curve are $x = 0$, $y = t^2$, $z = 4t$, and since $t = z/4$ we have $y = t^2 = (z/4)^2$ or $y = \frac{1}{16}z^2$, $x = 0$. This is an equation of a parabola in the yz-plane.

3. False. The vector function represents a line, but the line does not pass through the origin; the x-component is 0 only for $t = 0$ which corresponds to the point $(0, 3, 0)$ not $(0, 0, 0)$.

4. True. See Theorem 13.2.2.

5. False. By Formula 5 of Theorem 13.2.3, $\frac{d}{dt}\left[\mathbf{u}(t)\times\mathbf{v}(t)\right]=\mathbf{u}'(t)\times\mathbf{v}(t)+\mathbf{u}(t)\times\mathbf{v}'(t)$.

6. False. For example, let $\mathbf{r}(t)=\langle\cos t,\sin t\rangle$. Then $|\mathbf{r}(t)|=\sqrt{\cos^2 t+\sin^2 t}=1 \quad\Rightarrow\quad \frac{d}{dt}\,|\mathbf{r}(t)|=0$, but $|\mathbf{r}'(t)|=|\langle-\sin t,\cos t\rangle|=\sqrt{(-\sin t)^2+\cos^2 t}=1$.

7. False. κ is the magnitude of the rate of change of the unit tangent vector $\mathbf{T}$ with respect to arc length s, not with respect to t.

8. False. The binormal vector, by the definition given in Section 13.3, is $\mathbf{B}(t)=\mathbf{T}(t)\times\mathbf{N}(t)=-\left[\mathbf{N}(t)\times\mathbf{T}(t)\right]$.

9. True. At an inflection point where f is twice continuously differentiable we must have $f''(x)=0$, and by Equation 13.3.11, the curvature is 0 there.

10. True. From Equation 13.3.9 , $\kappa(t)=0 \quad\Leftrightarrow\quad |\mathbf{T}'(t)|=0 \quad\Leftrightarrow\quad \mathbf{T}'(t)=\mathbf{0}$ for all t. But then $\mathbf{T}(t)=\mathbf{C}$, a constant vector, which is true only for a straight line.

11. False. If $\mathbf{r}(t)$ is the position of a moving particle at time t and $|\mathbf{r}(t)|=1$ then the particle lies on the unit circle or the unit sphere, but this does not mean that the speed $|\mathbf{r}'(t)|$ must be constant. As a counterexample, let $\mathbf{r}(t)=\left\langle t,\sqrt{1-t^2}\right\rangle$, then $\mathbf{r}'(t)=\left\langle 1,-t/\sqrt{1-t^2}\right\rangle$ and $|\mathbf{r}(t)|=\sqrt{t^2+1-t^2}=1$ but $|\mathbf{r}'(t)|=\sqrt{1+t^2/(1-t^2)}=1/\sqrt{1-t^2}$ which is not constant.

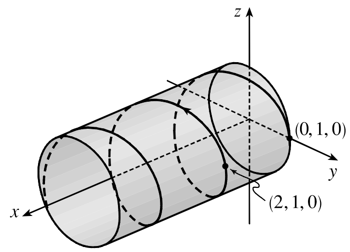
12. True. See Example 4 in Section 13.2 .

13. True. See the discussion preceding Example 7 in Section 13.3.

14. False. For example, $\mathbf{r}_1(t)=\langle t,t\rangle$ and $\mathbf{r}_2(t)=\langle 2t,2t\rangle$ both represent the same plane curve (the line $y=x$), but the tangent vector $\mathbf{r}_1'(t)=\langle 1,1\rangle$ for all t, while $\mathbf{r}_2'(t)=\langle 2,2\rangle$. In fact, different parametrizations give parallel tangent vectors at a point, but their magnitudes may differ.

EXERCISES

1. (a) The corresponding parametric equations for the curve are $x=t$, $y=\cos\pi t,\ z=\sin\pi t$. Since $y^2+z^2=1$, the curve is contained in a circular cylinder with axis the x-axis. Since $x=t$, the curve is a helix.



(b) $\mathbf{r}(t)=t\,\mathbf{i}+\cos\,\pi t\,\mathbf{j}+\sin\,\pi t\,\mathbf{k} \quad\Rightarrow$

$\mathbf{r}'(t)=\mathbf{i}-\pi\sin\,\pi t\,\mathbf{j}+\pi\cos\,\pi t\,\mathbf{k} \quad\Rightarrow$

$\mathbf{r}''(t)=-\pi^2\cos\,\pi t\,\mathbf{j}-\pi^2\sin\,\pi t\,\mathbf{k}$

2. (a) The expressions $\sqrt{2-t}$, $(e^t-1)/t$, and $\ln(t+1)$ are all defined when $2-t\geq 0 \quad\Rightarrow\quad t\leq 2, t\neq 0$, and $t+1>0 \quad\Rightarrow\quad t>-1$. Thus the domain of $\mathbf{r}$ is $(-1,0)\cup(0,2]$.

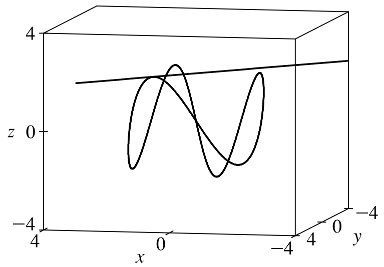
(b) $\displaystyle\lim_{t\to 0}\mathbf{r}(t)=\left\langle\lim_{t\to 0}\sqrt{2-t},\lim_{t\to 0}\frac{e^t-1}{t},\lim_{t\to 0}\ln(t+1)\right\rangle=\left\langle\sqrt{2-0},\lim_{t\to 0}\frac{e^t}{1},\ln(0+1)\right\rangle$

$=\left\langle\sqrt{2},1,0\right\rangle$ [using l'Hospital's Rule in the y-component]

(c) $\mathbf{r}'(t) = \left\langle \frac{d}{dt}\sqrt{2-t}, \frac{d}{dt}\frac{e^t-1}{t}, \frac{d}{dt}\ln(t+1) \right\rangle = \left\langle -\frac{1}{2\sqrt{2-t}}, \frac{te^t - e^t + 1}{t^2}, \frac{1}{t+1} \right\rangle$

3. The projection of the curve C of intersection onto the xy-plane is the circle $x^2 + y^2 = 16, z = 0$. So we can write $x = 4\cos t,\ y = 4\sin t,\ 0 \le t \le 2\pi$. From the equation of the plane, we have $z = 5 - x = 5 - 4\cos t$, so parametric equations for C are $x = 4\cos t,\ y = 4\sin t,\ z = 5 - 4\cos t, 0 \le t \le 2\pi$, and the corresponding vector function is $\mathbf{r}(t) = 4\cos t\,\mathbf{i} + 4\sin t\,\mathbf{j} + (5 - 4\cos t)\,\mathbf{k}, 0 \le t \le 2\pi$.

4. The curve is given by $\mathbf{r}(t) = \langle 2\sin t, 2\sin 2t, 2\sin 3t\rangle$, so $\mathbf{r}'(t) = \langle 2\cos t, 4\cos 2t, 6\cos 3t\rangle$. The point $\left(1, \sqrt{3}, 2\right)$ corresponds to $t = \frac{\pi}{6}$ (or $\frac{\pi}{6} + 2k\pi$, k an integer), so the tangent vector there is $\mathbf{r}'\left(\frac{\pi}{6}\right) = \left\langle \sqrt{3}, 2, 0 \right\rangle$. Then the tangent line has direction vector $\left\langle \sqrt{3}, 2, 0\right\rangle$ and includes the point $\left(1, \sqrt{3}, 2\right)$, so parametric equations are $x = 1 + \sqrt{3}\,t, y = \sqrt{3} + 2t, z = 2$.



5. $\int_0^1 (t^2\,\mathbf{i} + t\cos\pi t\,\mathbf{j} + \sin\pi t\,\mathbf{k})\,dt = \left(\int_0^1 t^2\,dt\right)\mathbf{i} + \left(\int_0^1 t\cos\pi t\,dt\right)\mathbf{j} + \left(\int_0^1 \sin\pi t\,dt\right)\mathbf{k}$

$$= \left[\tfrac{1}{3}t^3\right]_0^1 \mathbf{i} + \left(\tfrac{t}{\pi}\sin\pi t\right]_0^1 - \int_0^1 \tfrac{1}{\pi}\sin\pi t\,dt\Big)\mathbf{j} + \left[-\tfrac{1}{\pi}\cos\pi t\right]_0^1 \mathbf{k}$$

$$= \tfrac{1}{3}\,\mathbf{i} + \left[\tfrac{1}{\pi^2}\cos\pi t\right]_0^1 \mathbf{j} + \tfrac{2}{\pi}\,\mathbf{k} = \tfrac{1}{3}\,\mathbf{i} - \tfrac{2}{\pi^2}\,\mathbf{j} + \tfrac{2}{\pi}\,\mathbf{k}$$

where we integrated by parts in the y-component.

6. (a) C intersects the xz-plane where $y = 0 \;\Rightarrow\; 2t - 1 = 0 \;\Rightarrow\; t = \frac{1}{2}$, so the point is $\left(2 - \left(\frac{1}{2}\right)^3, 0, \ln\frac{1}{2}\right) = \left(\frac{15}{8}, 0, -\ln 2\right)$.

(b) The curve is given by $\mathbf{r}(t) = \left\langle 2 - t^3, 2t - 1, \ln t\right\rangle$, so $\mathbf{r}'(t) = \left\langle -3t^2, 2, 1/t\right\rangle$. The point $(1, 1, 0)$ corresponds to $t = 1$, so the tangent vector there is $\mathbf{r}'(1) = \langle -3, 2, 1\rangle$. Then the tangent line has direction vector $\langle -3, 2, 1\rangle$ and includes the point $(1, 1, 0)$, so parametric equations are $x = 1 - 3t, y = 1 + 2t, z = t$.

(c) The normal plane has normal vector $\mathbf{r}'(1) = \langle -3, 2, 1\rangle$ and equation $-3(x-1) + 2(y-1) + z = 0$ or $3x - 2y - z = 1$.

7. $\mathbf{r}(t) = \left\langle t^2, t^3, t^4\right\rangle \;\Rightarrow\; \mathbf{r}'(t) = \left\langle 2t, 3t^2, 4t^3\right\rangle \;\Rightarrow\; |\mathbf{r}'(t)| = \sqrt{4t^2 + 9t^4 + 16t^6}$ and $L = \int_0^3 |\mathbf{r}'(t)|\,dt = \int_0^3 \sqrt{4t^2 + 9t^4 + 16t^6}\,dt$. Using Simpson's Rule with $f(t) = \sqrt{4t^2 + 9t^4 + 16t^6}$ and $n = 6$ we have $\Delta t = \frac{3-0}{6} = \frac{1}{2}$ and

$$L \approx \tfrac{\Delta t}{3}\left[f(0) + 4f\left(\tfrac{1}{2}\right) + 2f(1) + 4f\left(\tfrac{3}{2}\right) + 2f(2) + 4f\left(\tfrac{5}{2}\right) + f(3)\right]$$

$$= \tfrac{1}{6}\Bigg[\sqrt{0+0+0} + 4\cdot\sqrt{4\left(\tfrac{1}{2}\right)^2 + 9\left(\tfrac{1}{2}\right)^4 + 16\left(\tfrac{1}{2}\right)^6} + 2\cdot\sqrt{4(1)^2 + 9(1)^4 + 16(1)^6}$$

$$+ 4\cdot\sqrt{4\left(\tfrac{3}{2}\right)^2 + 9\left(\tfrac{3}{2}\right)^4 + 16\left(\tfrac{3}{2}\right)^6} + 2\cdot\sqrt{4(2)^2 + 9(2)^4 + 16(2)^6}$$

$$+ 4\cdot\sqrt{4\left(\tfrac{5}{2}\right)^2 + 9\left(\tfrac{5}{2}\right)^4 + 16\left(\tfrac{5}{2}\right)^6} + \sqrt{4(3)^2 + 9(3)^4 + 16(3)^6}\,\Bigg]$$

$$\approx 86.631$$

8. $\mathbf{r}'(t) = \left\langle 3t^{1/2}, -2\sin 2t, 2\cos 2t \right\rangle$, $\quad |\mathbf{r}'(t)| = \sqrt{9t + 4(\sin^2 2t + \cos^2 2t)} = \sqrt{9t+4}$.

Thus $L = \int_0^1 \sqrt{9t+4}\,dt = \int_4^{13} \frac{1}{9} u^{1/2}\,du = \frac{1}{9} \cdot \frac{2}{3} u^{3/2} \Big]_4^{13} = \frac{2}{27}(13^{3/2} - 8)$.

9. The angle of intersection of the two curves, θ, is the angle between their respective tangents at the point of intersection.

For both curves the point $(1,0,0)$ occurs when $t = 0$.

$\mathbf{r}_1'(t) = -\sin t\,\mathbf{i} + \cos t\,\mathbf{j} + \mathbf{k} \quad \Rightarrow \quad \mathbf{r}_1'(0) = \mathbf{j} + \mathbf{k}$ and $\mathbf{r}_2'(t) = \mathbf{i} + 2t\,\mathbf{j} + 3t^2\,\mathbf{k} \quad \Rightarrow \quad \mathbf{r}_2'(0) = \mathbf{i}$.

$\mathbf{r}_1'(0) \cdot \mathbf{r}_2'(0) = (\mathbf{j} + \mathbf{k}) \cdot \mathbf{i} = 0$. Therefore, the curves intersect in a right angle, that is, $\theta = 90^\circ$.

10. The parametric value corresponding to the point $(1,0,1)$ is $t = 0$.

$\mathbf{r}'(t) = e^t\,\mathbf{i} + e^t(\cos t + \sin t)\,\mathbf{j} + e^t(\cos t - \sin t)\,\mathbf{k} \quad \Rightarrow \quad |\mathbf{r}'(t)| = e^t\sqrt{1 + (\cos t + \sin t)^2 + (\cos t - \sin t)^2} = \sqrt{3}\,e^t$

and $s(t) = \int_0^t e^u\sqrt{3}\,du = \sqrt{3}(e^t - 1) \quad \Rightarrow \quad t = \ln\!\left(1 + \frac{1}{\sqrt{3}}s\right)$.

Therefore, $\mathbf{r}(t(s)) = \left(1 + \frac{1}{\sqrt{3}}s\right)\mathbf{i} + \left(1 + \frac{1}{\sqrt{3}}s\right)\sin\ln\!\left(1 + \frac{1}{\sqrt{3}}s\right)\mathbf{j} + \left(1 + \frac{1}{\sqrt{3}}s\right)\cos\ln\!\left(1 + \frac{1}{\sqrt{3}}s\right)\mathbf{k}$.

11. (a) $\mathbf{r}(t) = \langle \sin^3 t, \cos^3 t, \sin^2 t \rangle \quad \Rightarrow \quad \mathbf{r}'(t) = \langle 3\sin^2 t\cos t, -3\cos^2 t\sin t, 2\sin t\cos t \rangle$,

$$\begin{aligned} |\mathbf{r}'(t)| &= \sqrt{9\sin^4 t\cos^2 t + 9\cos^4 t\sin^2 t + 4\sin^2 t\cos^2 t} \\ &= \sqrt{\sin^2 t\cos^2 t\,(9\sin^2 t + 9\cos^2 t + 4)} = \sqrt{13}\,\sin t\cos t \quad [\text{since } 0 \le t \le \pi/2 \quad \Rightarrow \quad \sin t, \cos t \ge 0] \end{aligned}$$

Then $\mathbf{T}(t) = \dfrac{\mathbf{r}'(t)}{|\mathbf{r}'(t)|} = \dfrac{1}{\sqrt{13}\,\sin t\cos t}\langle 3\sin^2 t\cos t, -3\cos^2 t\sin t, 2\sin t\cos t \rangle = \frac{1}{\sqrt{13}}\langle 3\sin t, -3\cos t, 2 \rangle$.

(b) $\mathbf{T}'(t) = \frac{1}{\sqrt{13}}\langle 3\cos t, 3\sin t, 0 \rangle$, $\quad |\mathbf{T}'(t)| = \frac{1}{\sqrt{13}}\sqrt{9\cos^2 t + 9\sin^2 t + 0} = \frac{3}{\sqrt{13}}$, and

$\mathbf{N}(t) = \dfrac{\mathbf{T}'(t)}{|\mathbf{T}'(t)|} = \frac{1}{3}\langle 3\cos t, 3\sin t, 0 \rangle = \langle \cos t, \sin t, 0 \rangle$.

(c) $\mathbf{B}(t) = \mathbf{T}(t) \times \mathbf{N}(t) = \frac{1}{\sqrt{13}}\langle 3\sin t, -3\cos t, 2 \rangle \times \langle \cos t, \sin t, 0 \rangle = \frac{1}{\sqrt{13}}\langle -2\sin t, 2\cos t, 3 \rangle$

(d) $\kappa(t) = \dfrac{|\mathbf{T}'(t)|}{|\mathbf{r}'(t)|} = \dfrac{3/\sqrt{13}}{\sqrt{13}\,\sin t\cos t} = \dfrac{3}{13\,\sin t\cos t}$ or $\frac{3}{13}\sec t\csc t$

12. Using Exercise 13.3.42, we have $\mathbf{r}'(t) = \langle -3\sin t, 4\cos t \rangle$, $\quad \mathbf{r}''(t) = \langle -3\cos t, -4\sin t \rangle$,

$|\mathbf{r}'(t)|^3 = \left(\sqrt{9\sin^2 t + 4\cos^2 t}\right)^3$ and then

$$\kappa(t) = \frac{|(-3\sin t)(-4\sin t) - (4\cos t)(-3\cos t)|}{(9\sin^2 t + 16\cos^2 t)^{3/2}} = \frac{12}{(9\sin^2 t + 16\,\cos^2 t)^{3/2}}.$$

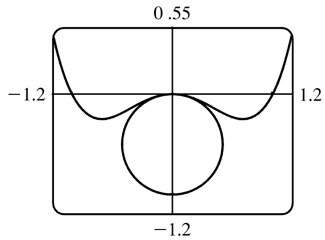
At $(3,0)$, $t = 0$ and $\kappa(0) = 12/(16)^{3/2} = \frac{12}{64} = \frac{3}{16}$. At $(0,4)$, $t = \frac{\pi}{2}$ and $\kappa\!\left(\frac{\pi}{2}\right) = 12/9^{3/2} = \frac{12}{27} = \frac{4}{9}$.

13. $y' = 4x^3$, $y'' = 12x^2$ and $\kappa(x) = \dfrac{|y''|}{[1 + (y')^2]^{3/2}} = \dfrac{|12x^2|}{(1 + 16x^6)^{3/2}}$, so $\kappa(1) = \dfrac{12}{17^{3/2}}$.

14. $\kappa(x) = \dfrac{|12x^2 - 2|}{[1 + (4x^3 - 2x)^2]^{3/2}} \quad \Rightarrow \quad \kappa(0) = 2.$

So the osculating circle has radius $\frac{1}{2}$ and center $\left(0, -\frac{1}{2}\right)$.

Thus its equation is $x^2 + \left(y + \frac{1}{2}\right)^2 = \frac{1}{4}$.



15. $\mathbf{r}(t) = \langle \sin 2t, t, \cos 2t \rangle \quad \Rightarrow \quad \mathbf{r}'(t) = \langle 2\cos 2t, 1, -2\sin 2t \rangle \quad \Rightarrow \quad \mathbf{T}(t) = \frac{1}{\sqrt{5}} \langle 2\cos 2t, 1, -2\sin 2t \rangle \quad \Rightarrow$

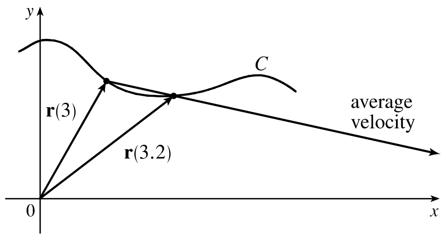
$\mathbf{T}'(t) = \frac{1}{\sqrt{5}} \langle -4\sin 2t, 0, -4\cos 2t \rangle \quad \Rightarrow \quad \mathbf{N}(t) = \langle -\sin 2t, 0, -\cos 2t \rangle$. So $\mathbf{N} = \mathbf{N}(\pi) = \langle 0, 0, -1 \rangle$ and

$\mathbf{B} = \mathbf{T} \times \mathbf{N} = \frac{1}{\sqrt{5}} \langle -1, 2, 0 \rangle$. So a normal to the osculating plane is $\langle -1, 2, 0 \rangle$ and an equation is

$-1(x - 0) + 2(y - \pi) + 0(z - 1) = 0$ or $x - 2y + 2\pi = 0$.

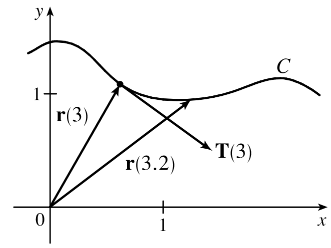
16. (a) The average velocity over $[3, 3.2]$ is given by

$\dfrac{\mathbf{r}(3.2) - \mathbf{r}(3)}{3.2 - 3} = 5[\mathbf{r}(3.2) - \mathbf{r}(3)]$, so we draw a vector with the same direction but 5 times the length of the vector $[\mathbf{r}(3.2) - \mathbf{r}(3)]$.



(b) $\mathbf{v}(3) = \mathbf{r}'(3) = \lim\limits_{h \to 0} \dfrac{\mathbf{r}(3 + h) - \mathbf{r}(3)}{h}$

(c) $\mathbf{T}(3) = \dfrac{\mathbf{r}'(3)}{|\mathbf{r}'(3)|}$, a unit vector in the same direction as $\mathbf{r}'(3)$, that is, parallel to the tangent line to the curve at $\mathbf{r}(3)$, pointing in the direction corresponding to increasing t, and with length 1.



17. $\mathbf{r}(t) = t\ln t\,\mathbf{i} + t\,\mathbf{j} + e^{-t}\,\mathbf{k}, \quad \mathbf{v}(t) = \mathbf{r}'(t) = (1 + \ln t)\,\mathbf{i} + \mathbf{j} - e^{-t}\,\mathbf{k},$

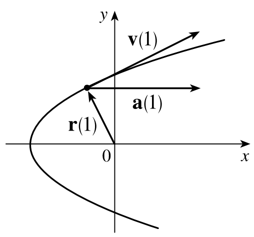
$|\mathbf{v}(t)| = \sqrt{(1 + \ln t)^2 + 1^2 + (-e^{-t})^2} = \sqrt{2 + 2\ln t + (\ln t)^2 + e^{-2t}}, \quad \mathbf{a}(t) = \mathbf{v}'(t) = \frac{1}{t}\,\mathbf{i} + e^{-t}\,\mathbf{k}$

18. $\mathbf{r}(t) = (2t^2 - 3)\,\mathbf{i} + 2t\,\mathbf{j} \quad \Rightarrow \quad \mathbf{v}(t) = \mathbf{r}'(t) = 4t\,\mathbf{i} + 2\,\mathbf{j}$,

speed $= |\mathbf{v}(t)| = \sqrt{16t^2 + 4} = 2\sqrt{4t^2 + 1}$, and $\mathbf{a}(t) = \mathbf{v}'(t) = \mathbf{r}''(t) = 4\,\mathbf{i}$.

At $t = 1$ we have $\mathbf{r}(1) = -\mathbf{i} + 2\,\mathbf{j}$, $\mathbf{v}(1) = 4\,\mathbf{i} + 2\,\mathbf{j}$, $\mathbf{a}(1) = 4\,\mathbf{i}$.

Notice that $y/2 = t \quad \Rightarrow \quad x = 2\,(y/2)^2 - 3 = \frac{1}{2}y^2 - 3$, so the path is a parabola.



19. $\mathbf{v}(t) = \int \mathbf{a}(t)\,dt = \int (6t\,\mathbf{i} + 12t^2\,\mathbf{j} - 6t\,\mathbf{k})\,dt = 3t^2\,\mathbf{i} + 4t^3\,\mathbf{j} - 3t^2\,\mathbf{k} + \mathbf{C}$, but $\mathbf{i} - \mathbf{j} + 3\,\mathbf{k} = \mathbf{v}(0) = \mathbf{0} + \mathbf{C}$,

so $\mathbf{C} = \mathbf{i} - \mathbf{j} + 3\,\mathbf{k}$ and $\mathbf{v}(t) = (3t^2 + 1)\,\mathbf{i} + (4t^3 - 1)\,\mathbf{j} + (3 - 3t^2)\,\mathbf{k}$.

$\mathbf{r}(t) = \int \mathbf{v}(t)\,dt = (t^3 + t)\,\mathbf{i} + (t^4 - t)\,\mathbf{j} + (3t - t^3)\,\mathbf{k} + \mathbf{D}$.

But $\mathbf{r}(0) = \mathbf{0}$, so $\mathbf{D} = \mathbf{0}$ and $\mathbf{r}(t) = (t^3 + t)\,\mathbf{i} + (t^4 - t)\,\mathbf{j} + (3t - t^3)\,\mathbf{k}$.

20. We set up the axes so that the shot leaves the athlete's hand 7 ft above the origin. Then we are given $\mathbf{r}(0) = 7\mathbf{j}$, $|\mathbf{v}(0)| = 43$ ft/s, and $\mathbf{v}(0)$ has direction given by a $45°$ angle of elevation. Then a unit vector in the direction of $\mathbf{v}(0)$ is $\frac{1}{\sqrt{2}}(\mathbf{i}+\mathbf{j}) \Rightarrow \mathbf{v}(0) = \frac{43}{\sqrt{2}}(\mathbf{i}+\mathbf{j})$. Assuming air resistance is negligible, the only external force is due to gravity, so as in Example 13.4.5 we have $\mathbf{a} = -g\,\mathbf{j}$ where here $g \approx 32$ ft/s^2. Since $\mathbf{v}'(t) = \mathbf{a}(t)$, we integrate, giving $\mathbf{v}(t) = -gt\,\mathbf{j} + \mathbf{C}$ where $\mathbf{C} = \mathbf{v}(0) = \frac{43}{\sqrt{2}}(\mathbf{i}+\mathbf{j}) \Rightarrow \mathbf{v}(t) = \frac{43}{\sqrt{2}}\,\mathbf{i} + \left(\frac{43}{\sqrt{2}} - gt\right)\mathbf{j}$. Since $\mathbf{r}'(t) = \mathbf{v}(t)$ we integrate again, so $\mathbf{r}(t) = \frac{43}{\sqrt{2}}t\,\mathbf{i} + \left(\frac{43}{\sqrt{2}}t - \frac{1}{2}gt^2\right)\mathbf{j} + \mathbf{D}$. But $\mathbf{D} = \mathbf{r}(0) = 7\,\mathbf{j} \Rightarrow \mathbf{r}(t) = \frac{43}{\sqrt{2}}t\,\mathbf{i} + \left(\frac{43}{\sqrt{2}}t - \frac{1}{2}gt^2 + 7\right)\mathbf{j}$.

(a) At 2 seconds, the shot is at $\mathbf{r}(2) = \frac{43}{\sqrt{2}}(2)\,\mathbf{i} + \left(\frac{43}{\sqrt{2}}(2) - \frac{1}{2}g(2)^2 + 7\right)\mathbf{j} \approx 60.8\,\mathbf{i} + 3.8\,\mathbf{j}$, so the shot is about 3.8 ft above the ground, at a horizontal distance of 60.8 ft from the athlete.

(b) The shot reaches its maximum height when the vertical component of velocity is 0: $\frac{43}{\sqrt{2}} - gt = 0 \Rightarrow$ $t = \dfrac{43}{\sqrt{2}\,g} \approx 0.95$ s. Then $\mathbf{r}(0.95) \approx 28.9\,\mathbf{i} + 21.4\,\mathbf{j}$, so the maximum height is approximately 21.4 ft.

(c) The shot hits the ground when the vertical component of $\mathbf{r}(t)$ is 0, so $\frac{43}{\sqrt{2}}t - \frac{1}{2}gt^2 + 7 = 0 \Rightarrow$ $-16t^2 + \frac{43}{\sqrt{2}}t + 7 = 0 \Rightarrow t \approx 2.11$ s. $\mathbf{r}(2.11) \approx 64.2\,\mathbf{i} - 0.08\,\mathbf{j}$, thus the shot lands approximately 64.2 ft from the athlete.

21. Example 13.4.5 showed that the maximum horizontal range is achieved with an angle of elevation of $45\,°$. In this case, however, the projectile would hit the top of the tunnel using that angle. The horizontal range will be maximized with the largest angle of elevation that keeps the projectile within a height of 30 m. From Example 13.4.5 we know that the position function of the projectile is $\mathbf{r}(t) = (v_0\cos\alpha)t\,\mathbf{i} + \left[(v_0\sin\alpha)t - \frac{1}{2}gt^2\right]\mathbf{j}$ and the velocity is $\mathbf{v}(t) = \mathbf{r}'(t) = (v_0\cos\alpha)\,\mathbf{i} + [(v_0\sin\alpha) - gt]\,\mathbf{j}$. The projectile achieves its maximum height when the vertical component of velocity is zero, so $(v_0\sin\alpha) - gt = 0 \Rightarrow t = \dfrac{v_0\sin\alpha}{g}$. We want the vertical height of the projectile at that time to be 30 m: $(v_0\sin\alpha)\left(\dfrac{v_0\sin\alpha}{g}\right) - \frac{1}{2}g\left(\dfrac{v_0\sin\alpha}{g}\right)^2 = 30 \Rightarrow$

$$\left(\frac{v_0^2\sin^2\alpha}{g}\right) - \frac{1}{2}\left(\frac{v_0^2\sin^2\alpha}{g}\right) = 30 \Rightarrow \frac{v_0^2\sin^2\alpha}{2g} = 30 \Rightarrow \sin^2\alpha = \frac{30(2g)}{v_0^2} = \frac{60(9.8)}{40^2} = 0.3675 \Rightarrow$$

$\sin\alpha = \sqrt{0.3675}$. Thus the desired angle of elevation is $\alpha = \sin^{-1}\sqrt{0.3675} \approx 37.3\,°$.

From the same example, the horizontal distance traveled is $d = \dfrac{v_0^2\sin 2\alpha}{g} \approx \dfrac{40^2\sin(74.6\,°)}{9.8} \approx 157.4$ m.

22. $\mathbf{r}'(t) = \mathbf{i} + 2\,\mathbf{j} + 2t\,\mathbf{k}$, $\mathbf{r}''(t) = 2\,\mathbf{k}$, $|\mathbf{r}'(t)| = \sqrt{1+4+4t^2} = \sqrt{4t^2+5}$.

Then $a_T = \dfrac{\mathbf{r}'(t)\cdot\mathbf{r}''(t)}{|\mathbf{r}'(t)|} = \dfrac{4t}{\sqrt{4t^2+5}}$ and $a_N = \dfrac{|\mathbf{r}'(t)\times\mathbf{r}''(t)|}{|\mathbf{r}'(t)|} = \dfrac{|4\,\mathbf{i} - 2\,\mathbf{j}|}{\sqrt{4t^2+5}} = \dfrac{2\sqrt{5}}{\sqrt{4t^2+5}}$.

23. (a) Instead of proceeding directly, we use Formula 3 of Theorem 13.2.3: $\mathbf{r}(t) = t\,\mathbf{R}(t) \quad \Rightarrow$

$\mathbf{v} = \mathbf{r}'(t) = \mathbf{R}(t) + t\,\mathbf{R}'(t) = \cos\omega t\,\mathbf{i} + \sin\omega t\,\mathbf{j} + t\,\mathbf{v}_d.$

(b) Using the same method as in part (a) and starting with $\mathbf{v} = \mathbf{R}(t) + t\,\mathbf{R}'(t)$, we have

$\mathbf{a} = \mathbf{v}' = \mathbf{R}'(t) + \mathbf{R}'(t) + t\,\mathbf{R}''(t) = 2\,\mathbf{R}'(t) + t\,\mathbf{R}''(t) = 2\,\mathbf{v}_d + t\,\mathbf{a}_d.$

(c) Here we have $\mathbf{r}(t) = e^{-t}\cos\omega t\,\mathbf{i} + e^{-t}\sin\omega t\,\mathbf{j} = e^{-t}\,\mathbf{R}(t)$. So, as in parts (a) and (b),

$\mathbf{v} = \mathbf{r}'(t) = e^{-t}\,\mathbf{R}'(t) - e^{-t}\,\mathbf{R}(t) = e^{-t}[\mathbf{R}'(t) - \mathbf{R}(t)] \quad \Rightarrow$

$$\begin{aligned}\mathbf{a} = \mathbf{v}' &= e^{-t}[\mathbf{R}''(t) - \mathbf{R}'(t)] - e^{-t}[\mathbf{R}'(t) - \mathbf{R}(t)] = e^{-t}[\mathbf{R}''(t) - 2\,\mathbf{R}'(t) + \mathbf{R}(t)] \\ &= e^{-t}\,\mathbf{a}_d - 2e^{-t}\,\mathbf{v}_d + e^{-t}\,\mathbf{R}\end{aligned}$$

Thus, the Coriolis acceleration (the sum of the "extra" terms not involving $\mathbf{a}_d$) is $-2e^{-t}\,\mathbf{v}_d + e^{-t}\,\mathbf{R}$.

24. (a) $F(x) = \begin{cases} 1 & \text{if } x \le 0 \\ \sqrt{1-x^2} & \text{if } 0 < x < \frac{1}{\sqrt{2}} \\ \sqrt{2} - x & \text{if } x \ge \frac{1}{\sqrt{2}} \end{cases} \quad \Rightarrow \quad F'(x) = \begin{cases} 0 & \text{if } x < 0 \\ -x/\sqrt{1-x^2} & \text{if } 0 < x < \frac{1}{\sqrt{2}} \\ -1 & \text{if } x > \frac{1}{\sqrt{2}} \end{cases} \quad \Rightarrow$

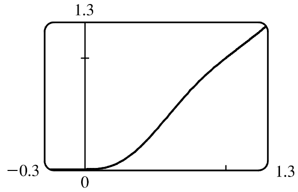
$F''(x) = \begin{cases} 0 & \text{if } x < 0 \\ -1/(1-x^2)^{3/2} & \text{if } 0 < x < \frac{1}{\sqrt{2}} \\ 0 & \text{if } x > \frac{1}{\sqrt{2}} \end{cases}$

since $\dfrac{d}{dx}[-x(1-x^2)^{-1/2}] = -(1-x^2)^{-1/2} - x^2(1-x^2)^{-3/2} = -(1-x^2)^{-3/2}$.

Now $\lim\limits_{x\to 0^+}\sqrt{1-x^2} = 1 = F(0)$ and $\lim\limits_{x\to(1/\sqrt{2})^-}\sqrt{1-x^2} = \frac{1}{\sqrt{2}} = F\left(\frac{1}{\sqrt{2}}\right)$, so F is continuous. Also, since $\lim\limits_{x\to 0^+} F'(x) = 0 = \lim\limits_{x\to 0^-} F'(x)$ and $\lim\limits_{x\to(1/\sqrt{2})^-} F'(x) = -1 = \lim\limits_{x\to(1/\sqrt{2})^+} F'(x)$, F' is continuous. But $\lim\limits_{x\to 0^+} F''(x) = -1 \ne 0 = \lim\limits_{x\to 0^-} F''(x)$, so F'' is not continuous at $x = 0$. (The same is true at $x = \frac{1}{\sqrt{2}}$.) So F does not have continuous curvature.

(b) Set $P(x) = ax^5 + bx^4 + cx^3 + dx^2 + ex + f$. The continuity conditions on P are $P(0) = 0$, $P(1) = 1$, $P'(0) = 0$ and $P'(1) = 1$. Also the curvature must be continuous. For $x \le 0$ and $x \ge 1$, $\kappa(x) = 0$; elsewhere

$\kappa(x) = \dfrac{|P''(x)|}{(1 + [P'(x)]^2)^{3/2}}$, so we need $P''(0) = 0$ and $P''(1) = 0$.



The conditions $P(0) = P'(0) = P''(0) = 0$ imply that $d = e = f = 0$. The other conditions imply that $a + b + c = 1$, $5a + 4b + 3c = 1$, and $10a + 6b + 3c = 0$. From these, we find that $a = 3$, $b = -8$, and $c = 6$. Therefore $P(x) = 3x^5 - 8x^4 + 6x^3$. Since there was no solution with $a = 0$, this could not have been done with a polynomial of degree 4.

PROBLEMS PLUS

1. (a) $\mathbf{r}(t) = R\cos\omega t\,\mathbf{i} + R\sin\omega t\,\mathbf{j} \quad\Rightarrow\quad \mathbf{v} = \mathbf{r}'(t) = -\omega R\sin\omega t\,\mathbf{i} + \omega R\cos\omega t\,\mathbf{j}$, so $\mathbf{r} = R(\cos\omega t\,\mathbf{i} + \sin\omega t\,\mathbf{j})$ and $\mathbf{v} = \omega R(-\sin\omega t\,\mathbf{i} + \cos\omega t\,\mathbf{j})$. $\mathbf{v}\cdot\mathbf{r} = \omega R^2(-\cos\omega t\sin\omega t + \sin\omega t\cos\omega t) = 0$, so $\mathbf{v}\perp\mathbf{r}$. Since $\mathbf{r}$ points along a radius of the circle, and $\mathbf{v}\perp\mathbf{r}$, $\mathbf{v}$ is tangent to the circle. Because it is a velocity vector, $\mathbf{v}$ points in the direction of motion.

(b) In (a), we wrote $\mathbf{v}$ in the form $\omega R\,\mathbf{u}$, where $\mathbf{u}$ is the unit vector $-\sin\omega t\,\mathbf{i} + \cos\omega t\,\mathbf{j}$. Clearly $|\mathbf{v}| = \omega R\,|\mathbf{u}| = \omega R$. At speed ωR, the particle completes one revolution, a distance $2\pi R$, in time $T = \dfrac{2\pi R}{\omega R} = \dfrac{2\pi}{\omega}$.

(c) $\mathbf{a} = \dfrac{d\mathbf{v}}{dt} = -\omega^2 R\cos\omega t\,\mathbf{i} - \omega^2 R\sin\omega t\,\mathbf{j} = -\omega^2 R(\cos\omega t\,\mathbf{i} + \sin\omega t\,\mathbf{j})$, so $\mathbf{a} = -\omega^2\mathbf{r}$. This shows that $\mathbf{a}$ is proportional to $\mathbf{r}$ and points in the opposite direction (toward the origin). Also, $|\mathbf{a}| = \omega^2\,|\mathbf{r}| = \omega^2 R$. $\leq$

(d) By Newton's Second Law (see Section 13.4), $\mathbf{F} = m\mathbf{a}$, so $|\mathbf{F}| = m\,|\mathbf{a}| = mR\omega^2 = \dfrac{m\,(\omega R)^2}{R} = \dfrac{m\,|\mathbf{v}|^2}{R}$.

2. (a) Dividing the equation $|\mathbf{F}|\sin\theta = \dfrac{mv_R^2}{R}$ by the equation $|\mathbf{F}|\cos\theta = mg$, we obtain $\tan\theta = \dfrac{v_R^2}{Rg}$, so $v_R^2 = Rg\tan\theta$.

(b) $R = 400$ ft and $\theta = 12^\circ$, so $v_R = \sqrt{Rg\tan\theta} \approx \sqrt{400\cdot 32\cdot\tan 12^\circ} \approx 52.16$ ft/s ≈ 36 mi/h.

(c) We want to choose a new radius R_1 for which the new rated speed is $\frac{3}{2}$ of the old one: $\sqrt{R_1 g\tan 12^\circ} = \frac{3}{2}\sqrt{Rg\tan 12^\circ}$. Squaring, we get $R_1 g\tan 12^\circ = \frac{9}{4}Rg\tan 12^\circ$, so $R_1 = \frac{9}{4}R = \frac{9}{4}(400) = 900$ ft.

3. (a) The projectile reaches maximum height when $0 = \dfrac{dy}{dt} = \dfrac{d}{dt}\left[(v_0\sin\alpha)t - \frac{1}{2}gt^2\right] = v_0\sin\alpha - gt$; that is, when $t = \dfrac{v_0\sin\alpha}{g}$ and $y = (v_0\sin\alpha)\left(\dfrac{v_0\sin\alpha}{g}\right) - \dfrac{1}{2}g\left(\dfrac{v_0\sin\alpha}{g}\right)^2 = \dfrac{v_0^2\sin^2\alpha}{2g}$. This is the maximum height attained when the projectile is fired with an angle of elevation α. This maximum height is largest when $\alpha = 90^\circ$. In that case, $\sin\alpha = 1$ and the maximum height is $\dfrac{v_0^2}{2g}$.

(b) Let $R = v_0^2/g$. We are asked to consider the parabola $x^2 + 2Ry - R^2 = 0$ which can be rewritten as $y = -\dfrac{1}{2R}x^2 + \dfrac{R}{2}$. The points on or inside this parabola are those for which $-R \leq x \leq R$ and $0 \leq y \leq \dfrac{-1}{2R}x^2 + \dfrac{R}{2}$. When the projectile is fired at angle of elevation α, the points (x, y) along its path satisfy the relations $x = (v_0\cos\alpha)\,t$ and $y = (v_0\sin\alpha)t - \frac{1}{2}gt^2$, where $0 \leq t \leq (2v_0\sin\alpha)/g$ (as in Example 13.4.5). Thus $|x| \leq \left|v_0\cos\alpha\left(\dfrac{2v_0\sin\alpha}{g}\right)\right| = \left|\dfrac{v_0^2}{g}\sin 2\alpha\right| \leq \left|\dfrac{v_0^2}{g}\right| = |R|$. This shows that $-R \leq x \leq R$.

For t in the specified range, we also have $y = t\big(v_0\sin\alpha - \frac{1}{2}gt\big) = \frac{1}{2}gt\left(\dfrac{2v_0\sin\alpha}{g} - t\right) \geq 0$ and

$y = (v_0 \sin\alpha)\,\dfrac{x}{v_0\cos\alpha} - \dfrac{g}{2}\left(\dfrac{x}{v_0\cos\alpha}\right)^2 = (\tan\alpha)\,x - \dfrac{g}{2v_0^2\cos^2\alpha}x^2 = -\dfrac{1}{2R\cos^2\alpha}\,x^2 + (\tan\alpha)\,x$. Thus

$$\begin{aligned} y - \left(\frac{-1}{2R}x^2 + \frac{R}{2}\right) &= \frac{-1}{2R\cos^2\alpha}\,x^2 + \frac{1}{2R}x^2 + (\tan\alpha)\,x - \frac{R}{2} \\ &= \frac{x^2}{2R}\left(1 - \frac{1}{\cos^2\alpha}\right) + (\tan\alpha)\,x - \frac{R}{2} = \frac{x^2(1-\sec^2\alpha) + 2R\,(\tan\alpha)\,x - R^2}{2R} \\ &= \frac{-(\tan^2\alpha)\,x^2 + 2R\,(\tan\alpha)\,x - R^2}{2R} = \frac{-\left[(\tan\alpha)\,x - R\right]^2}{2R} \le 0 \end{aligned}$$

We have shown that every target that can be hit by the projectile lies on or inside the parabola $y = -\dfrac{1}{2R}\,x^2 + \dfrac{R}{2}$.

Now let (a, b) be any point on or inside the parabola $y = -\dfrac{1}{2R}\,x^2 + \dfrac{R}{2}$. Then $-R \le a \le R$ and $0 \le b \le -\dfrac{1}{2R}\,a^2 + \dfrac{R}{2}$.

We seek an angle α such that (a, b) lies in the path of the projectile; that is, we wish to find an angle α such that

$b = -\dfrac{1}{2R\cos^2\alpha}\,a^2 + (\tan\alpha)\,a$ or equivalently $b = \dfrac{-1}{2R}\,(\tan^2\alpha + 1)a^2 + (\tan\alpha)\,a$. Rearranging this equation we get

$\dfrac{a^2}{2R}\tan^2\alpha - a\tan\alpha + \left(\dfrac{a^2}{2R} + b\right) = 0$ or $a^2(\tan\alpha)^2 - 2aR(\tan\alpha) + (a^2 + 2bR) = 0 \;\;(\star)$. This quadratic equation

for $\tan\alpha$ has real solutions exactly when the discriminant is nonnegative. Now $B^2 - 4AC \ge 0 \;\;\Leftrightarrow$

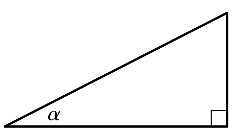
$(-2aR)^2 - 4a^2(a^2 + 2bR) \ge 0 \;\;\Leftrightarrow\;\; 4a^2(R^2 - a^2 - 2bR) \ge 0 \;\;\Leftrightarrow\;\; -a^2 - 2bR + R^2 \ge 0 \;\;\Leftrightarrow$

$b \le \dfrac{1}{2R}\,(R^2 - a^2) \;\;\Leftrightarrow\;\; b \le \dfrac{-1}{2R}\,a^2 + \dfrac{R}{2}$. This condition is satisfied since (a, b) is on or inside the parabola

$y = -\dfrac{1}{2R}\,x^2 + \dfrac{R}{2}$. It follows that (a, b) lies in the path of the projectile when $\tan\alpha$ satisfies $(\star)$, that is, when

$\tan\alpha = \dfrac{2aR \pm \sqrt{4a^2(R^2 - a^2 - 2bR)}}{2a^2} = \dfrac{R \pm \sqrt{R^2 - 2bR - a^2}}{a}$.

(c)



If the gun is pointed at a target with height h at a distance D downrange, then $\tan\alpha = h/D$. When the projectile reaches a distance D downrange (remember we are assuming that it doesn't hit the ground first), we have $D = x = (v_0\cos\alpha)t$, so $t = \dfrac{D}{v_0\cos\alpha}$ and $y = (v_0\sin\alpha)t - \frac{1}{2}gt^2 = D\tan\alpha - \dfrac{gD^2}{2v_0^2\cos^2\alpha}$.

Meanwhile, the target, whose x-coordinate is also D, has fallen from height h to height

$h - \frac{1}{2}gt^2 = D\tan\alpha - \dfrac{gD^2}{2v_0^2\cos^2\alpha}$. Thus the projectile hits the target.

4. (a) As in Problem 3, $\mathbf{r}(t) = (v_0\cos\alpha)t\,\mathbf{i} + \left[(v_0\sin\alpha)t - \frac{1}{2}gt^2\right]\mathbf{j}$, so $x = (v_0\cos\alpha)t$ and $y = (v_0\sin\alpha)t - \frac{1}{2}gt^2$. The difference here is that the projectile travels until it reaches a point where $x > 0$ and $y = -(\tan\theta)x$. (Here $0 \le \theta \le \frac{\pi}{2}$.)

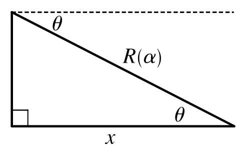
From the parametric equations, we obtain $t = \dfrac{x}{v_0\cos\alpha}$ and $y = \dfrac{(v_0\sin\alpha)x}{v_0\cos\alpha} - \dfrac{gx^2}{2v_0^2\cos^2\alpha} = (\tan\alpha)x - \dfrac{gx^2}{2v_0^2\cos^2\alpha}$.

Thus the projectile hits the inclined plane at the point where $(\tan\alpha)x - \dfrac{gx^2}{2v_0^2\cos^2\alpha} = -(\tan\theta)x$. Since

$\dfrac{gx^2}{2v_0^2\cos^2\alpha} = (\tan\alpha + \tan\theta)x$ and $x > 0$, we must have $\dfrac{gx}{2v_0^2\cos^2\alpha} = \tan\alpha + \tan\theta$. It follows that

$x = \dfrac{2v_0^2 \cos^2 \alpha}{g}(\tan\alpha + \tan\theta)$ and $t = \dfrac{x}{v_0 \cos\alpha} = \dfrac{2v_0 \cos\alpha}{g}(\tan\alpha + \tan\theta)$. This means that the parametric equations are defined for t in the interval $\left[0, \dfrac{2v_0 \cos\alpha}{g}(\tan\alpha + \tan\theta)\right]$.

(b) The downhill range (that is, the distance to the projectile's landing point as measured along the inclined plane) is $R(\alpha) = x \sec\theta$, where x is the coordinate of the landing point calculated in part (a). Thus



$$R(\alpha) = \frac{2v_0^2 \cos^2\alpha}{g}(\tan\alpha + \tan\theta)\sec\theta = \frac{2v_0^2}{g}\left(\frac{\sin\alpha\,\cos\alpha}{\cos\theta} + \frac{\cos^2\alpha\,\sin\theta}{\cos^2\theta}\right)$$
$$= \frac{2v_0^2\cos\alpha}{g\cos^2\theta}(\sin\alpha\,\cos\theta + \cos\alpha\,\sin\theta) = \frac{2v_0^2\cos\alpha\,\sin(\alpha+\theta)}{g\cos^2\theta}$$

$R(\alpha)$ is maximized when

$$0 = R'(\alpha) = \frac{2v_0^2}{g\cos^2\theta}\left[-\sin\alpha\,\sin(\alpha+\theta) + \cos\alpha\,\cos(\alpha+\theta)\right]$$
$$= \frac{2v_0^2}{g\cos^2\theta}\cos[(\alpha+\theta)+\alpha] = \frac{2v_0^2\cos(2\alpha+\theta)}{g\cos^2\theta}$$

This condition implies that $\cos(2\alpha+\theta) = 0 \;\Rightarrow\; 2\alpha+\theta = \frac{\pi}{2} \;\Rightarrow\; \alpha = \frac{1}{2}\left(\frac{\pi}{2} - \theta\right)$.

(c) The solution is similar to the solutions to parts (a) and (b). This time the projectile travels until it reaches a point where $x > 0$ and $y = (\tan\theta)x$. Since $\tan\theta = -\tan(-\theta)$, we obtain the solution from the previous one by replacing θ with $-\theta$. The desired angle is $\alpha = \frac{1}{2}\left(\frac{\pi}{2} + \theta\right)$.

(d) As observed in part (c), firing the projectile up an inclined plane with angle of inclination θ involves the same equations as in parts (a) and (b) but with θ replaced by $-\theta$. So if R is the distance up an inclined plane, we know from part (b) that $R = \dfrac{2v_0^2\cos\alpha\sin(\alpha-\theta)}{g\cos^2(-\theta)} \;\Rightarrow\; v_0^2 = \dfrac{Rg\cos^2\theta}{2\cos\alpha\sin(\alpha-\theta)}$. v_0^2 is minimized (and hence v_0 is minimized) with respect to α when

$$0 = \frac{d}{d\alpha}\left(v_0^2\right) = \frac{Rg\cos^2\theta}{2}\cdot\frac{-(\cos\alpha\cos(\alpha-\theta) - \sin\alpha\sin(\alpha-\theta))}{[\cos\alpha\sin(\alpha-\theta)]^2}$$
$$= \frac{-Rg\cos^2\theta}{2}\cdot\frac{\cos[\alpha+(\alpha-\theta)]}{[\cos\alpha\sin(\alpha-\theta)]^2} = \frac{-Rg\cos^2\theta}{2}\cdot\frac{\cos(2\alpha-\theta)}{[\cos\alpha\sin(\alpha-\theta)]^2}$$

Since $\theta < \alpha < \frac{\pi}{2}$, this implies $\cos(2\alpha-\theta) = 0 \;\Leftrightarrow\; 2\alpha-\theta = \frac{\pi}{2} \;\Rightarrow\; \alpha = \frac{1}{2}\left(\frac{\pi}{2}+\theta\right)$. Thus the initial speed, and hence the energy required, is minimized for $\alpha = \frac{1}{2}\left(\frac{\pi}{2}+\theta\right)$.

5. (a) $\mathbf{a} = -g\,\mathbf{j} \;\Rightarrow\; \mathbf{v} = \mathbf{v}_0 - gt\,\mathbf{j} = 2\,\mathbf{i} - gt\,\mathbf{j} \;\Rightarrow\; \mathbf{s} = \mathbf{s}_0 + 2t\,\mathbf{i} - \frac{1}{2}gt^2\,\mathbf{j} = 3.5\,\mathbf{j} + 2t\,\mathbf{i} - \frac{1}{2}gt^2\,\mathbf{j} \;\Rightarrow$ $\mathbf{s} = 2t\,\mathbf{i} + \left(3.5 - \frac{1}{2}gt^2\right)\mathbf{j}$. Therefore $y = 0$ when $t = \sqrt{7/g}$ seconds. At that instant, the ball is $2\sqrt{7/g} \approx 0.94$ ft to the right of the table top. Its coordinates (relative to an origin on the floor directly under the table's edge) are $(0.94, 0)$. At impact, the velocity is $\mathbf{v} = 2\,\mathbf{i} - \sqrt{7g}\,\mathbf{j}$, so the speed is $|\mathbf{v}| = \sqrt{4+7g} \approx 15$ ft/s.

(b) The slope of the curve when $t = \sqrt{\frac{7}{g}}$ is $\frac{dy}{dx} = \frac{dy/dt}{dx/dt} = \frac{-gt}{2} = \frac{-g\sqrt{7/g}}{2} = \frac{-\sqrt{7g}}{2}$. Thus $\cot\theta = \frac{\sqrt{7g}}{2}$ and $\theta \approx 7.6^\circ$.

(c) From (a), $|\mathbf{v}| = \sqrt{4+7g}$. So the ball rebounds with speed $0.8\sqrt{4+7g} \approx 12.08$ ft/s at angle of inclination $90^\circ - \theta \approx 82.3886^\circ$. By Example 13.4.5, the horizontal distance traveled between bounces is $d = \frac{v_0^2 \sin 2\alpha}{g}$, where $v_0 \approx 12.08$ ft/s and $\alpha \approx 82.3886^\circ$. Therefore, $d \approx 1.197$ ft. So the ball strikes the floor at about $2\sqrt{7/g} + 1.197 \approx 2.13$ ft to the right of the table's edge.

6. By the Fundamental Theorem of Calculus, $\mathbf{r}'(t) = \left\langle \sin\left(\frac{1}{2}\pi t^2\right), \cos\left(\frac{1}{2}\pi t^2\right)\right\rangle$, $|\mathbf{r}'(t)| = 1$ and so $\mathbf{T}(t) = \mathbf{r}'(t)$. Thus $\mathbf{T}'(t) = \pi t\left\langle \cos\left(\frac{1}{2}\pi t^2\right), -\sin\left(\frac{1}{2}\pi t^2\right)\right\rangle$ and the curvature is $\kappa = |\mathbf{T}'(t)| = \sqrt{(\pi t)^2(1)} = \pi\,|t|$.

7. The trajectory of the projectile is given by $\mathbf{r}(t) = (v\cos\alpha)t\,\mathbf{i} + \left[(v\sin\alpha)t - \frac{1}{2}gt^2\right]\mathbf{j}$, so

$\mathbf{v}(t) = \mathbf{r}'(t) = v\cos\alpha\,\mathbf{i} + (v\sin\alpha - gt)\,\mathbf{j}$ and

$$|\mathbf{v}(t)| = \sqrt{(v\cos\alpha)^2 + (v\sin\alpha - gt)^2} = \sqrt{v^2 - (2vg\sin\alpha)\,t + g^2t^2} = \sqrt{g^2\left(t^2 - \frac{2v}{g}(\sin\alpha)\,t + \frac{v^2}{g^2}\right)}$$

$$= g\sqrt{\left(t - \frac{v}{g}\sin\alpha\right)^2 + \frac{v^2}{g^2} - \frac{v^2}{g^2}\sin^2\alpha} = g\sqrt{\left(t - \frac{v}{g}\sin\alpha\right)^2 + \frac{v^2}{g^2}\cos^2\alpha}$$

The projectile hits the ground when $(v\sin\alpha)t - \frac{1}{2}gt^2 = 0 \quad\Rightarrow\quad t = \frac{2v}{g}\sin\alpha$, so the distance traveled by the projectile is

$$L(\alpha) = \int_0^{(2v/g)\sin\alpha} |\mathbf{v}(t)|\,dt = \int_0^{(2v/g)\sin\alpha} g\sqrt{\left(t - \frac{v}{g}\sin\alpha\right)^2 + \frac{v^2}{g^2}\cos^2\alpha}\,dt$$

$$= g\left[\frac{t - (v/g)\sin\alpha}{2}\sqrt{\left(t - \frac{v}{g}\sin\alpha\right)^2 + \left(\frac{v}{g}\cos\alpha\right)^2}\right.$$

$$\left. + \frac{[(v/g)\cos\alpha]^2}{2}\ln\left(t - \frac{v}{g}\sin\alpha + \sqrt{\left(t - \frac{v}{g}\sin\alpha\right)^2 + \left(\frac{v}{g}\cos\alpha\right)^2}\right)\right]_0^{(2v/g)\sin\alpha}$$

[using Formula 21 in the Table of Integrals]

$$= \frac{g}{2}\left[\frac{v}{g}\sin\alpha\sqrt{\left(\frac{v}{g}\sin\alpha\right)^2 + \left(\frac{v}{g}\cos\alpha\right)^2} + \left(\frac{v}{g}\cos\alpha\right)^2\ln\left(\frac{v}{g}\sin\alpha + \sqrt{\left(\frac{v}{g}\sin\alpha\right)^2 + \left(\frac{v}{g}\cos\alpha\right)^2}\right)\right.$$

$$\left. + \frac{v}{g}\sin\alpha\sqrt{\left(\frac{v}{g}\sin\alpha\right)^2 + \left(\frac{v}{g}\cos\alpha\right)^2} - \left(\frac{v}{g}\cos\alpha\right)^2\ln\left(-\frac{v}{g}\sin\alpha + \sqrt{\left(\frac{v}{g}\sin\alpha\right)^2 + \left(\frac{v}{g}\cos\alpha\right)^2}\right)\right]$$

$$= \frac{g}{2}\left[\frac{v}{g}\sin\alpha\cdot\frac{v}{g} + \frac{v^2}{g^2}\cos^2\alpha\ln\left(\frac{v}{g}\sin\alpha + \frac{v}{g}\right) + \frac{v}{g}\sin\alpha\cdot\frac{v}{g} - \frac{v^2}{g^2}\cos^2\alpha\ln\left(-\frac{v}{g}\sin\alpha + \frac{v}{g}\right)\right]$$

$$= \frac{v^2}{g}\sin\alpha + \frac{v^2}{2g}\cos^2\alpha\ln\left(\frac{(v/g)\sin\alpha + v/g}{-(v/g)\sin\alpha + v/g}\right) = \frac{v^2}{g}\sin\alpha + \frac{v^2}{2g}\cos^2\alpha\ln\left(\frac{1+\sin\alpha}{1-\sin\alpha}\right)$$

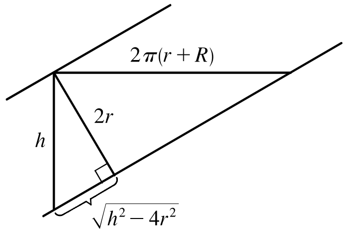
We want to maximize $L(\alpha)$ for $0 \le \alpha \le \pi/2$.

$$L'(\alpha) = \frac{v^2}{g}\cos\alpha + \frac{v^2}{2g}\left[\cos^2\alpha\cdot\frac{1-\sin\alpha}{1+\sin\alpha}\cdot\frac{2\cos\alpha}{(1-\sin\alpha)^2} - 2\cos\alpha\,\sin\alpha\,\ln\left(\frac{1+\sin\alpha}{1-\sin\alpha}\right)\right]$$
$$= \frac{v^2}{g}\cos\alpha + \frac{v^2}{2g}\left[\cos^2\alpha\cdot\frac{2}{\cos\alpha} - 2\cos\alpha\,\sin\alpha\,\ln\left(\frac{1+\sin\alpha}{1-\sin\alpha}\right)\right]$$
$$= \frac{v^2}{g}\cos\alpha + \frac{v^2}{g}\cos\alpha\left[1 - \sin\alpha\,\ln\left(\frac{1+\sin\alpha}{1-\sin\alpha}\right)\right] = \frac{v^2}{g}\cos\alpha\left[2 - \sin\alpha\,\ln\left(\frac{1+\sin\alpha}{1-\sin\alpha}\right)\right]$$

$L(\alpha)$ has critical points for $0 < \alpha < \pi/2$ when $L'(\alpha) = 0 \;\Rightarrow\; 2 - \sin\alpha\ln\left(\frac{1+\sin\alpha}{1-\sin\alpha}\right) = 0$ [since $\cos\alpha \neq 0$].

Solving by graphing (or using a CAS) gives $\alpha \approx 0.9855$. Compare values at the critical point and the endpoints: $L(0) = 0$, $L(\pi/2) = v^2/g$, and $L(0.9855) \approx 1.20v^2/g$. Thus the distance traveled by the projectile is maximized for $\alpha \approx 0.9855$ or $\approx 56°$.

8. As the cable is wrapped around the spool, think of the top or bottom of the cable forming a helix of radius $R + r$. Let h be the vertical distance between coils. Then, from similar triangles,



$$\frac{2r}{\sqrt{h^2-4r^2}} = \frac{2\pi(r+R)}{h} \quad\Rightarrow\quad h^2r^2 = \pi^2(r+R)^2(h^2-4r^2) \quad\Rightarrow$$
$$h = \frac{2\pi r(r+R)}{\sqrt{\pi^2(r+R)^2 - r^2}}.$$

If we parametrize the helix by $x(t) = (R+r)\cos t$, $y(t) = (R+r)\sin t$, then we must have $z(t) = [h/(2\pi)]t$. The length of one complete cycle is

$$\ell = \int_0^{2\pi}\sqrt{[x'(t)]^2 + [y'(t)]^2 + [z'(t)]^2}\,dt = \int_0^{2\pi}\sqrt{(R+r)^2 + \left(\frac{h}{2\pi}\right)^2}\,dt = 2\pi\sqrt{(R+r)^2 + \left(\frac{h}{2\pi}\right)^2}$$
$$= 2\pi\sqrt{(R+r)^2 + \frac{r^2(R+r)^2}{\pi^2(R+r)^2 - r^2}} = 2\pi(R+r)\sqrt{1 + \frac{r^2}{\pi^2(R+r)^2 - r^2}} = \frac{2\pi^2(R+r)^2}{\sqrt{\pi^2(R+r)^2 - r^2}}$$

The number of complete cycles is $[\![L/\ell]\!]$, and so the shortest length along the spool is

$$h\left[\!\!\left[\frac{L}{\ell}\right]\!\!\right] = \frac{2\pi r(R+r)}{\sqrt{\pi^2(R+r)^2 - r^2}}\left[\!\!\left[\frac{L\sqrt{\pi^2(R+r)^2 - r^2}}{2\pi^2(R+r)^2}\right]\!\!\right]$$

9. We can write the vector equation as $\mathbf{r}(t) = \mathbf{a}t^2 + \mathbf{b}t + \mathbf{c}$ where $\mathbf{a} = \langle a_1, a_2, a_3\rangle$, $\mathbf{b} = \langle b_1, b_2, b_3\rangle$, and $\mathbf{c} = \langle c_1, c_2, c_3\rangle$. Then $\mathbf{r}'(t) = 2t\,\mathbf{a} + \mathbf{b}$ which says that each tangent vector is the sum of a scalar multiple of $\mathbf{a}$ and the vector $\mathbf{b}$. Thus the tangent vectors are all parallel to the plane determined by $\mathbf{a}$ and $\mathbf{b}$ so the curve must be parallel to this plane. [Here we assume that $\mathbf{a}$ and $\mathbf{b}$ are nonparallel. Otherwise the tangent vectors are all parallel and the curve lies along a single line.] A normal vector for the plane is $\mathbf{a}\times\mathbf{b} = \langle a_2b_3 - a_3b_2, a_3b_1 - a_1b_3, a_1b_2 - a_2b_1\rangle$. The point (c_1, c_2, c_3) lies on the plane (when $t = 0$), so an equation of the plane is

$$(a_2b_3 - a_3b_2)(x - c_1) + (a_3b_1 - a_1b_3)(y - c_2) + (a_1b_2 - a_2b_1)(z - c_3) = 0$$

or

$$(a_2b_3 - a_3b_2)x + (a_3b_1 - a_1b_3)y + (a_1b_2 - a_2b_1)z = a_2b_3c_1 - a_3b_2c_1 + a_3b_1c_2 - a_1b_3c_2 + a_1b_2c_3 - a_2b_1c_3$$

14 □ PARTIAL DERIVATIVES

14.1 Functions of Several Variables

1. (a) From Table 1, $f(-15, 40) = -27$, which means that if the temperature is $-15°\text{C}$ and the wind speed is 40 km/h, then the air would feel equivalent to approximately $-27°\text{C}$ without wind.

(b) The question is asking: when the temperature is $-20°\text{C}$, what wind speed gives a wind-chill index of $-30°\text{C}$? From Table 1, the speed is 20 km/h.

(c) The question is asking: when the wind speed is 20 km/h, what temperature gives a wind-chill index of $-49°\text{C}$? From Table 1, the temperature is $-35°\text{C}$.

(d) The function $W = f(-5, v)$ means that we fix T at -5 and allow v to vary, resulting in a function of one variable. In other words, the function gives wind-chill index values for different wind speeds when the temperature is $-5°\text{C}$. From Table 1 (look at the row corresponding to $T = -5$), the function decreases and appears to approach a constant value as v increases.

(e) The function $W = f(T, 50)$ means that we fix v at 50 and allow T to vary, again giving a function of one variable. In other words, the function gives wind-chill index values for different temperatures when the wind speed is 50 km/h . From Table 1 (look at the column corresponding to $v = 50$), the function increases almost linearly as T increases.

2. (a) From Table 3, $f(95, 70) = 124$, which means that when the actual temperature is $95°\text{F}$ and the relative humidity is 70%, the perceived air temperature is approximately $124°\text{F}$.

(b) Looking at the row corresponding to $T = 90$, we see that $f(90, h) = 100$ when $h = 60$.

(c) Looking at the column corresponding to $h = 50$, we see that $f(T, 50) = 88$ when $T = 85$.

(d) $I = f(80, h)$ means that T is fixed at 80 and h is allowed to vary, resulting in a function of h that gives the humidex values for different relative humidities when the actual temperature is $80°\text{F}$. Similarly, $I = f(100, h)$ is a function of one variable that gives the humidex values for different relative humidities when the actual temperature is $100°\text{F}$. Looking at the rows of the table corresponding to $T = 80$ and $T = 100$, we see that $f(80, h)$ increases at a relatively constant rate of approximately $1°\text{F}$ per 10% relative humidity, while $f(100, h)$ increases more quickly (at first with an average rate of change of $5°\text{F}$ per 10% relative humidity) and at an increasing rate (approximately $12°\text{F}$ per 10% relative humidity for larger values of h).

3. $P(120, 20) = 1.47(120)^{0.65}(20)^{0.35} \approx 94.2$, so when the manufacturer invests \$20 million in capital and 120,000 hours of labor are completed yearly, the monetary value of the production is about \$94.2 million.

4. If the amounts of labor and capital are both doubled, we replace L, K in the function with $2L, 2K$, giving

$$P(2L, 2K) = 1.01(2L)^{0.75}(2K)^{0.25} = 1.01(2^{0.75})(2^{0.25})L^{0.75}K^{0.25} = (2^1)1.01L^{0.75}K^{0.25} = 2P(L, K)$$

Thus, the production is doubled. It is also true for the general case $P(L, K) = bL^{\alpha}K^{1-\alpha}$:

$P(2L, 2K) = b(2L)^{\alpha}(2K)^{1-\alpha} = b(2^{\alpha})(2^{1-\alpha})L^{\alpha}K^{1-\alpha} = (2^{\alpha+1-\alpha})bL^{\alpha}K^{1-\alpha} = 2P(L, K)$.

5. (a) $f(160, 70) = 0.1091(160)^{0.425}(70)^{0.725} \approx 20.5$, which means that the surface area of a person 70 inches (5 feet 10 inches) tall who weighs 160 pounds is approximately 20.5 square feet.

(b) Answers will vary depending on the height and weight of the reader.

6. We compare the values for the wind-chill index given by Table 1 with those given by the model function:

Modeled Wind-Chill Index Values $W(T, v)$

Wind Speed (km/h)

Actual temperature (°C)

T \ V	5	10	15	20	25	30	40	50	60	70	80
5	4.08	2.66	1.74	1.07	0.52	0.05	− 0.71	− 1.33	− 1.85	− 2.30	− 2.70
0	− 1.59	− 3.31	− 4.42	− 5.24	− 5.91	− 6.47	− 7.40	− 8.14	− 8.77	− 9.32	− 9.80
− 5	− 7.26	− 9.29	− 10.58	− 11.55	− 12.34	− 13.00	− 14.08	− 14.96	− 15.70	− 16.34	− 16.91
− 10	− 12.93	− 15.26	− 16.75	− 17.86	− 18.76	− 19.52	− 20.77	− 21.77	− 22.62	− 23.36	− 24.01
− 15	− 18.61	− 21.23	− 22.91	− 24.17	− 25.19	− 26.04	− 27.45	− 28.59	− 29.54	− 30.38	− 31.11
− 20	− 24.28	− 27.21	− 29.08	− 30.48	− 31.61	− 32.57	− 34.13	− 35.40	− 36.47	− 37.40	− 38.22
− 25	− 29.95	− 33.18	− 35.24	− 36.79	− 38.04	− 39.09	− 40.82	− 42.22	− 43.39	− 44.42	− 45.32
− 30	− 35.62	− 39.15	− 41.41	− 43.10	− 44.46	− 45.62	− 47.50	− 49.03	− 50.32	− 51.44	− 52.43
− 35	− 41.30	− 45.13	− 47.57	− 49.41	− 50.89	− 52.14	− 54.19	− 55.84	− 57.24	− 58.46	− 59.53
− 40	− 46.97	− 51.10	− 53.74	− 55.72	− 57.31	− 58.66	− 60.87	− 62.66	− 64.17	− 65.48	− 66.64

The values given by the function appear to be fairly close (within 0.5) to the values in Table 1.

7. (a) According to Table 4, $f(40, 15) = 25$, which means that if a 40-knot wind has been blowing in the open sea for 15 hours, it will create waves with estimated heights of 25 feet.

(b) $h = f(30, t)$ means we fix v at 30 and allow t to vary, resulting in a function of one variable. Thus here, $h = f(30, t)$ gives the wave heights produced by 30-knot winds blowing for t hours. From the table (look at the row corresponding to $v = 30$), the function increases but at a declining rate as t increases. In fact, the function values appear to be approaching a limiting value of approximately 19, which suggests that 30-knot winds cannot produce waves higher than about 19 feet.

(c) $h = f(v, 30)$ means we fix t at 30, again giving a function of one variable. So, $h = f(v, 30)$ gives the wave heights produced by winds of speed v blowing for 30 hours. From the table (look at the column corresponding to $t = 30$), the function appears to increase at an increasing rate, with no apparent limiting value. This suggests that faster winds (lasting 30 hours) always create higher waves.

8. (a) The cost of making x small boxes, y medium boxes, and z large boxes is $C = f(x, y, z) = 8000 + 2.5x + 4y + 4.5z$ dollars.

(b) $f(3000, 5000, 4000) = 8000 + 2.5(3000) + 4(5000) + 4.5(4000) = 53{,}500$ which means that it costs \$53,500 to make 3000 small boxes, 5000 medium boxes, and 4000 large boxes.

(c) Because no partial boxes will be produced, each of x, y, and z must be a positive integer or zero.

9. (a) $g(2,-1) = \cos(2 + 2(-1)) = \cos(0) = 1$

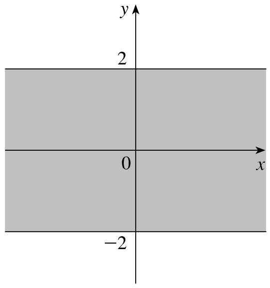
(b) $x + 2y$ is defined for all choices of values for x and y and the cosine function is defined for all input values, so the domain of g is $\mathbb{R}^2$.

(c) The range of the cosine function is $[-1, 1]$ and $x + 2y$ generates all possible input values for the cosine function, so the range of $\cos(x + 2y)$ is $[-1, 1]$.

10. (a) $F(3,1) = 1 + \sqrt{4 - 1^2} = 1 + \sqrt{3}$

(b) $\sqrt{4 - y^2}$ is defined only when $4 - y^2 \geq 0$, or $y^2 \leq 4 \quad \Leftrightarrow$ $-2 \leq y \leq 2$. So the domain of F is $\{(x,y) \mid -2 \leq y \leq 2\}$.

(c) We know $0 \leq \sqrt{4 - y^2} \leq 2$ so $1 \leq 1 + \sqrt{4 - y^2} \leq 3$. Thus the range of F is $[1, 3]$.



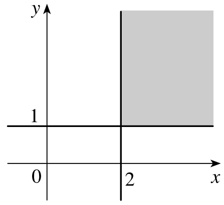
11. (a) $f(1,1,1) = \sqrt{1} + \sqrt{1} + \sqrt{1} + \ln(4 - 1^2 - 1^2 - 1^2) = 3 + \ln 1 = 3$

(b) $\sqrt{x}$, $\sqrt{y}$, $\sqrt{z}$ are defined only when $x \geq 0$, $y \geq 0$, $z \geq 0$, and $\ln(4 - x^2 - y^2 - z^2)$ is defined when $4 - x^2 - y^2 - z^2 > 0 \quad \Leftrightarrow \quad x^2 + y^2 + z^2 < 4$, thus the domain is $\{(x,y,z) \mid x^2 + y^2 + z^2 < 4,\ x \geq 0,\ y \geq 0,\ z \geq 0\}$, the portion of the interior of a sphere of radius 2, centered at the origin, that is in the first octant.

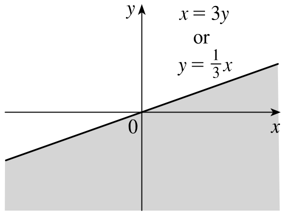
12. (a) $g(1,2,3) = 1^3 \cdot 2^2 \cdot 3\sqrt{10 - 1 - 2 - 3} = 12\sqrt{4} = 24$

(b) g is defined only when $10 - x - y - z \geq 0 \quad \Leftrightarrow \quad z \leq 10 - x - y$, so the domain is $\{(x,y,z) \mid z \leq 10 - x - y\}$, the points on or below the plane $x + y + z = 10$.

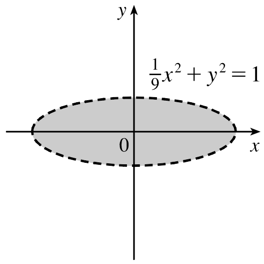
13. $\sqrt{x - 2}$ is defined only when $x - 2 \geq 0$, or $x \geq 2$, and $\sqrt{y - 1}$ is defined only when $y - 1 \geq 0$, or $y \geq 1$. So the domain of f is $\{(x,y) \mid x \geq 2,\ y \geq 1\}$.



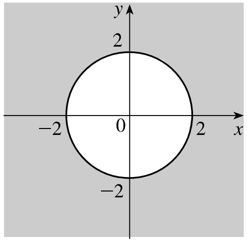
14. $\sqrt[4]{x - 3y}$ is defined only when $x - 3y \geq 0$, or $x \geq 3y$. So the domain of f is $\{(x,y) \mid x \geq 3y\}$ or equivalently $\{(x,y) \mid y \leq \frac{1}{3}x\}$.



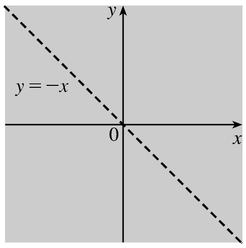
15. $\ln(9 - x^2 - 9y^2)$ is defined only when $9 - x^2 - 9y^2 > 0$, or $\frac{1}{9}x^2 + y^2 < 1$. So the domain of f is $\left\{(x, y) \mid \frac{1}{9}x^2 + y^2 < 1\right\}$, the interior of an ellipse.



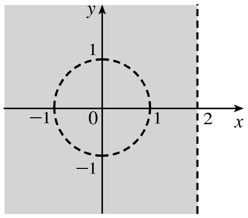
16. $\sqrt{x^2 + y^2 - 4}$ is defined only when $x^2 + y^2 - 4 \geq 0$ $\Leftrightarrow$ $x^2 + y^2 \geq 4$. So the domain of f is $\left\{(x, y) \mid x^2 + y^2 \geq 4\right\}$, the set of points on or outside a circle of radius 2 centered at the origin.



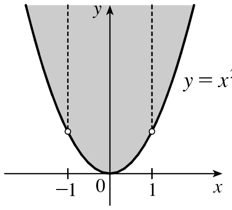
17. g is not defined if $x + y = 0$ $\Leftrightarrow$ $y = -x$ (and is defined otherwise). Thus the domain of g is $\{(x, y) \mid y \neq -x\}$, the set of all points in $\mathbb{R}^2$ that are not on the line $y = -x$.



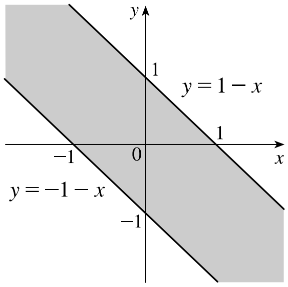
18. $\ln(2 - x)$ is defined only when $2 - x > 0$, or $x < 2$. In addition, g is not defined if $1 - x^2 - y^2 = 0$ $\Leftrightarrow$ $x^2 + y^2 = 1$. Thus the domain of g is $\left\{(x, y) \mid x < 2,\ x^2 + y^2 \neq 1\right\}$, the set of all points to the left of the line $x = 2$ and not on the unit circle.



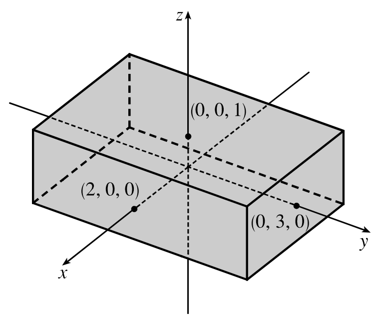
19. $\sqrt{y - x^2}$ is defined only when $y - x^2 \geq 0$, or $y \geq x^2$. In addition, f is not defined if $1 - x^2 = 0$ $\Leftrightarrow$ $x = \pm 1$. Thus the domain of f is $\left\{(x, y) \mid y \geq x^2,\ x \neq \pm 1\right\}$.



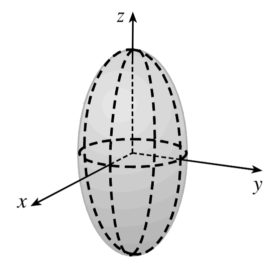
20. $\sin^{-1}(x + y)$ is defined only when $-1 \leq x + y \leq 1$ $\Leftrightarrow$ $-1 - x \leq y \leq 1 - x$. Thus the domain of f is $\{(x, y) \mid -1 - x \leq y \leq 1 - x\}$, consisting of those points on or between the parallel lines $y = -1 - x$ and $y = 1 - x$.



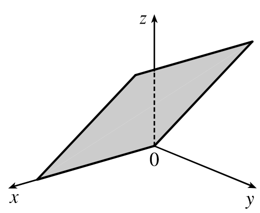
21. f is defined only when $4 - x^2 \geq 0 \quad \Leftrightarrow \quad -2 \leq x \leq 2$ and $9 - y^2 \geq 0 \quad \Leftrightarrow \quad -3 \leq y \leq 3$ and $1 - z^2 \geq 0 \quad \Leftrightarrow \quad -1 \leq z \leq 1$. Thus the domain of f is $\{(x, y, z) \mid -2 \leq x \leq 2,\ -3 \leq y \leq 3,\ -1 \leq z \leq 1\}$, a solid rectangular box with vertices $(\pm 2, \pm 3, \pm 1)$ (all combinations).



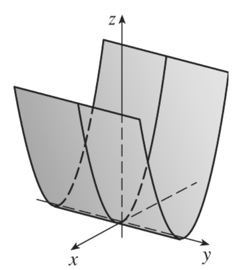
22. f is defined only when $16 - 4x^2 - 4y^2 - z^2 > 0 \quad \Rightarrow$ $\dfrac{x^2}{4} + \dfrac{y^2}{4} + \dfrac{z^2}{16} < 1$. Thus, $D = \left\{ (x, y, z) \,\middle|\, \dfrac{x^2}{4} + \dfrac{y^2}{4} + \dfrac{z^2}{16} < 1 \right\}$, that is, the points inside the ellipsoid $\dfrac{x^2}{4} + \dfrac{y^2}{4} + \dfrac{z^2}{16} = 1$.



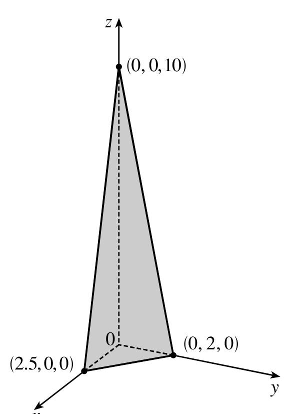
23. The graph of f has equation $z = y$, a plane which intersects the yz-plane in the line $z = y$, $x = 0$. The portion of this plane in the first octant is shown.



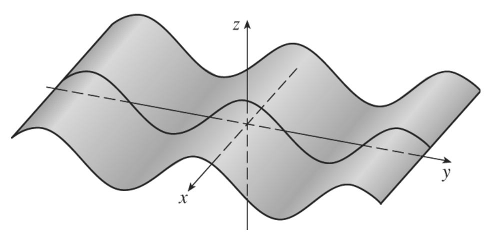
24. The graph of f has equation $z = x^2$, a parabolic cylinder.



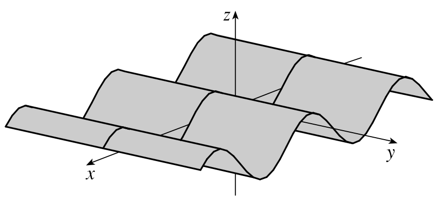
25. $z = 10 - 4x - 5y$ or $4x + 5y + z = 10$, a plane with intercepts 2.5, 2, and 10.



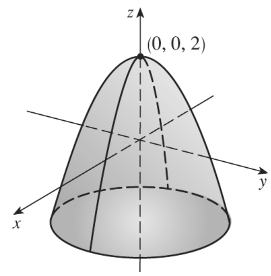
26. $z = \cos y$, a cylinder.



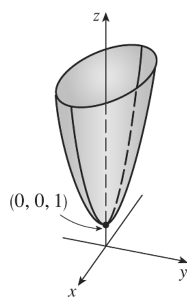
27. $z = \sin x$, a cylinder.



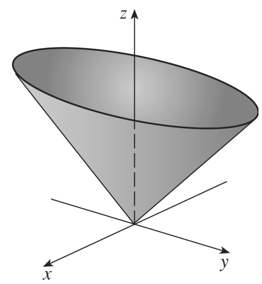
28. $z = 2 - x^2 - y^2$, a circular paraboloid opening downward with vertex at $(0, 0, 2)$.



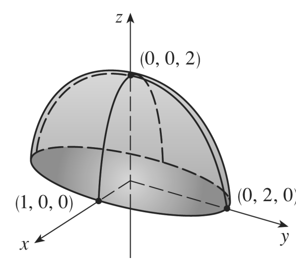
29. $z = x^2 + 4y^2 + 1$, an elliptic paraboloid opening upward with vertex at $(0, 0, 1)$.



30. $z = \sqrt{4x^2 + y^2}$ so $4x^2 + y^2 = z^2$ and $z \geq 0$, the top half of an elliptic cone.



31. $z = \sqrt{4 - 4x^2 - y^2}$ so $4x^2 + y^2 + z^2 = 4$ or $x^2 + \dfrac{y^2}{4} + \dfrac{z^2}{4} = 1$ and $z \geq 0$, the top half of an ellipsoid.



32. (a) $f(x, y) = \dfrac{1}{1 + x^2 + y^2}$. The trace in $x = 0$ is $z = \dfrac{1}{1 + y^2}$, and the trace in $y = 0$ is $z = \dfrac{1}{1 + x^2}$. The only possibility is graph III. Notice also that the level curves of f are $\dfrac{1}{1 + x^2 + y^2} = k \quad \Leftrightarrow \quad x^2 + y^2 = \dfrac{1}{k} - 1$, a family of circles for $k < 1$.

(b) $f(x, y) = \dfrac{1}{1 + x^2 y^2}$. The trace in $x = 0$ is the horizontal line $z = 1$, and the trace in $y = 0$ is also $z = 1$. Both graphs I and II have these traces; however, notice that here $z > 0$, so the graph is I.

(c) $f(x, y) = \ln(x^2 + y^2)$. The trace in $x = 0$ is $z = \ln y^2$, and the trace in $y = 0$ is $z = \ln x^2$. The level curves of f are $\ln(x^2 + y^2) = k \quad \Leftrightarrow \quad x^2 + y^2 = e^k$, a family of circles. In addition, f is large negative when $x^2 + y^2$ is small, so this is graph IV.

(d) $f(x,y) = \cos\sqrt{x^2+y^2}$. The trace in $x=0$ is $z=\cos\sqrt{y^2}=\cos|y|=\cos y$, and the trace in $y=0$ is $z=\cos\sqrt{x^2}=\cos|x|=\cos x$. Notice also that the level curve $f(x,y)=0$ is $\cos\sqrt{x^2+y^2}=0 \quad\Leftrightarrow$ $x^2+y^2=\left(\frac{\pi}{2}+n\pi\right)^2$, a family of circles, so this is graph V.

(e) $f(x,y)=|xy|$. The trace in $x=0$ is $z=0$, and the trace in $y=0$ is $z=0$, so it must be graph VI.

(f) $f(x,y)=\cos(xy)$. The trace in $x=0$ is $z=\cos 0=1$, and the trace in $y=0$ is $z=1$. As mentioned in part (b), these traces match both graphs I and II. Here z can be negative, so the graph is II. (Also notice that the trace in $x=1$ is $z=\cos y$, and the trace in $y=1$ is $z=\cos x$.)

33. The point $(-3,3)$ lies between the level curves with z-values 50 and 60. Since the point is a little closer to the level curve with $z=60$, we estimate that $f(-3,3)\approx 56$. The point $(3,-2)$ appears to be just about halfway between the level curves with z-values 30 and 40, so we estimate $f(3,-2)\approx 35$. The graph rises as we approach the origin, gradually from above, steeply from below.

34. (a) C (Chicago) lies between level curves with pressures 1012 and 1016 mb, and since C appears to be located about one-fourth the distance from the 1012 mb isobar to the 1016 mb isobar, we estimate the pressure at Chicago to be about 1013 mb. N lies very close to a level curve with pressure 1012 mb so we estimate the pressure at Nashville to be approximately 1012 mb. S appears to be just about halfway between level curves with pressures 1008 and 1012 mb, so we estimate the pressure at San Francisco to be about 1010 mb. V lies close to a level curve with pressure 1016 mb but we can't see a level curve to its left so it is more difficult to make an accurate estimate. There are lower pressures to the right of V and V is a short distance to the left of the level curve with pressure 1016 mb, so we might estimate that the pressure at Vancouver is about 1017 mb.

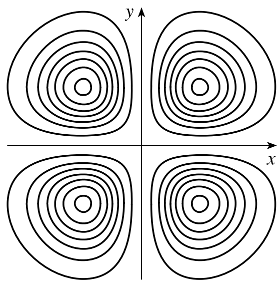
(b) Winds are stronger where the isobars are closer together (see Figure 13), and the level curves are closer near S than at the other locations, so the winds were strongest at San Francisco.

35. The point $(160,10)$, corresponding to day 160 and a depth of 10 m, lies between the isothermals with temperature values of 8 and 12°C. Since the point appears to be located about three-fourths the distance from the 8°C isothermal to the 12°C isothermal, we estimate the temperature at that point to be approximately 11°C. The point $(180,5)$ lies between the 16 and 20°C isothermals, very close to the 20°C level curve, so we estimate the temperature there to be about 19.5°C.

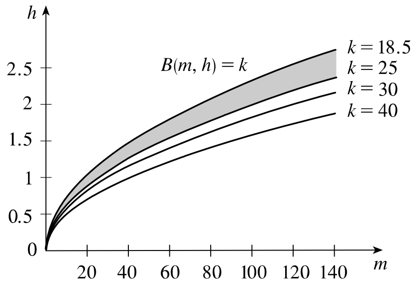
36. If we start at the origin and move along the x-axis, for example, the z-values of a cone centered at the origin increase at a constant rate, so we would expect its level curves to be equally spaced. A paraboloid with vertex the origin, on the other hand, has z-values which change slowly near the origin and more quickly as we move farther away. Thus, we would expect its level curves near the origin to be spaced more widely apart than those farther from the origin. Therefore contour map I must correspond to the paraboloid, and contour map II the cone.

37. Near A, the level curves are very close together, indicating that the terrain is quite steep. At B, the level curves are much farther apart, so we would expect the terrain to be much less steep than near A, perhaps almost flat.

38.



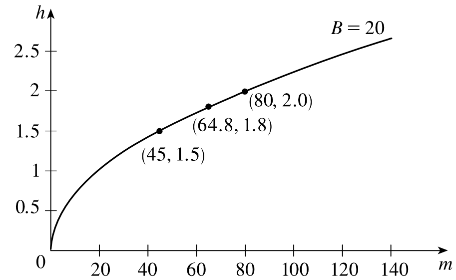
39. The level curves of $B(m,h) = \dfrac{m}{h^2}$ are $\dfrac{m}{h^2} = k \quad \Leftrightarrow \quad m = kh^2$ or equivalently $h = \sqrt{m/k} = \dfrac{1}{\sqrt{k}}\sqrt{m}$ since $m > 0$, $h > 0$. We draw the level curves for $k = 18.5$, 25, 30, and 40.



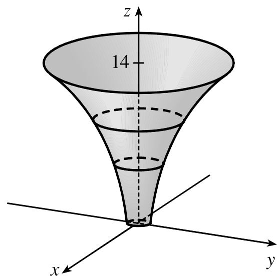
The shaded region corresponds to BMI values between 18.5 and 25, those considered optimal. For a mass of 62 kg and a height of 152 cm (1.52 m), the BMI is $B(62, 1.52) = \dfrac{62}{1.52^2} \approx 26.8$, which is outside the optimal range.

40. From Exercise 39, the body mass index function is $B(m,h) = m/h^2$. The BMI for a person 200 cm (2.0 m, about 6 ft 7 in) tall and with mass 80 kg (about 176 lb) is $B(80, 2.0) = 80/(2.0)^2 = 20$. The level curve $B(m,h) = 20 \quad \Leftrightarrow \quad m = 20h^2$ is shown in the graph.

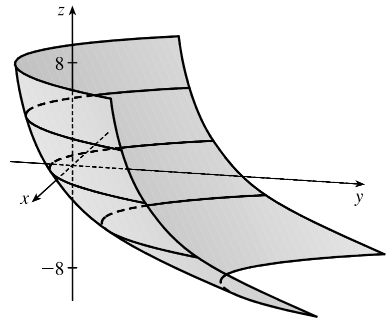
A person 1.5 m tall (about 4 ft 11 in) has a BMI on the same level curve if their mass is $m = 20(1.5)^2 = 45$ kg (about 99 lb), and a person 1.8 m (about 5 ft 11 in) tall would have mass $m = 20(1.8)^2 = 64.8$ kg (about 143 lb). (See the graph.)



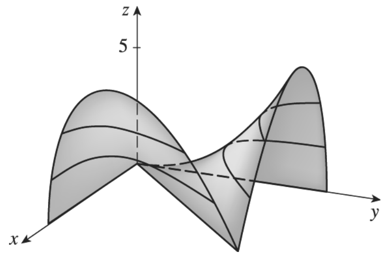
41.



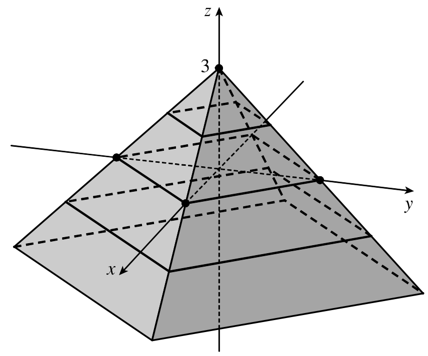
42.



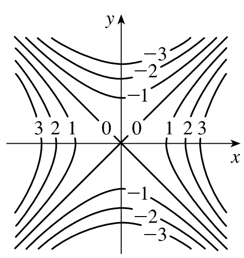
43.



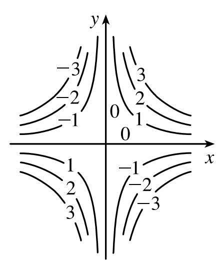
44.



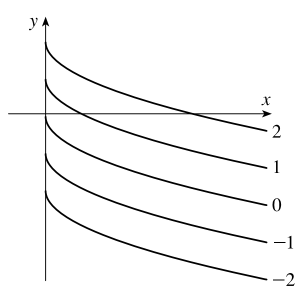
45. The level curves are $x^2 - y^2 = k$. When $k = 0$ the level curve is the pair of lines $y = \pm x$, and when $k \neq 0$ the level curves are a family of hyperbolas (oriented differently for $k > 0$ than for $k < 0$).



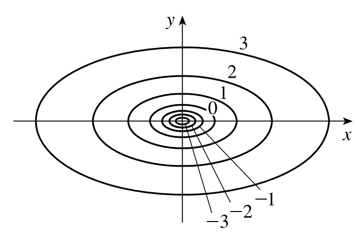
46. The level curves are $xy = k$ or $y = k/x$. When $k \neq 0$ the level curves are a family of hyperbolas. When $k = 0$ the level curve is the pair of lines $x = 0$, $y = 0$.



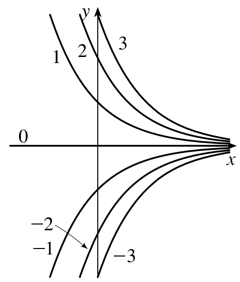
47. The level curves are $\sqrt{x} + y = k$ or $y = -\sqrt{x} + k$, a family of vertical translations of the graph of the root function $y = -\sqrt{x}$.



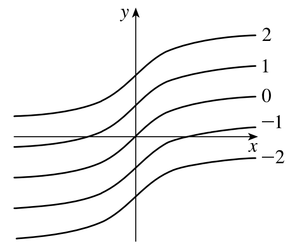
48. The level curves are $\ln(x^2 + 4y^2) = k$ or $x^2 + 4y^2 = e^k$, a family of ellipses.



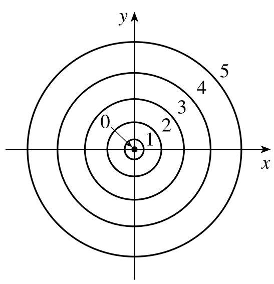
49. The level curves are $ye^x = k$ or $y = ke^{-x}$, a family of exponential curves.



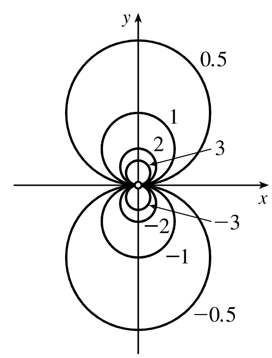
50. The level curves are $y - \arctan x = k$ or $y = (\arctan x) + k$, a family of vertical translations of the graph of the inverse tangent function $y = \arctan x$.



51. The level curves are $\sqrt[3]{x^2 + y^2} = k$ or $x^2 + y^2 = k^3$ $(k \geq 0)$, a family of circles centered at the origin with radius $k^{3/2}$.

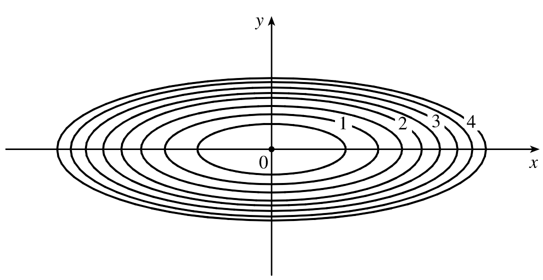


52. For $k \neq 0$ and $(x, y) \neq (0, 0)$, $k = \dfrac{y}{x^2 + y^2}$ $\Leftrightarrow$ $x^2 + y^2 - \dfrac{y}{k} = 0$ $\Leftrightarrow$ $x^2 + \left(y - \frac{1}{2k}\right)^2 = \dfrac{1}{4k^2}$, a family of circles with center $\left(0, \frac{1}{2k}\right)$ and radius $\frac{1}{2k}$ (without the origin). If $k = 0$, the level curve is the x-axis.

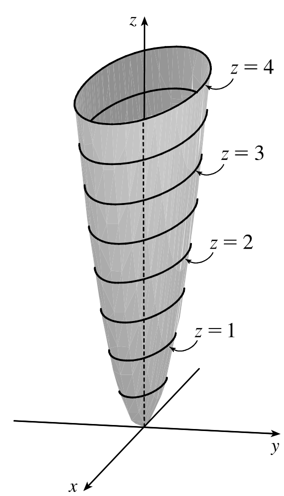


53. The contour map consists of the level curves $k = x^2 + 9y^2$, a family of ellipses with major axis the x-axis. (Or, if $k = 0$, the origin.)

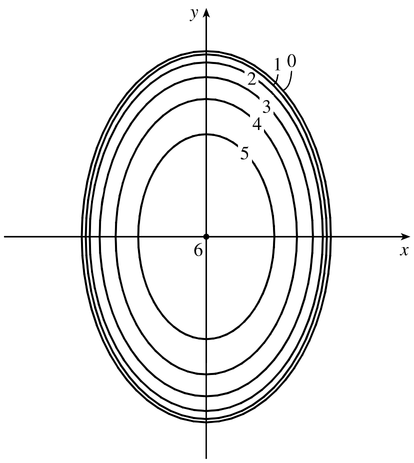
The graph of $f(x, y)$ is the surface $z = x^2 + 9y^2$, an elliptic paraboloid.



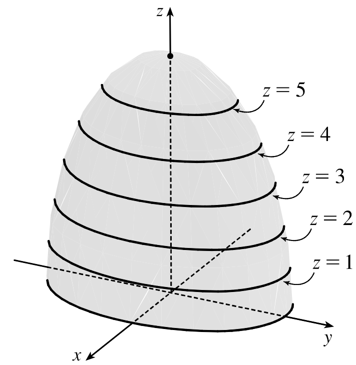
If we visualize lifting each ellipse $k = x^2 + 9y^2$ of the contour map to the plane $z = k$, we have horizontal traces that indicate the shape of the graph of f.



54.

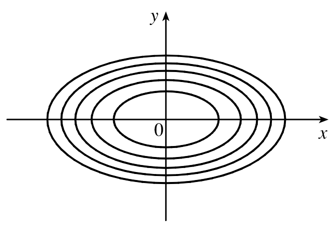


The contour map consists of the level curves $k = \sqrt{36 - 9x^2 - 4y^2} \Rightarrow 9x^2 + 4y^2 = 36 - k^2$, $k \geq 0$, a family of ellipses with major axis the y-axis. (Or, if $k = 6$, the origin.)



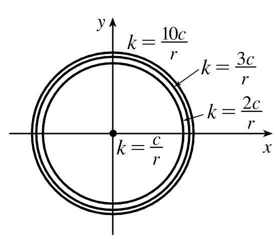
The graph of $f(x, y)$ is the surface $z = \sqrt{36 - 9x^2 - 4y^2}$, or equivalently the upper half of the ellipsoid $9x^2 + 4y^2 + z^2 = 36$. If we visualize lifting each ellipse $k = \sqrt{36 - 9x^2 - 4y^2}$ of the contour map to the plane $z = k$, we have horizontal traces that indicate the shape of the graph of f.

55. The isothermals are given by $k = 100/(1 + x^2 + 2y^2)$ or $x^2 + 2y^2 = (100 - k)/k$ $[0 < k \leq 100]$, a family of ellipses.

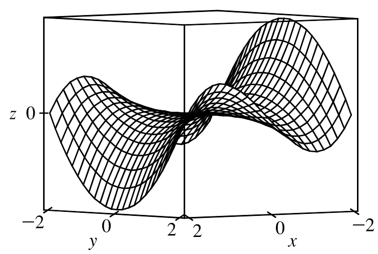


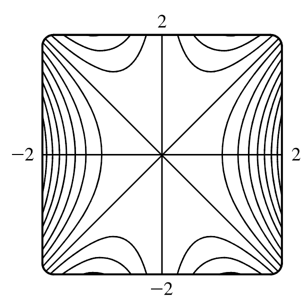
56. The equipotential curves are $k = \dfrac{c}{\sqrt{r^2 - x^2 - y^2}}$ or $x^2 + y^2 = r^2 - \left(\dfrac{c}{k}\right)^2$, a family of circles ($k \geq c/r$).

Note: As $k \to \infty$, the radius of the circle approaches r.



57. $f(x, y) = xy^2 - x^3$

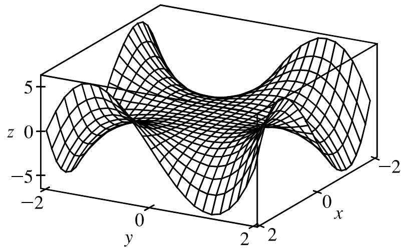


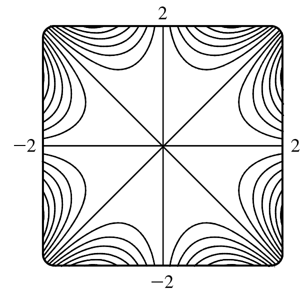


The traces parallel to the yz-plane (such as the left-front trace in the graph above) are parabolas; those parallel to the xz-plane (such as the right-front trace) are cubic curves. The surface is called a monkey saddle because a monkey sitting on the surface near the origin has places for both legs and tail to rest.

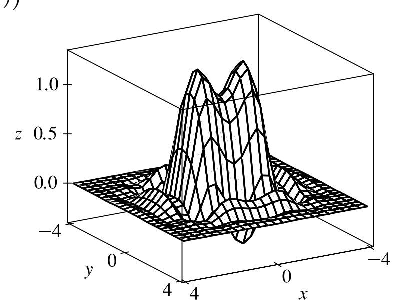
58. $f(x, y) = xy^3 - yx^3$

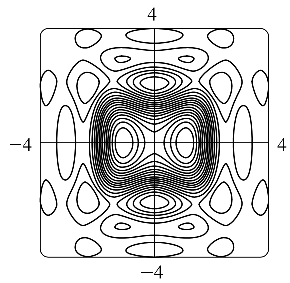
The traces parallel to either the yz-plane or the xz-plane are cubic curves.





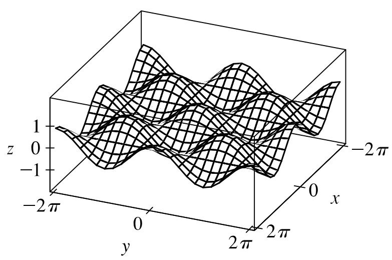
59. $f(x, y) = e^{-(x^2+y^2)/3}\left(\sin(x^2) + \cos(y^2)\right)$

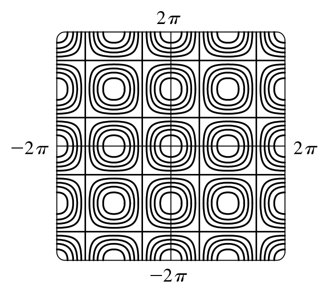




60. $f(x, y) = \cos x \, \cos y$

The traces parallel to either the yz- or xz-plane are cosine curves with amplitudes that vary from 0 to 1.





61. $z = \sin(xy)$ (a) C (b) II

Reasons: This function is periodic in both x and y, and the function is the same when x is interchanged with y, so its graph is symmetric about the plane $y = x$. In addition, the function is 0 along the x- and y-axes. These conditions are satisfied only by C and II.

62. $z = e^x \cos y$ (a) A (b) IV

Reasons: This function is periodic in y but not x, a condition satisfied only by A and IV. Also, note that traces in $x = k$ are cosine curves with amplitude that increases as x increases.

63. $z = \sin(x - y)$ (a) F (b) I

Reasons: This function is periodic in both x and y but is constant along the lines $y = x + k$, a condition satisfied only by F and I.

64. $z = \sin x - \sin y$ (a) E (b) III

Reasons: This function is periodic in both x and y, but unlike the function in Exercise 63, it is not constant along lines such as $y = x + \pi$, so the contour map is III. Also notice that traces in $y = k$ are vertically shifted copies of the sine wave $z = \sin x$, so the graph must be E.

65. $z = (1 - x^2)(1 - y^2)$ (a) B (b) VI

Reasons: This function is 0 along the lines $x = \pm 1$ and $y = \pm 1$. The only contour map in which this could occur is VI. Also note that the trace in the xz-plane is the parabola $z = 1 - x^2$ and the trace in the yz-plane is the parabola $z = 1 - y^2$, so the graph is B.

66. $z = \dfrac{x - y}{1 + x^2 + y^2}$ (a) D (b) V

Reasons: This function is not periodic, ruling out the graphs in A, C, E, and F. Also, the values of z approach 0 as we use points farther from the origin. The only graph that shows this behavior is D, which corresponds to V.

67. $k = x + 3y + 5z$ is a family of parallel planes with normal vector $\langle 1, 3, 5 \rangle$.

68. $k = x^2 + 3y^2 + 5z^2$ is a family of ellipsoids for $k > 0$ and the origin for $k = 0$.

69. Equations for the level surfaces are $k = y^2 + z^2$. For $k > 0$, we have a family of circular cylinders with axis the x-axis and radius $\sqrt{k}$. When $k = 0$ the level surface is the x-axis. (There are no level surfaces for $k < 0$.)

70. Equations for the level surfaces are $x^2 - y^2 - z^2 = k$. For $k = 0$, the equation becomes $y^2 + z^2 = x^2$ and the surface is a right circular cone with vertex the origin and axis the x-axis. For $k > 0$, we have a family of hyperboloids of two sheets with axis the x-axis, and for $k < 0$, we have a family of hyperboloids of one sheet with axis the x-axis.

71. (a) The graph of g is the graph of f shifted upward 2 units.

(b) The graph of g is the graph of f stretched vertically by a factor of 2.

(c) The graph of g is the graph of f reflected about the xy-plane.

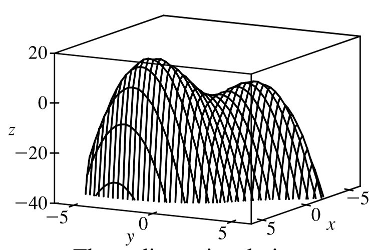
(d) The graph of $g(x, y) = -f(x, y) + 2$ is the graph of f reflected about the xy-plane and then shifted upward 2 units.

72. (a) The graph of g is the graph of f shifted 2 units in the positive x-direction.

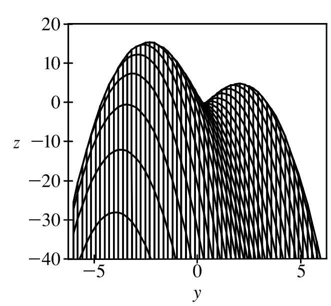
(b) The graph of g is the graph of f shifted 2 units in the negative y-direction.

(c) The graph of g is the graph of f shifted 3 units in the negative x-direction and 4 units in the positive y-direction.

73. $f(x, y) = 3x - x^4 - 4y^2 - 10xy$



Three-dimensional view

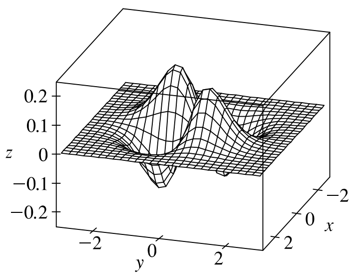


Front view

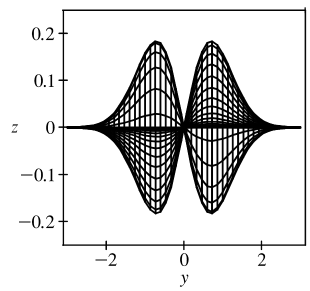
[continued]

It does appear that the function has a maximum value, at the higher of the two "hilltops." From the front view graph, the maximum value appears to be approximately 15. Both hilltops could be considered local maximum points, as the values of f there are larger than at the neighboring points. There does not appear to be any local minimum point; although the valley shape between the two peaks looks like a minimum of some kind, some neighboring points have lower function values.

74. $f(x,y) = xye^{-x^2-y^2}$



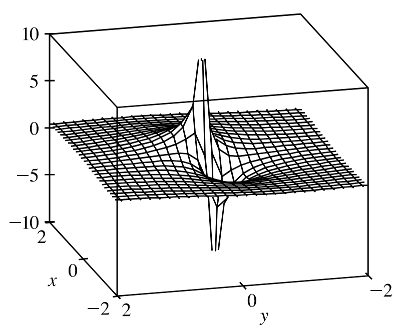
Three-dimensional view



Front view

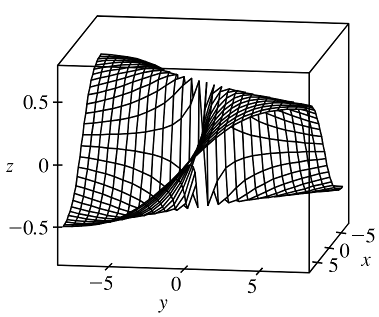
The function does have a maximum value, which it appears to achieve at two different points (the two "hilltops"). From the front view graph, we can estimate the maximum value to be approximately 0.18. These same two points can also be considered local maximum points. The two "valley bottoms" visible in the graph can be considered local minimum points, as all the neighboring points give greater values of f.

75.



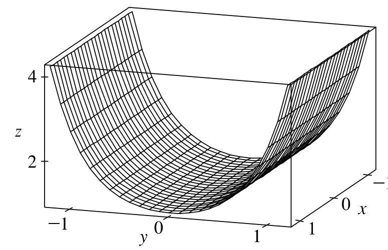
$f(x,y) = \dfrac{x+y}{x^2+y^2}$. As both x and y become large, the function values appear to approach 0, regardless of which direction is considered. As (x,y) approaches the origin, the graph exhibits asymptotic behavior. From some directions, $f(x,y) \to \infty$, while in others $f(x,y) \to -\infty$. (These are the vertical spikes visible in the graph.) If the graph is examined carefully, however, one can see that $f(x,y)$ approaches 0 along the line $y = -x$.

76.



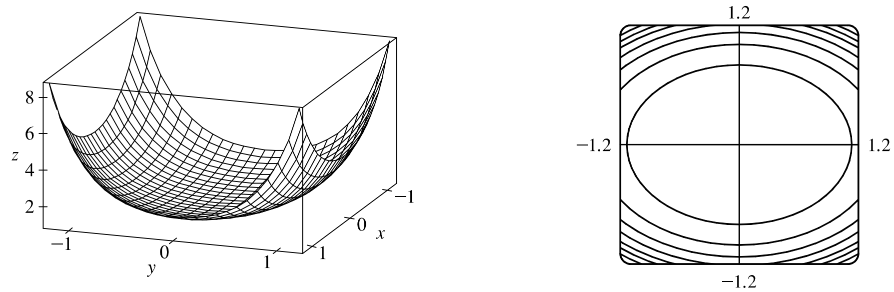
$f(x,y) = \dfrac{xy}{x^2+y^2}$. The graph exhibits different limiting values as x and y become large or as (x,y) approaches the origin, depending on the direction being examined. For example, although f is undefined at the origin, the function values appear to be $\frac{1}{2}$ along the line $y = x$, regardless of the distance from the origin. Along the line $y = -x$, the value is always $-\frac{1}{2}$. Along the axes, $f(x,y) = 0$ for all values of (x,y) except the origin. Other directions, heading toward the origin or away from the origin, give various limiting values between $-\frac{1}{2}$ and $\frac{1}{2}$.

77. $f(x,y) = e^{cx^2+y^2}$. First, if $c = 0$, the graph is the cylindrical surface $z = e^{y^2}$ (whose level curves are parallel lines). When $c > 0$, the vertical trace above the y-axis remains fixed while the sides of the surface in the x-direction "curl" upward, giving the graph a shape resembling an elliptic paraboloid. The level curves of the surface are ellipses centered at the origin.



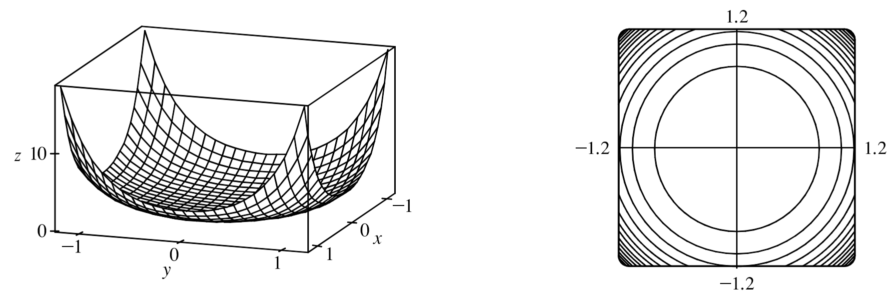
$c = 0$

For $0 < c < 1$, the ellipses have major axis the x-axis and the eccentricity increases as $c \to 0$.



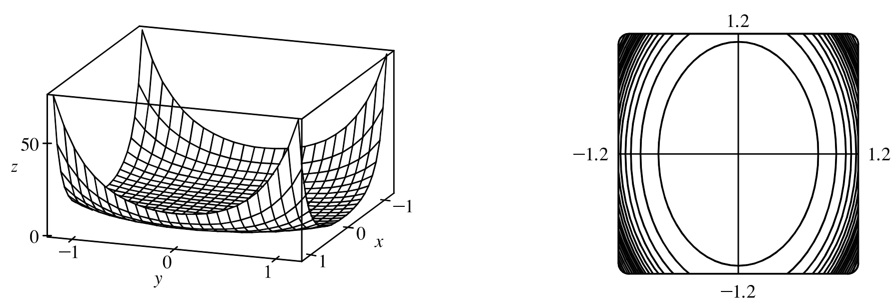
$c = 0.5$ (level curves in increments of 1)

For $c = 1$ the level curves are circles centered at the origin.



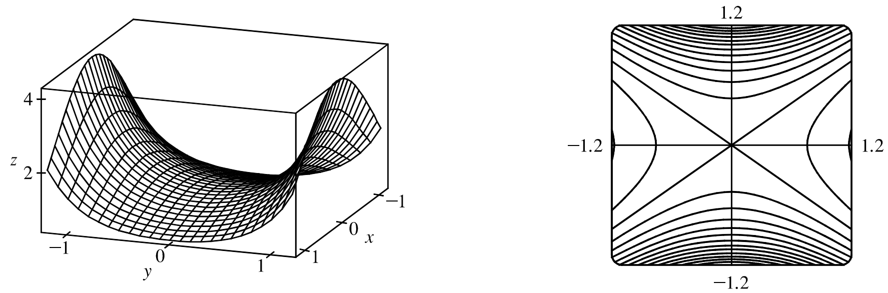
$c = 1$ (level curves in increments of 1)

When $c > 1$, the level curves are ellipses with major axis the y-axis, and the eccentricity increases as c increases.

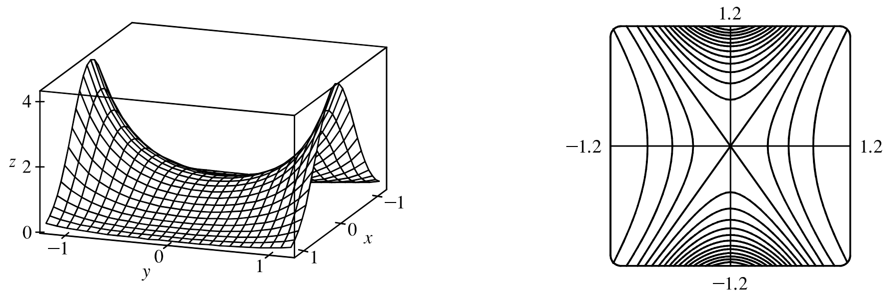


$c = 2$ (level curves in increments of 4)

For values of $c < 0$, the sides of the surface in the x-direction curl downward and approach the xy-plane (while the vertical trace $x = 0$ remains fixed), giving a saddle-shaped appearance to the graph near the point $(0, 0, 1)$. The level curves consist of a family of hyperbolas. As c decreases, the surface becomes flatter in the x-direction and the surface's approach to the curve in the trace $x = 0$ becomes steeper, as the graphs demonstrate.

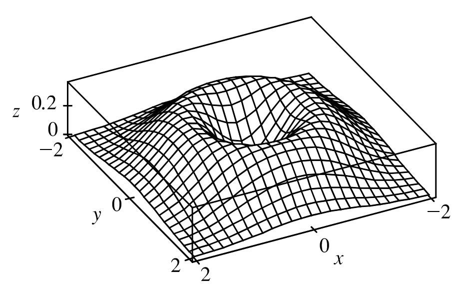


$c = -0.5$ (level curves in increments of 0.25)

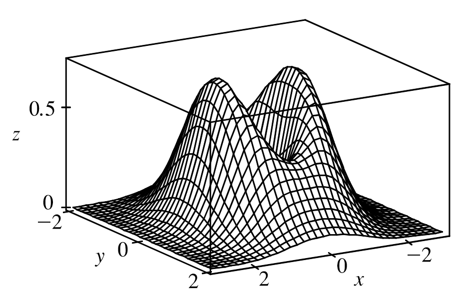


$c = -2$ (level curves in increments of 0.25)

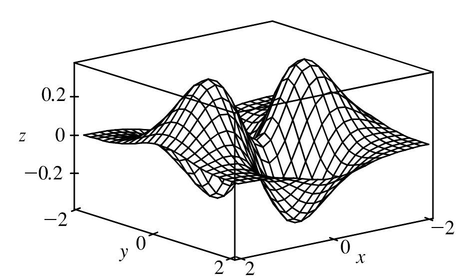
78. $z = (ax^2 + by^2)e^{-x^2-y^2}$. There are only three basic shapes which can be obtained (the fourth and fifth graphs are the reflections of the first and second ones in the xy-plane). Interchanging a and b rotates the graph by 90° about the z-axis.



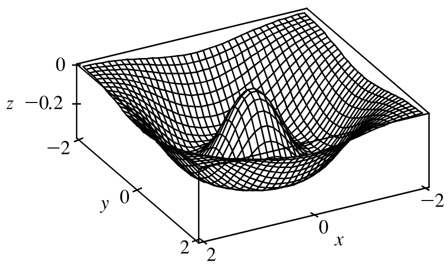
$a = 1, b = 1$



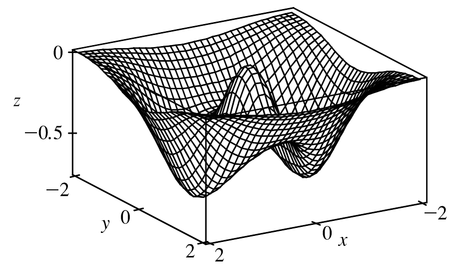
$a = 2, b = 1$



$a = 1, b = -1$



$a = -1, b = -1$

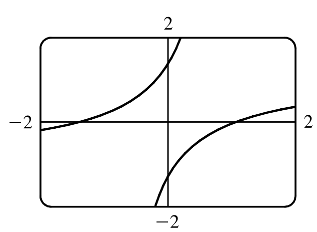


$a = -2, b = -1$

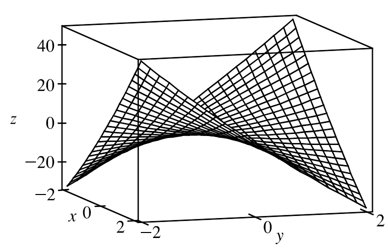
If a and b are both positive ($a \neq b$), we see that the graph has two maximum points whose height increases as a and b increase. If a and b have opposite signs, the graph has two maximum points and two minimum points, and if a and b are both negative, the graph has one maximum point and two minimum points.

79. $z = x^2 + y^2 + cxy$. When $c < -2$, the surface intersects the plane $z = k \neq 0$ in a hyperbola. (See the following graph.) It intersects the plane $x = y$ in the parabola $z = (2 + c)x^2$, and the plane $x = -y$ in the parabola $z = (2 - c)x^2$. These parabolas open in opposite directions, so the surface is a hyperbolic paraboloid.

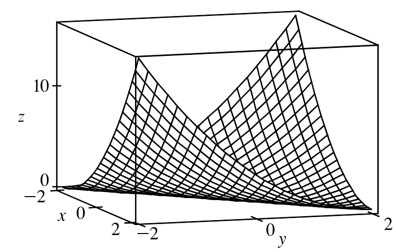
When $c = -2$ the surface is $z = x^2 + y^2 - 2xy = (x - y)^2$. So the surface is constant along each line $x - y = k$. That is, the surface is a cylinder with axis $x - y = 0$, $z = 0$. The shape of the cylinder is determined by its intersection with the plane $x + y = 0$, where $z = 4x^2$, and hence the cylinder is parabolic with minima of 0 on the line $y = x$.



$c = -5, z = 2$



$c = -10$

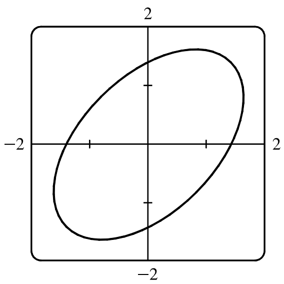


$c = -2$

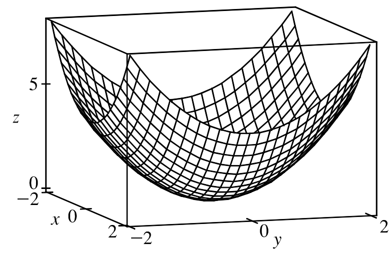
When $-2 < c \leq 0$, $z \geq 0$ for all x and y. If x and y have the same sign, then $x^2 + y^2 + cxy \geq x^2 + y^2 - 2xy = (x - y)^2 \geq 0$. If they have opposite signs, then $cxy \geq 0$. The intersection with the surface and the plane $z = k > 0$ is an ellipse (see graph below). The intersection with the surface and the planes $x = 0$ and $y = 0$ are parabolas $z = y^2$ and $z = x^2$ respectively, so the surface is an elliptic paraboloid.

When $c > 0$ the graphs have the same shape, but are reflected in the plane $x = 0$, because $x^2 + y^2 + cxy = (-x)^2 + y^2 + (-c)(-x)y$. That is, the value of z is the same for c at (x, y) as it is for $-c$ at $(-x, y)$.

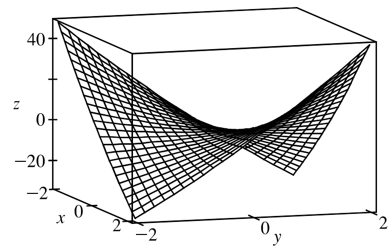
[continued]



$c = -1, z = 2$



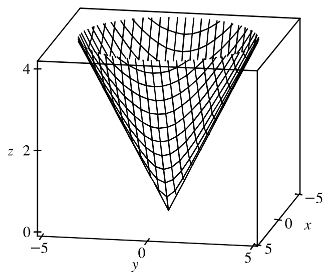
$c = 0$



$c = 10$

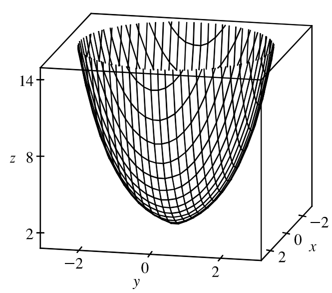
So the surface is an elliptic paraboloid for $0 < c < 2$, a parabolic cylinder for $c = 2$, and a hyperbolic paraboloid for $c > 2$.

80. First, we graph $f(x, y) = \sqrt{x^2 + y^2}$.

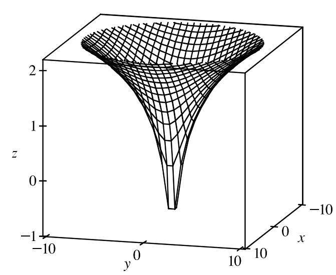


$f(x, y) = \sqrt{x^2 + y^2}$

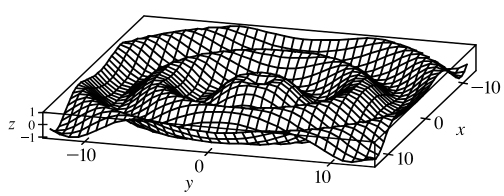
Graphs of the other four functions follow.



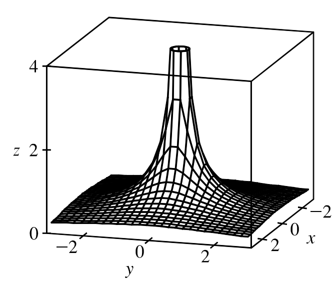
$f(x, y) = e^{\sqrt{x^2 + y^2}}$



$f(x, y) = \ln \sqrt{x^2 + y^2}$



$f(x, y) = \sin\left(\sqrt{x^2 + y^2}\right)$



$f(x, y) = \dfrac{1}{\sqrt{x^2 + y^2}}$

Notice that each graph $f(x, y) = g\left(\sqrt{x^2 + y^2}\right)$ exhibits radial symmetry about the z-axis and the trace in the xz-plane for

$x \geq 0$ is the graph of $z = g(x)$, $x \geq 0$. This suggests that the graph of $f(x, y) = g\left(\sqrt{x^2 + y^2}\right)$ is obtained from the graph of g by graphing $z = g(x)$ in the xz-plane and rotating the curve about the z-axis.

81. (a) $P = bL^\alpha K^{1-\alpha} \quad \Rightarrow \quad \dfrac{P}{K} = bL^\alpha K^{-\alpha} \quad \Rightarrow \quad \dfrac{P}{K} = b\left(\dfrac{L}{K}\right)^\alpha \quad \Rightarrow \quad \ln \dfrac{P}{K} = \ln\left(b\left(\dfrac{L}{K}\right)^\alpha\right) \quad \Rightarrow$

$$\ln \frac{P}{K} = \ln b + \alpha \ln\left(\frac{L}{K}\right)$$

(b) We list the values for $\ln(L/K)$ and $\ln(P/K)$ for the years 1899–1922. (Historically, these values were rounded to 2 decimal places.)

Year	$x = \ln(L/K)$	$y = \ln(P/K)$
1899	0	0
1900	−0.02	−0.06
1901	−0.04	−0.02
1902	−0.04	0
1903	−0.07	−0.05
1904	−0.13	−0.12
1905	−0.18	−0.04
1906	−0.20	−0.07
1907	−0.23	−0.15
1908	−0.41	−0.38
1909	−0.33	−0.24
1910	−0.35	−0.27

Year	$x = \ln(L/K)$	$y = \ln(P/K)$
1911	−0.38	−0.34
1912	−0.38	−0.24
1913	−0.41	−0.25
1914	−0.47	−0.37
1915	−0.53	−0.34
1916	−0.49	−0.28
1917	−0.53	−0.39
1918	−0.60	−0.50
1919	−0.68	−0.57
1920	−0.74	−0.57
1921	−1.05	−0.85
1922	−0.98	−0.59

After entering the (x, y) pairs into a calculator or CAS, the resulting least squares regression line through the points is approximately $y = 0.75136x + 0.01053$, which we round to $y = 0.75x + 0.01$.

(c) Comparing the regression line from part (b) to the equation $y = \ln b + \alpha x$ with $x = \ln(L/K)$ and $y = \ln(P/K)$, we have $\alpha = 0.75$ and $\ln b = 0.01 \quad \Rightarrow \quad b = e^{0.01} \approx 1.01$. Thus, the Cobb-Douglas production function is $P = bL^\alpha K^{1-\alpha} = 1.01L^{0.75}K^{0.25}$.

14.2 Limits and Continuity

1. In general, we can't say anything about $f(3, 1)$! $\lim\limits_{(x,y)\to(3,1)} f(x, y) = 6$ means that the values of $f(x, y)$ approach 6 as (x, y) approaches, but is not equal to, $(3, 1)$. If f is continuous, we know that $\lim\limits_{(x,y)\to(a,b)} f(x, y) = f(a, b)$, so $\lim\limits_{(x,y)\to(3,1)} f(x, y) = f(3, 1) = 6$.

2. (a) The outdoor temperature as a function of longitude, latitude, and time is continuous. Small changes in longitude, latitude, or time can produce only small changes in temperature, as the temperature doesn't jump abruptly from one value to another.

(b) Elevation is not necessarily continuous. If we think of a cliff with a sudden drop-off, a very small change in longitude or latitude can produce a comparatively large change in elevation, without all the intermediate values being attained. Elevation *can* jump from one value to another.

(c) The cost of a taxi ride is usually discontinuous. The cost normally increases in jumps, so small changes in distance traveled or time can produce a jump in cost. A graph of the function would show breaks in the surface.

3. We make a table of values of $f(x,y) = \dfrac{x^2y^3 + x^3y^2 - 5}{2 - xy}$ for a set of (x,y) points near the origin.

$x \backslash y$	-0.2	-0.1	-0.05	0	0.05	0.1	0.2
-0.2	-2.551	-2.525	-2.513	-2.500	-2.488	-2.475	-2.451
-0.1	-2.525	-2.513	-2.506	-2.500	-2.494	-2.488	-2.475
-0.05	-2.513	-2.506	-2.503	-2.500	-2.497	-2.494	-2.488
0	-2.500	-2.500	-2.500		-2.500	-2.500	-2.500
0.05	-2.488	-2.494	-2.497	-2.500	-2.503	-2.506	-2.513
0.1	-2.475	-2.488	-2.494	-2.500	-2.506	-2.513	-2.525
0.2	-2.451	-2.475	-2.488	-2.500	-2.513	-2.525	-2.551

As the table shows, the values of $f(x,y)$ seem to approach -2.5 as (x,y) approaches the origin from a variety of different directions. This suggests that $\lim_{(x,y)\to(0,0)} f(x,y) = -2.5$. Since f is a rational function, it is continuous on its domain. f is defined at $(0,0)$, so we can use direct substitution to establish that $\lim_{(x,y)\to(0,0)} f(x,y) = \dfrac{0^2 0^3 + 0^3 0^2 - 5}{2 - 0 \cdot 0} = -\dfrac{5}{2}$, verifying our guess.

4. We make a table of values of $f(x,y) = \dfrac{2xy}{x^2 + 2y^2}$ for a set of (x,y) points near the origin.

$x \backslash y$	-0.3	-0.2	-0.1	0	0.1	0.2	0.3
-0.3	0.667	0.706	0.545	0.000	-0.545	-0.706	-0.667
-0.2	0.545	0.667	0.667	0.000	-0.667	-0.667	-0.545
-0.1	0.316	0.444	0.667	0.000	-0.667	-0.444	-0.316
0	0.000	0.000	0.000		0.000	0.000	0.000
0.1	-0.316	-0.444	-0.667	0.000	0.667	0.444	0.316
0.2	-0.545	-0.667	-0.667	0.000	0.667	0.667	0.545
0.3	-0.667	-0.706	-0.545	0.000	0.545	0.706	0.667

It appears from the table that the values of $f(x,y)$ are not approaching a single value as (x,y) approaches the origin. For verification, if we first approach $(0,0)$ along the x-axis, we have $f(x,0) = 0$, so $f(x,y) \to 0$. But if we approach $(0,0)$ along the line $y = x$, $f(x,x) = \dfrac{2x^2}{x^2 + 2x^2} = \dfrac{2}{3}$ $(x \neq 0)$, so $f(x,y) \to \frac{2}{3}$. Since f approaches different values along different paths to the origin, this limit does not exist.

5. $f(x,y) = x^2y^3 - 4y^2$ is a polynomial, and hence continuous, so we can find the limit by direct substitution: $\lim_{(x,y)\to(3,2)} f(x,y) = f(3,2) = (3)^2(2)^3 - 4(2)^2 = 56$.

6. $f(x,y) = \dfrac{x^2y + xy^2}{x^2 - y^2}$ is a rational function and hence continuous on its domain.

$(2,-1)$ is in the domain of f, so f is continuous there and $\lim\limits_{(x,y)\to(2,-1)} f(x,y) = f(2,-1) = \dfrac{(2)^2(-1) + (2)(-1)^2}{(2)^2 - (-1)^2} = -\dfrac{2}{3}$.

7. $x - y$ is a polynomial and therefore continuous. Since $\sin t$ is a continuous function, the composition $\sin(x-y)$ is also continuous. The function y is a polynomial, and hence continuous, and the product of continuous functions is continuous, so $f(x,y) = y\sin(x-y)$ is a continuous function. Then $\lim\limits_{(x,y)\to(\pi,\pi/2)} f(x,y) = f\left(\pi, \frac{\pi}{2}\right) = \frac{\pi}{2}\sin\left(\pi - \frac{\pi}{2}\right) = \frac{\pi}{2}\sin\frac{\pi}{2} = \frac{\pi}{2}$.

8. $2x - y$ is a polynomial and therefore continuous. Since $\sqrt{t}$ is continuous for $t \geq 0$, the composition $\sqrt{2x-y}$ is continuous where $2x - y \geq 0$. The function e^u is continuous everywhere, so the composition $f(x,y) = e^{\sqrt{2x-y}}$ is a continuous function for $2x - y \geq 0$. If $x = 3$ and $y = 2$ then $2x - y \geq 0$, so $\lim\limits_{(x,y)\to(3,2)} f(x,y) = f(3,2) = e^{\sqrt{2(3)-2}} = e^2$.

9. $f(x,y) = (x^4 - 4y^2)/(x^2 + 2y^2)$. First approach $(0,0)$ along the x-axis. Then $f(x,0) = x^4/x^2 = x^2$ for $x \neq 0$, so $f(x,y) \to 0$. Now approach $(0,0)$ along the y-axis. For $y \neq 0$, $f(0,y) = -4y^2/2y^2 = -2$, so $f(x,y) \to -2$. Since f has two different limits along two different lines, the limit does not exist.

10. $f(x,y) = (5y^4\cos^2 x)/(x^4 + y^4)$. First approach $(0,0)$ along the x-axis. Then $f(x,0) = 0/x^4 = 0$ for $x \neq 0$, so $f(x,y) \to 0$. Next approach $(0,0)$ along the y-axis. For $y \neq 0$, $f(0,y) = 5y^4/y^4 = 5$, so $f(x,y) \to 5$. Since f has two different limits along two different lines, the limit does not exist.

11. $f(x,y) = (y^2\sin^2 x)/(x^4 + y^4)$. On the x-axis, $f(x,0) = 0$ for $x \neq 0$, so $f(x,y) \to 0$ as $(x,y) \to (0,0)$ along the x-axis. Approaching $(0,0)$ along the line $y = x$, $f(x,x) = \dfrac{x^2\sin^2 x}{x^4 + x^4} = \dfrac{\sin^2 x}{2x^2} = \dfrac{1}{2}\left(\dfrac{\sin x}{x}\right)^2$ for $x \neq 0$ and $\lim\limits_{x\to 0}\dfrac{\sin x}{x} = 1$, so $f(x,y) \to \frac{1}{2}$. Since f has two different limits along two different lines, the limit does not exist.

12. $f(x,y) = \dfrac{xy - y}{(x-1)^2 + y^2}$. On the x-axis, $f(x,0) = 0/(x-1)^2 = 0$ for $x \neq 1$, so $f(x,y) \to 0$ as $(x,y) \to (1,0)$ along the x-axis. Approaching $(1,0)$ along the line $y = x - 1$, $f(x, x-1) = \dfrac{x(x-1) - (x-1)}{(x-1)^2 + (x-1)^2} = \dfrac{(x-1)^2}{2(x-1)^2} = \dfrac{1}{2}$ for $x \neq 1$, so $f(x,y) \to \frac{1}{2}$ along this line. Thus the limit does not exist.

13. $f(x,y) = \dfrac{xy}{\sqrt{x^2 + y^2}}$. We can see that the limit along any line through $(0,0)$ is 0, as well as along other paths through $(0,0)$ such as $x = y^2$ and $y = x^2$. So we suspect that the limit exists and equals 0; we use the Squeeze Theorem to prove our assertion. Since $|y| \leq \sqrt{x^2 + y^2}$, we have $\dfrac{|y|}{\sqrt{x^2 + y^2}} \leq 1$ and so $0 \leq \left|\dfrac{xy}{\sqrt{x^2 + y^2}}\right| \leq |x|$. Now $|x| \to 0$ as $(x,y) \to (0,0)$, so $\left|\dfrac{xy}{\sqrt{x^2 + y^2}}\right| \to 0$ and hence $\lim\limits_{(x,y)\to(0,0)} f(x,y) = 0$.

14. $f(x,y) = \dfrac{x^3 - y^3}{x^2 + xy + y^2} = \dfrac{(x-y)(x^2+xy+y^2)}{x^2+xy+y^2} = x - y$ for $(x,y) \neq (0,0)$. [Note that $x^2 + xy + y^2 = 0$ only when $(x,y) = (0,0)$.] Thus $\lim\limits_{(x,y)\to(0,0)} f(x,y) = \lim\limits_{(x,y)\to(0,0)} (x-y) = 0 - 0 = 0$.

15. Let $f(x,y) = \dfrac{xy^2 \cos y}{x^2 + y^4}$. Then $f(x,0) = 0$ for $x \neq 0$, so $f(x,y) \to 0$ as $(x,y) \to (0,0)$ along the x-axis. Approaching $(0,0)$ along the y-axis or the line $y = x$ also gives a limit of 0. But $f\left(y^2, y\right) = \dfrac{y^2 y^2 \cos y}{(y^2)^2 + y^4} = \dfrac{y^4 \cos y}{2y^4} = \dfrac{\cos y}{2}$ for $y \neq 0$, so $f(x,y) \to \frac{1}{2}\cos 0 = \frac{1}{2}$ as $(x,y) \to (0,0)$ along the parabola $x = y^2$. Thus the limit doesn't exist.

16. We can use the Squeeze Theorem to show that $\lim\limits_{(x,y)\to(0,0)} \dfrac{xy^4}{x^4+y^4} = 0$:

$0 \leq \dfrac{|x|\,y^4}{x^4+y^4} \leq |x|$ since $0 \leq \dfrac{y^4}{x^4+y^4} \leq 1$, and $|x| \to 0$ as $(x,y) \to (0,0)$, so $\dfrac{|x|\,y^4}{x^4+y^4} \to 0 \quad \Rightarrow \quad \dfrac{xy^4}{x^4+y^4} \to 0$ as $(x,y) \to (0,0)$.

17.
$$\begin{aligned} \lim_{(x,y)\to(0,0)} \frac{x^2+y^2}{\sqrt{x^2+y^2+1}-1} &= \lim_{(x,y)\to(0,0)} \frac{x^2+y^2}{\sqrt{x^2+y^2+1}-1} \cdot \frac{\sqrt{x^2+y^2+1}+1}{\sqrt{x^2+y^2+1}+1} \\ &= \lim_{(x,y)\to(0,0)} \frac{\left(x^2+y^2\right)\left(\sqrt{x^2+y^2+1}+1\right)}{x^2+y^2} = \lim_{(x,y)\to(0,0)} \left(\sqrt{x^2+y^2+1}+1\right) = 2 \end{aligned}$$

18. $f(x,y) = xy^4/(x^2+y^8)$. On the x-axis, $f(x,0) = 0$ for $x \neq 0$, so $f(x,y) \to 0$ as $(x,y) \to (0,0)$ along the x-axis. Approaching $(0,0)$ along the curve $x = y^4$ gives $f(y^4, y) = y^8/2y^8 = \frac{1}{2}$ for $y \neq 0$, so along this path $f(x,y) \to \frac{1}{2}$ as $(x,y) \to (0,0)$. Thus the limit does not exist.

19. e^{y^2} is a composition of continuous functions and hence continuous. xz is a continuous function and $\tan t$ is continuous for $t \neq \frac{\pi}{2} + n\pi$ (n an integer), so the composition $\tan(xz)$ is continuous for $xz \neq \frac{\pi}{2} + n\pi$. Thus the product $f(x,y,z) = e^{y^2}\tan(xz)$ is a continuous function for $xz \neq \frac{\pi}{2} + n\pi$. If $x = \pi$ and $z = \frac{1}{3}$ then $xz \neq \frac{\pi}{2} + n\pi$, so $\lim\limits_{(x,y,z)\to(\pi,0,1/3)} f(x,y,z) = f(\pi, 0, 1/3) = e^{0^2}\tan(\pi \cdot 1/3) = 1 \cdot \tan(\pi/3) = \sqrt{3}$.

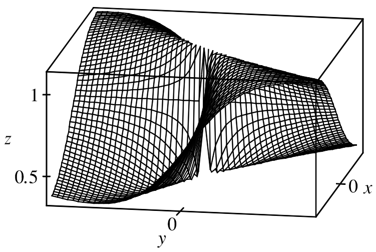
20. $f(x,y,z) = \dfrac{xy + yz}{x^2+y^2+z^2}$. Then $f(x,0,0) = 0/x^2 = 0$ for $x \neq 0$, so as $(x,y,z) \to (0,0,0)$ along the x-axis, $f(x,y,z) \to 0$. But $f(x,x,0) = x^2/(2x^2) = \frac{1}{2}$ for $x \neq 0$, so as $(x,y,z) \to (0,0,0)$ along the line $y = x$, $z = 0$, $f(x,y,z) \to \frac{1}{2}$. Thus the limit doesn't exist.

21. $f(x,y,z) = \dfrac{xy + yz^2 + xz^2}{x^2+y^2+z^4}$. Then $f(x,0,0) = 0/x^2 = 0$ for $x \neq 0$, so as $(x,y,z) \to (0,0,0)$ along the x-axis, $f(x,y,z) \to 0$. But $f(x,x,0) = x^2/(2x^2) = \frac{1}{2}$ for $x \neq 0$, so as $(x,y,z) \to (0,0,0)$ along the line $y = x$, $z = 0$, $f(x,y,z) \to \frac{1}{2}$. Thus the limit doesn't exist.

22. We can use the Squeeze Theorem to show that $\displaystyle\lim_{(x,y,z)\to(0,0,0)} \frac{x^2y^2z^2}{x^2+y^2+z^2} = 0$:

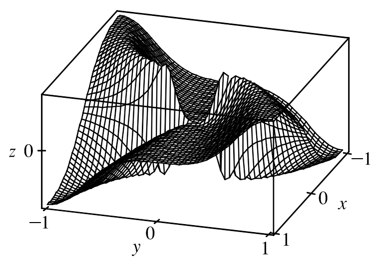
$0 \le \dfrac{x^2y^2z^2}{x^2+y^2+z^2} \le x^2y^2$ since $0 \le \dfrac{z^2}{x^2+y^2+z^2} \le 1$, and $x^2y^2 \to 0$ as $(x,y,z)\to(0,0,0)$, so $\dfrac{x^2y^2z^2}{x^2+y^2+z^2} \to 0$ as $(x,y,z)\to(0,0,0)$.

23.



From the ridges on the graph, we see that as $(x,y)\to(0,0)$ along the lines under the two ridges, $f(x,y)$ approaches different values. So the limit does not exist.

24.



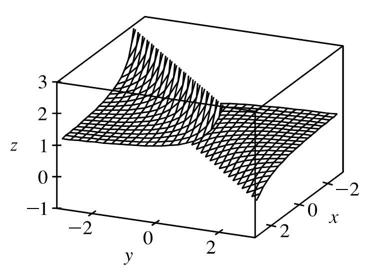
From the graph, it appears that as we approach the origin along the lines $x = 0$ or $y = 0$, the function is everywhere 0, whereas if we approach the origin along a certain curve it has a constant value of about $\frac{1}{2}$. [In fact, $f(y^3, y) = y^6/(2y^6) = \frac{1}{2}$ for $y \neq 0$, so $f(x,y) \to \frac{1}{2}$ as $(x,y)\to(0,0)$ along the curve $x = y^3$.] Since the function approaches different values depending on the path of approach, the limit does not exist.

25. $h(x,y) = g(f(x,y)) = (2x+3y-6)^2 + \sqrt{2x+3y-6}$. Since f is a polynomial, it is continuous on $\mathbb{R}^2$ and g is continuous on its domain $\{t \mid t \ge 0\}$. Thus h is continuous on its domain

$\{(x,y) \mid 2x+3y-6 \ge 0\} = \left\{(x,y) \mid y \ge -\frac{2}{3}x + 2\right\}$, which consists of all points on or above the line $y = -\frac{2}{3}x + 2$.

26. $h(x,y) = g(f(x,y)) = \dfrac{1-xy}{1+x^2y^2} + \ln\left(\dfrac{1-xy}{1+x^2y^2}\right)$. f is a rational function, so it is continuous on its domain. Because $1 + x^2y^2 > 0$, the domain of f is $\mathbb{R}^2$, so f is continuous everywhere. g is continuous on its domain $\{t \mid t > 0\}$. Thus h is continuous on its domain $\left\{(x,y) \;\middle|\; \dfrac{1-xy}{1+x^2y^2} > 0\right\} = \{(x,y) \mid xy < 1\}$ which consists of all points between (but not on) the two branches of the hyperbola $y = 1/x$.

27.



From the graph, it appears that f is discontinuous along the line $y = x$. If we consider $f(x,y) = e^{1/(x-y)}$ as a composition of functions, $g(x,y) = 1/(x-y)$ is a rational function and therefore continuous except where $x - y = 0 \quad\Leftrightarrow\quad y = x$. Since the function $h(t) = e^t$ is continuous everywhere, the composition $h(g(x,y)) = e^{1/(x-y)} = f(x,y)$ is continuous except along the line $y = x$, as we suspected.

28. 
We can see a circular break in the graph, corresponding approximately to the unit circle, where f is discontinuous. Since $f(x,y) = \dfrac{1}{1-x^2-y^2}$ is a rational function, it is continuous except where $1 - x^2 - y^2 = 0 \quad \Leftrightarrow$ $x^2 + y^2 = 1$, confirming our observation that f is discontinuous on the circle $x^2 + y^2 = 1$.

29. The functions xy and $1 + e^{x-y}$ are continuous everywhere, and $1 + e^{x-y}$ is never zero, so $F(x,y) = \dfrac{xy}{1+e^{x-y}}$ is continuous on its domain $\mathbb{R}^2$.

30. $F(x,y) = \cos\sqrt{1+x-y} = g(f(x,y))$ where $f(x,y) = \sqrt{1+x-y}$, continuous on its domain $\{(x,y) \mid 1+x-y \geq 0\} = \{(x,y) \mid y \leq x+1\}$, and $g(t) = \cos t$ is continuous everywhere. Thus F is continuous on its domain $\{(x,y) \mid y \leq x+1\}$.

31. $F(x,y) = \dfrac{1+x^2+y^2}{1-x^2-y^2}$ is a rational function and thus is continuous on its domain $\{(x,y) \mid 1-x^2-y^2 \neq 0\} = \{(x,y) \mid x^2+y^2 \neq 1\}$.

32. The functions $e^x + e^y$ and $e^{xy} - 1$ are continuous everywhere, so $H(x,y) = \dfrac{e^x+e^y}{e^{xy}-1}$ is continuous except where $e^{xy} - 1 = 0 \quad \Rightarrow \quad xy = 0 \quad \Rightarrow \quad x = 0$ or $y = 0$. Thus H is continuous on its domain $\{(x,y) \mid x \neq 0,\ y \neq 0\}$.

33. $\sqrt{x}$ is continuous on its domain $\{(x,y) \mid x \geq 0\}$ and $\sqrt{1-x^2-y^2}$ is continuous on its domain $\{(x,y) \mid 1-x^2-y^2 \geq 0\} = \{(x,y) \mid x^2+y^2 \leq 1\}$, so the sum $G(x,y) = \sqrt{x} + \sqrt{1-x^2-y^2}$ is continuous for $x \geq 0$ and $x^2+y^2 \leq 1$, that is, $\{(x,y) \mid x^2+y^2 \leq 1,\ x \geq 0\}$. This is the right half of the unit disk.

34. $G(x,y) = \ln(1+x-y) = g(f(x,y))$ where $f(x,y) = 1+x-y$, a polynomial and hence continuous on $\mathbb{R}^2$, and $g(t) = \ln t$, continuous on its domain $\{t \mid t > 0\}$. Thus G is continuous on its domain $\{(x,y) \mid 1+x-y > 0\} = \{(x,y) \mid y < x+1\}$, the region in $\mathbb{R}^2$ below the line $y = x+1$.

35. $f(x,y,z) = h(g(x,y,z))$ where $g(x,y,z) = x^2+y^2+z^2$, a polynomial that is continuous everywhere, and $h(t) = \arcsin t$, continuous on $[-1,1]$. Thus f is continuous on its domain $\{(x,y,z) \mid -1 \leq x^2+y^2+z^2 \leq 1\} = \{(x,y,z) \mid x^2+y^2+z^2 \leq 1\}$, so f is continuous on the unit ball.

36. $\sqrt{y-x^2}$ is continuous on its domain $\{(x,y) \mid y-x^2 \geq 0\} = \{(x,y) \mid y \geq x^2\}$ and $\ln z$ is continuous on its domain $\{z \mid z > 0\}$, so the product $f(x,y,z) = \sqrt{y-x^2}\ln z$ is continuous for $y \geq x^2$ and $z > 0$, that is, $\{(x,y,z) \mid y \geq x^2, z > 0\}$.

37. $f(x,y)=\begin{cases}\dfrac{x^2y^3}{2x^2+y^2} & \text{if } (x,y)\neq(0,0)\\ 1 & \text{if } (x,y)=(0,0)\end{cases}$ The first piece of f is a rational function defined everywhere except at the origin, so f is continuous on $\mathbb{R}^2$ except possibly at the origin. Since $x^2\leq 2x^2+y^2$, we have $\left|x^2y^3/(2x^2+y^2)\right|\leq\left|y^3\right|$. We know that $\left|y^3\right|\to 0$ as $(x,y)\to(0,0)$. So, by the Squeeze Theorem, $\lim\limits_{(x,y)\to(0,0)} f(x,y)=\lim\limits_{(x,y)\to(0,0)}\dfrac{x^2y^3}{2x^2+y^2}=0$. But $f(0,0)=1$, so f is discontinuous at $(0,0)$. Therefore, f is continuous on the set $\{(x,y)\mid(x,y)\neq(0,0)\}$.

38. $f(x,y)=\begin{cases}\dfrac{xy}{x^2+xy+y^2} & \text{if } (x,y)\neq(0,0)\\ 0 & \text{if } (x,y)=(0,0)\end{cases}$ The first piece of f is a rational function defined everywhere except at the origin, so f is continuous on $\mathbb{R}^2$ except possibly at the origin. $f(x,0)=0/x^2=0$ for $x\neq 0$, so $f(x,y)\to 0$ as $(x,y)\to(0,0)$ along the x-axis. But $f(x,x)=x^2/(3x^2)=\frac{1}{3}$ for $x\neq 0$, so $f(x,y)\to\frac{1}{3}$ as $(x,y)\to(0,0)$ along the line $y=x$. Thus $\lim\limits_{(x,y)\to(0,0)} f(x,y)$ doesn't exist, so f is not continuous at $(0,0)$ and the largest set on which f is continuous is $\{(x,y)\mid(x,y)\neq(0,0)\}$.

39. $$\lim_{(x,y)\to(0,0)}\frac{x^3+y^3}{x^2+y^2}=\lim_{r\to 0^+}\frac{(r\cos\theta)^3+(r\sin\theta)^3}{r^2}=\lim_{r\to 0^+}(r\cos^3\theta+r\sin^3\theta)=0$$

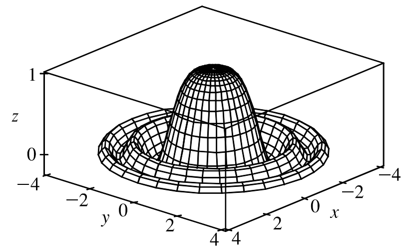
40. $$\lim_{(x,y)\to(0,0)}(x^2+y^2)\ln(x^2+y^2)=\lim_{r\to 0^+}r^2\ln r^2=\lim_{r\to 0^+}\frac{\ln r^2}{1/r^2}=\lim_{r\to 0^+}\frac{(1/r^2)(2r)}{-2/r^3}\quad\text{[using l'Hospital's Rule]}$$
$$=\lim_{r\to 0^+}(-r^2)=0$$

41. $$\lim_{(x,y)\to(0,0)}\frac{e^{-x^2-y^2}-1}{x^2+y^2}=\lim_{r\to 0^+}\frac{e^{-r^2}-1}{r^2}=\lim_{r\to 0^+}\frac{e^{-r^2}(-2r)}{2r}\quad\text{[using l'Hospital's Rule]}$$
$$=\lim_{r\to 0^+}-e^{-r^2}=-e^0=-1$$

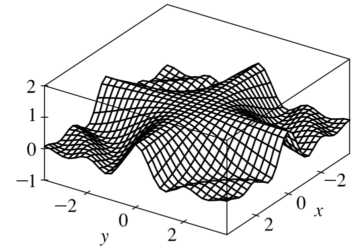
42. $\lim\limits_{(x,y)\to(0,0)}\dfrac{\sin(x^2+y^2)}{x^2+y^2}=\lim\limits_{r\to 0^+}\dfrac{\sin(r^2)}{r^2}$, which is an indeterminate form of type $0/0$. Using l'Hospital's Rule, we get

$$\lim_{r\to 0^+}\frac{\sin(r^2)}{r^2}\overset{\text{H}}{=}\lim_{r\to 0^+}\frac{2r\cos(r^2)}{2r}=\lim_{r\to 0^+}\cos(r^2)=1.$$

Or: Use the fact that $\lim\limits_{\theta\to 0}\dfrac{\sin\theta}{\theta}=1$.



43. $f(x,y)=\begin{cases}\dfrac{\sin(xy)}{xy} & \text{if } (x,y)\neq(0,0)\\ 1 & \text{if } (x,y)=(0,0)\end{cases}$



From the graph, it appears that f is continuous everywhere. We know xy is continuous on $\mathbb{R}^2$ and $\sin t$ is continuous everywhere, so $\sin(xy)$ is continuous on $\mathbb{R}^2$ and $\dfrac{\sin(xy)}{xy}$ is continuous on $\mathbb{R}^2$

[continued]

except possibly where $xy = 0$. To show that f is continuous at those points, consider any point (a, b) in $\mathbb{R}^2$ where $ab = 0$. Because xy is continuous, $xy \to ab = 0$ as $(x, y) \to (a, b)$. If we let $t = xy$, then $t \to 0$ as $(x, y) \to (a, b)$ and $\lim\limits_{(x,y)\to(a,b)} \dfrac{\sin(xy)}{xy} = \lim\limits_{t\to 0} \dfrac{\sin(t)}{t} = 1$ by Equation 2.4.2 [ET 3.3.2]. Thus $\lim\limits_{(x,y)\to(a,b)} f(x, y) = f(a, b)$ and f is continuous on $\mathbb{R}^2$.

44. (a) $f(x,y) = \begin{cases} 0 & \text{if } y \le 0 \quad \text{or} \quad y \ge x^4 \\ 1 & \text{if } 0 < y < x^4 \end{cases}$ Consider the path $y = mx^a$, $0 < a < 4$. [The path does not pass through $(0, 0)$ if $a \le 0$ except for the trivial case where $m = 0$.] If $mx^a \le 0$ then $f(x, mx^a) = 0$. If $mx^a > 0$ then $mx^a = |mx^a| = |m|\ |x^a|$ and $mx^a \ge x^4 \quad \Leftrightarrow \quad |m|\ |x^a| \ge x^4 \quad \Leftrightarrow \quad \dfrac{x^4}{|x^a|} \le |m| \quad \Leftrightarrow \quad |x|^{4-a} \le |m|$ whenever x^a is defined. Then $mx^a \ge x^4 \quad \Leftrightarrow \quad |x| \le |m|^{1/(4-a)}$ so $f(x, mx^a) = 0$ for $|x| \le |m|^{1/(4-a)}$ and $f(x, y) \to 0$ as $(x, y) \to (0, 0)$ along this path.

(b) If we approach $(0, 0)$ along the path $y = x^5$, $x > 0$ then we have $f(x, x^5) = 1$ for $0 < x < 1$ because $0 < x^5 < x^4$ there. Thus $f(x, y) \to 1$ as $(x, y) \to (0, 0)$ along this path, but in part (a) we found a limit of 0 along other paths, so $\lim\limits_{(x,y)\to(0,0)} f(x, y)$ doesn't exist and f is discontinuous at $(0, 0)$.

(c) First we show that f is discontinuous at any point $(a, 0)$ on the x-axis. If we approach $(a, 0)$ along the path $x = a$, $y > 0$ then $f(a, y) = 1$ for $0 < y < a^4$, so $f(x, y) \to 1$ as $(x, y) \to (a, 0)$ along this path. If we approach $(a, 0)$ along the path $x = a$, $y < 0$ then $f(a, y) = 0$ since $y < 0$ and $f(x, y) \to 0$ as $(x, y) \to (a, 0)$. Thus the limit does not exist and f is discontinuous on the line $y = 0$. f is also discontinuous on the curve $y = x^4$: For any point (a, a^4) on this curve, approaching the point along the path $x = a$, $y > a^4$ gives $f(a, y) = 0$ since $y > a^4$, so $f(x, y) \to 0$ as $(x, y) \to (a, a^4)$. But approaching the point along the path $x = a$, $y < a^4$ gives $f(a, y) = 1$ for $y > 0$, so $f(x, y) \to 1$ as $(x, y) \to (a, a^4)$ and the limit does not exist there.

45. Since $|\mathbf{x} - \mathbf{a}|^2 = |\mathbf{x}|^2 + |\mathbf{a}|^2 - 2\,|\mathbf{x}|\,|\mathbf{a}| \cos\theta \ge |\mathbf{x}|^2 + |\mathbf{a}|^2 - 2\,|\mathbf{x}|\,|\mathbf{a}| = (|\mathbf{x}| - |\mathbf{a}|)^2$, we have $\big||\mathbf{x}| - |\mathbf{a}|\big| \le |\mathbf{x} - \mathbf{a}|$. Let $\epsilon > 0$ be given and set $\delta = \epsilon$. Then if $0 < |\mathbf{x} - \mathbf{a}| < \delta$, $\big||\mathbf{x}| - |\mathbf{a}|\big| \le |\mathbf{x} - \mathbf{a}| < \delta = \epsilon$. Hence $\lim_{\mathbf{x}\to\mathbf{a}} |\mathbf{x}| = |\mathbf{a}|$ and $f(\mathbf{x}) = |\mathbf{x}|$ is continuous on $\mathbb{R}^n$.

46. Let $\epsilon > 0$ be given. We need to find $\delta > 0$ such that if $0 < |\mathbf{x} - \mathbf{a}| < \delta$ then $|f(\mathbf{x}) - f(\mathbf{a})| = |\mathbf{c}\cdot\mathbf{x} - \mathbf{c}\cdot\mathbf{a}| < \epsilon$. But $|\mathbf{c}\cdot\mathbf{x} - \mathbf{c}\cdot\mathbf{a}| = |\mathbf{c}\cdot(\mathbf{x} - \mathbf{a})|$ and $|\mathbf{c}\cdot(\mathbf{x} - \mathbf{a})| \le |\mathbf{c}|\,|\mathbf{x} - \mathbf{a}|$ by Exercise 12.3.61 (the Cauchy-Schwartz Inequality). Set $\delta = \epsilon/|\mathbf{c}|$. Then if $0 < |\mathbf{x} - \mathbf{a}| < \delta$, $|f(\mathbf{x}) - f(\mathbf{a})| = |\mathbf{c}\cdot\mathbf{x} - \mathbf{c}\cdot\mathbf{a}| \le |\mathbf{c}|\,|\mathbf{x} - \mathbf{a}| < |\mathbf{c}|\,\delta = |\mathbf{c}|\,(\epsilon/|\mathbf{c}|) = \epsilon$. So f is continuous on $\mathbb{R}^n$.

14.3 Partial Derivatives

1. (a) $\partial T/\partial x$ represents the rate of change of T when we fix y and t and consider T as a function of the single variable x, which describes how quickly the temperature changes when longitude changes but latitude and time are constant. $\partial T/\partial y$ represents the rate of change of T when we fix x and t and consider T as a function of y, which describes how quickly the temperature changes when latitude changes but longitude and time are constant. $\partial T/\partial t$ represents the rate of change of T when we fix x and y and consider T as a function of t, which describes how quickly the temperature changes over time for a constant longitude and latitude.

(b) $f_x(158, 21, 9)$ represents the rate of change of temperature at longitude $158°$W, latitude $21°$N at 9:00 AM when only longitude varies. Since the air is warmer to the west than to the east, increasing longitude results in an increased air temperature, so we would expect $f_x(158, 21, 9)$ to be positive. $f_y(158, 21, 9)$ represents the rate of change of temperature at the same time and location when only latitude varies. Since the air is warmer to the south and cooler to the north, increasing latitude results in a decreased air temperature, so we would expect $f_y(158, 21, 9)$ to be negative. $f_t(158, 21, 9)$ represents the rate of change of temperature at the same time and location when only time varies. Since typically air temperature increases from the morning to the afternoon as the sun warms it, we would expect $f_t(158, 21, 9)$ to be positive.

2. By Definition 4, $f_T(92, 60) = \lim\limits_{h\to 0} \dfrac{f(92+h, 60) - f(92, 60)}{h}$, which we can approximate by considering $h = 2$ and $h = -2$ and using the values given in Table 1: $f_T(92, 60) \approx \dfrac{f(94, 60) - f(92, 60)}{2} = \dfrac{111 - 105}{2} = 3$,

$f_T(92, 60) \approx \dfrac{f(90, 60) - f(92, 60)}{-2} = \dfrac{100 - 105}{-2} = 2.5$. Averaging these values, we estimate $f_T\,(92, 60)$ to be approximately 2.75. Thus, when the actual temperature is $92°$F and the relative humidity is 60%, the apparent temperature rises by about $2.75°$F for every degree that the actual temperature rises.

Similarly, $f_H(92, 60) = \lim\limits_{h\to 0} \dfrac{f(92, 60+h) - f(92, 60)}{h}$ which we can approximate by considering $h = 5$ and $h = -5$:

$f_H(92, 60) \approx \dfrac{f(92, 65) - f(92, 60)}{5} = \dfrac{108 - 105}{5} = 0.6$, $f_H(92, 60) \approx \dfrac{f(92, 55) - f(92, 60)}{-5} = \dfrac{103 - 105}{-5} = 0.4$.

Averaging these values, we estimate $f_H(92, 60)$ to be approximately 0.5. Thus, when the actual temperature is $92°$F and the relative humidity is 60%, the apparent temperature rises by about $0.5°$F for every percent that the relative humidity increases.

3. (a) By Definition 4, $f_T(-15, 30) = \lim\limits_{h\to 0} \dfrac{f(-15+h, 30) - f(-15, 30)}{h}$, which we can approximate by considering $h = 5$ and $h = -5$ and using the values given in the table:

$f_T(-15, 30) \approx \dfrac{f(-10, 30) - f(-15, 30)}{5} = \dfrac{-20 - (-26)}{5} = \dfrac{6}{5} = 1.2$,

$f_T(-15, 30) \approx \dfrac{f(-20, 30) - f(-15, 30)}{-5} = \dfrac{-33 - (-26)}{-5} = \dfrac{-7}{-5} = 1.4$. Averaging these values, we estimate

$f_T(-15, 30)$ to be approximately 1.3. Thus, when the actual temperature is -15°C and the wind speed is 30 km/h, the apparent temperature rises by about 1.3°C for every degree that the actual temperature rises.

Similarly, $f_v(-15, 30) = \lim\limits_{h \to 0} \dfrac{f(-15, 30 + h) - f(-15, 30)}{h}$ which we can approximate by considering $h = 10$ and $h = -10$: $f_v(-15, 30) \approx \dfrac{f(-15, 40) - f(-15, 30)}{10} = \dfrac{-27 - (-26)}{10} = \dfrac{-1}{10} = -0.1$,

$f_v(-15, 30) \approx \dfrac{f(-15, 20) - f(-15, 30)}{-10} = \dfrac{-24 - (-26)}{-10} = \dfrac{2}{-10} = -0.2$. Averaging these values, we estimate $f_v(-15, 30)$ to be approximately -0.15. Thus, when the actual temperature is -15°C and the wind speed is 30 km/h, the apparent temperature decreases by about 0.15°C for every km/h that the wind speed increases.

(b) For a fixed wind speed v, the values of the wind-chill index W increase as temperature T increases (look at a column of the table), so $\dfrac{\partial W}{\partial T}$ is positive. For a fixed temperature T, the values of W decrease (or remain constant) as v increases (look at a row of the table), so $\dfrac{\partial W}{\partial v}$ is negative (or perhaps 0).

(c) For fixed values of T, the function values $f(T, v)$ appear to become constant (or nearly constant) as v increases, so the corresponding rate of change is 0 or near 0 as v increases. This suggests that $\lim\limits_{v \to \infty} (\partial W/\partial v) = 0$.

4. (a) $\partial h/\partial v$ represents the rate of change of h when we fix t and consider h as a function of v, which describes how quickly the wave heights change when the wind speed changes for a fixed time duration. $\partial h/\partial t$ represents the rate of change of h when we fix v and consider h as a function of t, which describes how quickly the wave heights change when the duration of time changes, but the wind speed is constant.

(b) By Definition 4, $f_v(40, 15) = \lim\limits_{h \to 0} \dfrac{f(40 + h, 15) - f(40, 15)}{h}$ which we can approximate by considering $h = 10$ and $h = -10$ and using the values given in the table: $f_v(40, 15) \approx \dfrac{f(50, 15) - f(40, 15)}{10} = \dfrac{36 - 25}{10} = 1.1$,

$f_v(40, 15) \approx \dfrac{f(30, 15) - f(40, 15)}{-10} = \dfrac{16 - 25}{-10} = 0.9$. Averaging these values, we have $f_v(40, 15) \approx 1.0$. Thus, when a 40-knot wind has been blowing for 15 hours, the wave heights should increase by about 1 foot for every knot that the wind speed increases (with the same time duration). Similarly, $f_t(40, 15) = \lim\limits_{h \to 0} \dfrac{f(40, 15 + h) - f(40, 15)}{h}$ which we can approximate by considering $h = 5$ and $h = -5$: $f_t(40, 15) \approx \dfrac{f(40, 20) - f(40, 15)}{5} = \dfrac{28 - 25}{5} = 0.6$,

$f_t(40, 15) \approx \dfrac{f(40, 10) - f(40, 15)}{-5} = \dfrac{21 - 25}{-5} = 0.8$. Averaging these values, we have $f_t(40, 15) \approx 0.7$. Thus, when a 40-knot wind has been blowing for 15 hours, the wave heights increase by about 0.7 feet for every additional hour that the wind blows.

(c) For fixed values of v, the function values $f(v, t)$ appear to increase in smaller and smaller increments, becoming nearly constant as t increases. Thus, the corresponding rate of change is nearly 0 as t increases, suggesting that $\lim\limits_{t \to \infty} (\partial h/\partial t) = 0$.

5. (a) If we start at $(1, 2)$ and move in the positive x-direction, the graph of f increases. Thus $f_x(1, 2)$ is positive.

(b) If we start at $(1, 2)$ and move in the positive y-direction, the graph of f decreases. Thus $f_y(1, 2)$ is negative.

6. (a) The graph of f decreases if we start at $(-1, 2)$ and move in the positive x-direction, so $f_x(-1, 2)$ is negative.

(b) The graph of f decreases if we start at $(-1, 2)$ and move in the positive y-direction, so $f_y(-1, 2)$ is negative.

7. (a) $f_{xx} = \frac{\partial}{\partial x}(f_x)$, so f_{xx} is the rate of change of f_x in the x-direction. f_x is negative at $(-1, 2)$ and if we move in the positive x-direction, the surface becomes less steep. Thus the values of f_x are increasing and $f_{xx}(-1, 2)$ is positive.

(b) f_{yy} is the rate of change of f_y in the y-direction. f_y is negative at $(-1, 2)$ and if we move in the positive y-direction, the surface becomes steeper. Thus the values of f_y are decreasing, and $f_{yy}(-1, 2)$ is negative.

8. (a) $f_{xy} = \frac{\partial}{\partial y}(f_x)$, so f_{xy} is the rate of change of f_x in the y-direction. f_x is positive at $(1, 2)$ and if we move in the positive y-direction, the surface becomes steeper, looking in the positive x-direction. Thus the values of f_x are increasing and $f_{xy}(1, 2)$ is positive.

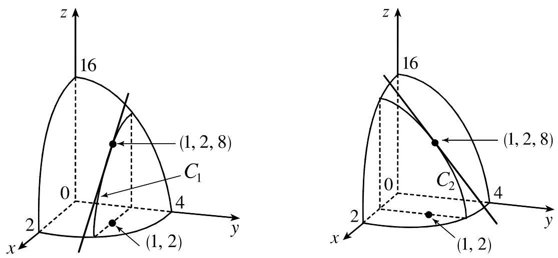
(b) f_x is negative at $(-1, 2)$ and if we move in the positive y-direction, the surface gets steeper (with negative slope), looking in the positive x-direction. This means that the values of f_x are decreasing as y increases, so $f_{xy}(-1, 2)$ is negative.

9. First of all, if we start at the point $(3, -3)$ and move in the positive y-direction, we see that both b and c decrease, while a increases. Both b and c have a low point at about $(3, -1.5)$, while a is 0 at this point. So a is definitely the graph of f_y, and one of b and c is the graph of f. To see which is which, we start at the point $(-3, -1.5)$ and move in the positive x-direction. b traces out a line with negative slope, while c traces out a parabola opening downward. This tells us that b is the x-derivative of c. So c is the graph of f, b is the graph of f_x, and a is the graph of f_y.

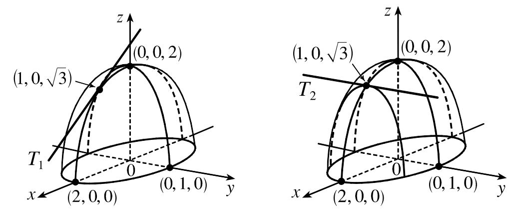
10. $f_x(2, 1)$ is the rate of change of f at $(2, 1)$ in the x-direction. If we start at $(2, 1)$, where $f(2, 1) = 10$, and move in the positive x-direction, we reach the next contour line [where $f(x, y) = 12$] after approximately 0.6 units. This represents an average rate of change of about $\frac{2}{0.6}$. If we approach the point $(2, 1)$ from the left (moving in the positive x-direction) the output values increase from 8 to 10 with an increase in x of approximately 0.9 units, corresponding to an average rate of change of $\frac{2}{0.9}$. A good estimate for $f_x(2, 1)$ would be the average of these two, so $f_x(2, 1) \approx 2.8$. Similarly, $f_y(2, 1)$ is the rate of change of f at $(2, 1)$ in the y-direction. If we approach $(2, 1)$ from below, the output values decrease from 12 to 10 with a change in y of approximately 1 unit, corresponding to an average rate of change of -2. If we start at $(2, 1)$ and move in the positive y-direction, the output values decrease from 10 to 8 after approximately 0.9 units, a rate of change of $\frac{-2}{0.9}$. Averaging these two results, we estimate $f_y(2, 1) \approx -2.1$.

11. $f(x, y) = 16 - 4x^2 - y^2 \quad \Rightarrow \quad f_x(x, y) = -8x$ and $f_y(x, y) = -2y \quad \Rightarrow \quad f_x(1, 2) = -8$ and $f_y(1, 2) = -4$. The graph of f is the paraboloid $z = 16 - 4x^2 - y^2$ and the vertical plane $y = 2$ intersects it in the parabola $z = 12 - 4x^2$, $y = 2$

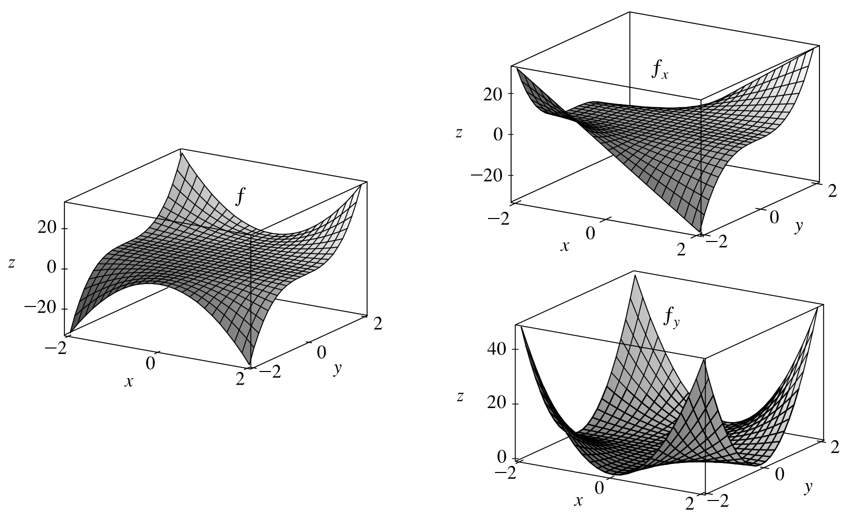
(the curve C_1 in the first figure). The slope of the tangent line to this parabola at $(1, 2, 8)$ is $f_x(1, 2) = -8$. Similarly the plane $x = 1$ intersects the paraboloid in the parabola $z = 12 - y^2$, $x = 1$ (the curve C_2 in the second figure) and the slope of the tangent line at $(1, 2, 8)$ is $f_y(1, 2) = -4$.



12. $f(x, y) = (4 - x^2 - 4y^2)^{1/2} \;\Rightarrow\; f_x(x, y) = -x(4 - x^2 - 4y^2)^{-1/2}$ and $f_y(x, y) = -4y(4 - x^2 - 4y^2)^{-1/2} \;\Rightarrow$ $f_x(1, 0) = -\frac{1}{\sqrt{3}}$, $f_y(1, 0) = 0$. The graph of f is the upper half of the ellipsoid $z^2 + x^2 + 4y^2 = 4$ and the plane $y = 0$ intersects the graph in the semicircle $x^2 + z^2 = 4$, $z \geq 0$ and the slope of the tangent line T_1 to this semicircle at $\left(1, 0, \sqrt{3}\right)$ is $f_x(1, 0) = -\frac{1}{\sqrt{3}}$. Similarly the plane $x = 1$ intersects the graph in the semi-ellipse $z^2 + 4y^2 = 3$, $z \geq 0$ and the slope of the tangent line T_2 to this semi-ellipse at $\left(1, 0, \sqrt{3}\right)$ is $f_y(1, 0) = 0$.



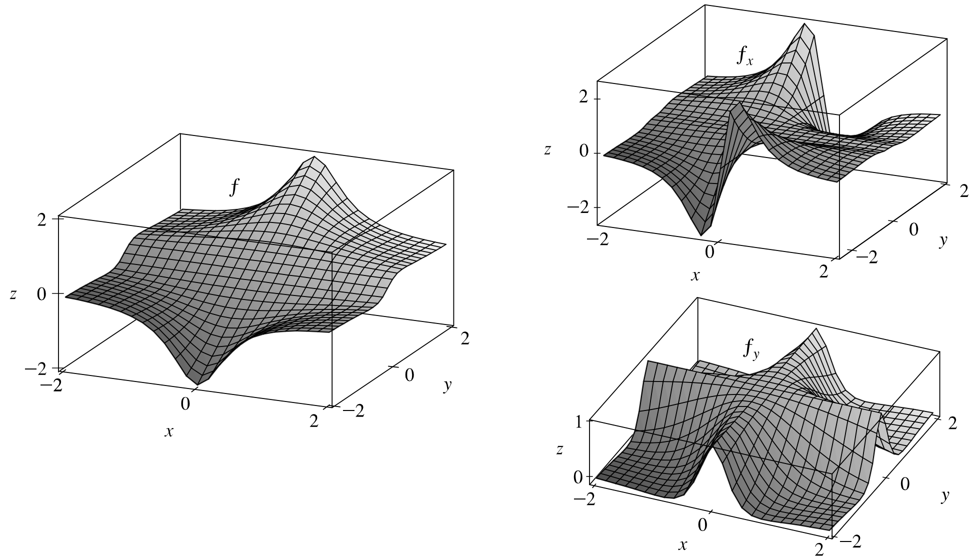
13. $f(x, y) = x^2y^3 \;\Rightarrow\; f_x = 2xy^3, \;\; f_y = 3x^2y^2$



Note that traces of f in planes parallel to the xz-plane are parabolas which open downward for $y < 0$ and upward for $y > 0$, and the traces of f_x in these planes are straight lines, which have negative slopes for $y < 0$ and positive slopes for $y > 0$. The traces of f in planes parallel to the yz-plane are cubic curves, and the traces of f_y in these planes are parabolas.

14. $f(x, y) = \dfrac{y}{1 + x^2y^2} \;\Rightarrow\; f_x = \dfrac{(1 + x^2y^2)(0) - y(2xy^2)}{(1 + x^2y^2)^2} = -\dfrac{2xy^3}{(1 + x^2y^2)^2}$,

$$f_y = \frac{(1 + x^2y^2)(1) - y(2x^2y)}{(1 + x^2y^2)^2} = \frac{1 - x^2y^2}{(1 + x^2y^2)^2}$$



Note that traces of f in planes parallel to the xz-plane have only one extreme value (a minimum for $y < 0$, a maximum for $y > 0$), and the traces of f_x in these planes have only one zero (going from negative to positive if $y < 0$ and from positive to negative if $y > 0$). The traces of f in planes parallel to the yz-plane have two extreme values, and the traces of f_y in these planes have two zeros.

15. $f(x, y) = x^4 + 5xy^3 \quad \Rightarrow \quad f_x(x, y) = 4x^3 + 5y^3,\ f_y(x, y) = 0 + 5x \cdot 3y^2 = 15xy^2$

16. $f(x, y) = x^2y - 3y^4 \quad \Rightarrow \quad f_x(x, y) = 2x \cdot y - 0 = 2xy,\ f_y(x, y) = x^2 \cdot 1 - 3 \cdot 4y^3 = x^2 - 12y^3$

17. $f(x, t) = t^2e^{-x} \quad \Rightarrow \quad f_x(x, t) = t^2 \cdot e^{-x}(-1) = -t^2e^{-x},\ f_t(x, t) = 2te^{-x}$

18. $f(x, t) = \sqrt{3x + 4t} \quad \Rightarrow \quad f_x(x, t) = \frac{1}{2}(3x + 4t)^{-1/2}(3) = \dfrac{3}{2\sqrt{3x + 4t}},\ f_t(x, t) = \frac{1}{2}(3x + 4t)^{-1/2}(4) = \dfrac{2}{\sqrt{3x + 4t}}$

19. $z = \ln(x + t^2) \quad \Rightarrow \quad \dfrac{\partial z}{\partial x} = \dfrac{1}{x + t^2},\ \dfrac{\partial z}{\partial t} = \dfrac{2t}{x + t^2}$

20. $z = x\sin(xy) \quad \Rightarrow \quad \dfrac{\partial z}{\partial x} = x \cdot [\cos(xy)](y) + [\sin(xy)] \cdot 1 = xy\cos(xy) + \sin(xy),\ \dfrac{\partial z}{\partial y} = x\,[\cos(xy)](x) = x^2\cos(xy)$

21. $f(x, y) = x/y = xy^{-1} \quad \Rightarrow \quad f_x(x, y) = y^{-1} = 1/y,\ f_y(x, y) = -xy^{-2} = -x/y^2$

22. $f(x, y) = \dfrac{x}{(x + y)^2} \quad \Rightarrow \quad f_x(x, y) = \dfrac{(x + y)^2(1) - (x)(2)(x + y)}{[(x + y)^2]^2} = \dfrac{x + y - 2x}{(x + y)^3} = \dfrac{y - x}{(x + y)^3}$,

$f_y(x, y) = \dfrac{(x + y)^2(0) - (x)(2)(x + y)}{[(x + y)^2]^2} = -\dfrac{2x}{(x + y)^3}$

23. $f(x, y) = \dfrac{ax + by}{cx + dy} \quad \Rightarrow \quad f_x(x, y) = \dfrac{(cx + dy)(a) - (ax + by)(c)}{(cx + dy)^2} = \dfrac{(ad - bc)y}{(cx + dy)^2}$,

$f_y(x, y) = \dfrac{(cx + dy)(b) - (ax + by)(d)}{(cx + dy)^2} = \dfrac{(bc - ad)x}{(cx + dy)^2}$

24. $w = \dfrac{e^v}{u+v^2} \quad \Rightarrow \quad \dfrac{\partial w}{\partial u} = \dfrac{0(u+v^2) - e^v(1)}{(u+v^2)^2} = -\dfrac{e^v}{(u+v^2)^2}, \ \ \dfrac{\partial w}{\partial v} = \dfrac{e^v(u+v^2) - e^v(2v)}{(u+v^2)^2} = \dfrac{e^v(u+v^2-2v)}{(u+v^2)^2}$

25. $g(u,v) = (u^2v - v^3)^5 \quad \Rightarrow \quad g_u(u,v) = 5(u^2v-v^3)^4 \cdot 2uv = 10uv(u^2v-v^3)^4,$

$g_v(u,v) = 5(u^2v-v^3)^4(u^2-3v^2) = 5(u^2-3v^2)(u^2v-v^3)^4$

26. $u(r,\theta) = \sin(r\cos\theta) \quad \Rightarrow \quad u_r(r,\theta) = \cos(r\cos\theta)\cdot\cos\theta = \cos\theta\cos(r\cos\theta),$

$u_\theta(r,\theta) = \cos(r\cos\theta)(-r\sin\theta) = -r\sin\theta\cos(r\cos\theta)$

27. $R(p,q) = \tan^{-1}(pq^2) \quad \Rightarrow \quad R_p(p,q) = \dfrac{1}{1+(pq^2)^2}\cdot q^2 = \dfrac{q^2}{1+p^2q^4}, \ \ R_q(p,q) = \dfrac{1}{1+(pq^2)^2}\cdot 2pq = \dfrac{2pq}{1+p^2q^4}$

28. $f(x,y) = x^y \quad \Rightarrow \quad f_x(x,y) = yx^{y-1}, \ f_y(x,y) = x^y\ln x$

29. $F(x,y) = \displaystyle\int_y^x \cos(e^t)\,dt \quad \Rightarrow \quad F_x(x,y) = \dfrac{\partial}{\partial x}\int_y^x \cos(e^t)\,dt = \cos(e^x)$ by the Fundamental Theorem of Calculus, Part 1;

$F_y(x,y) = \dfrac{\partial}{\partial y}\displaystyle\int_y^x \cos(e^t)\,dt = \dfrac{\partial}{\partial y}\left[-\int_x^y \cos(e^t)\,dt\right] = -\dfrac{\partial}{\partial y}\int_x^y \cos(e^t)\,dt = -\cos(e^y).$

30. $F(\alpha,\beta) = \displaystyle\int_\alpha^\beta \sqrt{t^3+1}\,dt \quad \Rightarrow$

$F_\alpha(\alpha,\beta) = \dfrac{\partial}{\partial\alpha}\displaystyle\int_\alpha^\beta \sqrt{t^3+1}\,dt = \dfrac{\partial}{\partial\alpha}\left[-\int_\beta^\alpha \sqrt{t^3+1}\,dt\right] = -\dfrac{\partial}{\partial\alpha}\int_\beta^\alpha \sqrt{t^3+1}\,dt = -\sqrt{\alpha^3+1}$ by the Fundamental Theorem of Calculus, Part 1; $F_\beta(\alpha,\beta) = \dfrac{\partial}{\partial\beta}\displaystyle\int_\alpha^\beta \sqrt{t^3+1}\,dt = \sqrt{\beta^3+1}.$

31. $f(x,y,z) = x^3yz^2 + 2yz \quad \Rightarrow \quad f_x(x,y,z) = 3x^2yz^2, \ f_y(x,y,z) = x^3z^2 + 2z, \ f_z(x,y,z) = 2x^3yz + 2y$

32. $f(x,y,z) = xy^2e^{-xz} \quad \Rightarrow \quad f_x(x,y,z) = y^2\left[x\cdot e^{-xz}(-z) + e^{-xz}\cdot 1\right] = (1-xz)y^2e^{-xz}, \ \ f_y(x,y,z) = 2xye^{-xz},$

$f_z(x,y,z) = xy^2e^{-xz}(-x) = -x^2y^2e^{-xz}$

33. $w = \ln(x+2y+3z) \quad \Rightarrow \quad \dfrac{\partial w}{\partial x} = \dfrac{1}{x+2y+3z}, \ \dfrac{\partial w}{\partial y} = \dfrac{2}{x+2y+3z}, \ \dfrac{\partial w}{\partial z} = \dfrac{3}{x+2y+3z}$

34. $w = y\tan(x+2z) \quad \Rightarrow \quad \dfrac{\partial w}{\partial x} = y\left[\sec^2(x+2z)\right](1) = y\sec^2(x+2z), \ \ \dfrac{\partial w}{\partial y} = \tan(x+2z),$

$\dfrac{\partial w}{\partial z} = y\left[\sec^2(x+2z)\right](2) = 2y\sec^2(x+2z)$

35. $p = \sqrt{t^4+u^2\cos v} \quad \Rightarrow \quad \dfrac{\partial p}{\partial t} = \tfrac{1}{2}(t^4+u^2\cos v)^{-1/2}(4t^3) = \dfrac{2t^3}{\sqrt{t^4+u^2\cos v}},$

$\dfrac{\partial p}{\partial u} = \tfrac{1}{2}(t^4+u^2\cos v)^{-1/2}(2u\cos v) = \dfrac{u\cos v}{\sqrt{t^4+u^2\cos v}}, \ \ \dfrac{\partial p}{\partial v} = \tfrac{1}{2}(t^4+u^2\cos v)^{-1/2}[u^2(-\sin v)] = -\dfrac{u^2\sin v}{2\sqrt{t^4+u^2\cos v}}$

36. $u = x^{y/z} \quad \Rightarrow \quad u_x = \dfrac{y}{z}\,x^{(y/z)-1}, \ u_y = x^{y/z}\ln x\cdot\dfrac{1}{z} = \dfrac{x^{y/z}}{z}\ln x, \ \ u_z = x^{y/z}\ln x\cdot\dfrac{-y}{z^2} = -\dfrac{yx^{y/z}}{z^2}\ln x$

37. $h(x,y,z,t)=x^2y\cos(z/t) \quad\Rightarrow\quad h_x(x,y,z,t)=2xy\cos(z/t),\; h_y(x,y,z,t)=x^2\cos(z/t),$

$h_z(x,y,z,t)=-x^2y\sin(z/t)(1/t)=(-x^2y/t)\sin(z/t),\; h_t(x,y,z,t)=-x^2y\sin(z/t)(-zt^{-2})=(x^2yz/t^2)\sin(z/t)$

38. $\phi(x,y,z,t)=\dfrac{\alpha x+\beta y^2}{\gamma z+\delta t^2} \quad\Rightarrow\quad \phi_x(x,y,z,t)=\dfrac{1}{\gamma z+\delta t^2}(\alpha)=\dfrac{\alpha}{\gamma z+\delta t^2},$

$\phi_y(x,y,z,t)=\dfrac{1}{\gamma z+\delta t^2}(2\beta y)=\dfrac{2\beta y}{\gamma z+\delta t^2},\; \phi_z(x,y,z,t)=\dfrac{(\gamma z+\delta t^2)(0)-(\alpha x+\beta y^2)(\gamma)}{(\gamma z+\delta t^2)^2}=\dfrac{-\gamma(\alpha x+\beta y^2)}{(\gamma z+\delta t^2)^2},$

$\phi_t(x,y,z,t)=\dfrac{(\gamma z+\delta t^2)(0)-(\alpha x+\beta y^2)(2\delta t)}{(\gamma z+\delta t^2)^2}=-\dfrac{2\delta t(\alpha x+\beta y^2)}{(\gamma z+\delta t^2)^2}$

39. $u=\sqrt{x_1^2+x_2^2+\cdots+x_n^2}$. For each $i=1,\ldots,n$, $u_{x_i}=\frac{1}{2}\left(x_1^2+x_2^2+\cdots+x_n^2\right)^{-1/2}(2x_i)=\dfrac{x_i}{\sqrt{x_1^2+x_2^2+\cdots+x_n^2}}$.

40. $u=\sin(x_1+2x_2+\cdots+nx_n)$. For each $i=1,\ldots,n$, $u_{x_i}=i\cos(x_1+2x_2+\cdots+nx_n)$.

41. $R(s,t)=te^{s/t} \quad\Rightarrow\quad R_t(s,t)=t\cdot e^{s/t}(-s/t^2)+e^{s/t}\cdot 1=\left(1-\dfrac{s}{t}\right)e^{s/t}$, so $R_t(0,1)=\left(1-\dfrac{0}{1}\right)e^{0/1}=1$.

42. $f(x,y)=y\sin^{-1}(xy) \quad\Rightarrow\quad f_y(x,y)=y\cdot\dfrac{1}{\sqrt{1-(xy)^2}}(x)+\sin^{-1}(xy)\cdot 1=\dfrac{xy}{\sqrt{1-x^2y^2}}+\sin^{-1}(xy),$

so $f_y\left(1,\frac{1}{2}\right)=\dfrac{1\cdot\frac{1}{2}}{\sqrt{1-1^2\left(\frac{1}{2}\right)^2}}+\sin^{-1}\left(1\cdot\frac{1}{2}\right)=\dfrac{\frac{1}{2}}{\sqrt{\frac{3}{4}}}+\sin^{-1}\frac{1}{2}=\frac{1}{\sqrt{3}}+\frac{\pi}{6}$.

43. $f(x,y,z)=\ln\dfrac{1-\sqrt{x^2+y^2+z^2}}{1+\sqrt{x^2+y^2+z^2}} \quad\Rightarrow$

$$f_y(x,y,z)=\frac{1}{\dfrac{1-\sqrt{x^2+y^2+z^2}}{1+\sqrt{x^2+y^2+z^2}}}\cdot\frac{\left(1+\sqrt{x^2+y^2+z^2}\right)\left(-\frac{1}{2}(x^2+y^2+z^2)^{-1/2}\cdot 2y\right)-\left(1-\sqrt{x^2+y^2+z^2}\right)\left(\frac{1}{2}(x^2+y^2+z^2)^{-1/2}\cdot 2y\right)}{\left(1+\sqrt{x^2+y^2+z^2}\right)^2}$$

$$=\frac{1+\sqrt{x^2+y^2+z^2}}{1-\sqrt{x^2+y^2+z^2}}\cdot\frac{-y(x^2+y^2+z^2)^{-1/2}\left(1+\sqrt{x^2+y^2+z^2}+1-\sqrt{x^2+y^2+z^2}\right)}{\left(1+\sqrt{x^2+y^2+z^2}\right)^2}$$

$$=\frac{-y(x^2+y^2+z^2)^{-1/2}\,(2)}{\left(1-\sqrt{x^2+y^2+z^2}\right)\left(1+\sqrt{x^2+y^2+z^2}\right)}=\frac{-2y}{\sqrt{x^2+y^2+z^2}\,[1-(x^2+y^2+z^2)]}$$

so $f_y(1,2,2)=\dfrac{-2(2)}{\sqrt{1^2+2^2+2^2}\,[1-(1^2+2^2+2^2)]}=\dfrac{-4}{\sqrt{9}\,(1-9)}=\dfrac{1}{6}$.

44. $f(x,y,z)=x^{yz} \quad\Rightarrow\quad f_z(x,y,z)=(x^{yz}\ln x)(y)=yx^{yz}\ln x$, so $f_z(e,1,0)=1e^{(1)(0)}\ln e=1$.

45. $f(x,y) = xy^2 - x^3y \quad \Rightarrow$

$$f_x(x,y) = \lim_{h\to 0} \frac{f(x+h,y) - f(x,y)}{h} = \lim_{h\to 0} \frac{(x+h)y^2 - (x+h)^3y - (xy^2 - x^3y)}{h}$$

$$= \lim_{h\to 0} \frac{h(y^2 - 3x^2y - 3xyh - yh^2)}{h} = \lim_{h\to 0}(y^2 - 3x^2y - 3xyh - yh^2) = y^2 - 3x^2y$$

$$f_y(x,y) = \lim_{h\to 0} \frac{f(x,y+h) - f(x,y)}{h} = \lim_{h\to 0} \frac{x(y+h)^2 - x^3(y+h) - (xy^2 - x^3y)}{h} = \lim_{h\to 0} \frac{h(2xy + xh - x^3)}{h}$$

$$= \lim_{h\to 0}(2xy + xh - x^3) = 2xy - x^3$$

46. $f(x,y) = \dfrac{x}{x+y^2} \quad \Rightarrow$

$$f_x(x,y) = \lim_{h\to 0} \frac{f(x+h,y) - f(x,y)}{h} = \lim_{h\to 0} \frac{\frac{x+h}{x+h+y^2} - \frac{x}{x+y^2}}{h} \cdot \frac{(x+h+y^2)(x+y^2)}{(x+h+y^2)(x+y^2)}$$

$$= \lim_{h\to 0} \frac{(x+h)(x+y^2) - x(x+h+y^2)}{h(x+h+y^2)(x+y^2)} = \lim_{h\to 0} \frac{y^2h}{h(x+h+y^2)(x+y^2)}$$

$$= \lim_{h\to 0} \frac{y^2}{(x+h+y^2)(x+y^2)} = \frac{y^2}{(x+y^2)^2}$$

$$f_y(x,y) = \lim_{h\to 0} \frac{f(x,y+h) - f(x,y)}{h} = \lim_{h\to 0} \frac{\frac{x}{x+(y+h)^2} - \frac{x}{x+y^2}}{h} \cdot \frac{\left[x+(y+h)^2\right](x+y^2)}{\left[x+(y+h)^2\right](x+y^2)}$$

$$= \lim_{h\to 0} \frac{x(x+y^2) - x\left[x+(y+h)^2\right]}{h[x+(y+h)^2](x+y^2)} = \lim_{h\to 0} \frac{h(-2xy - xh)}{h[x+(y+h)^2](x+y^2)}$$

$$= \lim_{h\to 0} \frac{-2xy - xh}{[x+(y+h)^2](x+y^2)} = \frac{-2xy}{(x+y^2)^2}$$

47. $x^2 + 2y^2 + 3z^2 = 1 \quad \Rightarrow \quad \dfrac{\partial}{\partial x}(x^2 + 2y^2 + 3z^2) = \dfrac{\partial}{\partial x}(1) \quad \Rightarrow \quad 2x + 0 + 6z\,\dfrac{\partial z}{\partial x} = 0 \quad \Rightarrow \quad 6z\,\dfrac{\partial z}{\partial x} = -2x \quad \Rightarrow$

$\dfrac{\partial z}{\partial x} = \dfrac{-2x}{6z} = -\dfrac{x}{3z}$, and $\dfrac{\partial}{\partial y}(x^2 + 2y^2 + 3z^2) = \dfrac{\partial}{\partial y}(1) \quad \Rightarrow \quad 0 + 4y + 6z\,\dfrac{\partial z}{\partial y} = 0 \quad \Rightarrow \quad 6z\,\dfrac{\partial z}{\partial y} = -4y \quad \Rightarrow$

$\dfrac{\partial z}{\partial y} = \dfrac{-4y}{6z} = -\dfrac{2y}{3z}$.

48. $x^2 - y^2 + z^2 - 2z = 4 \quad \Rightarrow \quad \dfrac{\partial}{\partial x}(x^2 - y^2 + z^2 - 2z) = \dfrac{\partial}{\partial x}(4) \quad \Rightarrow \quad 2x - 0 + 2z\,\dfrac{\partial z}{\partial x} - 2\,\dfrac{\partial z}{\partial x} = 0 \quad \Rightarrow$

$(2z-2)\,\dfrac{\partial z}{\partial x} = -2x \quad \Rightarrow \quad \dfrac{\partial z}{\partial x} = \dfrac{-2x}{2z-2} = \dfrac{x}{1-z}$, and $\dfrac{\partial}{\partial y}(x^2 - y^2 + z^2 - 2z) = \dfrac{\partial}{\partial y}(4) \quad \Rightarrow$

$0 - 2y + 2z\,\dfrac{\partial z}{\partial y} - 2\,\dfrac{\partial z}{\partial y} = 0 \quad \Rightarrow \quad (2z-2)\,\dfrac{\partial z}{\partial y} = 2y \quad \Rightarrow \quad \dfrac{\partial z}{\partial y} = \dfrac{2y}{2z-2} = \dfrac{y}{z-1}$.

49. $e^z = xyz \quad \Rightarrow \quad \dfrac{\partial}{\partial x}(e^z) = \dfrac{\partial}{\partial x}(xyz) \quad \Rightarrow \quad e^z\,\dfrac{\partial z}{\partial x} = y\left(x\,\dfrac{\partial z}{\partial x} + z\cdot 1\right) \quad \Rightarrow \quad e^z\,\dfrac{\partial z}{\partial x} - xy\,\dfrac{\partial z}{\partial x} = yz \quad \Rightarrow$

$(e^z - xy)\,\dfrac{\partial z}{\partial x} = yz$, so $\dfrac{\partial z}{\partial x} = \dfrac{yz}{e^z - xy}$.

$\frac{\partial}{\partial y}(e^z) = \frac{\partial}{\partial y}(xyz) \quad \Rightarrow \quad e^z \frac{\partial z}{\partial y} = x\left(y \frac{\partial z}{\partial x} + z \cdot 1\right) \quad \Rightarrow \quad e^z \frac{\partial z}{\partial y} - xy \frac{\partial z}{\partial y} = xz \quad \Rightarrow \quad (e^z - xy)\frac{\partial z}{\partial y} = xz$, so

$\frac{\partial z}{\partial y} = \frac{xz}{e^z - xy}$.

50. $yz + x \ln y = z^2 \quad \Rightarrow \quad \frac{\partial}{\partial x}(yz + x \ln y) = \frac{\partial}{\partial x}(z^2) \quad \Rightarrow \quad y \frac{\partial z}{\partial x} + \ln y = 2z \frac{\partial z}{\partial x} \quad \Rightarrow \quad \ln y = 2z \frac{\partial z}{\partial x} - y \frac{\partial z}{\partial x} \quad \Rightarrow$

$\ln y = (2z - y)\frac{\partial z}{\partial x}$, so $\frac{\partial z}{\partial x} = \frac{\ln y}{2z - y}$.

$\frac{\partial}{\partial y}(yz + x \ln y) = \frac{\partial}{\partial y}(z^2) \quad \Rightarrow \quad y \frac{\partial z}{\partial y} + z \cdot 1 + x \cdot \frac{1}{y} = 2z \frac{\partial z}{\partial y} \quad \Rightarrow \quad z + \frac{x}{y} = 2z \frac{\partial z}{\partial y} - y \frac{\partial z}{\partial y} \quad \Rightarrow$

$z + \frac{x}{y} = (2z - y)\frac{\partial z}{\partial y}$, so $\frac{\partial z}{\partial y} = \frac{z + (x/y)}{2z - y} = \frac{x + yz}{y(2z - y)}$.

51. (a) $z = f(x) + g(y) \quad \Rightarrow \quad \frac{\partial z}{\partial x} = f'(x), \quad \frac{\partial z}{\partial y} = g'(y)$

(b) $z = f(x + y)$. Let $u = x + y$. Then $\frac{\partial z}{\partial x} = \frac{df}{du}\frac{\partial u}{\partial x} = \frac{df}{du}(1) = f'(u) = f'(x + y)$,

$\frac{\partial z}{\partial y} = \frac{df}{du}\frac{\partial u}{\partial y} = \frac{df}{du}(1) = f'(u) = f'(x + y)$.

52. (a) $z = f(x)g(y) \quad \Rightarrow \quad \frac{\partial z}{\partial x} = f'(x)g(y), \quad \frac{\partial z}{\partial y} = f(x)g'(y)$

(b) $z = f(xy)$. Let $u = xy$. Then $\frac{\partial u}{\partial x} = y$ and $\frac{\partial u}{\partial y} = x$. Hence $\frac{\partial z}{\partial x} = \frac{df}{du}\frac{\partial u}{\partial x} = \frac{df}{du} \cdot y = yf'(u) = yf'(xy)$

and $\frac{\partial z}{\partial y} = \frac{df}{du}\frac{\partial u}{\partial y} = \frac{df}{du} \cdot x = xf'(u) = xf'(xy)$.

(c) $z = f\left(\frac{x}{y}\right)$. Let $u = \frac{x}{y}$. Then $\frac{\partial u}{\partial x} = \frac{1}{y}$ and $\frac{\partial u}{\partial y} = -\frac{x}{y^2}$. Hence $\frac{\partial z}{\partial x} = \frac{df}{du}\frac{\partial u}{\partial x} = f'(u)\frac{1}{y} = \frac{f'(x/y)}{y}$

and $\frac{\partial z}{\partial y} = \frac{df}{du}\frac{\partial u}{\partial y} = f'(u)\left(-\frac{x}{y^2}\right) = -\frac{xf'(x/y)}{y^2}$.

53. $f(x,y) = x^4y - 2x^3y^2 \quad \Rightarrow \quad f_x(x,y) = 4x^3y - 6x^2y^2, \;\; f_y(x,y) = x^4 - 4x^3y$. Then $f_{xx}(x,y) = 12x^2y - 12xy^2$,

$f_{xy}(x,y) = 4x^3 - 12x^2y, \;\; f_{yx}(x,y) = 4x^3 - 12x^2y$, and $f_{yy}(x,y) = -4x^3$.

54. $f(x,y) = \ln(ax + by) \quad \Rightarrow \quad f_x(x,y) = \frac{a}{ax + by} = a(ax + by)^{-1}, \;\; f_y(x,y) = \frac{b}{ax + by} = b(ax + by)^{-1}$. Then

$f_{xx}(x,y) = -a(ax + by)^{-2}(a) = -\frac{a^2}{(ax + by)^2}, \;\; f_{xy}(x,y) = -a(ax + by)^{-2}(b) = -\frac{ab}{(ax + by)^2}$,

$f_{yx}(x,y) = -b(ax + by)^{-2}(a) = -\frac{ab}{(ax + by)^2}$, and $f_{yy}(x,y) = -b(ax + by)^{-2}(b) = -\frac{b^2}{(ax + by)^2}$.

55. $z = \dfrac{y}{2x+3y} = y(2x+3y)^{-1} \quad \Rightarrow \quad z_x = y(-1)(2x+3y)^{-2}(2) = -\dfrac{2y}{(2x+3y)^2}$,

$z_y = \dfrac{(2x+3y)\cdot 1 - y \cdot 3}{(2x+3y)^2} = \dfrac{2x}{(2x+3y)^2}$. Then $z_{xx} = -2y(-2)(2x+3y)^{-3}(2) = \dfrac{8y}{(2x+3y)^3}$,

$z_{xy} = -\dfrac{(2x+3y)^2\cdot 2 - 2y\cdot 2(2x+3y)(3)}{[(2x+3y)^2]^2} = -\dfrac{(2x+3y)\,(4x+6y-12y)}{(2x+3y)^4} = \dfrac{6y-4x}{(2x+3y)^3}$,

$z_{yx} = \dfrac{(2x+3y)^2\cdot 2 - 2x\cdot 2(2x+3y)(2)}{[(2x+3y)^2]^2} = \dfrac{6y-4x}{(2x+3y)^3}$, $z_{yy} = 2x(-2)(2x+3y)^{-3}(3) = -\dfrac{12x}{(2x+3y)^3}$.

56. $T = e^{-2r}\cos\theta \quad \Rightarrow \quad T_r = -2e^{-2r}\cos\theta$, $T_\theta = -e^{-2r}\sin\theta$. Then $T_{rr} = -2e^{-2r}(-2)\cos\theta = 4e^{-2r}\cos\theta$,

$T_{r\theta} = 2e^{-2r}\sin\theta$, $T_{\theta r} = -e^{-2r}(-2)\sin\theta = 2e^{-2r}\sin\theta$, $T_{\theta\theta} = -e^{-2r}\cos\theta$.

57. $v = \sin(s^2 - t^2) \quad \Rightarrow \quad v_s = \cos(s^2-t^2)\cdot 2s = 2s\cos(s^2-t^2)$, $v_t = \cos(s^2-t^2)\cdot(-2t) = -2t\cos(s^2-t^2)$. Then

$v_{ss} = 2s\left[-\sin(s^2-t^2)\cdot 2s\right] + \cos(s^2-t^2)\cdot 2 = 2\cos(s^2-t^2) - 4s^2\sin(s^2-t^2)$,

$v_{st} = 2s\left[-\sin(s^2-t^2)\cdot(-2t)\right] = 4st\sin(s^2-t^2)$, $v_{ts} = -2t\left[-\sin(s^2-t^2)\cdot 2s\right] = 4st\sin(s^2-t^2)$,

$v_{tt} = -2t\cdot\left[-\sin(s^2-t^2)\cdot(-2t)\right] + \cos(s^2-t^2)\cdot(-2) = -2\cos(s^2-t^2) - 4t^2\sin(s^2-t^2)$.

58. $w = \sqrt{1+uv^2} \quad \Rightarrow \quad w_u = \frac{1}{2}(1+uv^2)^{-1/2}\cdot v^2 = \dfrac{v^2}{2\sqrt{1+uv^2}}$, $w_v = \frac{1}{2}(1+uv^2)^{-1/2}\cdot 2uv = \dfrac{uv}{\sqrt{1+uv^2}}$.

Then $w_{uu} = \frac{1}{2}v^2\left(-\frac{1}{2}\right)(1+uv^2)^{-3/2}(v^2) = -\dfrac{v^4}{4(1+uv^2)^{3/2}}$,

$$w_{uv} = \frac{2\sqrt{1+uv^2}\cdot 2v - v^2\cdot 2\left(\frac{1}{2}\right)(1+uv^2)^{-1/2}(2uv)}{\left(2\sqrt{1+uv^2}\right)^2} = \frac{4v\sqrt{1+uv^2} - 2uv^3/\sqrt{1+uv^2}}{4(1+uv^2)}$$

$$= \frac{4v(1+uv^2) - 2uv^3}{4\,(1+uv^2)^{3/2}} = \frac{2v+uv^3}{2\,(1+uv^2)^{3/2}}$$

$$w_{vu} = \frac{\sqrt{1+uv^2}\cdot v - uv\cdot\frac{1}{2}(1+uv^2)^{-1/2}(v^2)}{\left(\sqrt{1+uv^2}\right)^2} = \frac{v\sqrt{1+uv^2} - \frac{1}{2}uv^3/\sqrt{1+uv^2}}{(1+uv^2)}$$

$$= \frac{v(1+uv^2) - \frac{1}{2}uv^3}{(1+uv^2)^{3/2}} = \frac{2v+uv^3}{2\,(1+uv^2)^{3/2}}$$

$$w_{vv} = \frac{\sqrt{1+uv^2}\cdot u - uv\cdot\frac{1}{2}(1+uv^2)^{-1/2}(2uv)}{\left(\sqrt{1+uv^2}\right)^2} = \frac{u\sqrt{1+uv^2} - u^2v^2/\sqrt{1+uv^2}}{(1+uv^2)}$$

$$= \frac{u(1+uv^2) - u^2v^2}{(1+uv^2)^{3/2}} = \frac{u}{(1+uv^2)^{3/2}}$$

59. $u = x^4y^3 - y^4 \quad \Rightarrow \quad u_x = 4x^3y^3$, $u_{xy} = 12x^3y^2$ and $u_y = 3x^4y^2 - 4y^3$, $u_{yx} = 12x^3y^2$.

Thus $u_{xy} = u_{yx}$.

60. $u = e^{xy}\sin y \Rightarrow u_x = ye^{xy}\sin y,\ u_{xy} = ye^{xy}\cos y + (\sin y)(y \cdot xe^{xy} + e^{xy} \cdot 1) = e^{xy}(y\cos y + xy\sin y + \sin y),$

$u_y = e^{xy}\cos y + (\sin y)(xe^{xy}) = e^{xy}(\cos y + x\sin y),$

$u_{yx} = e^{xy} \cdot \sin y + (\cos y + x\sin y) \cdot ye^{xy} = e^{xy}(\sin y + y\cos y + xy\sin y)$. Thus $u_{xy} = u_{yx}$.

61. $u = \cos(x^2y) \Rightarrow u_x = -\sin(x^2y) \cdot 2xy = -2xy\sin(x^2y),$

$u_{xy} = -2xy \cdot \cos(x^2y) \cdot x^2 + \sin(x^2y) \cdot (-2x) = -2x^3y\cos(x^2y) - 2x\sin(x^2y)$ and

$u_y = -\sin(x^2y) \cdot x^2 = -x^2\sin(x^2y),\ u_{yx} = -x^2 \cdot \cos(x^2y) \cdot 2xy + \sin(x^2y) \cdot (-2x) = -2x^3y\cos(x^2y) - 2x\sin(x^2y).$

Thus $u_{xy} = u_{yx}$.

62. $u = \ln(x+2y) \Rightarrow u_x = \dfrac{1}{x+2y} = (x+2y)^{-1},\ u_{xy} = (-1)(x+2y)^{-2}(2) = -\dfrac{2}{(x+2y)^2}$ and

$u_y = \dfrac{1}{x+2y} \cdot 2 = 2(x+2y)^{-1},\ u_{yx} = (-2)(x+2y)^{-2} = -\dfrac{2}{(x+2y)^2}$. Thus $u_{xy} = u_{yx}$.

63. $f(x,y) = x^4y^2 - x^3y \Rightarrow f_x = 4x^3y^2 - 3x^2y,\ f_{xx} = 12x^2y^2 - 6xy,\ f_{xxx} = 24xy^2 - 6y$ and

$f_{xy} = 8x^3y - 3x^2,\ f_{xyx} = 24x^2y - 6x.$

64. $f(x,y) = \sin(2x+5y) \Rightarrow f_y = \cos(2x+5y) \cdot 5 = 5\cos(2x+5y),\ f_{yx} = -5\sin(2x+5y) \cdot 2 = -10\sin(2x+5y),$

$f_{yxy} = -10\cos(2x+5y) \cdot 5 = -50\cos(2x+5y)$

65. $f(x,y,z) = e^{xyz^2} \Rightarrow f_x = e^{xyz^2} \cdot yz^2 = yz^2e^{xyz^2},\ f_{xy} = yz^2 \cdot e^{xyz^2}(xz^2) + e^{xyz^2} \cdot z^2 = (xyz^4 + z^2)e^{xyz^2},$

$f_{xyz} = (xyz^4 + z^2) \cdot e^{xyz^2}(2xyz) + e^{xyz^2} \cdot (4xyz^3 + 2z) = (2x^2y^2z^5 + 6xyz^3 + 2z)e^{xyz^2}.$

66. $g(r,s,t) = e^r\sin(st) \Rightarrow g_r = e^r\sin(st),\ g_{rs} = e^r\cos(st) \cdot t = te^r\cos(st),$

$g_{rst} = te^r(-\sin(st) \cdot s) + \cos(st) \cdot e^r = e^r[\cos(st) - st\sin(st)].$

67. $W = \sqrt{u+v^2} \Rightarrow \dfrac{\partial W}{\partial v} = \frac{1}{2}(u+v^2)^{-1/2}(2v) = v(u+v^2)^{-1/2},$

$\dfrac{\partial^2 W}{\partial u\,\partial v} = v\left(-\frac{1}{2}\right)(u+v^2)^{-3/2}(1) = -\frac{1}{2}v(u+v^2)^{-3/2},\ \dfrac{\partial^3 W}{\partial u^2\,\partial v} = -\frac{1}{2}v\left(-\frac{3}{2}\right)(u+v^2)^{-5/2}(1) = \frac{3}{4}v(u+v^2)^{-5/2}.$

68. $V = \ln(r+s^2+t^3) \Rightarrow \dfrac{\partial V}{\partial t} = \dfrac{3t^2}{r+s^2+t^3} = 3t^2(r+s^2+t^3)^{-1},$

$\dfrac{\partial^2 V}{\partial s\,\partial t} = 3t^2(-1)(r+s^2+t^3)^{-2}(2s) = -6st^2(r+s^2+t^3)^{-2},$

$\dfrac{\partial^3 V}{\partial r\,\partial s\,\partial t} = -6st^2(-2)(r+s^2+t^3)^{-3}(1) = 12st^2(r+s^2+t^3)^{-3} = \dfrac{12st^2}{(r+s^2+t^3)^3}.$

69. $w = \dfrac{x}{y+2z} = x(y+2z)^{-1} \Rightarrow \dfrac{\partial w}{\partial x} = (y+2z)^{-1},\ \dfrac{\partial^2 w}{\partial y\,\partial x} = -(y+2z)^{-2}(1) = -(y+2z)^{-2},$

$\dfrac{\partial^3 w}{\partial z\,\partial y\,\partial x} = -(-2)(y+2z)^{-3}(2) = 4(y+2z)^{-3} = \dfrac{4}{(y+2z)^3}$ and $\dfrac{\partial w}{\partial y} = x(-1)(y+2z)^{-2}(1) = -x(y+2z)^{-2},$

$\dfrac{\partial^2 w}{\partial x\,\partial y} = -(y+2z)^{-2},\ \dfrac{\partial^3 w}{\partial x^2\,\partial y} = 0.$

70. $u = x^a y^b z^c$. If $a = 0$, or if $b = 0$ or 1, or if $c = 0$, 1, or 2, then $\dfrac{\partial^6 u}{\partial x\,\partial y^2\,\partial z^3} = 0$. Otherwise $\dfrac{\partial u}{\partial z} = cx^a y^b z^{c-1}$,

$\dfrac{\partial^2 u}{\partial z^2} = c(c-1)x^a y^b z^{c-2}$, $\dfrac{\partial^3 u}{\partial z^3} = c(c-1)(c-2)x^a y^b z^{c-3}$, $\dfrac{\partial^4 u}{\partial y\,\partial z^3} = bc(c-1)(c-2)x^a y^{b-1} z^{c-3}$,

$\dfrac{\partial^5 u}{\partial y^2\,\partial z^3} = b(b-1)c(c-1)(c-2)x^a y^{b-2} z^{c-3}$, and $\dfrac{\partial^6 u}{\partial x\,\partial y^2\,\partial z^3} = ab(b-1)c(c-1)(c-2)x^{a-1} y^{b-2} z^{c-3}$.

71. Assuming that the third partial derivatives of f are continuous (easily verified), we can write $f_{xzy} = f_{yxz}$. Then

$f(x,y,z) = xy^2z^3 + \arcsin\left(x\sqrt{z}\right) \;\Rightarrow\; f_y = 2xyz^3 + 0$, $f_{yx} = 2yz^3$, and $f_{yxz} = 6yz^2 = f_{xzy}$.

72. Let $f(x,y,z) = \sqrt{1+xz}$ and $h(x,y,z) = \sqrt{1-xy}$ so that $g = f + h$. Then $f_y = 0 = f_{yx} = f_{yxz}$ and $h_z = 0 = h_{zx} = h_{zxy}$. But (since the partial derivatives are continous on their domains) $f_{xyz} = f_{yxz}$ and $h_{xyz} = h_{zxy}$, so $g_{xyz} = f_{xyz} + h_{xyz} = 0 + 0 = 0$.

73. By Definition 4, $f_x(3,2) = \lim\limits_{h\to 0} \dfrac{f(3+h,2) - f(3,2)}{h}$ which we can approximate by considering $h = 0.5$ and $h = -0.5$:

$f_x(3,2) \approx \dfrac{f(3.5,2) - f(3,2)}{0.5} = \dfrac{22.4 - 17.5}{0.5} = 9.8$, $f_x(3,2) \approx \dfrac{f(2.5,2) - f(3,2)}{-0.5} = \dfrac{10.2 - 17.5}{-0.5} = 14.6$. Averaging these values, we estimate $f_x(3,2)$ to be approximately 12.2. Similarly, $f_x(3,2.2) = \lim\limits_{h\to 0} \dfrac{f(3+h,2.2) - f(3,2.2)}{h}$ which we can approximate by considering $h = 0.5$ and $h = -0.5$: $f_x(3,2.2) \approx \dfrac{f(3.5,2.2) - f(3,2.2)}{0.5} = \dfrac{26.1 - 15.9}{0.5} = 20.4$,

$f_x(3,2.2) \approx \dfrac{f(2.5,2.2) - f(3,2.2)}{-0.5} = \dfrac{9.3 - 15.9}{-0.5} = 13.2$. Averaging these values, we have $f_x(3,2.2) \approx 16.8$.

To estimate $f_{xy}(3,2)$, we first need an estimate for $f_x(3,1.8)$:

$f_x(3,1.8) \approx \dfrac{f(3.5,1.8) - f(3,1.8)}{0.5} = \dfrac{20.0 - 18.1}{0.5} = 3.8$, $f_x(3,1.8) \approx \dfrac{f(2.5,1.8) - f(3,1.8)}{-0.5} = \dfrac{12.5 - 18.1}{-0.5} = 11.2$.

Averaging these values, we get $f_x(3,1.8) \approx 7.5$. Now $f_{xy}(x,y) = \dfrac{\partial}{\partial y}\left[f_x(x,y)\right]$ and $f_x(x,y)$ is itself a function of two variables, so Definition 4 says that $f_{xy}(x,y) = \dfrac{\partial}{\partial y}\left[f_x(x,y)\right] = \lim\limits_{h\to 0} \dfrac{f_x(x,y+h) - f_x(x,y)}{h} \;\Rightarrow$

$f_{xy}(3,2) = \lim\limits_{h\to 0} \dfrac{f_x(3,2+h) - f_x(3,2)}{h}$. We can estimate this value using our previous work with $h = 0.2$ and $h = -0.2$:

$f_{xy}(3,2) \approx \dfrac{f_x(3,2.2) - f_x(3,2)}{0.2} = \dfrac{16.8 - 12.2}{0.2} = 23$, $f_{xy}(3,2) \approx \dfrac{f_x(3,1.8) - f_x(3,2)}{-0.2} = \dfrac{7.5 - 12.2}{-0.2} = 23.5$.

Averaging these values, we estimate $f_{xy}(3,2)$ to be approximately 23.25.

74. (a) If we fix y and allow x to vary, the level curves indicate that the value of f decreases as we move through P in the positive x-direction, so f_x is negative at P.

(b) If we fix x and allow y to vary, the level curves indicate that the value of f increases as we move through P in the positive y-direction, so f_y is positive at P.

(c) $f_{xx} = \frac{\partial}{\partial x}(f_x)$, so if we fix y and allow x to vary, f_{xx} is the rate of change of f_x as x increases. Note that at points to the right of P the level curves are spaced farther apart (in the x-direction) than at points to the left of P, demonstrating that f decreases less quickly with respect to x to the right of P. So as we move through P in the positive x-direction the (negative) value of f_x increases, hence $\frac{\partial}{\partial x}(f_x) = f_{xx}$ is positive at P.

(d) $f_{xy} = \frac{\partial}{\partial y}(f_x)$, so if we fix x and allow y to vary, f_{xy} is the rate of change of f_x as y increases. The level curves are closer together (in the x-direction) at points above P than at those below P, demonstrating that f decreases more quickly with respect to x for y-values above P. So as we move through P in the positive y-direction, the (negative) value of f_x decreases, hence f_{xy} is negative.

(e) $f_{yy} = \frac{\partial}{\partial y}(f_y)$, so if we fix x and allow y to vary, f_{yy} is the rate of change of f_y as y increases. The level curves are closer together (in the y-direction) at points above P than at those below P, demonstrating that f increases more quickly with respect to y above P. So as we move through P in the positive y-direction the (positive) value of f_y increases, hence $\frac{\partial}{\partial y}(f_y) = f_{yy}$ is positive at P.

75. $u = e^{-\alpha^2 k^2 t} \sin kx \quad \Rightarrow \quad u_x = ke^{-\alpha^2 k^2 t} \cos kx, \;\; u_{xx} = -k^2 e^{-\alpha^2 k^2 t} \sin kx$, and $u_t = -\alpha^2 k^2 e^{-\alpha^2 k^2 t} \sin kx$. Thus $\alpha^2 u_{xx} = u_t$.

76. (a) $u = x^2 + y^2 \quad \Rightarrow \quad u_x = 2x, \; u_{xx} = 2; \quad u_y = 2y, \; u_{yy} = 2$. Thus $u_{xx} + u_{yy} \neq 0$ and $u = x^2 + y^2$ does not satisfy Laplace's Equation.

(b) $u = x^2 - y^2$ is a solution: $u_{xx} = 2, \; u_{yy} = -2$ so $u_{xx} + u_{yy} = 0$.

(c) $u = x^3 + 3xy^2$ is not a solution: $u_x = 3x^2 + 3y^2, \; u_{xx} = 6x; \quad u_y = 6xy, \; u_{yy} = 6x$.

(d) $u = \ln\sqrt{x^2 + y^2}$ is a solution: $u_x = \dfrac{1}{\sqrt{x^2 + y^2}}\left(\dfrac{1}{2}\right)(x^2 + y^2)^{-1/2}(2x) = \dfrac{x}{x^2 + y^2}$,

$u_{xx} = \dfrac{(x^2 + y^2) - x(2x)}{(x^2 + y^2)^2} = \dfrac{y^2 - x^2}{(x^2 + y^2)^2}$. By symmetry, $u_{yy} = \dfrac{x^2 - y^2}{(x^2 + y^2)^2}$, so $u_{xx} + u_{yy} = 0$.

(e) $u = \sin x \, \cosh y + \cos x \, \sinh y$ is a solution: $u_x = \cos x \, \cosh y - \sin x \, \sinh y$, $u_{xx} = -\sin x \, \cosh y - \cos x \, \sinh y$, and $u_y = \sin x \, \sinh y + \cos x \, \cosh y$, $u_{yy} = \sin x \, \cosh y + \cos x \, \sinh y$.

(f) $u = e^{-x} \cos y - e^{-y} \cos x$ is a solution: $u_x = -e^{-x} \cos y + e^{-y} \sin x, \quad u_{xx} = e^{-x} \cos y + e^{-y} \cos x$, and $u_y = -e^{-x} \sin y + e^{-y} \cos x, \quad u_{yy} = -e^{-x} \cos y - e^{-y} \cos x$.

77. $u = \dfrac{1}{\sqrt{x^2 + y^2 + z^2}} \quad \Rightarrow \quad u_x = \left(-\tfrac{1}{2}\right)(x^2 + y^2 + z^2)^{-3/2}(2x) = -x(x^2 + y^2 + z^2)^{-3/2}$ and

$$u_{xx} = -(x^2 + y^2 + z^2)^{-3/2} - x\left(-\tfrac{3}{2}\right)(x^2 + y^2 + z^2)^{-5/2}(2x) = \frac{2x^2 - y^2 - z^2}{(x^2 + y^2 + z^2)^{5/2}}.$$

By symmetry, $u_{yy} = \dfrac{2y^2 - x^2 - z^2}{(x^2+y^2+z^2)^{5/2}}$ and $u_{zz} = \dfrac{2z^2 - x^2 - y^2}{(x^2+y^2+z^2)^{5/2}}$.

Thus $u_{xx} + u_{yy} + u_{zz} = \dfrac{2x^2 - y^2 - z^2 + 2y^2 - x^2 - z^2 + 2z^2 - x^2 - y^2}{(x^2+y^2+z^2)^{5/2}} = 0$.

78. (a) $u = \sin(kx)\,\sin(akt) \;\Rightarrow\; u_t = ak\sin(kx)\,\cos(akt)$, $u_{tt} = -a^2k^2\sin(kx)\,\sin(akt)$, $u_x = k\cos(kx)\,\sin(akt)$,

$u_{xx} = -k^2\sin(kx)\,\sin(akt)$. Thus $u_{tt} = a^2u_{xx}$.

(b) $u = \dfrac{t}{a^2t^2 - x^2} \;\Rightarrow\; u_t = \dfrac{(a^2t^2 - x^2) - t(2a^2t)}{(a^2t^2-x^2)^2} = -\dfrac{a^2t^2 + x^2}{(a^2t^2-x^2)^2}$,

$$u_{tt} = \frac{-2a^2t(a^2t^2-x^2)^2 + (a^2t^2+x^2)(2)(a^2t^2-x^2)(2a^2t)}{(a^2t^2-x^2)^4} = \frac{2a^4t^3 + 6a^2tx^2}{(a^2t^2-x^2)^3},$$

$$u_x = t(-1)(a^2t^2-x^2)^{-2}(-2x) = \frac{2tx}{(a^2t^2-x^2)^2},$$

$$u_{xx} = \frac{2t(a^2t^2-x^2)^2 - 2tx\,(2)(a^2t^2-x^2)(-2x)}{(a^2t^2-x^2)^4} = \frac{2a^2t^3 - 2tx^2 + 8tx^2}{(a^2t^2-x^2)^3} = \frac{2a^2t^3 + 6tx^2}{(a^2t^2-x^2)^3}.$$

Thus $u_{tt} = a^2u_{xx}$.

(c) $u = (x-at)^6 + (x+at)^6 \;\Rightarrow\; u_t = -6a(x-at)^5 + 6a(x+at)^5,\; u_{tt} = 30a^2(x-at)^4 + 30a^2(x+at)^4$,

$u_x = 6(x-at)^5 + 6(x+at)^5,\; u_{xx} = 30(x-at)^4 + 30(x+at)^4$. Thus $u_{tt} = a^2u_{xx}$.

(d) $u = \sin(x-at) + \ln(x+at) \;\Rightarrow\; u_t = -a\cos(x-at) + \dfrac{a}{x+at},\quad u_{tt} = -a^2\sin(x-at) - \dfrac{a^2}{(x+at)^2}$,

$u_x = \cos(x-at) + \dfrac{1}{x+at},\quad u_{xx} = -\sin(x-at) - \dfrac{1}{(x+at)^2}$. Thus $u_{tt} = a^2u_{xx}$.

79. Let $v = x + at,\;\; w = x - at$. Then $u_t = \dfrac{\partial[f(v)+g(w)]}{\partial t} = \dfrac{df(v)}{dv}\dfrac{\partial v}{\partial t} + \dfrac{dg(w)}{dw}\dfrac{\partial w}{\partial t} = af'(v) - ag'(w)$ and

$u_{tt} = \dfrac{\partial[af'(v) - ag'(w)]}{\partial t} = a[af''(v) + ag''(w)] = a^2[f''(v) + g''(w)]$. Similarly, by using the Chain Rule we have

$u_x = f'(v) + g'(w)$ and $u_{xx} = f''(v) + g''(w)$. Thus $u_{tt} = a^2u_{xx}$.

80. For each i, $i = 1, \ldots, n$, $\partial u/\partial x_i = a_ie^{a_1x_1 + a_2x_2 + \cdots + a_nx_n}$ and $\partial^2u/\partial x_i^2 = a_i^2e^{a_1x_1 + a_2x_2 + \cdots + a_nx_n}$.

Then $\dfrac{\partial^2u}{\partial x_1^2} + \dfrac{\partial^2u}{\partial x_2^2} + \cdots + \dfrac{\partial^2u}{\partial x_n^2} = \left(a_1^2 + a_2^2 + \cdots + a_n^2\right)e^{a_1x_1 + a_2x_2 + \cdots + a_nx_n} = e^{a_1x_1 + a_2x_2 + \cdots + a_nx_n} = u$

since $a_1^2 + a_2^2 + \cdots + a_n^2 = 1$.

81. $c(x,t) = \dfrac{1}{\sqrt{4\pi Dt}}\,e^{-x^2/(4Dt)} \;\Rightarrow$

$$\begin{aligned}\frac{\partial c}{\partial t} &= \frac{1}{\sqrt{4\pi Dt}}\cdot e^{-x^2/(4Dt)}\left[-x^2(-1)(4Dt)^{-2}(4D)\right] + e^{-x^2/(4Dt)}\cdot\left(-\tfrac{1}{2}\right)(4\pi Dt)^{-3/2}(4\pi D)\\ &= (4\pi Dt)^{-3/2}\left(4\pi Dt\cdot\frac{x^2}{4Dt^2} - 2\pi D\right)e^{-x^2/(4Dt)} = \frac{2\pi D}{(4\pi Dt)^{3/2}}\left(\frac{x^2}{2Dt} - 1\right)e^{-x^2/(4Dt)},\end{aligned}$$

$$\frac{\partial c}{\partial x} = \frac{1}{\sqrt{4\pi Dt}}\,e^{-x^2/(4Dt)}\cdot\frac{-2x}{4Dt} = \frac{-2\pi x}{(4\pi Dt)^{3/2}}\,e^{-x^2/(4Dt)},\text{ and}$$

$$\frac{\partial^2 c}{\partial x^2} = \frac{-2\pi}{(4\pi Dt)^{3/2}} \left[x \cdot e^{-x^2/(4Dt)} \cdot \frac{-2x}{4Dt} + e^{-x^2/(4Dt)} \cdot 1 \right]$$

$$= \frac{-2\pi}{(4\pi Dt)^{3/2}} \left(-\frac{x^2}{2Dt} + 1 \right) e^{-x^2/(4Dt)} = \frac{2\pi}{(4\pi Dt)^{3/2}} \left(\frac{x^2}{2Dt} - 1 \right) e^{-x^2/(4Dt)}.$$

Thus $\dfrac{\partial c}{\partial t} = \dfrac{2\pi D}{(4\pi Dt)^{3/2}} \left(\dfrac{x^2}{2Dt} - 1 \right) e^{-x^2/(4Dt)} = D \left[\dfrac{2\pi}{(4\pi Dt)^{3/2}} \left(\dfrac{x^2}{2Dt} - 1 \right) e^{-x^2/(4Dt)} \right] = D \dfrac{\partial^2 c}{\partial x^2}.$

82. (a) $\partial T/\partial x = -60(2x)/(1 + x^2 + y^2)^2$, so at $(2, 1)$, $T_x = -240/(1 + 4 + 1)^2 = -\frac{20}{3}$.

(b) $\partial T/\partial y = -60(2y)/(1 + x^2 + y^2)^2$, so at $(2, 1)$, $T_y = -120/36 = -\frac{10}{3}$. Thus from the point $(2, 1)$ the temperature is decreasing at a rate of $\frac{20}{3}{}^\circ\text{C/m}$ in the x-direction and is decreasing at a rate of $\frac{10}{3}{}^\circ\text{C/m}$ in the y-direction.

83. By the Chain Rule, taking the partial derivative of both sides with respect to R_1 gives

$$\frac{\partial R^{-1}}{\partial R} \frac{\partial R}{\partial R_1} = \frac{\partial \left[(1/R_1) + (1/R_2) + (1/R_3) \right]}{\partial R_1} \quad \text{or} \quad -R^{-2} \frac{\partial R}{\partial R_1} = -R_1^{-2}. \text{ Thus } \frac{\partial R}{\partial R_1} = \frac{R^2}{R_1^2}.$$

84. $P = bL^\alpha K^\beta$, so $\dfrac{\partial P}{\partial L} = \alpha b L^{\alpha-1} K^\beta$ and $\dfrac{\partial P}{\partial K} = \beta b L^\alpha K^{\beta - 1}$. Then

$$L \frac{\partial P}{\partial L} + K \frac{\partial P}{\partial K} = L(\alpha b L^{\alpha-1} K^\beta) + K(\beta b L^\alpha K^{\beta-1}) = \alpha b L^{1+\alpha-1} K^\beta + \beta b L^\alpha K^{1+\beta-1} = (\alpha + \beta) b L^\alpha K^\beta = (\alpha + \beta) P$$

85. If we fix $K = K_0$, $P(L, K_0)$ is a function of a single variable L, and $\dfrac{dP}{dL} = \alpha \dfrac{P}{L}$ is a separable differential equation. Then

$\dfrac{dP}{P} = \alpha \dfrac{dL}{L} \quad \Rightarrow \quad \displaystyle\int \frac{dP}{P} = \int \alpha \frac{dL}{L} \quad \Rightarrow \quad \ln |P| = \alpha \ln |L| + C(K_0)$, where $C(K_0)$ can depend on K_0. Then $|P| = e^{\alpha \ln |L| + C(K_0)}$, and since $P > 0$ and $L > 0$, we have $P = e^{\alpha \ln L} e^{C(K_0)} = e^{C(K_0)} e^{\ln L^\alpha} = C_1(K_0) L^\alpha$ where $C_1(K_0) = e^{C(K_0)}$.

86. (a) $P(L, K) = 1.01 L^{0.75} K^{0.25} \quad \Rightarrow \quad P_L(L, K) = 1.01(0.75 L^{-0.25}) K^{0.25} = 0.7575 L^{-0.25} K^{0.25}$ and $P_K(L, K) = 1.01 L^{0.75} (0.25 K^{-0.75}) = 0.2525 L^{0.75} K^{-0.75}$.

(b) The marginal productivity of labor in 1920 is $P_L(194, 407) = 0.7575(194)^{-0.25}(407)^{0.25} \approx 0.912$. Recall that P, L, and K are expressed as percentages of the respective amounts in 1899, so this means that in 1920, if the amount of labor is increased, production increases at a rate of about 0.912 percentage points per percentage point increase in labor. The marginal productivity of capital in 1920 is $P_K(194, 407) = 0.2525(194)^{0.75}(407)^{-0.75} \approx 0.145$, so an increase in capital investment would cause production to increase at a rate of about 0.145 percentage points per percentage point increase in capital.

(c) The value of $P_L(194, 407)$ is greater than the value of $P_K(194, 407)$, suggesting that increasing labor in 1920 would have increased production more than increasing capital.

87. $\left(P + \dfrac{n^2a}{V^2}\right)(V - nb) = nRT \quad \Rightarrow \quad T = \dfrac{1}{nR}\left(P + \dfrac{n^2a}{V^2}\right)(V - nb)$, so $\dfrac{\partial T}{\partial P} = \dfrac{1}{nR}(1)(V - nb) = \dfrac{V - nb}{nR}$.

We can also write $P + \dfrac{n^2a}{V^2} = \dfrac{nRT}{V - nb} \quad \Rightarrow \quad P = \dfrac{nRT}{V - nb} - \dfrac{n^2a}{V^2} = nRT(V - nb)^{-1} - n^2aV^{-2}$, so

$\dfrac{\partial P}{\partial V} = -nRT(V - nb)^{-2}(1) + 2n^2aV^{-3} = \dfrac{2n^2a}{V^3} - \dfrac{nRT}{(V - nb)^2}$.

88. $P = \dfrac{mRT}{V}$ so $\dfrac{\partial P}{\partial V} = \dfrac{-mRT}{V^2}$; $\quad V = \dfrac{mRT}{P}$, so $\dfrac{\partial V}{\partial T} = \dfrac{mR}{P}$; $\quad T = \dfrac{PV}{mR}$, so $\dfrac{\partial T}{\partial P} = \dfrac{V}{mR}$.

Thus $\dfrac{\partial P}{\partial V}\dfrac{\partial V}{\partial T}\dfrac{\partial T}{\partial P} = \dfrac{-mRT}{V^2}\dfrac{mR}{P}\dfrac{V}{mR} = \dfrac{-mRT}{PV} = -1$, since $PV = mRT$.

89. By Exercise 88, $PV = mRT \quad \Rightarrow \quad P = \dfrac{mRT}{V}$, so $\dfrac{\partial P}{\partial T} = \dfrac{mR}{V}$. Also, $PV = mRT \quad \Rightarrow \quad V = \dfrac{mRT}{P}$ and $\dfrac{\partial V}{\partial T} = \dfrac{mR}{P}$.

Since $T = \dfrac{PV}{mR}$, we have $T\,\dfrac{\partial P}{\partial T}\,\dfrac{\partial V}{\partial T} = \dfrac{PV}{mR} \cdot \dfrac{mR}{V} \cdot \dfrac{mR}{P} = mR$.

90. $\dfrac{\partial W}{\partial T} = 0.6215 + 0.3965v^{0.16}$. When $T = -15^\circ\text{C}$ and $v = 30$ km/h, $\dfrac{\partial W}{\partial T} = 0.6215 + 0.3965(30)^{0.16} \approx 1.3048$, so we would expect the apparent temperature to drop by approximately 1.3°C if the actual temperature decreases by 1°C.

$\dfrac{\partial W}{\partial v} = -11.37(0.16)v^{-0.84} + 0.3965T(0.16)v^{-0.84}$ and when $T = -15^\circ\text{C}$ and $v = 30$ km/h,

$\dfrac{\partial W}{\partial v} = -11.37(0.16)(30)^{-0.84} + 0.3965(-15)(0.16)(30)^{-0.84} \approx -0.1592$, so we would expect the apparent temperature to drop by approximately 0.16°C if the wind speed increases by 1 km/h.

91. (a) $S = f(w, h) = 0.1091w^{0.425}h^{0.725} \quad \Rightarrow \quad \dfrac{\partial S}{\partial w} = 0.1091(0.425)w^{0.425-1}h^{0.725} = 0.0463675w^{-0.575}h^{0.725}$, so

$\dfrac{\partial S}{\partial w}(160, 70) = 0.0463675(160)^{-0.575}(70)^{0.725} \approx 0.0545$. This means that for a person 70 inches tall who weighs 160 pounds, an increase in weight (while height remains constant) causes the surface area to increase at a rate of about 0.0545 square feet (about 7.85 square inches) per pound.

(b) $\dfrac{\partial S}{\partial h} = 0.1091(0.725)w^{0.425}h^{0.725-1} = 0.0790975w^{0.425}h^{-0.275}$, so

$\dfrac{\partial S}{\partial h}(160, 70) = 0.0790975(160)^{0.425}(70)^{-0.275} \approx 0.213$. This means that for a person 70 inches tall who weighs 160 pounds, an increase in height (while weight remains unchanged at 160 pounds) causes the surface area to increase at a rate of about 0.213 square feet (about 30.7 square inches) per inch of height.

92. $R = C\dfrac{L}{r^4} \quad \Rightarrow \quad \dfrac{\partial R}{\partial L} = \dfrac{C}{r^4}$ and $\dfrac{\partial R}{\partial r} = CL\left(-4r^{-5}\right) = -4C\dfrac{L}{r^5}$.

$\partial R/\partial L$ is the rate at which the resistance of the flowing blood increases with respect to the length of the artery when the radius stays constant. $\partial R/\partial r$ is the rate of change of the resistance with respect to the radius of the artery when the length remains unchanged. Because $\partial R/\partial r$ is negative, the resistance decreases if the radius increases.

93. $P(v,x,m) = Av^3 + \dfrac{B(mg/x)^2}{v} = Av^3 + Bm^2g^2x^{-2}v^{-1}$.

$\partial P/\partial v = 3Av^2 - \dfrac{B(mg/x)^2}{v^2}$ is the rate of change of the power needed during flapping mode with respect to the bird's velocity when the mass and fraction of flapping time remain constant. $\partial P/\partial x = -2Bm^2g^2x^{-3}v^{-1} = -\dfrac{2Bm^2g^2}{x^3v}$ is the rate at which the power changes with respect to the fraction of time spent in flapping mode when the mass and velocity are held constant. $\partial P/\partial m = 2Bmg^2x^{-2}v^{-1} = \dfrac{2Bmg^2}{x^2v}$ is the rate of change of the power with respect to mass when the velocity and fraction of flapping time remain constant.

94. $E(m,v) = 2.65m^{0.66} + \dfrac{3.5m^{0.75}}{v} \quad \Rightarrow$

$E_m(m,v) = 2.65(0.66)m^{0.66-1} + \dfrac{3.5(0.75)m^{0.75-1}}{v} = 1.749m^{-0.34} + \dfrac{2.625m^{-0.25}}{v}$,

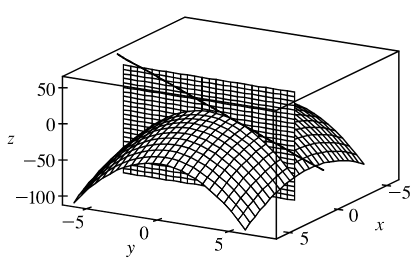
$E_v(m,v) = 3.5m^{0.75}\left(-v^{-2}\right) = -\dfrac{3.5m^{0.75}}{v^2}$. Then $E_m(400,8) = 1.749(400)^{-0.34} + \dfrac{2.625(400)^{-0.25}}{8} \approx 0.301$ which means that the average energy needed for a lizard to walk or run 1 km increases at a rate of about 0.301 kcal per gram of body mass increase from 400 g if the speed is 8 km/h. $E_v(400,8) = -\dfrac{3.5(400)^{0.75}}{8^2} \approx -4.89$, which means that the average energy needed by a lizard with body mass 400 g decreases at a rate of about 4.89 kcal per km/h when the speed increases from 8 km/h.

95. $\dfrac{\partial K}{\partial m} = \frac{1}{2}v^2$, $\dfrac{\partial K}{\partial v} = mv$, $\dfrac{\partial^2 K}{\partial v^2} = m$. Thus $\dfrac{\partial K}{\partial m} \cdot \dfrac{\partial^2 K}{\partial v^2} = \frac{1}{2}v^2m = K$.

96. The Law of Cosines says that $a^2 = b^2 + c^2 - 2bc\cos A$. Thus $\dfrac{\partial(a^2)}{\partial a} = \dfrac{\partial(b^2+c^2-2ab\cos A)}{\partial a}$ or $2a = -2bc\,(-\sin A)\,\dfrac{\partial A}{\partial a}$, implying that $\dfrac{\partial A}{\partial a} = \dfrac{a}{bc\sin A}$. Taking the partial derivative of both sides with respect to b gives $0 = 2b - 2c(\cos A) - 2bc\,(-\sin A)\,\dfrac{\partial A}{\partial b}$. Thus $\dfrac{\partial A}{\partial b} = \dfrac{c\cos A - b}{bc\sin A}$. By symmetry, $\dfrac{\partial A}{\partial c} = \dfrac{b\cos A - c}{bc\sin A}$.

97. $f_x(x,y) = x + 4y \quad \Rightarrow \quad f_{xy}(x,y) = 4$ and $f_y(x,y) = 3x - y \quad \Rightarrow \quad f_{yx}(x,y) = 3$. Since f_{xy} and f_{yx} are continuous everywhere but $f_{xy}(x,y) \neq f_{yx}(x,y)$, Clairaut's Theorem implies that such a function $f(x,y)$ does not exist.

98. Setting $x = 1$, the equation of the parabola of intersection is $z = 6 - 1 - 1 - 2y^2 = 4 - 2y^2$. The slope of the tangent is $\partial z/\partial y = -4y$, so at $(1,2,-4)$ the slope is -8. Parametric equations for the line are therefore $x = 1$, $y = 2 + t$, $z = -4 - 8t$.



99. By the geometry of partial derivatives, the slope of the tangent line is $f_x(1,2)$. By implicit differentiation of $4x^2 + 2y^2 + z^2 = 16$, we get $8x + 2z\,(\partial z/\partial x) = 0 \;\Rightarrow\; \partial z/\partial x = -4x/z$, so when $x = 1$ and $z = 2$ we have $\partial z/\partial x = -2$. So the slope is $f_x(1,2) = -2$. Thus the tangent line is given by $z - 2 = -2(x-1)$, $y = 2$. Taking the parameter to be $t = x - 1$, we can write parametric equations for this line: $x = 1 + t$, $y = 2$, $z = 2 - 2t$.

100. $T(x,t) = T_0 + T_1 e^{-\lambda x}\sin(\omega t - \lambda x)$

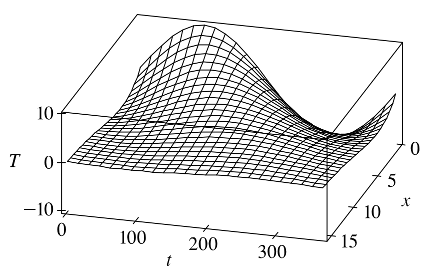
(a) $\partial T/\partial x = T_1 e^{-\lambda x}\left[\cos(\omega t - \lambda x)(-\lambda)\right] + T_1(-\lambda e^{-\lambda x})\sin(\omega t - \lambda x) = -\lambda T_1 e^{-\lambda x}\left[\sin(\omega t - \lambda x) + \cos(\omega t - \lambda x)\right]$.
This quantity represents the rate of change of temperature with respect to depth below the surface, at a given time t.

(b) $\partial T/\partial t = T_1 e^{-\lambda x}\left[\cos(\omega t - \lambda x)(\omega)\right] = \omega T_1 e^{-\lambda x}\cos(\omega t - \lambda x)$. This quantity represents the rate of change of temperature with respect to time at a fixed depth x.

(c) $$T_{xx} = \frac{\partial}{\partial x}\left(\frac{\partial T}{\partial x}\right)$$
$$= -\lambda T_1\left(e^{-\lambda x}\left[\cos(\omega t - \lambda x)(-\lambda) - \sin(\omega t - \lambda x)(-\lambda)\right] + e^{-\lambda x}(-\lambda)\left[\sin(\omega t - \lambda x) + \cos(\omega t - \lambda x)\right]\right)$$
$$= 2\lambda^2 T_1 e^{-\lambda x}\cos(\omega t - \lambda x)$$

But from part (b), $T_t = \omega T_1 e^{-\lambda x}\cos(\omega t - \lambda x) = \dfrac{\omega}{2\lambda^2}T_{xx}$. So with $k = \dfrac{\omega}{2\lambda^2}$, the function T satisfies the heat equation.

(d)



Note that near the surface (that is, for small x) the temperature varies greatly as t changes, but deeper (for large x) the temperature is more stable.

(e) The term $-\lambda x$ is a phase shift: it represents the fact that since heat diffuses slowly through soil, it takes time for changes in the surface temperature to affect the temperature at deeper points. As x increases, the phase shift also increases. For example, when $\lambda = 0.2$, the highest temperature at the surface is reached when $t \approx 91$, whereas at a depth of 5 feet the peak temperature is attained at $t \approx 149$, and at a depth of 10 feet, at $t \approx 207$.

101. By Clairaut's Theorem, $f_{xyy} = (f_{xy})_y = (f_{yx})_y = f_{yxy} = (f_y)_{xy} = (f_y)_{yx} = f_{yyx}$.

102. (a) Since we are differentiating n times, with two choices of variable at each differentiation, there are 2^n nth-order partial derivatives.

(b) If these partial derivatives are all continuous, then the order in which the partials are taken doesn't affect the value of the result, that is, all nth-order partial derivatives with p partials with respect to x and $n - p$ partials with respect to y are equal. Since the number of partials taken with respect to x for an nth-order partial derivative can range from 0 to n, a function of two variables has $n + 1$ distinct partial derivatives of order n if these partial derivatives are all continuous.

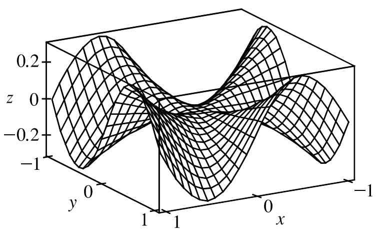
(c) Since n differentiations are to be performed with three choices of variable at each differentiation, there are 3^n nth-order partial derivatives of a function of three variables.

103. Let $g(x) = f(x, 0) = x(x^2)^{-3/2}e^0 = x\,|x|^{-3}$. But we are using the point $(1, 0)$, so near $(1, 0)$, $g(x) = x^{-2}$. Then $g'(x) = -2x^{-3}$ and $g'(1) = -2$, so using (1) we have $f_x(1, 0) = g'(1) = -2$.

104. $f_x(0, 0) = \lim\limits_{h\to 0} \dfrac{f(0 + h, 0) - f(0, 0)}{h} = \lim\limits_{h\to 0} \dfrac{(h^3 + 0)^{1/3} - 0}{h} = \lim\limits_{h\to 0} \dfrac{h}{h} = 1.$

Or: Let $g(x) = f(x, 0) = \sqrt[3]{x^3 + 0} = x$. Then $g'(x) = 1$ and $g'(0) = 1$ so, by (1), $f_x(0, 0) = g'(0) = 1$.

105. (a)



(b) For $(x, y) \neq (0, 0)$,

$$f_x(x, y) = \frac{(3x^2y - y^3)(x^2 + y^2) - (x^3y - xy^3)(2x)}{(x^2 + y^2)^2} = \frac{x^4y + 4x^2y^3 - y^5}{(x^2 + y^2)^2}$$

and by symmetry $f_y(x, y) = \dfrac{x^5 - 4x^3y^2 - xy^4}{(x^2 + y^2)^2}$.

(c) $f_x(0, 0) = \lim\limits_{h\to 0} \dfrac{f(h, 0) - f(0, 0)}{h} = \lim\limits_{h\to 0} \dfrac{(0/h^2) - 0}{h} = 0$ and $f_y(0, 0) = \lim\limits_{h\to 0} \dfrac{f(0, h) - f(0, 0)}{h} = 0.$

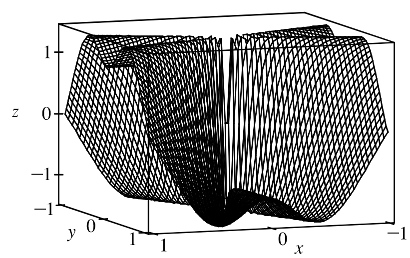
(d) By (3), $f_{xy}(0, 0) = \dfrac{\partial f_x}{\partial y} = \lim\limits_{h\to 0} \dfrac{f_x(0, h) - f_x(0, 0)}{h} = \lim\limits_{h\to 0} \dfrac{(-h^5 - 0)/h^4}{h} = -1$ while by (2),

$$f_{yx}(0, 0) = \frac{\partial f_y}{\partial x} = \lim_{h\to 0} \frac{f_y(h, 0) - f_y(0, 0)}{h} = \lim_{h\to 0} \frac{h^5/h^4}{h} = 1.$$

(e) For $(x, y) \neq (0, 0)$, we use a CAS to compute

$$f_{xy}(x, y) = \frac{x^6 + 9x^4y^2 - 9x^2y^4 - y^6}{(x^2 + y^2)^3}$$

Now as $(x, y) \to (0, 0)$ along the x-axis, $f_{xy}(x, y) \to 1$ while as $(x, y) \to (0, 0)$ along the y-axis, $f_{xy}(x, y) \to -1$. Thus f_{xy} isn't continuous at $(0, 0)$ and Clairaut's Theorem doesn't apply, so there is no contradiction. The graphs of f_{xy} and f_{yx} are identical except at the origin, where we observe the discontinuity.



14.4 Tangent Planes and Linear Approximations

1. $z = f(x, y) = 2x^2 + y^2 - 5y \;\;\Rightarrow\;\; f_x(x, y) = 4x,\; f_y(x, y) = 2y - 5,$ so $f_x(1, 2) = 4,\; f_y(1, 2) = -1.$

By Equation 2, an equation of the tangent plane is $z - (-4) = f_x(1, 2)(x - 1) + f_y(1, 2)(y - 2) \;\;\Rightarrow$

$z + 4 = 4(x - 1) + (-1)(y - 2)$ or $z = 4x - y - 6$.

2. $z = f(x, y) = (x+2)^2 - 2(y-1)^2 - 5 \quad \Rightarrow \quad f_x(x, y) = 2(x+2), \quad f_y(x, y) = -4(y-1)$, so $f_x(2, 3) = 8$ and $f_y(2, 3) = -8$. By Equation 2, an equation of the tangent plane is $z - 3 = f_x(2, 3)(x-2) + f_y(2, 3)(y-3) \quad \Rightarrow$ $z - 3 = 8(x-2) + (-8)(y-3)$ or $z = 8x - 8y + 11$.

3. $z = f(x, y) = e^{x-y} \quad \Rightarrow \quad f_x(x, y) = e^{x-y}(1) = e^{x-y}, \quad f_y(x, y) = e^{x-y}(-1) = -e^{x-y}$, so $f_x(2, 2) = 1$ and $f_y(2, 2) = -1$. Thus an equation of the tangent plane is $z - 1 = f_x(2, 2)(x-2) + f_y(2, 2)(y-2) \quad \Rightarrow$ $z - 1 = 1(x-2) + (-1)(y-2)$ or $z = x - y + 1$.

4. $z = f(x, y) = x/y^2 = xy^{-2} \quad \Rightarrow \quad f_x(x, y) = 1/y^2, \quad f_y(x, y) = -2xy^{-3} = -2x/y^3$, so $f_x(-4, 2) = \frac{1}{4}$ and $f_y(-4, 2) = 1$. Thus an equation of the tangent plane is $z - (-1) = f_x(-4, 2)\,[x - (-4)] + f_y(-4, 2)(y-2) \quad \Rightarrow$ $z + 1 = \frac{1}{4}(x+4) + 1(y-2)$ or $z = \frac{1}{4}x + y - 2$.

5. $z = f(x, y) = x\sin(x+y) \quad \Rightarrow \quad f_x(x, y) = x \cdot \cos(x+y) + \sin(x+y) \cdot 1 = x\cos(x+y) + \sin(x+y)$, $f_y(x, y) = x\cos(x+y)$, so $f_x(-1, 1) = (-1)\cos 0 + \sin 0 = -1, \quad f_y(-1, 1) = (-1)\cos 0 = -1$ and an equation of the tangent plane is $z - 0 = (-1)(x+1) + (-1)(y-1)$ or $x + y + z = 0$.

6. $z = f(x, y) = \ln(x - 2y) \quad \Rightarrow \quad f_x(x, y) = 1/(x-2y), \; f_y(x, y) = -2/(x-2y)$, so $f_x(3, 1) = 1, \; f_y(3, 1) = -2$, and an equation of the tangent plane is $z - 0 = f_x(3, 1)(x-3) + f_y(3, 1)(y-1) \quad \Rightarrow \quad z = 1(x-3) + (-2)(y-1)$ or $z = x - 2y - 1$.

7. $z = f(x, y) = x^2 + xy + 3y^2$, so $f_x(x, y) = 2x + y \quad \Rightarrow \quad f_x(1, 1) = 3, \quad f_y(x, y) = x + 6y \quad \Rightarrow \quad f_y(1, 1) = 7$ and an equation of the tangent plane is $z - 5 = 3(x-1) + 7(y-1)$ or $z = 3x + 7y - 5$. After zooming in, the surface and the tangent plane become almost indistinguishable. (Here, the tangent plane is below the surface.) If we zoom in farther, the surface and the tangent plane will appear to coincide.
